The CLUT format can be 24 or 32 bits. It is configured through CCM in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) as shown in table below.

Table 118. Supported CLUT color mode

CCM	CLUT color mode
0	32-bit ARGB8888
1	24-bit RGB888

The way the CLUT data are organized in the system memory is specified in the table below.

Table 119. CLUT data order in memory

CLUT Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]

21.3.7 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.

The blending is performed according to the following equation:

$$\text{with } \alpha_{Mult} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}$$

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}.\alpha_{FG} + C_{BG}.\alpha_{BG} - C_{BG}.\alpha_{Mult}}{\alpha_{OUT}} \quad \text{with C = R or G or B}$$

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender use depends on the DMA2D operating mode defined by MODE[2:0] in DMA2D_CR.

21.3.8 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined by CM[2:0] in DMA2D_OPFCCR.

Supported output formats are given in the table below

Table 120. Supported color mode in output

CM[2:0]	Color mode
000	ARGB8888
001	RGB888
010	RGB565
011	ARGB1555
100	ARGB4444

Note: To support the alternate format, the calculated alpha value can be inverted setting AI bit in DMA2D_OPFCCR. This applies also to the Alpha value used in DMA2D_OCOLR.

The R and B fields can also be swapped setting RBS in DMA2D_OPFCCR. This applies also to the RGB order used in DMA2D_OCOLR.

21.3.9 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through the following registers:

- DMA2D output memory address register (DMA2D_OMAR)
- DMA2D output offset register (DMA2D_OOR**)**
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR**)**

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in DMA2D_OCOLR which contains a fixed 32-, 24-, or 16-bit value. The format is selected by CM[2:0] in DMA2D_OPFCCR.

The data are stored into the memory in the order defined in the table below.

Table 121. Data order in memory

Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]
ARGB1555	A_1[0]R_1[4:0]G_1[4:3]	G_1[2:0]B_1[4:0]	A_0[0]R_0[4:0]G_0[4:3]	G_0[2:0]B_0[4:0]
ARGB4444	A_1[3:0]R_1[3:0]	G_1[3:0]B_1[3:0]	A_0[3:0]R_0[3:0]	G_0[3:0]B_0[3:0]

The RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

21.3.10 DMA2D output FIFO byte reordering

The output FIFO bytes can be reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:

- RBS bit to swap red and blue component
- SB bit to swap byte two by two in the output FIFO

When the byte swapping is activated (SB = 1 in DMA2D_OPFCR), the number of pixel per line (PL field in DMA2D_NLR) must be even, and the output memory address (MA field in DMA2D_OMAR) must be even. The output line offset computed in bytes (resulting from LOM field in DMA2D_CR and LO field in DMA2D_OOR values) must also be even. If not a configuration error is detected.

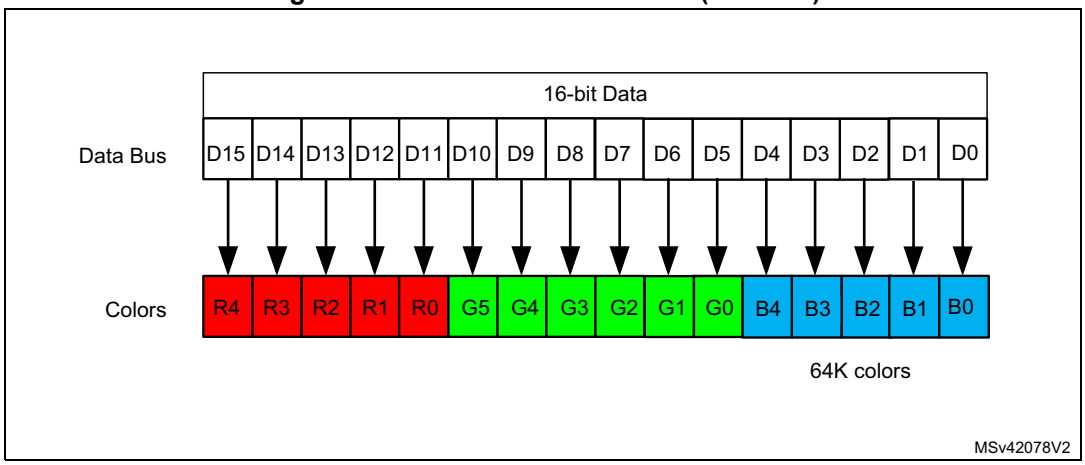
Table 122. Standard data order in memory

Color Mode	@ + 3	@ + 2	@ + 1	@ + 0
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]

16-bit mode (RGB565)

This mode is supported without byte reordering by the DMA2D.

Figure 132. Intel 8080 16-bit mode (RGB565)



18/24-bit mode (RGB888)

This mode needs data reordering:

1. The red and the blue have to be swapped (setting the RBS bit).
2. MSB and the LSB bytes of an half-word must be swapped (setting SB bit).

Figure 133. Intel 8080 18/24-bit mode (RGB888)

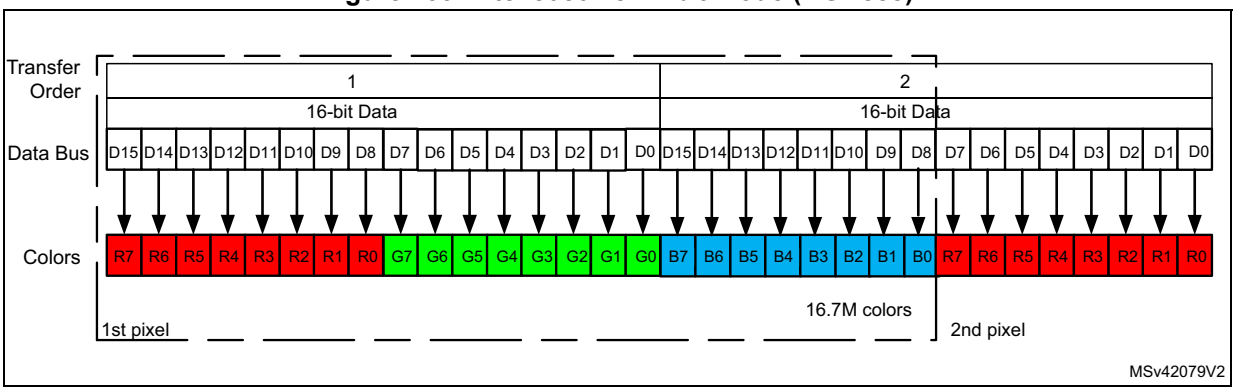


Table 123. Output FIFO byte reordering steps

Steps	@ + 3	@ + 2	@ + 1	@ + 0
Original data ordering	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
Setting the RBS bit				
Data ordering after Red and Blue swap (RBS set)	R_1[7:0]	B_0[7:0]	G_0[7:0]	R_0[7:0]
	G_2[7:0]	R_2[7:0]	B_1[7:0]	G_1[7:0]
	B_3[7:0]	G_3[7:0]	R_3[7:0]	B_2[7:0]
Setting the SB bit				

Table 123. Output FIFO byte reordering steps (continued)

Steps	@ + 3	@ + 2	@ + 1	@ + 0
Data ordering after byte swapping (SB set)	B_0[7:0]	R_1[7:0]	R_0[7:0]	G_0[7:0]
	R_2[7:0]	G_2[7:0]	G_1[7:0]	B_1[7:0]
	G_3[7:0]	B_3[7:0]	B_2[7:0]	R_3[7:0]

21.3.11 DMA2D AXI master port timer

An 8-bit timer is embedded into the AXI master port to provide an optional limitation of the bandwidth on the crossbar. This timer is clocked by the AXI clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and dead time value are configured through DMA2D_AMPTCR.

21.3.12 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. Number of data and width can be programmed by software.

Each DMA2D data transfer is composed of up to four steps:

1. Data loading from the memory location pointed by DMA2D_FGMAR and pixel format conversion as defined in DMA2D_FGCR
2. Data loading from a memory location pointed by DMA2D_BGMAR and pixel format conversion as defined in DMA2D_BGCR
3. Blending of all retrieved pixels according to the alpha channels resulting of PFC operation on alpha values
4. Pixel format conversion of resulting pixels according to DMA2D_OCR and programming of data to the memory location addressed through DMA2D_OMAR

21.3.13 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4-Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the following modes selected through MODE[2:0] in DMA2D_CR:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color. The color format is set in DMA2D_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in DMA2D_OCOLR to the area located at the address pointed by DMA2D_OMAR and defined in DMA2D_NLR and DMA2D_OOR.

Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer, and data are transferred from the source memory location defined in DMA2D_FGMAR, to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed by CM[3:0] in DMA2D_FGPFCCR defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data, and stores them in the destination memory location.

The size of the areas to be transferred are defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Data are fetched from the location defined in DMA2D_FGMAR, and processed by the foreground PFC. The original pixel format is configured through DMA2D_FGPFCCR.

If the original pixel format is direct-color mode, the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into DMA2D_FGCMAR.
2. Set the CLUT size with CS[7:0] in DMA2D_FGPFCCR.
3. Set the CLUT format (24 or 32 bits) with CCM in DMA2D_FGPFCCR.
4. Start the CLUT loading by setting START in DMA2D_FGPFCCR.

Once the CLUT loading is complete, CTCIF flag in DMA2D_IFR is raised, and an interrupt is generated if CTCIE is set in DMA2D_CR. The automatic CLUT loading process cannot work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the AHB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing, and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in DMA2D_FGPFCCR. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel.

The alpha value is modified as follows according to AM[1:0] in DMA2D_FGPFCCR:

- It is unchanged.
- It is replaced by ALPHA[7:0] value in DMA2D_FGPFCCR.
- It is replaced by the original value multiplied by ALPHA[7:0] value in DMA2D_FGPFCCR divided by 255.

The resulting 32-bit data are encoded by the output PFC into the format specified by CM[2:0] in DMA2D_OPFCCR. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

Processed data are written into destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC and blending

In this mode, two sources are fetched in the foreground and background FIFOs from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR respectively.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended according to the equation below:

$$\text{with } \alpha_{Mult} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}$$

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}.\alpha_{FG} + C_{BG}.\alpha_{BG} - C_{BG}.\alpha_{Mult}}{\alpha_{OUT}} \quad \text{with C = R or G or B}$$

Division are rounded to the nearest lower integer

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color FG

In this mode, only one source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by DMA2D_FGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_FGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color BG

In this mode, only open source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.

The value of the background color is given by DMA2D_BGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_BGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory

Once each pixel has been converted into 32 bits by their respective PFCs, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

Configuration error detection

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if CEIE = 1 in DMA2D_CR.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits in DMA2D_FGCMAR are not aligned with CCM in DMA2D_FGPFCCR.
- Background CLUT automatic loading: MA bits in DMA2D_BGCMAR are not aligned with CCM in DMA2D_BGPFCCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): MA bits in DMA2D_FGMAR are not aligned with CM in DMA2D_FGPFCCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): CM bits in DMA2D_FGPFCCR are invalid.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): PL bits in DMA2D_NLR are odd while CM is DMA2D_FGPFCCR is A4 or L4.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): LO bits in DMA2D_FGOR are odd while CM in DMA2D_FGPFCCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode, except in memory-to-memory with blending and fixed color FG): MA bits in DMA2D_BGMAR are not aligned with the CM in DMA2D_BGPFCCR
- Memory transfer (only in blending and blending with fixed color FG): CM bits in DMA2D_BGPFCCR are invalid.
- Memory transfer (only in blending and blending with fixed color FG mode): PL bits in DMA2D_NLR odd while CM inDMA2D_BGPFCCR is A4 or L4.
- Memory transfer (only in blending and blending with fixed color FG): LO bits in DMA2D_BGOR are odd while CM inDMA2D_BGPFCCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (except in memory-to-memory): MA bits in DMA2D_OMAR are not aligned with CM in DMA2D_OPFCCR.
- Memory transfer (except in memory-to-memory): CM bits in DMA2D_OPFCCR are invalid.

- Memory transfer with byte swapping: PL bits in DMA2D_NLR are odd, or MA bits in DMA2D_OMAR are odd, or LO in bytes (resulting from LOM in DMA2D_CR and LO in DMA2D_OOR) are odd while SB = 1 in DMA2D_OPFCCR.
- Memory transfer: NL bits in DMA2D_NLR are all zeros.
- Memory transfer: PL bits in DMA2D_NLR are all zeros.
- Memory transfer: MODE bits in DMA2D_CR are invalid.
- YCbCr format: when a CLUT loading starts setting START in DMA2D_FGPFCCR
- YCbCr format: when memory-to-memory mode is selected
- YCbCr format: when YCbCR4:4:4 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 8 pixels
- YCbCr format: when YCbCr4:2:2 or YCbCr4:2:0 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 16 pixels

21.3.14 YCbCr support

The DMA2D foreground plane can support 8x8 block-based YCbCr as output by the JPEG decoder with different chroma subsampling factors.

The memory organization follows the standard JFIF rules:

- Each of the three color components must be coded on 8-bit.
- Each component must be arranged by blocks of 8x8 (64 bytes) called MCU.

Depending of the chroma subsampling factor, the MCU must be arranged in the memory as described in the table below.

Table 124. MCU order in memory

Sub-sampling	@	@ + 64	@ + 128	@+192	@+256	@ + 320
4:4:4	Y_1	Cb_1	Cr_1	Y_2	Cb_2	Cr_2
4:2:2	Y_1	Y_2	Cb_{12}	Cr_{12}	Y_3	Y_4
4:2:0	Y_1	Y_2	Y_3	Y_4	Cb_{1234}	Cr_{1234}

The chroma subsampling factor is configured through CSS in DMA2D_FGPFCCR.

Once the DMA2D has started with the foreground configured in YCbCr color mode, the first two chroma MCUs are loaded in the foreground CLUT. Once the chroma MCUs are loaded, the DMA2D performs the loading of the Y MCU as for a classical color mode.

21.3.15 DMA2D transfer control (start, suspend, abort, and completion)

Once the DMA2D is configured, the transfer can be launched by setting START in DMA2D_CR. Once the transfer is completed, START is automatically reset, and TCIF flag is raised in DMA2D_ISR. An interrupt can be generated if TCIE is set in DMA2D_CR.

The user application can suspend the DMA2D at any time by setting SUSP in DMA2D_CR. The transaction can be aborted by setting ABORT i nDMA2D_CR, or can be restarted by resetting SUSP in DMA2D_CR.

The user application can abort at any time an ongoing transaction by setting ABORT in DMA2D_CR. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using their own START bits in DMA2D_FGPFCCR and DMA2D_BGPFCCR.

21.3.16 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in LW[15:0] in DMA2D_LWR.

When the last pixel of this line has been transferred, TWIF flag is raised in DMA2D_ISR, and an interrupt is generated if TWIE is set in DMA2D_CR.

21.3.17 Error management

Two kind of errors can be triggered:

- AXI master port errors signaled by TEIF flag in DMA2D_ISR
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signaled by CAEIF flag in DMA2D_ISR

Both flags are associated to their own interrupt enable flag in DMA2D_CR to generate an interrupt if need be (TEIE and CAEIE).

21.3.18 AXI dead time

To limit the AXI bandwidth use, a dead time between two consecutive AXI accesses can be programmed. This feature can be enabled by setting EN in DMA2D_AMTCR.

The dead-time value is stored in DT[7:0] in DMA2D_AMTCR. This value represents the guaranteed minimum number of cycles between two consecutive transactions on AXI bus.

The update of the dead-time value while the DMA2D is running is taken into account for the next AXI transfer.

21.4 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Table 125. DMA2D interrupt requests

Interrupt event	Event flag	Enable control bit
Configuration error	CEIF	CEIE
CLUT transfer complete	CTCIF	CTCIE

Table 125. DMA2D interrupt requests (continued)

Interrupt event	Event flag	Enable control bit
CLUT access error	CAEIF	CAEIE
Transfer watermark	TWF	TWIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

21.5 DMA2D registers

21.5.1 DMA2D control register (DMA2D_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CEIE	CTCIE	CAEIE	TWIE	TCIE	TEIE	Res.	LOM	Res.	Res.	Res.	ABORT	SUSP	START
		rw	rw	rw	rw	rw	rw		rw				rs	rw	rs

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE[2:0]**: DMA2D mode
This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.
000: Memory-to-memory (FG fetch only)
001: Memory-to-memory with PFC (FG fetch only with FG PFC active)
010: Memory-to-memory with blending (FG and BG fetch with PFC and blending)
011: Register-to-memory (no FG nor BG, only output stage active)
100: Memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active)
101: Memory-to-memory with blending and fixed color BG (FG fetch only with FG and BG PFC active)
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CEIE**: Configuration error (CE) interrupt enable
This bit is set and cleared by software.
0: CE interrupt disabled
1: CE interrupt enabled

Bit 12 **CTCIE**: CLUT transfer complete (CTC) interrupt enable
This bit is set and cleared by software.
0: CTC interrupt disabled
1: CTC interrupt enabled

Bit 11 **CAEIE**: CLUT access error (CAE) interrupt enable
This bit is set and cleared by software.
0: CAE interrupt disabled
1: CAE interrupt enabled

Bit 10 **TWIE**: Transfer watermark (TW) interrupt enable
This bit is set and cleared by software.
0: TW interrupt disabled
1: TW interrupt enabled

Bit 9 **TCIE**: Transfer complete (TC) interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 8 **TEIE**: Transfer error (TE) interrupt enable
This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LOM**: Line offset mode
This bit configures how the line offset is expressed (pixels or bytes) for the foreground, background and output.
This bit is set and cleared by software. It can not be modified while a transfer is ongoing.
0: Line offsets expressed in pixels
1: Line offsets expressed in bytes

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **ABORT**: Abort
This bit can be used to abort the current transfer. This bit is set by software, and is automatically reset by hardware when START = 0.
0: No transfer abort requested
1: Transfer abort requested

Bit 1 **SUSP**: Suspend
This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when START = 0.
0: Transfer not suspended
1: Transfer suspended

Bit 0 **START**: Start
This bit can be used to launch the DMA2D according to parameters loaded in the various configuration registers. This bit is automatically reset by the following events:
- at the end of the transfer
- when the data transfer is aborted by the user by setting ABORT in this register
- when a data transfer error occurs
- when the data transfer has not started due to a configuration error, or another transfer operation already ongoing (automatic CLUT loading)

21.5.2 DMA2D interrupt status register (DMA2D_ISR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CEIF	CTCIF	CAEIF	TWIF	TCIF	TEIF
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CEIF**: Configuration error interrupt flag
This bit is set when START is set in DMA2D_CR, DMA2DFGPFCCR or DMA2D_BGPFCCR, and a wrong configuration has been programmed.

Bit 4 **CTCIF**: CLUT transfer complete interrupt flag
This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3 **CAEIF**: CLUT access error interrupt flag
This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2 **TWIF**: Transfer watermark interrupt flag
This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1 **TCIF**: Transfer complete interrupt flag
This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0 **TEIF**: Transfer error interrupt flag
This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

21.5.3 DMA2D interrupt flag clear register (DMA2D_IFCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

										rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CCEIF**: Clear configuration error interrupt flag
Programming this bit to 1 clears the CEIF flag in DMA2D_ISR.

Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag
Programming this bit to 1 clears the CTCIF flag in DMA2D_ISR.

Bit 3 **CAECIF**: Clear CLUT access error interrupt flag
Programming this bit to 1 clears the CAEIF flag in DMA2D_ISR.

Bit 2 **CTWIF**: Clear transfer watermark interrupt flag
Programming this bit to 1 clears the TWIF flag in DMA2D_ISR.

Bit 1 **CTCIF**: Clear transfer complete interrupt flag
Programming this bit to 1 clears the TCIF flag in DMA2D_ISR.

Bit 0 **CTEIF**: Clear transfer error interrupt flag
Programming this bit to 1 clears the TEIF flag in DMA2D_ISR.

21.5.4 DMA2D foreground memory address register (DMA2D_FGMAR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address, address of the data used for the foreground image
The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned, and a 4-bit per pixel format must be 8-bit aligned.

21.5.5 DMA2D foreground offset register (DMA2D_FGOR)

Address offset: 0x010

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the foreground image, expressed:

– in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.

– in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

If the image format is 4-bit per pixel, the line offset must be even.

21.5.6 DMA2D background memory address register (DMA2D_BGMAR)

Address offset: 0x014

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address, address of the data used for the background image

The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

21.5.7 DMA2D background offset register (DMA2D_BGOR)

Address offset: 0x018

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the background image, expressed:

– in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.

– in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

If the image format is 4-bit per pixel, the line offset must be even.

21.5.8 DMA2D foreground PFC control register (DMA2D_FGPFCCR)

Address offset: 0x01C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								Res.	Res.	RBS	AI	CSS[1:0]		AM[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rc_w1	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied by the original alpha value, according to the alpha mode selected through AM[1:0] in this register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap

This bit allows to swap Red and Blue to support BGR or ABGR color formats.

0: Regular mode (RGB or ARGB)

1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha inverted

This bit inverts the alpha value.

0: Regular alpha

1: Inverted alpha

Bits 19:18 **CSS[1:0]**: Chroma subsampling

These bits define the chroma subsampling mode for YCbCr color mode.

00: 4:4:4 (no chroma subsampling)

01: 4:2:2

10: 4:2:0

Others: Reserved

Bits 17:16 **AM[1:0]**: Alpha mode
These bits select the alpha channel value to be used for the foreground image.
00: No modification of the foreground image alpha channel value
01: Replace original foreground image alpha channel value by ALPHA[7: 0]
10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Others: Reserved

Bits 15:8 **CS[7:0]**: CLUT size
These bits define the size of the CLUT used for the foreground image.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start
This bit can be set to start the automatic loading of the CLUT. It is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user by setting ABORT in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode
This bit defines the color format of the CLUT.
0: ARGB8888
1: RGB888

Bits 3:0 **CM[3:0]**: Color mode
These bits defines the color format of the foreground image.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
1011: YCbCr
Others: Reserved

21.5.9 DMA2D foreground color register (DMA2D_FGCOLR)

Address offset: 0x020

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RED[7:0]

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

Bits 15:8 **GREEN[7:0]**: Green value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

Bits 7:0 **BLUE[7:0]**: Blue value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

21.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR)

Address offset: 0x024

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rc_w1	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied with the original alpha value according to the alpha mode selected with AM[1:0].

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap
This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted
This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **AM[1:0]**: Alpha mode
These bits define which alpha channel value to be used for the background image.
00: No modification of the foreground image alpha channel value
01: Replace original background image alpha channel value by ALPHA[7: 0]
10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Others: Reserved

Bits 15:8 **CS[7:0]**: CLUT size
These bits define the size of the CLUT used for the BG.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start
This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user by setting ABORT bit in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode
These bits define the color format of the CLUT.
0: ARGB8888
1: RGB888

Bits 3:0 **CM[3:0]**: Color mode
These bits define the color format of the foreground image.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
Others: Reserved

21.5.11 DMA2D background color register (DMA2D_BGCOLR)

Address offset: 0x028

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

Bits 15:8 **GREEN[7:0]**: Green value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

Bits 7:0 **BLUE[7:0]**: Blue value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

21.5.12 DMA2D foreground CLUT memory address register (DMA2D_FGCMAR)

Address offset: 0x02C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address
Address of the data used for the CLUT address dedicated to the foreground image.
If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.

21.5.13 DMA2D background CLUT memory address register (DMA2D_BGCMAR)

Address offset: 0x030

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

Address of the data used for the CLUT address dedicated to the background image. If the background CLUT format is 32-bit, the address must be 32-bit aligned.

21.5.14 DMA2D output PFC control register (DMA2D_OPFCCR)

Address offset: 0x034

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw						rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap

This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted

This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:9 Reserved, must be kept at reset value.

Bit 8 **SB**: Swap bytes
When this bit is set, the bytes in the output FIFO are swapped two by two. The number of pixels per line (PL) must be even, and the output memory address (OMAR) must be even.
0: Bytes in regular order in the output FIFO
1: Bytes swapped two by two in the output FIFO

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **CM[2:0]**: Color mode
These bits define the color format of the output image.
000: ARGB8888
001: RGB888
010: RGB565
011: ARGB1555
100: ARGB4444
Others: Reserved

21.5.15 DMA2D output color register (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARGB8888 or RGB888 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								RED[7:0]

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha channel value of the output color in ARGB8888 mode (otherwise reserved)

Bits 23:16 **RED[7:0]**: Red value of the output image in ARGB8888 or RGB888 mode

Bits 15:8 **GREEN[7:0]**: Green value of the output image in ARGB8888 or RGB888

Bits 7:0 **BLUE[7:0]**: Blue value of the output image in ARGB8888 or RGB888

21.5.16 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

RGB565 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

Address of the data used for the output FIFO.

The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.

21.5.20 DMA2D output offset register (DMA2D_OOR)

Address offset: 0x040

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the output, expressed:

- in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
- in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

21.5.21 DMA2D number of line register (DMA2D_NLR)

Address offset: 0x044

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

NL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **PL[13:0]**: Pixel per lines per lines of the area to be transferred

If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 **NL[15:0]**: Number of lines of the area to be transferred.

21.5.22 DMA2D line watermark register (DMA2D_LWR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

rw	rw	rw	rw	rw	rw	rw	rw								rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DT[7:0]**: Dead time

Dead time value in the AXI clock cycle inserted between two consecutive accesses on the AXI master port. These bits represent the minimum guaranteed number of cycles between two consecutive AXI accesses.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **EN**: Dead-time functionality enable

21.5.24 DMA2D foreground CLUT (DMA2D_FGCLUTx)

Address offset: 0x400 + 0x4 * x, (x = 0 to 255)

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

22 Chrom-GRC (GFXMMU)

22.1 Introduction

The Chrom-GRC (GFXMMU) is a graphical oriented memory management unit aimed to optimize memory usage according to the display shape.

22.2 GFXMMU main features

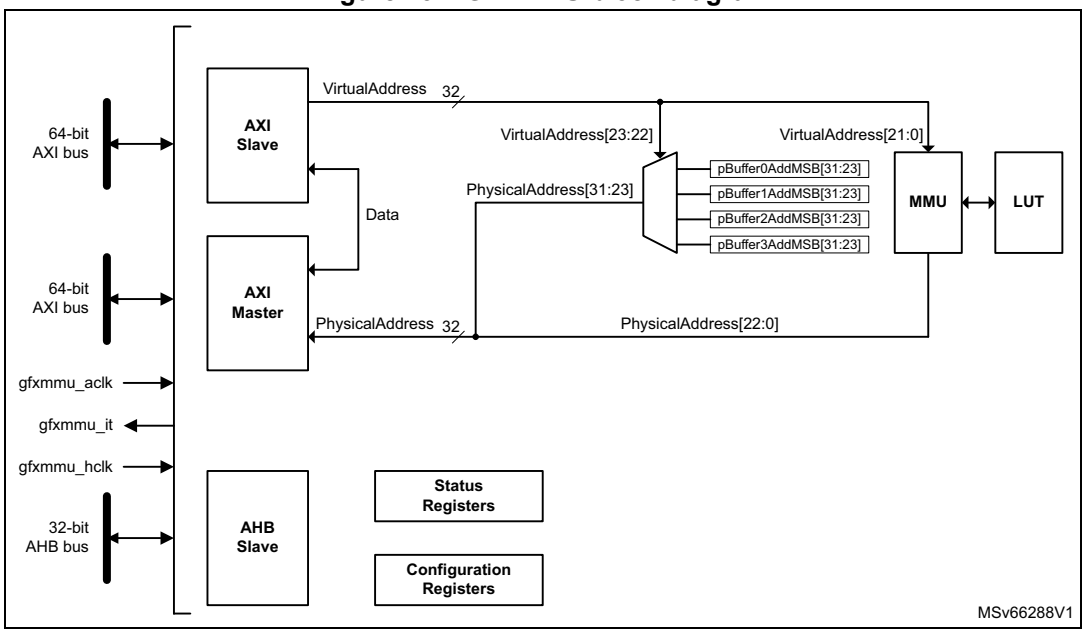
- Fully programmable display shape to physically store only the visible pixel
- Up to 4 virtual buffers
- Each virtual buffer have 3072 or 4096 bytes per line and 1024 lines
- Each virtual buffer can be physically mapped to any system memory
- Packing and unpacking operation to store 32-bit pixel data into 24-bit packed
- Interrupt in case of buffer overflow (1 per buffer)
- Interrupt in case of memory transfer error

22.3 GFXMMU functional and architectural description

The GFXMMU is responsible of address resolution to convert the virtual buffer address into the physical buffer address.

22.3.1 GFXMMU block diagram

Figure 134. GFXMMU block diagram



22.3.2 GFXMMU internal signals

Table 127. GFXMMU internal input/output signals

Internal signal name	Signal type	Description
gfxmmu_aclk	input	GFXMMU AXI clock
gfxmmu_hclk	Input	GFXMMU AHB clock
gfxmmu_it	Output	GFXMMU global interrupt

22.3.3 Virtual memory

The GFXMMU provides a virtual memory space seen by the system masters. This virtual memory space is divided into four virtual buffers.

Virtual buffer

A virtual buffer is seen by any system master as a continuous memory space representing a virtual frame buffer of 1024 lines.

Each line is divided into 256 12-byte or 16-byte blocks depending on the BS bit of the GFXMMU configuration register (GFXMMU_CR).

When the address translation is enabled setting the address translation enable (ATE) bit of the graphic MMU configuration register (GFXMMU_CR), each line can be configured individually to be mapped onto a physical memory.

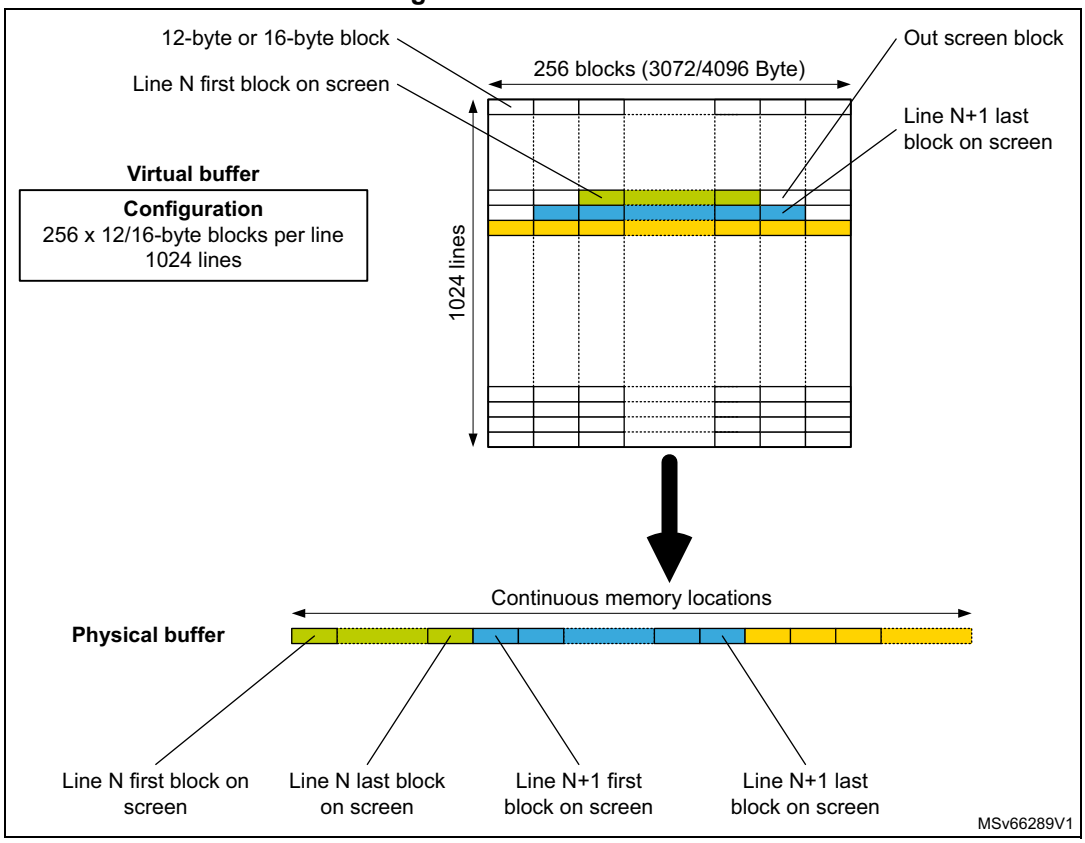
Depending on the display shape and size, only the necessary blocks are mapped to a physical memory location. This mapping is done programming the LUT entry for each line:

- The enable of the line
- The number of the first “visible” block
- The number of the last “visible” block
- The address offset of the line within the physical buffer

The “visible” blocks can be arranged in the physical buffer in a continuous way programming the address offset of each line.

The LUT is common to all the buffers i.e. all the buffers have the same “shape”.

Figure 135. Virtual buffer



Virtual buffer overview

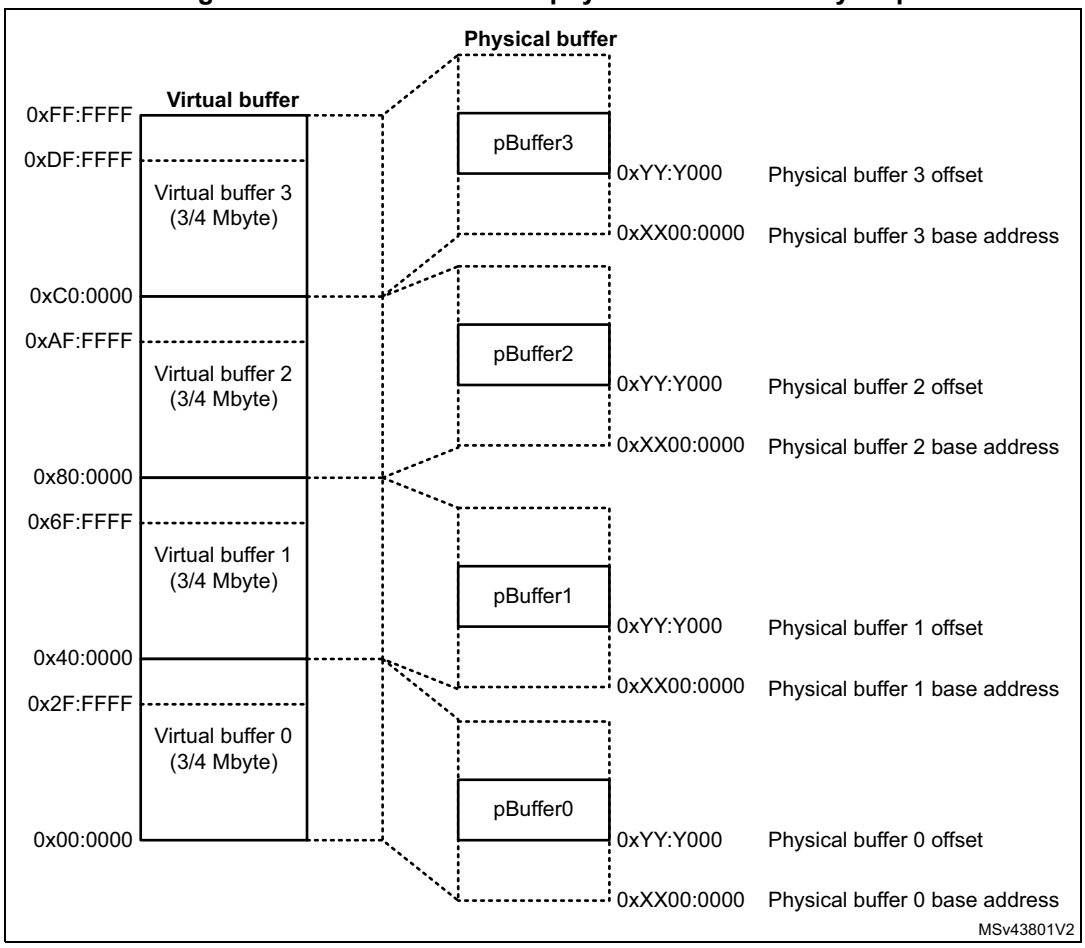
For a frame buffer coded in 32 bpp or 16 bpp, the virtual buffer can be configured to have 12-byte or 16-byte blocks. This results in a virtual frame buffer of 768 x 1024 or 1024 x 1024 pixels for 32 bpp and 1536 x 1024 or 2048 x 1024 for 16 bpp.

For a frame buffer coded in 24 bpp, the virtual buffer must be configured to have 12-byte blocks to have an integer number of pixel per lines. This results in a virtual frame buffer of 1024 x 1024 pixels for 24 bpp.

Each buffer can be physically mapped anywhere in the physical memory thanks to:

- The physical buffer base address (PBBA) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR). It configures the physical location of the 8-Mbyte area where the buffer is mapped.
- The physical buffer location respective to the physical buffer base address is defined by the physical buffer offset (PBO) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR).

Figure 136. Virtual buffer and physical buffer memory map



The buffer can not overflow the 8-Mbyte boundary of the zone defined by its base address. In case of overflow, the buffer x overflow flag (BxOF) of the GFXMMU status register (GFXMMU_SR) is set and an interrupt is generated if the buffer x overflow interrupt enable (BxOIE) bit of the GFXMMU configuration register (GFXMMU_CR) is set.

Virtual buffer application use case

As the physical locations are independently configurable, the four virtual buffers can be physically mapped to non continuous locations. This would allow for example to have the four buffers mapped on to four different SDRAM banks and avoid extra precharge cycles accessing the SDRAM.

As a consequence, one buffer must be used by the CPU/Graphic accelerator for frame buffer calculation while an other one must be used by the LTDC.

The two remaining buffers can be used as a graphical library requiring extra drawing buffers.

22.3.4 Packing and unpacking

When addressing 24bpp frame buffers, the virtual buffer must be configured in 12-byte block mode to have an integer number of pixel per block.

Nevertheless, it is possible to access these 24-bit data as if they where unpacked in a 32-bit word.

The packing mode is enabled, per buffer setting the buffer x packing enable (BxPE) bit of the graphic MMU configuration register (GFXMMU_CR).

When the packing mode is enabled and the 12-byte mode is selected, the access to the buffer are done as in 16-byte mode, but either the most significant byte or the less significant byte is ignored to transform each 32-bit word into a 24-bit word.

The ignored byte is selected with the buffer x packing mode (BxPM) bit of the graphic MMU configuration register (GFXMMU_CR).

During write operation MSB or LSB is ignored. During read operation, the ignored MSB or LSB is replaced by the 8-bit default value programmed in the default alpha (DA) field of the graphic MMU default alpha register (GFXMMU_DAR)

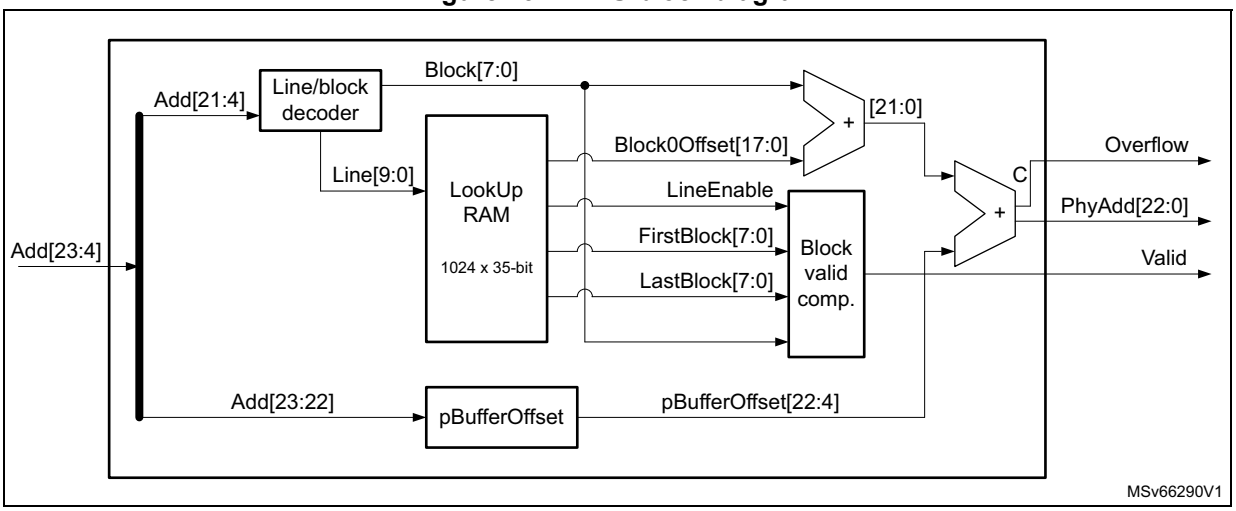
The buffer x packing enable (BxPE) bit has no effect when the graphic MMU is configured in 16-byte block.

22.3.5 MMU architecture

The MMU block is responsible of the address resolution. It receives the 24-bit address and returns the physical 23-bit address and a valid signals to indicate the address is physically mapped or not. The MMU also checks overflow of a area boundary.

The MMU LUT is implemented as a 1024 x 35-bit RAM

Figure 137. MMU block diagram



Line block decoder

The line block decoder is generating the block number and the line number according the address.

Look up RAM

The look up RAM is a 1024 x 35-bit RAM with the following fields:

- 1-bit line enable
- 8-bit first valid block
- 8-bit last valid block
- 18-bit for line offset

As the RAM is bigger than a word, each entry is split into two words on the memory map. The write access are done in two steps:

1. Write the first word with enable/first valid block/last valid block in the GFXMMU_LUTxL memory location (internally buffered).
2. Write the second word with line offset in the GFXMMU_LUTxH memory location (effective write into the memory together with the internally buffered value).

A write in the LUT can happen any time but it can lead to inconsistencies if a master is using the MMU at the same time. As the CPU has the priority during LUT programming, this may slow down MMU calculation.

There is no restriction during read operations, but this may slow down CPU as the MMU has the priority on LUT accesses.

Block validation/comparator

This block is checking if the block is valid.

A block is considered as valid (physically mapped) when:

- Line is enable.
- The block number is greater or equal to the first valid block.
- The block number is lower or equal to the last valid block.

When the block is valid, the physical address generated is considered as correct.

If the result of the MMU evaluation is not valid, the write operations are ignored, and read operations return the default 32-bit value stored in the default value (DV) field of the GFXMMU default value register (GFXMMU_DVR).

Block offset address calculation within the buffer

The block number is added to the line offset to get the offset of the block within the physical buffer.

As a consequence, the line offset stored in the LUT is given by the following formula:

$$\text{Line offset} = [(\text{Number of visible blocks already used}) - (1^{st} \text{ visible block})]$$

with:

- The maximum value for the line offset is when all the block of all the line are used. As the consequence the line offset for the last line can be maximum:
  1023 x 256 = 0x3:FF00
- The minimum value for the line offset is when the last block of the first line is the first valid block: -255 = - 0xFF i.e 0x3:FF01

As the consequence the full range of the line offset entry of the LUT is used.

Carry is not taken into account as this stage to be able to perform negative offset calculations (values from 0x3:FF01 to 0x3:FFFF)

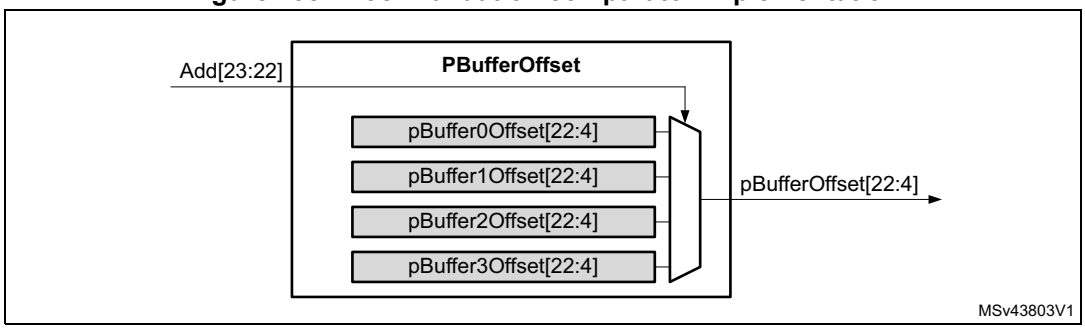
As the block offset is within a 4-Mbyte buffer, the address generated is 22-bit wide.

Block offset address calculation

Once the offset of the block within the buffer as been calculated, this value is added to the offset of the block respective to the physical buffer base address.

The offset of the blocks are defined in registers as shown in *Figure 138*:

Figure 138. Block validation/comparator implementation



The resulting address and the buffer offset address must be on 23-bit.

The carry is taken into account to trigger address overflow. The carry is propagated to the GFXMMU status register (GFXMMU_SR) to set the buffer x overflow flag (BxOF).

Example of calculation

Consider the following configuration for virtual buffer 0:

- 16-byte block mode
- First visible block of line 0: block 7
- Number of visible block in line 0: 10
- First visible block of line 1: block 6
- Number of visible block in line 1: 12
- Address of the physical buffer: 0xC020:0000

The configuration must be:

- The base address of the physical buffer 0: 0xC000:0000
- The offset of buffer 0: 0x20:0000
- First visible block of line 0: block 7
- Last visible block of line 0: block 16
- Block 0 offset of line 0: (0 - 7) = -0x7 = 0x3:FFF9
- First visible block of line 1: block 6
- Last visible block of line 1: block 17
- Block 0 offset of line 1: (10 - 6) = (0xA - 0x6) = 0x4

As a consequence:

- the physical address of block 7 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x7 without carry) x 0x10 = 0xC020:0000

- the physical address of block 16 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x10 without carry) x 0x10 = 0xC020:0090

- the physical address of block 6 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x4 + 0x6 without carry) x 0x10 = 0xC020:00A0

- the physical address of block 17 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x4 + 0x11 without carry) x 0x10 = 0xC020:0150

For the same example in 12-byte mode, the user has the same configuration regarding the offsets by the addresses are different in the physical buffer:

- the physical address of block 7 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x7 without carry) x 0x0C = 0xC020:0000

- the physical address of block 16 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x10 without carry) x 0x0C = 0xC020:006C

- the physical address of block 6 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x4 + 0x6 without carry) x 0x0C = 0xC020:0078

- the physical address of block 17 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x4 + 0x11 without carry) x 0x0C = 0xC020:00FC

22.4 GFXMMU interrupts

An interrupt can be produced on the following events:

- Buffer 0 overflow
- Buffer 1 overflow
- Buffer 2 overflow
- Buffer 3 overflow
- AXI master error

Separate interrupt enable bits are available for flexibility.

Table 128. GFXMMU interrupt requests

Interrupt event	Event flag	Enable control bit
Buffer 0 overflow	B0OF	B0OIE
Buffer 1 overflow	B1OF	B1OIE
Buffer 2 overflow	B2OF	B2OIE
Buffer 3 overflow	B3OF	B3OIE
AXI master error	AMEF	AMEIE

22.5 GFXMMU registers

22.5.1 GFXMMU configuration register (GFXMMU_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
B3PM	B3PE	B2PM	B2PE	B1PM	B1PE	B0PM	B0PE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ATE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BS	Res.	AMEIE	B3OIE	B2OIE	B1OIE	B0OIE
rw									rw		rw	rw	rw	rw	rw

Bit 31 **B3PM**: Buffer 3 packing mode

This bit selects the byte to be removed during packing operations on buffer 3

0: MSB is removed

1: LSB is removed

Bit 30 **B3PE**: Buffer 3 packing enable

This bit enables the packing on buffer 3.

The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.

0: Packing is disabled

1: Packing is enable

Bit 29 **B2PM**: Buffer 2 packing mode

This bit selects the byte to be removed during packing operations on buffer 2

0: MSB is removed

1: LSB is removed

Bit 28 **B2PE**: Buffer 2 packing enable

This bit enables the packing on buffer 2.

The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.

0: Packing is disabled

1: Packing is enable

Bit 27 **B1PM**: Buffer 1 packing mode

This bit selects the byte to be removed during packing operations on buffer 1

0: MSB is removed

1: LSB is removed

Bit 26 **B1PE**: Buffer 1 packing enable

This bit enables the packing on buffer 1.

The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.

0: Packing is disabled

1: Packing is enable

Bit 25 **B0PM**: Buffer 0 packing mode

This bit selects the byte to be removed during packing operations on buffer 0

0: MSB is removed

1: LSB is removed

Bit 24 **B0PE**: Buffer 0 packing enable
This bit enables the packing on buffer 0.
The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.
0: Packing is disabled
1: Packing is enable

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 **ATE**: Address translation enable
This bit enables the address translation based on the values programmed in the LUT.
0: Address translation is disable
1: Address translation is enable

Bits 14:7 Reserved, must be kept at reset value.

Bit 6 **BS**: Block size
This bit defines the size of the blocks
0: 16-byte blocks
1: 12-byte blocks

Bit 5 Reserved, must be kept at reset value.

Bit 4 **AMEIE**: AXI master error interrupt enable
This bit enables the AXI master error interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 3 **B3OIE**: Buffer 3 overflow interrupt enable
This bit enables the buffer 3 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 2 **B2OIE**: Buffer 2 overflow interrupt enable
This bit enables the buffer 2 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 1 **B1OIE**: Buffer 1 overflow interrupt enable
This bit enables the buffer 1 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 0 **B0OIE**: Buffer 0 overflow interrupt enable
This bit enables the buffer 0 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

22.5.2 GFXMMU status register (GFXMMU_SR)

Address offset: 0x0004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AMEF	B3OF	B2OF	B1OF	B0OF
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **AMEF**: AXI master error flag
This bit is set when an AXI error happens during a transaction. It is cleared by writing 1 to CAMEF.

Bit 3 **B3OF**: Buffer 3 overflow flag
This bit is set when an overflow occurs during the offset calculation of the buffer 3. It is cleared by writing 1 to CB3OF.

Bit 2 **B2OF**: Buffer 2 overflow flag
This bit is set when an overflow occurs during the offset calculation of the buffer 2. It is cleared by writing 1 to CB2OF.

Bit 1 **B1OF**: Buffer 1 overflow flag
This bit is set when an overflow occurs during the offset calculation of the buffer 1. It is cleared by writing 1 to CB1OF.

Bit 0 **B0OF**: Buffer 0 overflow flag
This bit is set when an overflow occurs during the offset calculation of the buffer 0. It is cleared by writing 1 to CB0OF.

22.5.3 GFXMMU flag clear register (GFXMMU_FCR)

Address offset: 0x0008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CAMEF	CB3OF	CB2OF	CB1OF	CB0OF
											rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CAMEF**: Clear AXI master error flag
Writing 1 clears the AXI master error flag in the GFXMMU_SR register.

Bit 3 **CB3OF**: Clear buffer 3 overflow flag
Writing 1 clears the buffer 3 overflow flag in the GFXMMU_SR register.

Bit 2 **CB2OF**: Clear buffer 2 overflow flag
Writing 1 clears the buffer 2 overflow flag in the GFXMMU_SR register.

Bit 1 **CB1OF**: Clear buffer 1 overflow flag
Writing 1 clears the buffer 1 overflow flag in the GFXMMU_SR register.

Bit 0 **CB0OF**: Clear buffer 0 overflow flag
Writing 1 clears the buffer 0 overflow flag in the GFXMMU_SR register.

22.5.4 GFXMMU default value register (GFXMMU_DVR)

Address offset: 0x0010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw								rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **LVB[7:0]**: Last valid block
Number of the last valid block of line number X.

Bits 15:8 **FVB[7:0]**: First valid block
Number of the first valid block of line number x.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **EN**: Enable
Line enable.
0: Line is disabled (no MMU evaluation is performed)
1: Line is enabled (MMU evaluation is performed)

22.5.8 GFXMMU LUT entry x high (GFXMMU_LUTxH)

Address offset: 0x1004 + 0x8 * x, (x = 0 to 1023)

Reset value: 0x0000 0000

Refer to *Section 2.3* for the register boundary addresses.

23 Graphic timer (GFXTIM)

23.1 Introduction

The graphic timer (GFXTIM) is a graphic oriented timer allowing smart management of graphical events for frame or line counting.

23.2 GFXTIM main features

- Integrated frame and line clock generation
- One absolute frame counter with one compare channel
- Two auto-reload relative frame counters
- One line timer with two compare channels
- External tearing-effect line management and synchronization
- Four programmable event generators with external trigger generation
- One watchdog counter

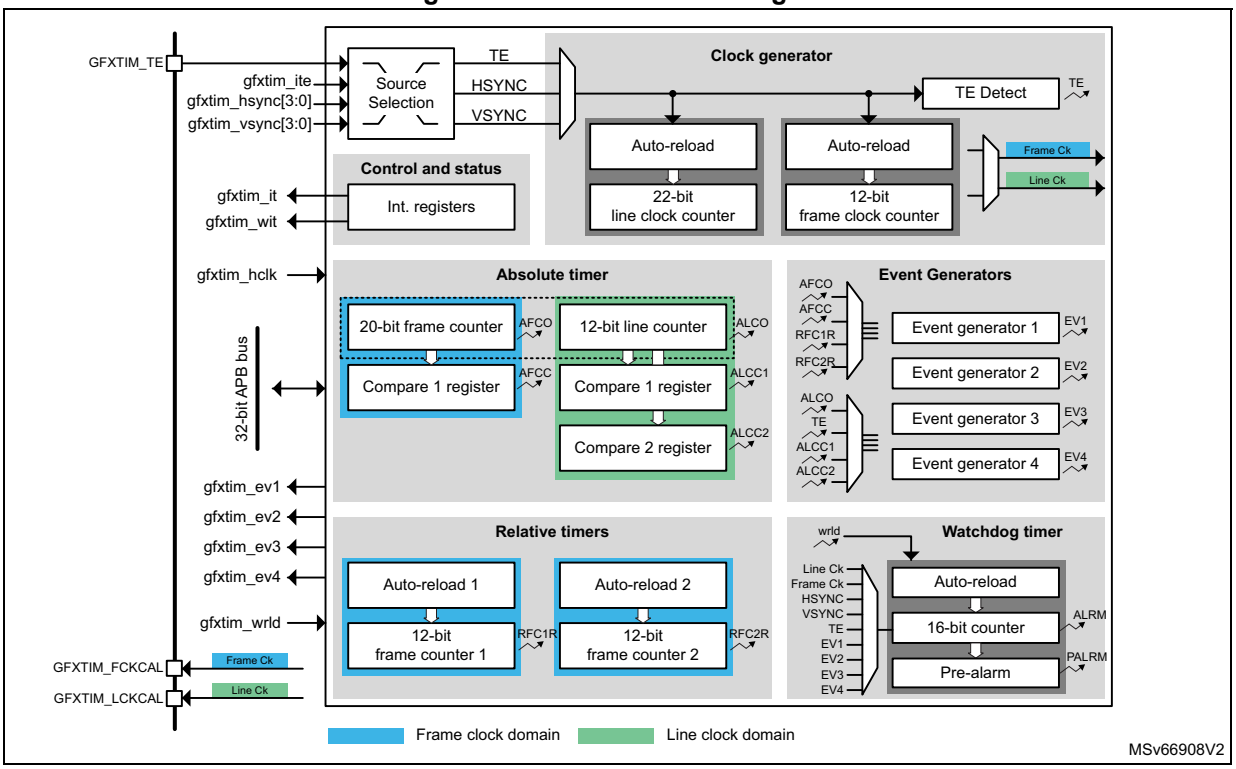
23.3 GFXTIM functional description

23.3.1 Block diagram

The graphic timer is split into six functional blocks

- Clock generator
- Absolute timers
- Relative timers
- Tearing-effect detection
- Event generators
- Watchdog timer

Figure 139. GFXTIM block diagram



23.3.2 GFXTIM pins and internal signals

Table 130. GFXTIM input/output pins

Pin name	Signal type	Description
GFXTIM_TE	Input	Tearing effect
GFXTIM_FCKCAL	Output	Frame clock calibration output
GFXTIM_LCKCAL	Output	Line clock calibration output

Table 131. GFXTIM internal signals

Signal name	Signal type	Description
gfxtim_hclk	Digital input	Kernel and register interface clock
gfxtim_it	Digital output	Global interrupt
gfxtim_wit	Digital output	Watchdog global interrupt
gfxtim_ev1	Digital output	Graphic timer event 1
gfxtim_ev2	Digital output	Graphic timer event 2
gfxtim_ev3	Digital output	Graphic timer event 3
gfxtim_ev4	Digital output	Graphic timer event 4
gfxtim_wrld	Digital input	Watchdog reload
gfxtim_ite	Digital input	Internal tearing effect

Table 131. GFXTIM internal signals (continued)

Signal name	Signal type	Description
gfxtim_hsync[3:0]	Digital input	Horizontal synchronization
gfxtim_vsync[3:0]	Digital input	Vertical synchronization

The table below shows how GFXTIM triggers are connected.

Table 132. GFXTIM trigger interconnections

Trigger name	Direction	Trigger source/destination
gfxtim_ev1	Output	hpdma_trigsel[28]
		gpdma_trigsel[28]
gfxtim_ev2	Output	hpdma_trigsel[27]
		gpdma_trigsel[27]
gfxtim_ev3	Output	hpdma_trigsel[26]
		gpdma_trigsel[26]

		gpdma_trigsel[25]
gfxtim_wrld	Input	reserved
gfxtim_ite	Input	reserved
gfxtim_hsync[0]	Input	LCD_HSYNC
gfxtim_hsync[1]	Input	dcmipp_p0_hsync_evt
gfxtim_hsync[2]	Input	dcmipp_p1_hsync_evt
gfxtim_hsync[3]	Input	dcmipp_p2_hsync_evt
gfxtim_vsync[0]	Input	LCD_VSYNC
gfxtim_vsync[1]	Input	dcmipp_p0_vsync_evt
gfxtim_vsync[2]	Input	dcmipp_p1_vsync_evt
gfxtim_vsync[3]	Input	dcmipp_p2_vsync_evt

23.3.3 Clock generator

Two clocks are generated internally to fed the absolute and relative timers:

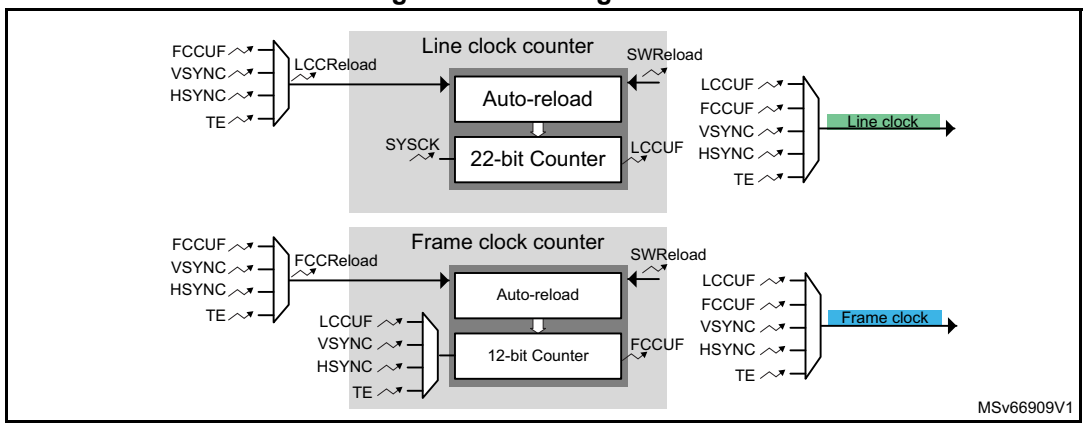
- the frame clock: clocking frame counters
- the line clock: clocking line counters

Internal counter for time base generation

The GFXTIM embeds a two-clock generation counter:

- a 22-bit auto-reload down-counter on the system clock
- a 12-bit auto-reload down-counter on selectable internal or external event

Figure 140. Clock generator



Line clock counter

The line clock counter is a 22-bit auto-reload down-counter on the system clock.

The line clock counter is enabled selecting its clock source with LCCCS (line clock counter clock source) in GFXTIM_CGCR (clock generator control register).

The line clock counter can be reloaded automatically when one of the following event occurs:

- frame clock counter underflows
- VSYNC edge (with control of polarity)
- HSYNC edge (with control of polarity)
- TE edge (with control of polarity)

The hardware reload function and source can be selected with LCCHRS (line clock counter hardware reload source) in GFXTIM_CGCR (clock generator control register).

The line clock counter can be reloaded by software, setting LCCFR (line clock counter force reload) in GFXTIM_CGCR (clock generator control register).

The reload value is programmed in GFXTIM_LCCRR (line clock counter reload register).

Frame clock counter

The frame clock counter if an 12-bit auto-reload down-counter clocked by either, TE, HYSNC, VSYNC or a line clock counter underflow.

The frame clock counter is enabled selecting its clock source with FCCCS in GFXTIM_CGCR.

The frame clock counter can be reloaded automatically when one of the following event occurs:

- line clock counter underflow
- VSYNC edge (with control of polarity)
- HSYNC edge (with control of polarity)
- TE edge (with control of polarity)

The hardware reload function and source can be selected with FCCHRS in GFXTIM_CGCR.

The frame clock counter can be reloaded by software, setting FCCFR in GFXTIM_CGCR.

The reload value is programmed in GFXTIM_FCCRR.

Clock generation

The line clock source can be one of the following:

- underflow flag of the internal 22-bit down-counter
- underflow flag of the internal 12-bit down-counter
- HSYNC, VSYNC or TE pin (with control of polarity)

The frame clock source can be one of the following:

- underflow flag of the internal 22-bit down-counter
- underflow flag of the internal 12-bit down-counter
- HSYNC, VSYNC or TE pin (with control of polarity)

Clock calibration output

For calibration/debug purpose, the frame clock and line clock can be output on a specific I/O.

The frame clock calibration output is enabled by setting FCCOE (frame clock calibration output enable) in GFXTIM_CR (configuration register).

The line clock calibration output is enabled by setting LCCOE in GFXTIM_CR.

Synchronization and tearing-effect sources

The GFXTIM can be connected to peripherals providing HSYNC and/or VSYNC synchronization signals, like the LCD-TFT controller or the camera interface.

The source of HSYNC and/or VSYNC is selected through SYNCS (synchronization source) in GFXTIM_CR.

The tearing-effect source can be an external pin or can be provided by the MIPI® DSI Host on system embedding this interface. To extend the orthogonality versus the synchronization signals, the tearing-effect source can be also the selected HSYNC or VSYNC input.

The tearing-effect source can be selected with TES (TE source) in GFXTIM_CR.

23.3.4 Example of clock generator configuration

The clock generator can have several configuration to work:

- in standalone (without any external synchronization)
- with external HSYNC and VSYNC
- with external HSYNC only
- with external VSYNC only
- with external CSYNC (TE) only

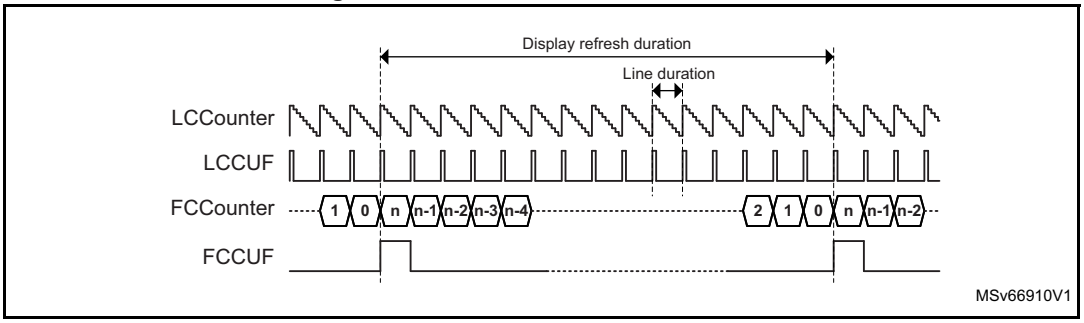
The synchronization signals, HSYNC, VSYNC and TE, are symmetrical in the implementation and can be exchanged if needed.

The set of examples detailed below are given for reference, but other combinations can be programmed int the clock generator.

Standalone

In standalone configuration, the clock generator provides to the GFXTIM, the frame clock and the line clock without any external signals.

Figure 141. Waveforms in standalone

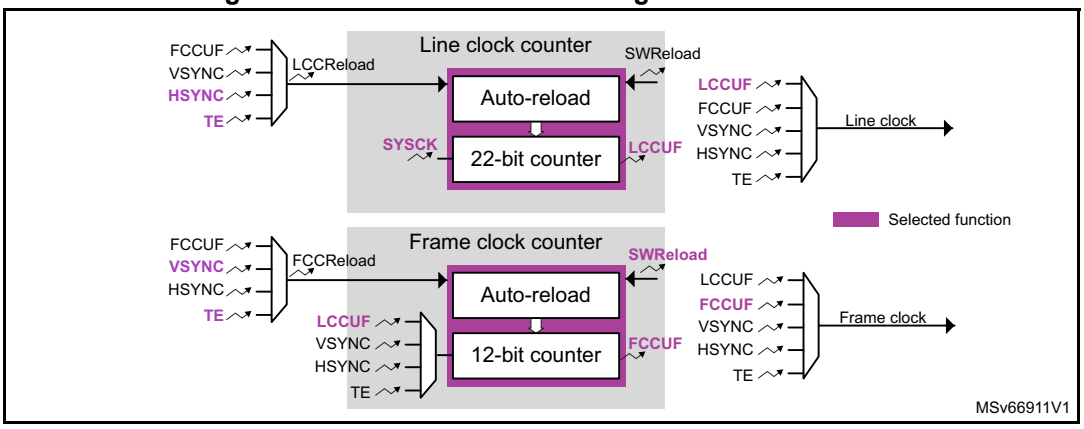


The LCCUF (line-clock counter underflow) event acts as line clock and the FCCUF (frame-clock counter underflow) acts as frame clock.

The clock generator can be synchronized by one of the following ways:

- by software reload, setting the FCCFR in GFXTIM_CGCR.
- by hardware reload on an external VSYNC (or TE)

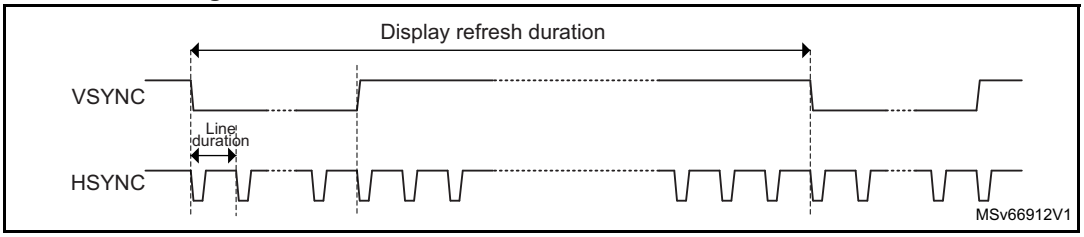
Figure 142. Active counters and signals in standalone



External HSYNC and VSYNC

When using external HSYNC and VSYNC, the counters are not used for the line and frame clock generation. The clock generator copy directly HSYNC to the line clock and VSYNC to the frame clock.

Figure 143. Waveforms with external HSYNC and VSYNC

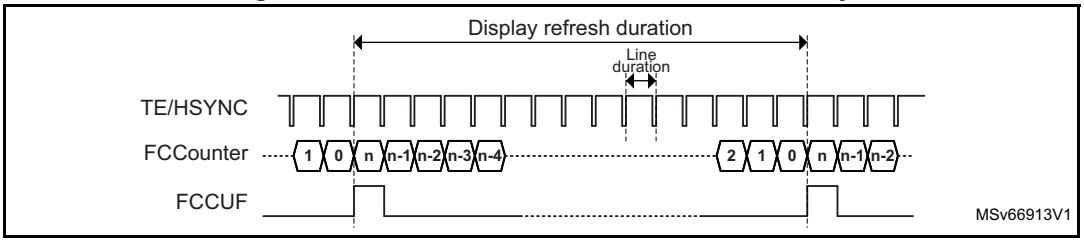


HSYNC acts as line clock and VSYNC acts as frame clock.

External HSYNC only

With external HSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on HSYNC.

Figure 144. Waveforms with external HSYNC only

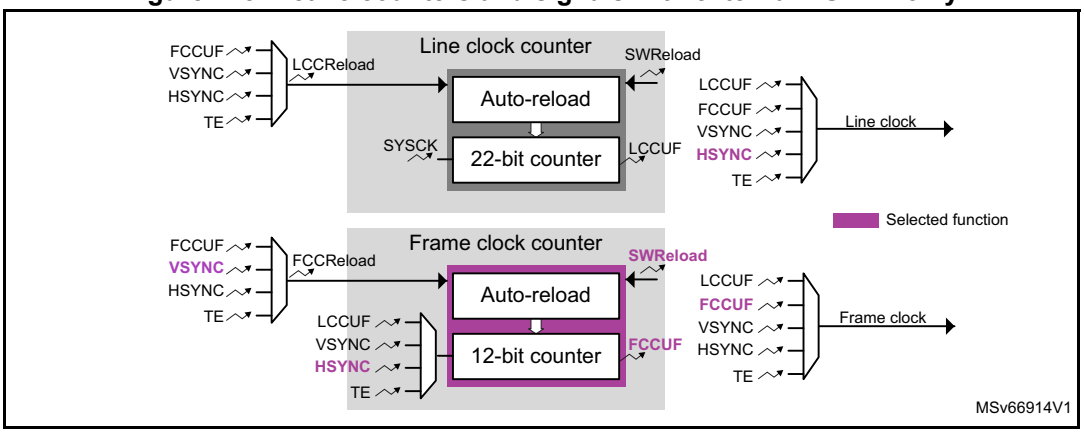


HSYNC acts as line clock and FCCUF acts as frame clock.

The clock generator can be synchronized by one of the following ways:

- by software reload, setting FCCFR in GFXTIM_CGCR
- by hardware reload on an external VSYNC (or TE)

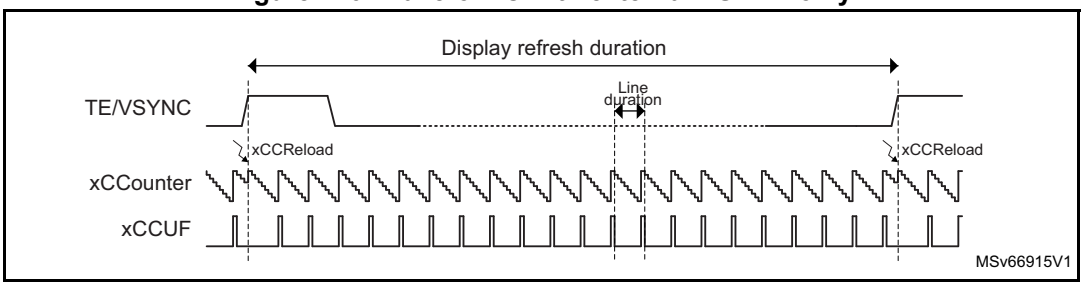
Figure 145. Active counters and signals with external HSYNC only



External VSYNC only

With external VSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on VSYNC.

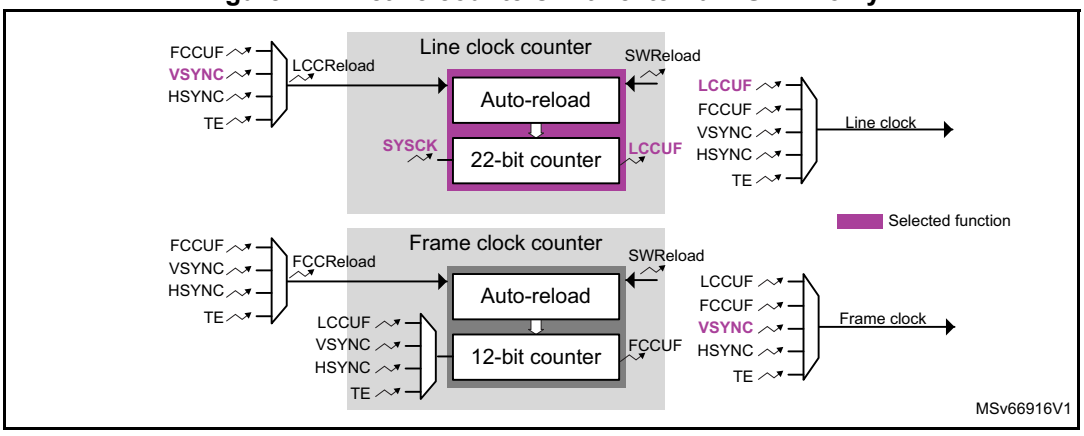
Figure 146. Waveforms with external VSYNC only



LCCUF (line clock counter underflow) acts as line clock and VSYNC acts as frame clock.

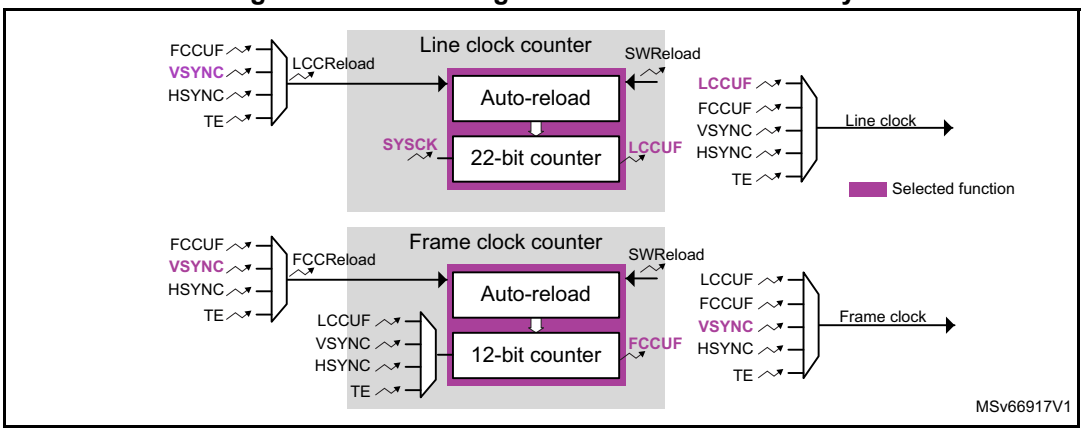
The line clock counter generating the line clock is reloaded on VSYNC event.

Figure 147. Active counters with external VSYNC only



The line clock counter can also act as a prescaler for the frame clock counter to have a wider range of counting. FCCUF acts as line clock.

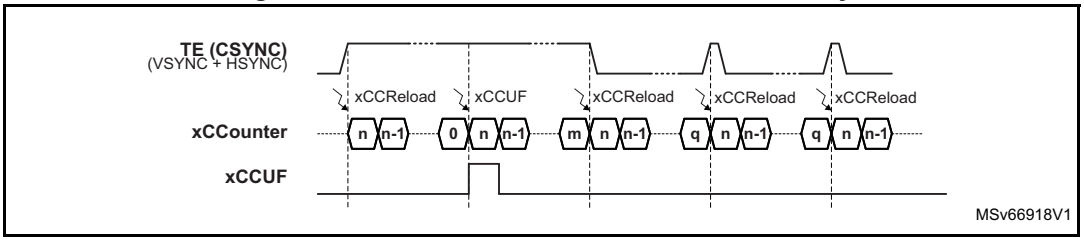
Figure 148. Prescaling when external VSYNC only



External CSYNC only

With external CSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on CSYNC (in the following figures, CSYNC is input on TE).

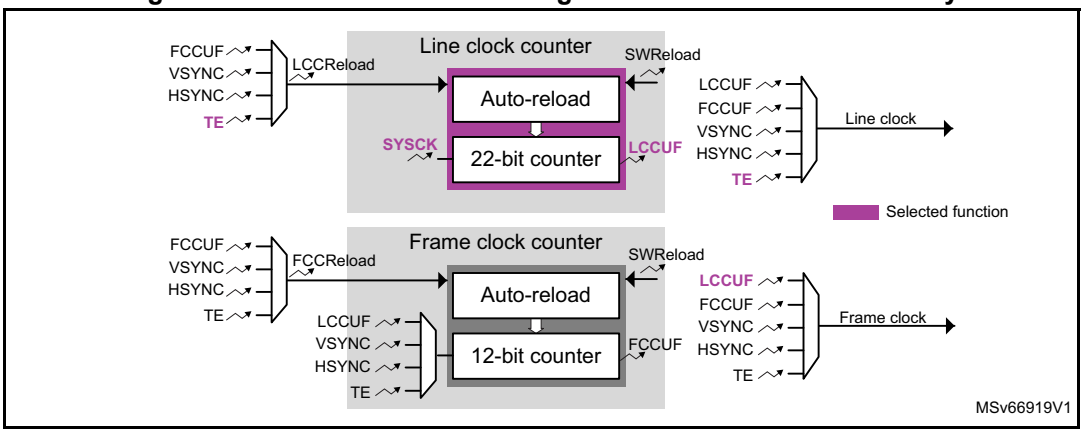
Figure 149. Waveforms with external CSYNC only



The CSYNC (on TE pin in this example) acts as line clock and LCCUF acts as frame clock.

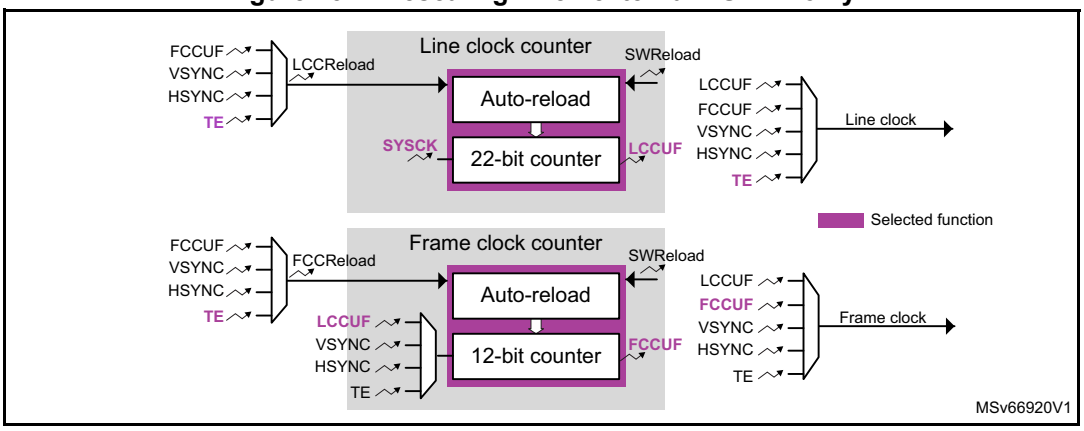
The line clock counter generating the frame clock is reloaded on CSYNC event.

Figure 150. Active counters and signals with external CSYNC only



The line-clock counter can also act as a prescaler for the frame clock counter to have a wider range of counting. FCCUF acts as frame clock.

Figure 151. Prescaling when external CSYNC only



23.3.5 Absolute timers

Absolute time

The absolute time 32-bit value can be read directly in GFXTIM_ATR (absolute time register) to provide a global time and to generate absolute time accurate event to synchronize the graphical software.

The absolute time is generated by the combination of:

- the absolute frame counter
- the absolute line counter

Absolute frame counter

The absolute frame counter is a 20-bit free running up-counter with a software controlled reset.

It can be enabled by writing 1 in AFCEN (absolute-frame counter enable) of GFXTIM_TCR (timers configuration register).

The counter is incremented at each rising edge of the frame clock and is reset by setting FAFCR (force absolute-frame counter reset) in GFXTIM_TCR.

In case of overflow of the absolute frame counter, AFCOF (overflow flag) is set in GFXTIM_ISR (interrupt status register), and an interrupt is generated if AFCOIE (overflow interrupt enable) is set in (interrupt enable register).

A 20-bit compare register can generate an absolute-frame counter compare event when the counter value matches the compare value. When a compare event occurs, AFCC1F (compare 1 flag) is set in GFXTIM_ISR, and an interrupt is generated if AFCC1IE (compare 1 interrupt enable) is set in GFXTIM_IER.

The absolute frame counter can be disabled by writing 1 in AFCDIS (counter disable) of GFXTIM_TDR (timers disable register).

The status (enabled/disabled) can be monitored through AFCS (counter status) in GFXTIM_TSR (timers status register).

Absolute line counter

The absolute line counter is 12-bit free running-up counter with an hardware controlled reset.

It can be enabled by writing 1 in ALCEN of GFXTIM_TCR.

The counter is incremented at each rising edge of the line clock an is reset at each rising edge of the frame clock or setting FALCR in GFXTIM_TCR).

In case of overflow of the absolute line counter, ALCOF is set in GFXTIM_ISR, and an interrupt is generated if ALCOIE is set in GFXTIM_IER.

Two 12-bit compare registers can generate an absolute line counter compare events when the counter value matches the compare value. When a compare event occurs, ALCC1F or ALCC2F is set in GFXTIM_ISR, and an interrupt is generated if ALCC1IE or ALCC2IE is set in GFXTIM_IER.

The absolute line counter can be disabled writing 1 in ALCDIS of GFXTIM_TDR.

The status (enabled/disabled) can be monitored through ALCS in GFXTIM_TSR.

23.3.6 Relative timers

The relative timers can generate periodic events to synchronize the graphical tasks at frame level.

The relative frame counters are 12-bit down-counting auto-reload timers that are decremented at each rising edge of the frame clock. The counter is started by writing 1 in RFCxEN (relative frame counter x enable) of GFXTIM_TCR. The starting value is automatically loaded from GFXTIM_RFCxRR (relative frame counter x reload register).

The current relative frame counter value can be read directly in GFXTIM_RFCxR.

Once the counter reaches zero, it is automatically reloaded with the value of GFXTIM_RFCxRR. RFCxRF (reload flag) is set in GFXTIM_ISR is set, and an interrupt is generated if RFCxRIE (interrupt enable) is set in GFXTIM_IER.

Once the reload operation occurs, the timer can be disabled automatically or continue counting if RFCxCM (continuous mode) is set in GFXTIM_TCR.

The status (enabled/disabled) can be monitored through RFCxS in GFXTIM_TSR.

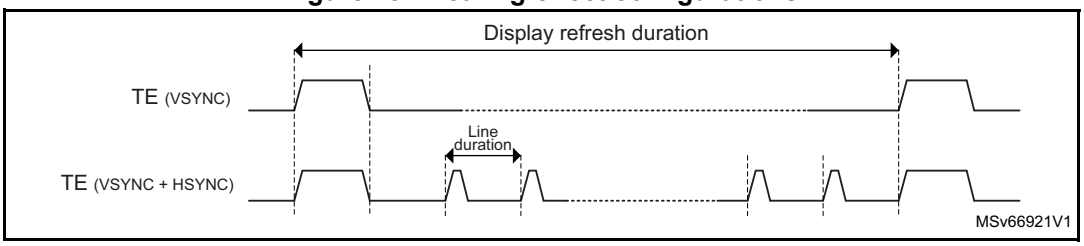
The counter can be reloaded on the fly by setting FRFCRx in GFXTIM_TCR. This force reload neither stop the timer (even if RFCxCM = 0 in GFXTIM_TCR), nor set RFCxRF (reload flag) in GFXTIM_ISR.

The relative frame counter can be disabled by setting RFCxDIS (disable) in GFXTIM_TDR.

23.3.7 Tearing-effect detection

A tearing-effect line can work in one of the two configurations shown in the figure below.

Figure 152. Tearing-effect configurations



A tearing-effect event can be generated on rising or falling edge depending on TEPOL (tearing-effect polarity) in GFXTIM_CR.

When a tearing-effect event is detected, TEF (tearing-event flag) is set in GFXTIM_ISR, and an interrupt is generated if TEIE (interrupt enable) is set in GFXTIM_IER.

23.3.8 Event generator

The event generator can combine timer events into complex events. Up to four combined events can be generated.

The events can be used for:

- interrupt generation
- watchdog clocking
- external trigger generation

A complex event is a combination between a frame event and a line event.

Once a frame event occurs, the GFXTIM waits for the line event to occur before generating the complex event.

The frame event is selected by the corresponding FESx (frame event selection x) in GFXTIM_EVSR (events selection y register). The line event is selected by the corresponding LESx in GFXTIM_EVSR.

The complex event generation is enabled by setting the corresponding EVxEN (event x enable) in GFXTIM_EVCR (event control register).

It is recommended to disable the event generation prior to any event configuration to avoid spurious complex event generation

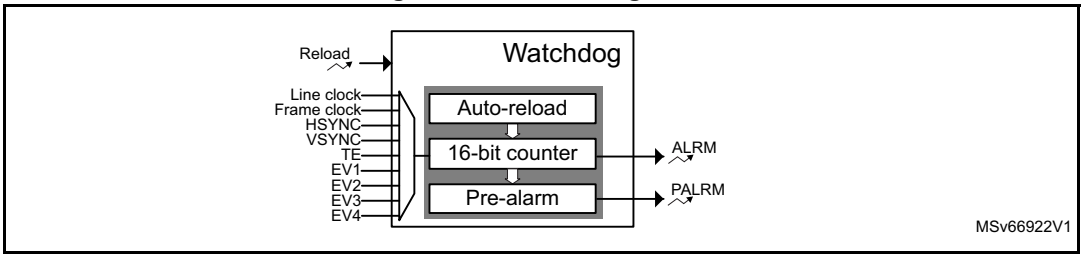
When a complex event occurs, the corresponding EVxF (event x flag) is set in GFXTIM_ISR, and an interrupt is generated if EVxIE (event x interrupt enable) is set in GFXTIM_IER.

Each of the events can be connected to another peripherals (such as DMA) to generate hardware triggers.

23.3.9 Watchdog timer

The watchdog timer is a 16-bit auto-reload down-counter with a programmable clock source.

Figure 153. Watchdog timer



Clock source

The watchdog clock source can be selected through WDGCS (clock source) in GTXTIM_WDGTCR (watchdog timer configuration register), between one of the following:

- line clock
- frame clock
- HSYNC
- VSYNC
- TE
- event 1
- event 2
- event 3
- event 4

Startup

The watchdog is started by setting WDGEN in GFXTIM_WDGTCR and stops automatically when reaching 0.

On start, the watchdog counter is automatically loaded with the auto-reload value programmed in GFXTIM_WDGRR (watchdog reload register).

The current watchdog value can be read through GFXTIM_WDGCR.

Auto-reload

The auto-reload can be forced in one of the following ways:

- by software, setting FWDGR (force watchdog reload) in GTXTIM_WDGTCR (watchdog timer configuration register)
- by hardware through an external trigger (gfxtim_wrld signal)

  The polarity of the trigger is configured by WDGHRC (watchdog hardware reload configuration) in GFXTIM_WDGTCR.

Event and interrupt generation

The watchdog can generate two events:

- an alarm when the watchdog down-counter reaches 0

  The watchdog counter is automatically stopped, and WDGAF (alarm flag) is set in GFXTIM_ISR. An interrupt is generated if WDGAIE (alarm interrupt enable) is set in GFXTIM_IER.
- a pre-alarm when the watchdog counter matches the pre-alarm register value in GFXTIM_WDGPAR (watchdog pre-alarm register)

  WDGPF (pre-alarm flag) is set in GFXTIM_ISR, and an interrupt is generated if WDGPIE (pre-alarm interrupt enable) is set in GFXTIM_IER.

23.4 GFXTIM interrupts

An interrupt can be produced on the following events:

- absolute frame counter compare event
- absolute frame counter overflow
- absolute line counter compare events
- absolute line counter overflow
- relative frame counter reload events
- external tearing effect
- combined events
- watchdog alarm event
- watchdog pre-alarm event

Separate interrupt enable bits are available for flexibility.

Table 133. Graphic timer interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
GFXTIM	Absolute frame counter overflow	AFCOF	AFCOIE	write 1 in CAFCOF
	Absolute frame counter compare 1	AFCC1F	AFCC1IE	write 1 in CAFCC1F
	Absolute line counter overflow	ALCOF	ALCOIE	write 1 in CALCOF
	Absolute line counter compare 1	ALCC1F	ALCC1IE	write 1 in CALCC1F
	Absolute line counter compare 2	ALCC2F	ALCC2IE	write 1 in CALCC2F
	Relative frame counter 1 reload	RFC1RF	RFC1RIE	write 1 in CRFC1RF
	Relative frame counter 2 reload	RFC2RF	RFC2RIE	write 1 in CRFC2RF
	External tearing effect	TEF	TEIE	write 1 in CTEF
	Event 1	EV1F	EV1IE	write 1 in CEV1F
	Event 2	EV2F	EV2IE	write 1 in CEV2F
	Event 3	EV3F	EV3IE	write 1 in CEV3F
	Event 4	EV4F	EV4IE	write 1 in CEV4F

Table 133. Graphic timer interrupt requests (continued)

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
GFXTIMW	Watchdog alarm	WDGAF	WDGAIE	write 1 in CWDGAF
	Watchdog pre-alarm	WDGPF	WDGPIE	write 1 in CWDGPF

23.5 GFXTIM registers

23.5.1 GFXTIM configuration register (GFXTIM_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw				rw			rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **LCCOE**: Line-clock calibration output enable
This bit enables the line-clock output.
0: Line-clock output disabled
1: Line-clock output enabled

Bit 16 **FCCOE**: Frame-clock calibration output enable
This bit enables the frame-clock output.
0: Frame-clock output disabled
1: Frame-clock output enabled

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **SYNCS[1:0]**: Synchronization source
This bitfield selects the synchronization signals (HSYNC and VSYNC) sources.
00: gfxtim_hsync[0] and gfxtim_vsync[0] selected
01: gfxtim_hsync[1] and gfxtim_vsync[1] selected
10: gfxtim_hsync[2] and gfxtim_vsync[2] selected
11: gfxtim_hsync[3] and gfxtim_vsync[3] selected

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TEPOL**: Tearing--effect polarity
This bit selects the tearing-effect polarity.
0: Tearing effect active on rising edge
1: Tearing effect active on falling edge

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **TES[1:0]**: Tearing source
This bitfield selects the tearing-effect source.
00: TE input pad selected
01: gfxtim_ite selected
10: HSYNC input selected by SYNCS[1:0]
11: VSYNC input selected by SYNCS[1:0]

23.5.2 GFXTIM clock generator configuration register (GFXTIM_CGCR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **FCCHRS[2:0]**: Frame clock counter hardware reload source
This bitfield configures the hardware reload source for the frame clock counter.
000: No hardware reload
001: Line- -clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **FCCFR**: Frame clock counter force reload
This bit forces frame clock counter reload
0: No effect
1: Frame clock counter reload forced

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **FCCCS[2:0]**: Frame clock counter clock source
This bitfield configures the clock source for the frame clock counter.
000: Frame clock counter disabled
001: Line clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **FCS[2:0]**: Frame clock source
This bitfield configures the frame clock source.
000: Line clock counter underflow
001: Frame clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **LCCHRS[2:0]**: Line clock counter hardware reload source
This bitfield configures the hardware reload source for the line clock counter.
000: No hardware reload
001: Frame clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **LCCFR**: Line clock counter force reload
This bit forces line clock counter reload.
0: No effect
1: Line clock counter reload forced

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **LCCCS**: Line clock counter clock source
This bit configures the clock source for the line clock counter.
0: Line clock counter disabled
1: System clock selected

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LCS[2:0]**: Line clock source
This bitfield configures the line clock source.
000: Line clock counter underflow
001: Frame clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

23.5.3 GFXTIM timers configuration register (GFXTIM_TCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **FRFC2R**: Force relative frame counter 2 reload
This bit forces the reload of the relative frame counter 2.
0: No effect
1: Relative frame counter 2 reload forced

Bit 21 **RFC2CM**: Relative frame counter 2 continuous mode
This bit enables the continuous mode of the relative frame counter 2.
0: Relative frame counter 2 is one shot.
1: Relative frame counter 2 is in continuous mode.

Bit 20 **RFC2EN**: Relative frame counter 2 enable
This bit enables the relative frame counter 2.
0: No effect
1: Relative frame counter 2 enabled

Bit 19 Reserved, must be kept at reset value.

Bit 18 **FRFC1R**: Force relative frame counter 1 reload
This bit forces the reload of the relative frame counter 1.
0: No effect
1: Relative frame counter 1 reload forced

Bit 17 **RFC1CM**: Relative frame counter 1 continuous mode
This bit enables the continuous mode of the relative frame counter 1.
0: Relative frame counter 1 is one shot.
1: Relative frame counter 1 is in continuous mode.

Bit 16 **RFC1EN**: Relative frame counter 1 enable
This bit enables the relative frame counter 1.
0: No effect
1: Relative frame counter enabled

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **FALCR**: Force absolute line counter reset
This bit forces the reset of the absolute line counter.
0: No effect
1: Absolute line counter reset forced

Bit 4 **ALCEN**: Absolute line counter enable
This bit enables the absolute line counter.
0: No effect
1: Absolute line counter enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **FAFCR**: Force absolute frame counter reset
This bit forces the reset of the absolute frame counter.
0: No effect
1: Absolute frame counter reset forced

Bit 0 **AFCEN**: Absolute frame counter enable
This bit enables the absolute frame counter.
0: No effect
1: Absolute frame counter enabled

23.5.4 GFXTIM timers disable register (GFXTIM_TDR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **RFC2DIS**: Relative frame counter 2 disable
This bit disables the relative frame counter 2.
0: No effect
1: Relative frame counter 2 disabled

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **RFC1DIS**: Relative frame counter 1 disable
This bit disables the relative frame counter 1.
0: No effect
1: Relative frame counter 1 disabled

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **ALCDIS**: Absolute line counter disable
This bit disables the absolute line counter.
0: No effect
1: Absolute line counter disabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **AFCDIS**: Absolute frame counter disable
This bit disables the absolute frame counter.
0: No effect
1: Absolute frame counter disabled

23.5.5 GFXTIM events control register (GFXTIM_EVCR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **EV4EN**: Event 4 enable
This bit enables the complex event 4 generation.
0: Event 4 generation disabled
1: Event 4 generation enabled

Bit 2 **EV3EN**: Event 3 enable
This bit enables the complex event 3 generation.
0: Event 3 generation disabled
1: Event 3 generation enabled

Bit 1 **EV2EN**: Event 2 enable
This bit enables the complex event 2 generation.
0: Event 2 generation disabled
1: Event 2 generation enabled

Bit 0 **EV1EN**: Event 1 enable
This bit enables the complex event 1 generation.
0: Event 1 generation disabled
1: Event 1 generation enabled

23.5.6 GFXTIM events selection register (GFXTIM_EVSR)

Address offset: 0x014

Reset value: 0x0000 0000

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **FES4[2:0]**: Frame-event selection 4
This bitfield defines the frame-event selection for complex event 4 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **LES4[2:0]**: Line-event selection 4
This bitfield defines the line-event selection for complex event 4 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **FES3[2:0]**: Frame-event selection 3
This bitfield defines the frame-event selection for complex event 3 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **LES3[2:0]**: Line-event selection 3
This bitfield defines the line-event selection for complex event 3 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **FES2[2:0]**: Frame-event selection 2
This bitfield defines the frame-event selection for complex event 2 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **LES2[2:0]**: Line-event selection 2
This bitfield defines the line-event selection for complex event 2 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **FES1[2:0]**: Frame-event selection 1
This bitfield defines the frame-event selection for complex event 1 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LES1[2:0]**: Line-event selection 1
This bitfield defines the line-event selection for complex event 1 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

23.5.7 GFXTIM watchdog timer configuration register (GFXTIM_WDGTCR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FWDGR
															w

				rw	rw	rw	rw			rw	rw		r	w	w

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **FWDGR**: Force watchdog reload
This bit forces the reload of the graphic watchdog.
0: nNo effect
1: Graphic watchdog reload forced

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **WDGCS[3:0]**: Watchdog clock source
This bitfield selects the watchdog clock source.
0000: Line clock
0001: Frame clock
0010: HSYNC rising edge
0011: HSYNC falling edge
0100: VSYNC rising edge
0101: VSYNC falling edge
0110: TE rising edge
0111: TE falling edge
1000: Event 1
1001: Event 2
1010: Event 3
1011: Event 4
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **WDGHRC[1:0]**: Watchdog hardware reload configuration
This bitfield configures the watchdog hardware reload.
00: Watchdog hardware reload disabled
01: Watchdog reloaded a rising edge of gfxtim_wrld
10: Watchdog reloaded a falling edge of gfxtim_wrld
11: Reserved

Bit 3 Reserved, must be kept at reset value.

Bit 2 **WDGS**: Watchdog status
This bit returns the status of the graphic watchdog.
0: Graphic watchdog disabled
1: Graphic watchdog enabled

Bit 1 **WDGDIS**: Watchdog disable
This bit disables the graphic watchdog.
0: No effect
1: Graphic watchdog disabled

Bit 0 **WDGEN**: Watchdog enable
This bit enables the graphic watchdog.
0: No effect
1: Graphic watchdog enabled

23.5.8 GFXTIM interrupt status register (GFXTIM_ISR)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	WDGPF	WDGAF	Res.	Res.	Res.	Res.	EV4F	EV3F	EV2F	EV1F

		r	r			r	r				r		r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **WDGPF**: Watchdog pre-alarm flag
This bit indicates that a graphic watchdog pre-alarm occurred.
0: No graphic watchdog pre-alarm occurred.
1: A graphic watchdog pre-alarm occurred.

Bit 24 **WDGAF**: Watchdog alarm flag
This bit indicates that a graphic watchdog alarm occurred.
0: No graphic watchdog alarm occurred.
1: A graphic watchdog alarm occurred.

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **EV4F**: Event 4 flag
This bit indicates a complex event 4 occurred.
0: No complex event 4 occurred.
1: A complex event 4 occurred.

Bit 18 **EV3F**: Event 3 flag
This bit indicates a complex event 3 occurred.
0: No complex event 3 occurred.
1: A complex event 3 occurred.

Bit 17 **EV2F**: Event 2 flag
This bit indicates a complex event 2 occurred.
0: No complex event 2 occurred.
1: A complex event 2 occurred.

Bit 16 **EV1F**: Event 1 flag
This bit indicates a complex event 1 occurred.
0: No complex event 1 occurred.
1: Complex event 1 occurred.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **RFC2RF**: Relative frame counter 2 reload flag
This bit indicates relative frame counter 2 has been reloaded.
0: No reload occurred on relative frame counter 2.
1: A reload on relative frame counter 2 occurred.

Bit 12 **RFC1RF**: Relative frame counter 1 reload flag
This bit indicates relative frame counter 1 has been reloaded.
0: No reload occurred on relative frame counter 1.
1: A reload on relative frame counter 1 occurred.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **ALCC2F**: Absolute line counter compare 2 flag
This bit indicates match on compare 2 of the absolute line counter.
0: No match occurred on compare 2 of the absolute line counter.
1: A match on compare 2 of the absolute line counter occurred.

Bit 8 **ALCC1F**: Absolute line counter compare 1 flag
This bit indicates match on compare 1 of the absolute line counter.
0: No match occurred on compare 1 of the absolute line counter.
1: A match on compare 1 of the absolute line counter occurred.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **AFCC1F**: Absolute frame counter compare 1 flag
This bit indicates match on compare 1 of the absolute frame counter.
0: No match occurred on compare 1 of the absolute frame counter.
1: A match on compare 1 of the absolute frame counter occurred.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TEF**: Tearing-effect flag
This bit indicates a tearing effect event occurred.
0: No tearing effect occurred.
1: A tearing effect occurred.

Bit 1 **ALCOF**: Absolute line counter overflow flag
This bit indicates an overflow occurred on the absolute line counter.
0: No overflow occurred on the absolute line counter.
1: A overflow on the absolute line counter occurred.

Bit 0 **AFCOF**: absolute frame counter overflow flag
This bit indicates an overflow occurred on the absolute frame counter.
0: No overflow occurred on the absolute frame counter.
1: An overflow on the absolute frame counter occurred.

23.5.9 GFXTIM interrupt clear register (GFXTIM_ICR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	CWDGPF	CWDGAF	Res.	Res.	Res.	Res.	CEV4F	CEV3F	CEV2F	CEV1F

		w	w			w	w				w		w	w	w

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **CWDGPF**: Clear watchdog pre-alarm flag
This bit clears WDGPF in GXFXTIM_ISR.
0: No effect
1: WDGPF cleared

Bit 24 **CWDGAF**: Clear watchdog alarm flag
This bit clears WDGAF in GXFXTIM_ISR.
0: No effect
1: WDGAF cleared

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CEV4F**: Clear event 4 flag
This bit clears EV4F in GXFXTIM_ISR.
0: No effect
1: EV4F cleared

Bit 18 **CEV3F**: Clear event 3 flag
This bit clears EV3F in GXFXTIM_ISR.
0: No effect
1: EV3F cleared

Bit 17 **CEV2F**: Clear event 2 flag
This bit clears EV2F in GXFXTIM_ISR.
0: No effect
1: EV2F cleared

Bit 16 **CEV1F**: Clear event 1 flag
This bit EV1F in GXFXTIM_ISR.
0: No effect
1: EV1F cleared

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CRFC2RF**: Clear relative frame counter 2 reload flag
This bit clears RFC2RF in GXFXTIM_ISR.
0: No effect
1: RFC2RF cleared

Bit 12 **CRFC1RF**: Clear relative frame counter 1 reload flag
This bit clears RFC1RF in GXTIM_ISR.
0: No effect
1: RFC1RF cleared

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **CALCC2F**: Clear absolute line counter compare 2 flag
This bit clears ALCC2F in GXTIM_ISR.
0: No effect
1: ALCC2F cleared

Bit 8 **CALCC1F**: Clear absolute line counter compare 1 flag
This bit clears ALCC1F in GXTIM_ISR.
0: No effect
1: ALCC1F cleared

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CAFCC1F**: Clear absolute frame counter compare 1 flag
This bit clears AFCC1F in GXTIM_ISR.
0: No effect
1: AFCC1F cleared

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CTEF**: Clear tearing-effect flag
This bit clears TEF in GXTIM_ISR.
0: No effect
1: TEF cleared

Bit 1 **CALCOF**: Clear absolute line counter overflow flag
This bit clears ALCOF in GXTIM_ISR.
0: No effect
1: ALCOF cleared

Bit 0 **CAFCOF**: Clear absolute frame counter overflow flag
This bit clears AFCOF in GXTIM_ISR.
0: No effect
1: AFCOF cleared

23.5.10 GFXTIM interrupt enable register (GFXTIM_IER)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw			rw	rw				rw		rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **WDGPIE**: Watchdog pre-alarm interrupt enable
This bit enables the watchdog pre-alarm interrupt generation.
0: Watchdog pre-alarm interrupt disabled
1: Watchdog pre-alarm interrupt enabled

Bit 24 **WDGAIE**: Watchdog alarm interrupt enable
This bit enables the watchdog alarm interrupt generation.
0: Watchdog alarm interrupt disabled
1: Watchdog alarm interrupt enabled

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **EV4IE**: Event 4 interrupt enable
This bit enables the complex event 4 interrupt generation.
0: Event 4 interrupt disabled
1: Event 4 interrupt enabled

Bit 18 **EV3IE**: Event 3 interrupt enable
This bit enables the complex event 3 interrupt generation.
0: Event 3 interrupt disabled
1: Event 3 interrupt enabled

Bit 17 **EV2IE**: Event 2 interrupt enable
This bit enables the complex event 2 interrupt generation.
0: Event 2 interrupt disabled
1: Event 2 interrupt enabled

Bit 16 **EV1IE**: Event 1 interrupt enable
This bit enables the complex event 1 interrupt generation.
0: Event 1 interrupt disabled
1: Event 1 interrupt enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **RFC2RIE**: Relative frame counter 2 reload interrupt enable
This bit enables the relative frame counter 2 reload interrupt generation.
0: Relative frame counter 2 reload interrupt disabled
1: Relative frame counter 2 reload interrupt enabled

Bit 12 **RFC1RIE**: Relative frame counter 1 reload interrupt enable
This bit enables the relative frame counter 1 reload interrupt generation.
0: Relative frame counter 1 reload interrupt disabled
1: Relative frame counter 1 reload interrupt enabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **ALCC2IE**: Absolute line counter compare 2 interrupt enable
This bit enables the absolute line counter compare 2 interrupt generation.
0: Absolute line counter compare 2 interrupt disabled
1: Absolute line counter compare 2 interrupt enabled

Bit 8 **ALCC1IE**: Absolute line counter compare 1 interrupt enable
This bit enables the absolute line counter compare 1 interrupt generation.
0: Absolute line counter compare 1 interrupt disabled
1: Absolute line counter compare 1 interrupt enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **AFCC1IE**: Absolute frame counter compare 1 interrupt enable
This bit enables the absolute frame counter compare interrupt generation.
0: Absolute frame counter compare 1 interrupt disabled
1: Absolute frame counter compare 1 interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TEIE**: Tearing-effect interrupt enable
This bit enables the Tearing Effect interrupt generation.
0: Tearing-effect interrupt disabled
1: Tearing-effect interrupt enabled

Bit 1 **ALCOIE**: Absolute line counter overflow interrupt enable
This bit enables the absolute line counter overflow interrupt generation.
0: Absolute line counter overflow interrupt disabled
1: Absolute line counter overflow interrupt enabled

Bit 0 **AFCOIE**: Absolute frame counter overflow interrupt enable
This bit enables the absolute frame counter overflow interrupt generation.
0: Absolute frame counter overflow interrupt disabled
1: Absolute frame counter overflow interrupt enabled

23.5.11 GFXTIM timers status register (GFXTIM_TSR)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											r				r

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **RFC2S**: Relative frame counter 2 status
This bit returns the status of the relative frame counter 2.
0: Relative frame counter 2 disabled
1: Relative frame counter 2 enabled

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **RFC1S**: Relative frame counter 1 status
This bit returns the status of the relative frame counter 1.
0: Relative frame counter 1 disabled
1: Relative frame counter 1 enabled

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **ALCS**: Absolute line counter status
This bit returns the status of the absolute line counter.
0: Absolute line counter disabled
1: Absolute line counter enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **AFCS**: Absolute frame counter status
This bit returns the status of the absolute frame counter.
0: Absolute frame counter disabled
1: Absolute frame counter enabled

23.5.12 GFXTIM line clock counter reload register (GFXTIM_LCCRR)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RELOAD[21:16]					
										rw	rw	rw	rw	rw	rw

Refer to *Section 2.3* for the register boundary addresses.

24 Nested vectored interrupt controller (NVIC)

24.1 NVIC features

The NVIC includes the following features:

- Up to 196 maskable interrupt channels (not including the Cortex-M55 interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low-latency interrupt processing and efficient processing of late-arriving interrupts.

All interrupts, including the core exceptions, are managed by the NVIC.

24.1.1 SysTick calibration value register

The SysTick calibration value (SYST_CALIB) is fixed to 0x3E8. It provides a reference timebase of 1 ms based when the SysTick clock frequency is 1 MHz. To match the 1 ms timebase whatever the application frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- If the SysTick clock source is the 100 MHz CPU clock (HCLK):

$$\text{reload value} = (F_{HCLK} \times \text{SYST_CALIB}) - 1$$

- If the SysTick clock source is an external clock:

$$\text{reload value} = ((F_{HCLK} / 8) \times \text{SYST_CALIB}) - 1$$

where F_{HCLK} refers to the AHB frequency expressed in MHz

For example, to achieve a timebase of 1 ms when the SysTick clock source is the 100 MHz HCLK:

$$\text{reload value} = (100 \times \text{SYST_CALIB}) - 1 = 0\text{x}1869\text{F}$$

24.1.2 Interrupt and exception vectors

Exception vectors connected to the NVIC are the following: reset, NMI, HardFault, MemManage, BusFault, UsageFault, SVCall, DebugMonitor, PendSV, and SysTick

Table 135. STM32N6x7xx vector table

NVIC position	Priority	Priority type	Acronym	Description	Address

25 Extended interrupts and event controller (EXTI)

The extended interrupts and event controller (EXTI) manages the CPU and system wake-up through configurable and direct event inputs. It provides wake-up requests to the power control, and generates a combined secure/nonsecure interrupt request to the CPU NVIC, and events to the CPU event input. An additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wake-up requests allow the system to be woken up from Stop modes, and the CPU to be woken up from CStop and CStandby modes.

The interrupt request and event request generation can be used also in Run modes.

25.1 EXTI main features

- EXTI 73 input events supported
- Most event inputs allow to wake up the system
- Some events can only be used to generate a CPU wake-up
- Events without an associated wake-up flag in the peripheral have a flag in the EXTI, and generate a combined secure/nonsecure interrupt to the CPUs from the EXTI
- Events can be used to generate a CPU wake-up event

The asynchronous event inputs are classified in two groups:

- configurable events (signals from I/Os or peripherals able to generate a pulse), with the following features:
  - Selectable active trigger edge
  - Interrupt pending status register bits independent for the rising and falling edge
  - Individual interrupt and event generation mask, used to condition the CPU wake-up, interrupt, and event generation
  - Individual interrupt lines per CPU
  - Software trigger possibility
- direct events (interrupt and wake-up sources from peripherals having an associated flag, which requires to be cleared in the peripheral), with the following features:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status flag is provided by the peripheral generating the event)
  - Individual interrupt and event generation mask, used to condition the CPU wake-up and event generation
  - No software trigger possibility
- Secure events
  - The access to control and configuration bits of secure input events can be made secure and or privileged
- EXTI I/O port selection

25.2 EXTI implementation

Table 136. EXTI implementation

EXTI features(1)	EXTI
EXTI I/O port selection	X
EXTI I/O port to interconnect other peripherals	-
Number of events	73
Security	X

1. X = supported.

25.3 EXTI block diagram

The EXTI consists of the following blocks (see *Figure 154*):

- register block accessed via an AHB interface, which contains all the EXTI registers
- event input trigger block, which provides event input edge trigger logic
- masking block, which provides the event input distribution to the different wake-up, interrupts, and event outputs, plus their masking
- EXTI mux, which provides the I/O port selection on to the EXTI event signal

Figure 154. EXTI block diagram

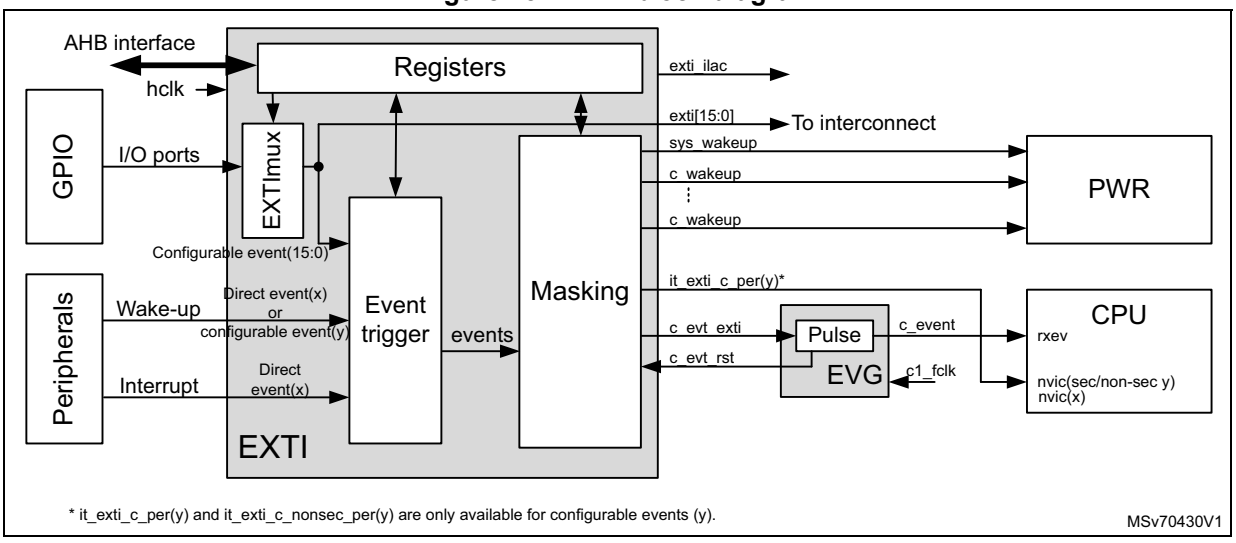

Table 137. EXTI signals

Name	I/O	Description
AHB interface	I/O	EXTI register bus interface. When one event is configured to allow security, the AHB interface support secure accesses.
hclk	I	AHB bus clock and EXTI system clock.
exti_ilac	O	Illegal access event

Table 137. EXTI signals (continued)

Name	I/O	Description
Configurable event(y)	I	Asynchronous wake-up events from peripherals without an associated interrupt and flag in the peripheral
Direct event(x)	I	Synchronous and asynchronous wake-up events from peripherals with an associated interrupt and flag in the peripheral
I/O ports	I	GPIO I/O ports[15:0]
exti[15:0]	O	EXTI GPIO output port to trigger other peripherals
it_exti_c_per(y)	O	Combined secure/nonsecure interrupts to the CPU with configurable event (y)
c_evt_exti	O	High-level sensitive event output for the CPU
c_evt_rst	I	Asynchronous reset input to clear c_evt_exti
sys_wakeup	O	Asynchronous system wake-up request to PWR for ck_sys and hclk
c_wakeup	O	Wake-up request to PWR for the CPU, synchronous to hclk

Table 138. EVG signals

Name	I/O	Description
c_fclk	I	CPU free running clock
c_evt_in	I	High-level sensitive events input from EXTI, asynchronous to CPU clock
c_event	O	Event pulse, synchronous to CPU clock
c_evt_rst	O	Event reset signal, synchronous to CPU clock

25.3.1 EXTI connections between peripherals and CPU

Peripherals able to generate wake-up or interrupt events when the system is in Stop mode or a CPU is in CStop mode, are connected to the EXTI.

Peripheral wake-up signals that generate a pulse, or which do not have interrupt status bits in the peripheral, are connected to an EXTI configurable event input. For these events, the EXTI provides a status pending bit, which requires to be cleared. It is the EXTI interrupt associated with the status bit that interrupts the CPU.

Peripheral interrupt and wake-up signals that have a status bit in the peripheral, which requires to be cleared in the peripheral, are connected to an EXTI direct event input. There is no status pending bit within the EXTI. The interrupt or wake-up is cleared by the CPU in the peripheral. It is the peripheral interrupt that interrupts the CPU directly.

All GPIO ports are inputs for the EXTI multiplexer and used to select a port pin to wake up the system via a configurable event.

EXTI configurable event interrupts are connected to the NVIC. A secure CPU receives both its secure and nonsecure interrupts on the combined secure/nonsecure it_exti_c_per(y) interrupt signal. A nonsecure CPU only receives its nonsecure interrupts on the it_exti_c_per(y) interrupt signal. The CPU has its dedicated individual interrupt signal, which allows CPU interrupt masking based on EXTI_IMRx settings.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

EXTI CPU wake-up signals are connected to the PWR, and are used to wake up the system and CPU subsystem bus clocks.

25.3.2 EXTI wake-up interrupt list

The wake-up sources are listed in the table below. Peripherals able to generate wake-up or interrupt events are connected to the EXTI.

All wake-up sources are able to generate en event to the CPU. The EXTI CPU wake-up signals are connected. They are used to wake up the system, and CPU subsystem bus clocks.

For CPU interrupt handling, see *Section 24: Nested vectored interrupt controller (NVIC)*.

25.4 EXTI functional description

Depending on the EXTI event input type and wake-up targets, different logic implementations are used. The applicable features are controlled from register bits:

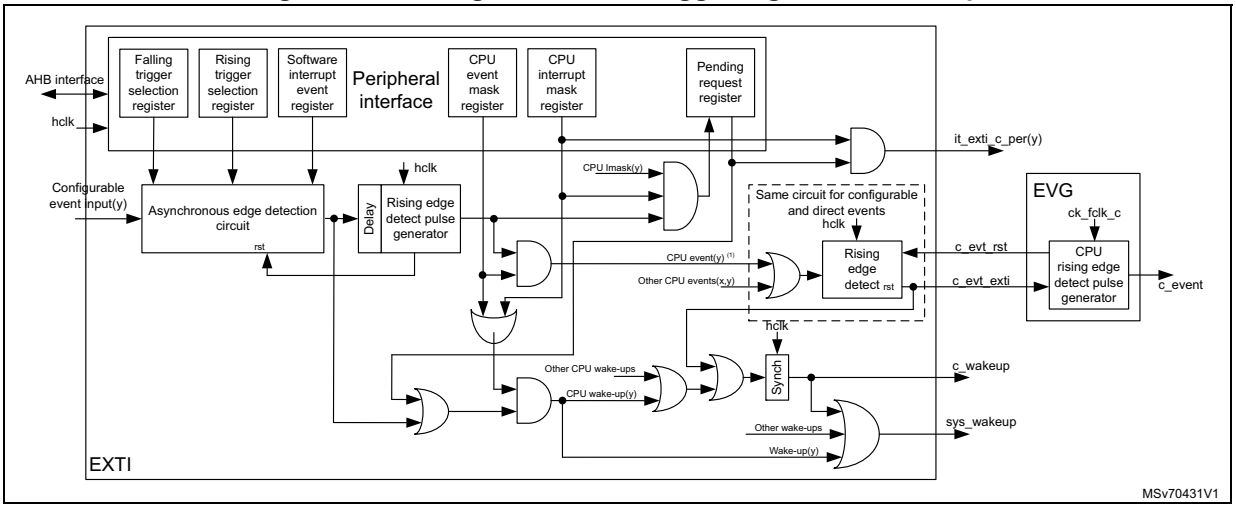
Table 140. EXTI event input configurations and register control

Event input type	Logic implementation	EXTI_RTSR	EXTI_FTSR	EXTI_SWIER	EXTI_RPR	EXTI_FPR	EXTI_SECCFGR	EXTI_PRIVCFGR
Configurable	Configurable event input wake-up logic	X	X	X	X	X	X	X
Direct	Direct event input wake-up logic	-	-	-	-	-	X	X

25.4.1 EXTI configurable event input wake-up

Figure 155 details the logic associated with configurable event inputs that wake up CPU subsystem bus clocks, and generate an EXTI pending flag and combined secure/non-secure interrupt to the CPU and/or a CPU wake-up event.

Figure 155. Configurable event trigger logic CPU wake-up



The software interrupt event register is used to trigger configurable events by software, writing the corresponding register bit, irrespective of the edge selection setting.

Rising and falling edge selection registers are used to enable and to select the configurable event active trigger edge or both edges.

The CPU has its dedicated wake-up (interrupt) mask register, and a dedicated event mask register. The enabled event is used to generate an event on the CPU. All CPU events are ORed together into a single CPU event signal. The event pending registers (EXTI_RPR and EXTI_FPR) are not set for an unmasked CPU event.

The configurable events have unique interrupt pending request register bits. The pending register is only set for an unmasked interrupt. Each configurable event provides dedicated combined secure/nonsecure interrupts to the CPU. The configurable event interrupts need to be acknowledged by software in EXTI_RPR and/or EXTI_FPR.

When a CPU wake-up (interrupt) or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.

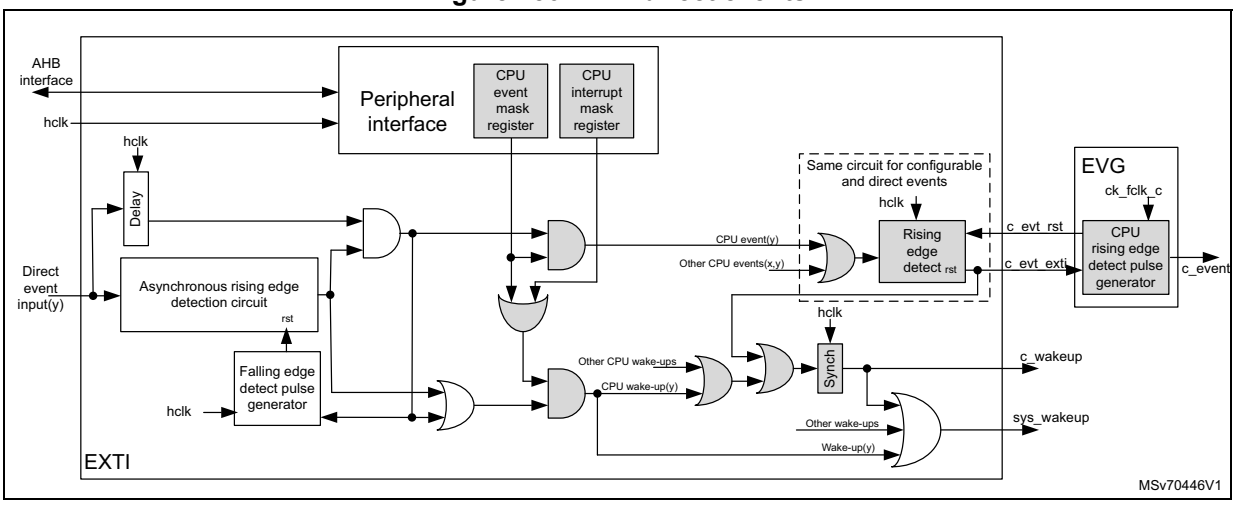
Note: A detected configurable event interrupt pending request can be cleared by the CPU with the correct access permission. The system is not able to enter into low-power modes as long as an interrupt pending request is active.

25.4.2 EXTI direct event input wake-up

Direct events do not have an associated EXTI interrupt. The EXTI only wakes up the system and CPU subsystem clocks, and can generate a CPU wake-up event. The peripheral synchronous interrupt, associated with the direct wake-up event, wakes up the CPU.

The EXTI direct event is able to generate a CPU event that wakes up the CPU. The CPU event may occur before the associated peripheral interrupt flag is set.

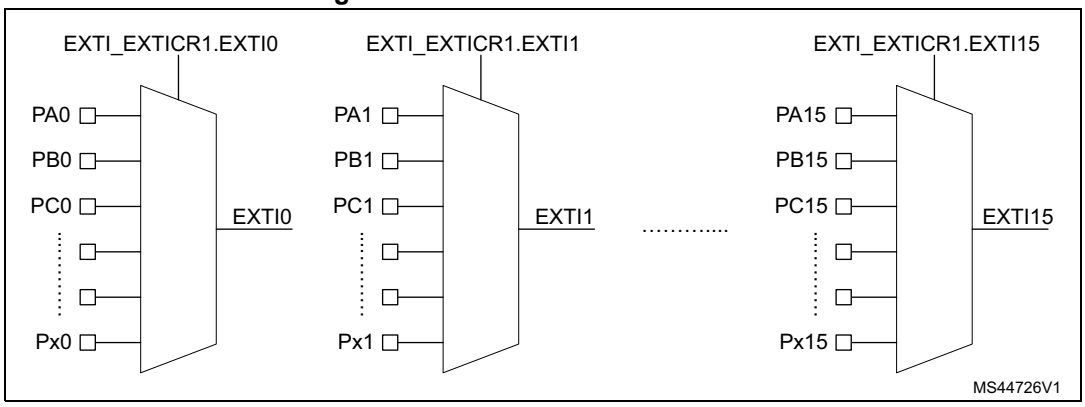
Figure 156. EXTI direct events



25.4.3 EXTI multiplexer selection

The EXTI multiplexer is used to select GPIOs as interrupts and wake-up. The GPIOs are connected via 16 EXTI multiplexers to the first 16 EXTI events as configurable event. The selection of GPIO port as EXTI multiplexer output is controlled by EXTIn_EXTICRx (x = 1 to 4) registers.

Figure 157. EXTI mux GPIO selection



25.5 EXTI functional behavior

The direct event inputs are enabled in the respective peripheral generating the wake-up event. The configurable events are enabled by enabling at least one of the trigger edges.

Once an event input is enabled, the generation of the CPU wake-up is conditioned by the CPU interrupt mask and the CPU event mask.

Table 141. Masking functionality

CPU interrupt enable EXTI_IMR.IMn	CPU event enable EXTI_EMR1.EMn	Configurable event inputs EXTI_RPR.RPIFn EXTI_FPR.FPIFn	exti(n) interrupt(1)	CPU event	CPU wake-up
0	0	No	Masked	Masked	Masked
	1	No	Masked	Yes	Yes
1	0	Status latched	Yes	Masked	Yes(2)
	1	Status latched	Yes	Yes	Yes

1. The CPU dedicated exti(n), combined secure/nonsecure interrupts, goes to the CPU. If no interrupt is required for the CPU, the exti(n) interrupt must be masked in EXTI_IMR.
2. Only if the CPU interrupt is enabled by IMn in EXTI_IMR.

For configurable event inputs, when the enabled edges occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding RPIFn in EXTI_RPR and/or FPIFn in EXTI_FPR is/are set. The CPU subsystem is woken up, and the CPU combined secure/nonsecure interrupt signal is activated.

RPIFn in EXTI_RPR and/or FPIFn in EXTI_FPR must be cleared by software (writing them to 1). This clears the CPU interrupt. An interrupt is only generated on the dedicated interrupt line when it is enabled in EXTI_IMR.

For direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit in the EXTI. When the associated CPU interrupt is unmasked, the corresponding CPU subsystem is woken up. The CPU is woken up (interrupted) by the peripheral synchronous interrupt.

The CPU event must be unmasked to generate an event. When an enabled edge occurs on the event input, a CPU event pulse is generated. There is no event pending bit.

For the configurable event inputs, an event request can be generated by software when writing 1 in EXTI_SWIERx. This generates a rising edge on the event. The rising edge event pending bit is set in EXTI_RPR, whatever the setting in EXTI_RTSR.

25.6 EXTI event protection

The EXTI is able to protect event register bits from being modified by nonsecure and unprivileged accesses. The protection can be activated individually per input event, via EXTI_SECCFGRx and EXTI_PRIVCFGRx. At EXTI level, the protection consists in preventing unauthorized write access to change settings of secure configurable events, change masking of secure input events, and clear pending status of secure input events.

Table 142. Register protection overview

Register name	Access type	Security(1)(2)
EXTI_RTSRx	RW	Secure and privileged can be enabled bit-wise in EXTI_SECCFGRx and EXTI_PRIVCFGRx
EXTI_FTSRx	RW	
EXTI_SWIERx	RW	
EXTI_RPRx	RW	
EXTI_FPRx	RW	
EXTI_SECCFGRx	RW	Always secure and privileged
EXTI_PRIVCFGRx	RW	Always privileged, secure can be enabled bit-wise in EXTI_SECCFGRx
EXTI_EXTICRx	RW	Secure and privileged can be enabled bit-wise in EXTI_SECCFGRx and EXTI_PRIVCFGRx
EXTI_LOCKR	RW	Always secure and privileged
EXTI_IMRx	RW	Secure and privileged can be enabled bit-wise in EXTI_SECCFGRx and EXTI_PRIVCFGRx
EXTI_EMRx	RW	

1. Security is enabled with EXTI_SECCFGRx registers.
2. Privilege is enabled with EXTI_PRIVCFGRx registers.

25.6.1 EXTI register security protection

When security is enabled for an input event, the associated input event configuration and the control bits can only be modified and read by a secure access. A nonsecure write access is discarded and a read returns 0.

When input events are nonsecure, the security is disabled. The associated input event configuration and control bits can be modified and read by a secure access and nonsecure access.

The security configuration in EXTI_SECCFGRx can be globally locked after reset by GLOCK in EXTI_LOCKR.

25.6.2 EXTI register privilege protection

When the privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privileged access. An unprivileged write access is discarded, and a read returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privileged or unprivileged access.

The privilege configuration in EXTI_PRIVCFGRx can be globally locked after reset by GLOCK in EXTI_LOCKR.

25.7 EXTI registers

The EXTI register map is divided in the following sections:

Table 143. EXTI register map sections

Address offset	Description
0x000 - 0x01C	General configurable event [31:0] configuration
0x020 - 0x03C	General configurable event [63:32] configuration
0x040 - 0x05C	General configurable event [95:64] configuration
0x060 - 0x06C	EXTI I/O port mux selection
0x070	EXTI protection lock configuration
0x080 - 0x0BC	CPU input event configuration

All registers can be accessed with word (32-bit), half-word (16-bit), and byte (8-bit) access.

25.7.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x000

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT21	RT20	Res.	Res.	Res.	Res.
										rw	rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RT15	RT14	RT13	RT12	RT11	RT10	RT9	RT8	RT7	RT6	RT5	RT4	RT3	RT2	RT1	RT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **RTx:** Rising trigger event configuration bit of configurable event input x (x = 21 to 20)

0: Rising trigger disabled (for event and interrupt) for input line

1: Rising trigger enabled (for event and interrupt) for input line

- When SECx is disabled in EXTI_SECCFGR1, RTx can be accessed with nonsecure and secure access.
- When SECx is enabled in EXTI_SECCFGR1, RTx can be accessed only with secure access. Nonsecure write to RTx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR1, RTx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR1, RTx can be accessed only with privileged access. Unprivileged write to RTx is discarded. Unprivileged read returns 0.

Note: The configurable event input is edge triggered. No glitch must be generated on this input. If a rising edge on the configurable event input occurs while writing to the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **RTx:** Rising trigger event configuration bit of configurable event input x (x = 15 to 0)

25.7.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x004

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT21	FT20	Res.	Res.	Res.	Res.
										rw	rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FT15	FT14	FT13	FT12	FT11	FT10	FT9	FT8	FT7	FT6	FT5	FT4	FT3	FT2	FT1	FT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **FTx:** Falling trigger event configuration bit of configurable event input x (x = 21 to 20)

0: Falling trigger disabled (for event and interrupt) for input line

1: Falling trigger enabled (for event and interrupt) for input line.

- When SECx is disabled in EXTI_SECCFGR1, FTx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR1, FTx can be accessed only with secure access. Nonsecure write to FTx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR1, FTx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR1, FTx can be accessed only with privileged access. Unprivileged write to FTx is discarded. Unprivileged read returns 0.

Note: The configurable event input is edge triggered. No glitch must be generated on this input. If a falling edge on the configurable event input occurs while writing to the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **FTx:** Falling trigger event configuration bit of configurable event input x (x = 15 to 0)

25.7.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x008

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI21	SWI20	Res.	Res.	Res.	Res.
										rw	rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWI15	SWI14	SWI13	SWI12	SWI11	SWI10	SWI9	SWI8	SWI7	SWI6	SWI5	SWI4	SWI3	SWI2	SWI1	SWI0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **SWIx:** Software interrupt on event x (x = 21 to 20)

0: Writing 0 has no effect.

1: Writing 1 to this bit triggers a rising edge event on event x (bit auto cleared by hardware).

- When SECx is disabled in EXTI_SECCFGR1, SWIx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR1, SWIx can be accessed only with secure access. Nonsecure write to SWIx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR1,SWIx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR1,SWIx can be accessed only with privileged access. Unprivileged write to SWIx is discarded. Unprivileged read returns 0.
- A software interrupt is generated whatever the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **SWIx:** Software interrupt on event x (x = 15 to 0)

25.7.4 EXTI rising edge pending register (EXTI_RPR1)

Address offset: 0x00C

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF21	RPIF20	Res.	Res.	Res.	Res.

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **RPIFx:** Configurable event input x rising edge pending bit (x = 21 to 20)

This bit is set when the selected rising edge event or an EXTI_SWIER1 software trigger arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

- When SECx is disabled in EXTI_SECCFGR1, RPIFx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR1, RPIFx can be accessed only with secure access. Nonsecure write to RPIFx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR1, RPIFx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR1, RPIFx can be accessed only with privileged access. Unprivileged write to RPIFx is discarded. Unprivileged read returns 0.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **RPIFx:** Configurable event input x rising edge pending bit (x = 15 to 0)

25.7.5 EXTI falling edge pending register (EXTI_FPR1)

Address offset: 0x010

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF21	FPIF20	Res.	Res.	Res.	Res.

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **FPIFx:** configurable event input x falling edge pending bit (x = 21 to 20)

This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing a 1 into this bit.

0: No falling edge trigger request occurred

1: Falling edge trigger request occurred

- When SECx is disabled in EXTI_SECCFGR1, FPIFx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR1, FPIFx can be accessed only with secure access. Nonsecure write to FPIFx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR1, FPIFx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR1, FPIFx can be accessed only with privileged access. Unprivileged write to FPIFx is discarded. Unprivileged read returns 0.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **FPIFx:** Configurable event input x rising edge pending bit (x = 15 to 0)

25.7.6 EXTI security configuration register (EXTI_SECCFGR1)

Address offset: 0x014

Reset value: 0x0000 0000

This register provides write access security and privilege. A nonsecure or unprivileged write access is ignored, and causes the generation of an secure illegal access event. All read return the register data.

Write to this register is ignored if GLOCK is enabled in EXTI_LOCKR.

This register contains only bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SEC 31	SEC 30	SEC 29	SEC 28	SEC 27	SEC 26	SEC 25	SEC 24	SEC 23	SEC 22	SEC 21	SEC 20	SEC 19	SEC 18	SEC 17	Res.

Bits 31:17 **SECx:** Security enable on event input x (x = 31 to 17)

0: Event security disabled (nonsecure)

1: Event security enabled (secure)

Bit 16 Reserved, must be kept at reset value.

Bits 15:0 **SECx:** Security enable on event input x (x = 15 to 0)

25.7.7 EXTI privilege configuration register (EXTI_PRIVCFGR1)

Address offset: 0x018

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged write access is discarded, and causes the generation of a privileged illegal access event. An unprivileged read returns the register data.

Write to this register are ignored if GLOCK is enabled in EXTI_LOCKR.

This register contains only bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:17 **PRIVx:** Privilege enable on event input x (x = 31 to 17)

0: Event privilege disabled (unprivileged)

1: Event privilege enabled (privileged)

- When SECx is disabled in EXT_SECCFGR1, PRIVx can be accessed with secure and nonsecure access.
- When SECx is enabled in EXTI_SECCFGR1, PRIVx can only be written with secure access. Nonsecure write to PRIVx is discarded.

Bit 16 Reserved, must be kept at reset value.

Bits 15:0 **PRIVx:** Privilege enable on event input x (x = 15 to 0)

25.7.8 EXTI rising trigger selection register (EXTI_RTSR2)

Address offset: 0x020

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw	rw							

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **RT56:** Rising trigger event configuration bit of configurable event input 56

0: Rising trigger disabled (for event and Interrupt) for input line x

1: Rising trigger enabled (for event and Interrupt) for input line x

- When SECx is disabled in EXTI_SECCFGR2, RTx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR2, RTx can be accessed only with secure access. Nonsecure write to RTx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR2, RTx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR2, RTx can be accessed only with privileged access. Unprivileged write to RTx is discarded. Unprivileged read returns 0.

Note: The configurable event input is edge triggered. No glitch must be generated on this input. If a rising edge on the configurable event input occurs while writing to the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **RT54:** Rising trigger event configuration bit of configurable event input 54

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **RT51:** Rising trigger event configuration bit of configurable event input 51

Bits 18:9 Reserved, must be kept at reset value.

Bits 8:7 **RTx:** Rising trigger event configuration bit of configurable event input x (x = 40 to 39)

Bits 6:0 Reserved, must be kept at reset value.

25.7.9 EXTI falling trigger selection register (EXTI_FTSR2)

Address offset: 0x024

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT56	Res.	FT54	Res.	Res.	FT51	Res.	Res.	Res.
							rw		rw			rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT40	FT39	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw	rw							

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FT56:** Falling trigger event configuration bit of configurable event input 56

0: Falling trigger disabled (for event and Interrupt) for input line

1: Falling trigger enabled (for event and Interrupt) for input line.

- When SECx is disabled in EXTI_SECCFGR2, FTx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTISECCFGR2, FTx can be accessed only with secure access. Nonsecure write to FTx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR2, FTx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR2, FTx can be accessed only with privileged access. Unprivileged write to FTx is discarded. Unprivileged read returns 0.

Note: The configurable event input is edge triggered. No glitch must be generated on this input. If a falling edge on the configurable event input occurs while writing to the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **FT54:** Falling trigger event configuration bit of configurable event input 54

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **FT51:** Falling trigger event configuration bit of configurable event input 51

Bits 18:9 Reserved, must be kept at reset value.

Bits 8:7 **FTx:** Falling trigger event configuration bit of configurable event input x (x = 40 to 39)

Bits 6:0 Reserved, must be kept at reset value.

25.7.10 EXTI software interrupt event register (EXTI_SWIER2)

Address offset: 0x028

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI56	Res.	SWI54	Res.	Res.	SWI51	Res.	Res.	Res.
							rw		rw			rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI40	SWI39	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw	rw							

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **SWI56:** Software interrupt on event 56

0: Writing 0 has no effect.

1: Writing 1 to this bit triggers a rising edge event on event x (bit auto cleared by hardware).

- When SECx is disabled in EXTI_SECCFGR2, SWIx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR2, SWIx can be accessed only with secure access. Nonsecure write to SWIx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR2, SWIx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR2, SWIx can be accessed only with privileged access. Unprivileged write to SWIx is discarded. Unprivileged read returns 0.
- A software interrupt is generated whatever the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SWI54:** Software interrupt on event 54

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **SWI51:** Software interrupt on event 51

Bits 18:9 Reserved, must be kept at reset value.

Bits 8:7 **SWIx:** Software interrupt on event x (x = 40 to 39)

Bits 6:0 Reserved, must be kept at reset value.

25.7.11 EXTI rising edge pending register (EXTI_RPR2)

Address offset: 0x02C

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF56	Res.	RPIF54	Res.	Res.	RPIF51	Res.	Res.	Res.

							rc_w1	rc_w1							

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **RPIF56:** Configurable event input 56 rising edge pending bit

This bit is set when the selected rising edge event or an EXTI_SWIER2 software trigger arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

- When SECx is disabled in EXTI_SECCFGR2, RPIFx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR2, RPIFx can be accessed only with secure access. Nonsecure write to RPIFx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR2, RPIFx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR2, this bit can be accessed only with privileged access. Unprivileged write to RPIFx is discarded. Unprivileged read returns 0.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **RPIF54:** Configurable event input 54 rising edge pending bit

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **RPIF51:** Configurable event input 51 rising edge pending bit

Bits 18:9 Reserved, must be kept at reset value.

Bits 8:7 **RPIFx:** Configurable event input x rising edge pending bit (x = 40 to 39)

Bits 6:0 Reserved, must be kept at reset value.

25.7.12 EXTI falling edge pending register (EXTI_FPR2)

Address offset: 0x030

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF56	Res.	FPIF54	Res.	Res.	FPIF51	Res.	Res.	Res.

							rc_w1	rc_w1							

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FPIF56:** Configurable event input 56 falling edge pending bit

This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.

0: No falling edge trigger request occurred

1: Falling edge trigger request occurred

- When SECx is disabled in EXTI_SECCFGR2, FPIFx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR2, FPIFx can be accessed only with secure access. Nonsecure write to this FPIFx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR2, FPIFx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR2, FPIFx can be accessed only with privileged access. Unprivileged write to FPIFx is discarded. Unprivileged read returns 0.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **FPIF54:** Configurable event input 54 falling edge pending bit

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **FPIF51:** Configurable event input 51 falling edge pending bit

Bits 18:9 Reserved, must be kept at reset value.

Bits 8:7 **FPIFx:** Configurable event input x falling edge pending bit (x = 40 to 39)

Bits 6:0 Reserved, must be kept at reset value.

25.7.13 EXTI security enable register (EXTI_SECCFGR2)

Address offset: 0x034

Reset value: 0x0000 0000

This register provides write access security and privilege. A nonsecure or unprivileged write access is ignored, and causes the generation of an secure illegal access event. All read return the register data.

Write to this register is ignored if GLOCK is enabled in EXTI_LOCKR.

This register contains only bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:28 **SECx:** Security enable on event input x (x = 63 to 60)

0: Event security disabled (nonsecure)

1: Event security enabled (secure)

Bit 27 Reserved, must be kept at reset value.

Bits 26:0 **SECx:** Security enable on event input x (x = 58 to 32)

25.7.14 EXTI privilege enable register (EXTI_PRIVCFGR2)

Address offset: 0x038

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged write access is discarded, and causes the generation of a privileged illegal access event. An unprivileged read returns the register data.

Write to this register is ignored if GLOCK is enabled in EXTI_LOCKR.

This register contains only bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 **PRIVx:** Privilege enable on event input x (x = 63 to 60)

0: Event privilege disabled (unprivileged)

1: Event privilege enabled (privileged)

- When SECx is disabled in EXTI_SECCFGR2, PRIVx can be accessed with secure and nonsecure access.
- When SECx is enabled in EXTI_SECCFGR2, PRIVx can be accessed only with secure access. Nonsecure write to PRIVx is discarded.

Bit 27 Reserved, must be kept at reset value.

Bits 26:0 **PRIVx:** Privilege enable on event input x (x = 58 to 32)

25.7.15 EXTI rising trigger selection register (EXTI_RTSR3)

Address offset: 0x040

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	RT74	RT73	RT72	RT71	RT70	RT69	RT68	Res.	RT66	Res.	Res.
					rw	rw	rw	rw	rw	rw	rw		rw		

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:4 **RTx:** Rising trigger event configuration bit of configurable event input x (x = 74 to 68)

0: Rising trigger disabled (for event and interrupt) for input line

1: Rising trigger enabled (for event and interrupt) for input line

- When SECx is disabled in EXTI_SECCFGR3, RTx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR3, RTx can be accessed only with secure access. Nonsecure write to RTx is discarded. Nonsecure read returns 0.
- When PRIVx i disabled in EXTI_PRIVCFGR3, RTx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR3, RTx can be accessed only with privileged access. Unprivileged write to RTx is discarded. Unprivileged read returns 0.

Note: The configurable event input is edge triggered. No glitch must be generated on this input. If a rising edge on the configurable event input occurs while writing to the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **RT66:** Rising trigger event configuration bit of configurable event input 66

Bits 1:0 Reserved, must be kept at reset value.

25.7.16 EXTI falling trigger selection register (EXTI_FTSR3)

Address offset: 0x044

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	FT74	FT73	FT72	FT71	FT70	FT69	FT68	Res.	FT66	Res.	Res.
					rw	rw	rw	rw	rw	rw	rw		rw		

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:4 **FTx:** Falling trigger event configuration bit of configurable event input x (x = 74 to 68)

0: Falling trigger disabled (for event and interrupt) for input line

1: Falling trigger enabled (for event and interrupt) for input line

- When SECx is disabled in EXTI_SECCFGR3, FTx can be accessed with nonsecure and secure access.
- When SECx is enabled in EXTI_SECCFGR3, FTx can be accessed only with secure access. Nonsecure write to FTx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR3, FTx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR3, FTx can be accessed only with privileged access. Unprivileged write to FTx is discarded. Unprivileged read returns 0.

Note: The configurable event input is edge triggered. No glitch must be generated on this input. If a falling edge on the configurable event input occurs while writing to the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FT66:** Falling trigger event configuration bit of configurable event input 66

Bits 1:0 Reserved, must be kept at reset value.

25.7.17 EXTI software interrupt event register (EXTI_SWIER3)

Address offset: 0x048

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SWI74	SWI73	SWI72	SWI71	SWI70	SWI69	SWI68	Res.	SWI66	Res.	Res.
					rw	rw	rw	rw	rw	rw	rw		rw		

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:4 **SWIx:** Software interrupt on event x (x = 74 to 68)

0: Writing 0 has no effect.

1: Writing 1 to this bit triggers a rising edge event on event x (bit auto cleared by hardware).

- When SECx is disabled in EXTI_SECCFGR3, SWIx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR3, SWIx can be accessed only with secure access. Nonsecure write to SWIx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR3, SWIx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR3, SWIx can be accessed only with privileged access. Unprivileged write to SWIx is discarded. Unprivileged read returns 0.
- A software interrupt is generated whatever the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SWI66:** Software interrupt on event 66

Bits 1:0 Reserved, must be kept at reset value.

25.7.18 EXTI rising edge pending register (EXTI_RPR3)

Address offset: 0x04C

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

					rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1		rc_w1		

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:4 **RPIFx:** configurable event input x rising edge pending bit (x = 74 to 68)

This bit is set when the selected rising edge event or an EXTI_SWIER3 software trigger arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

- When SECx is disabled in EXTI_SECCFGR3, RPIFx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTI_SECCFGR3, RPIFx can be accessed only with secure access. Nonsecure write to this RPIFx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR3, RPIFx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR3, RPIFx can be accessed only with privileged access. Unprivileged write to RPIFx is discarded. Unprivileged read returns 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **RPIF66:** configurable event input 66rising edge pending bit

Bits 1:0 Reserved, must be kept at reset value.

25.7.19 EXTI falling edge pending register (EXTI_FPR3)

Address offset: 0x050

Reset value: 0x0000 0000

This register contains only bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

					rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1		rc_w1		

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:4 **FPIFx:** configurable event input x falling edge pending bit (x = 74 to 68)

This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.

0: No falling edge trigger request occurred

1: Falling edge trigger request occurred

- When SECx is disabled in EXTI_SECCFGR3, FPIFx can be accessed with non-secure and secure access.
- When SECx is enabled in EXTISECCFGR3, FPIFx can be accessed only with secure access. Nonsecure write to FPIFx is discarded. Nonsecure read returns 0.
- When PRIVx is disabled in EXTI_PRIVCFGR3, FPIFx can be accessed with unprivileged and privileged access.
- When PRIVx is enabled in EXTI_PRIVCFGR3, FPIFx can be accessed only with privileged access. Unprivileged write to FPIFx is discarded. Unprivileged read returns 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FPIF66:** configurable event input 66 falling edge pending bit

Bits 1:0 Reserved, must be kept at reset value.

25.7.20 EXTI security enable register (EXTI_SECCFGR3)

Address offset: 0x054

Reset value: 0x0000 0000

This register provides write access security and privilege. A nonsecure or unprivileged write access is ignored and causes the generation of an secure illegal access event. All reads return the register data.

Write to this register are ignored if GLOCK is enabled in EXTI_LOCKR.

This register contains only bits for security capable input events.

		rw			rw	rw	rw	rw	rw	rw	rw		rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SEC77:** Security enable on event input 77
0: Event security disabled (nonsecure)
1: Event security enabled (secure)

Bits 12:11 Reserved, must be kept at reset value.

Bits 10:4 **SECx:** Security enable on event input x (x = 74 to 68)

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SECx:** Security enable on event input x (x = 66 to 64)

25.7.21 EXTI privilege enable register (EXTI_PRIVCFGR3)

Address offset: 0x058

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged write access is discarded and causes the generation of a privileged illegal access event. An unprivileged read returns the register data.

Write to this register are ignored if GLOCK is enabled in EXTI_LOCKR.

This register contains only bits for security capable Input events.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **EXTI7[7:0]:** EXTI7 GPIO port selection.

These bits are written by software to select the source input for EXTI7 external interrupt.

0x00: PA7 pin
0x01: PB7 pin
0x02: PC7 pin
0x03: PD7 pin
0x04: PE7 pin
0x05: PF7 pin
0x06: PG7 pin
0x07: PH7 pin
0x08: PN7 pin
0x09: PO7 pin
0x0A: PP7 pin
0x0B: PQ7 pin
Others: reserved

- When SEC7 is disabled in EXTI_SECCFGR1 this field can be accessed with non-secure and secure access.
- When SEC7 is enabled in EXTI_SECCFGR1, this field can be accessed only with secure access. Nonsecure write is discarded, nonsecure read returns 0.
- When PRIV7 is disabled in EXTI_PRIVCFGR1, this field can be accessed with privileged and unprivileged access.
- When PRIV7 is enabled in EXTI_PRIVCFGR1, this field can be accessed only with privileged access. Unprivileged write to this field is discarded and read returns 0.

Bits 23:16 **EXTI6[7:0]:** EXTI6 GPIO port selection.

These bits are written by software to select the source input for EXTI6 external interrupt.

0x00: PA6 pin
0x01: PB6 pin
0x02: PC6 pin
0x03: PD6 pin
0x04: PE6 pin
0x05: PF6 pin
0x06: PG6 pin
0x07: PH6 pin
0x08: PN6 pin
0x09: PO6 pin
0x0A: PP6 pin
0x0B: PQ6 pin
Others: reserved

- When SEC6 is disabled in EXTI_SECCFGR1 this field can be accessed with non-secure and secure access.
- When SEC6 is enabled in EXTI_SECCFGR1, this field can be accessed only with secure access. Nonsecure write is discarded, nonsecure read returns 0.
- When PRIV6 is disabled in EXTI_PRIVCFGR1, this field can be accessed with privileged and unprivileged access.
- When PRIV6 is enabled in EXTI_PRIVCFGR1, this field can be accessed only with privileged access. Unprivileged write to this field is discarded and read returns 0.

Bits 15:8 **EXTI5[7:0]:** EXTI5 GPIO port selection.

These bits are written by software to select the source input for EXTI5 external interrupt.

0x00: PA5 pin
0x01: PB5 pin
0x02: PC5 pin
0x03: PD5 pin
0x04: PE5 pin
0x05: PF5 pin
0x06: PG5 pin
0x07: PH5 pin
0x08: PN5 pin
0x09: PO5 pin
0x0A: PP5 pin

- When SEC12 is disabled in EXTI_SECCFGR1 this field can be accessed with non-secure and secure access.
- When SEC12 is enabled in EXTI_SECCFGR1, this field can be accessed only with secure access. Nonsecure write is discarded, nonsecure read returns 0.
- When PRIV12 is disabled in EXTI_PRIVCFGR1, this field can be accessed with privileged and unprivileged access.
- When PRIV12 is enabled in EXTI_PRIVCFGR1, this field can be accessed only with privileged access. Unprivileged write to this field is discarded and read returns 0.

25.7.26 EXTI lock register (EXTI_LOCKR)

Address offset: 0x070

Reset value: 0x0000 0000

This register can only be written by secure or privileged access. A write access from any other protection level is discarded, and any read returns zero value. Both illegal write and read access generate an illegal access event.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GLOCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK:** Global security privilege EXTI_SECCFGRx/PRIVCFGRx
This bit is written once after reset.
0: Security, privilege open can be modified.
1: Security, privilege locked can no longer be modified.

25.7.27 EXTI CPU wake-up with interrupt mask register 1 (EXTI_IMR1)

Address offset: 0x080

Reset value: 0x0000 0000

This register contains only bits for configurable events and direct events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IM31	IM30	IM29	IM28	IM27	IM26	IM25	IM24	IM23	IM22	IM21	IM20	IM19	IM18	IM17	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

26 Cyclic redundancy check calculation unit (CRC)

26.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

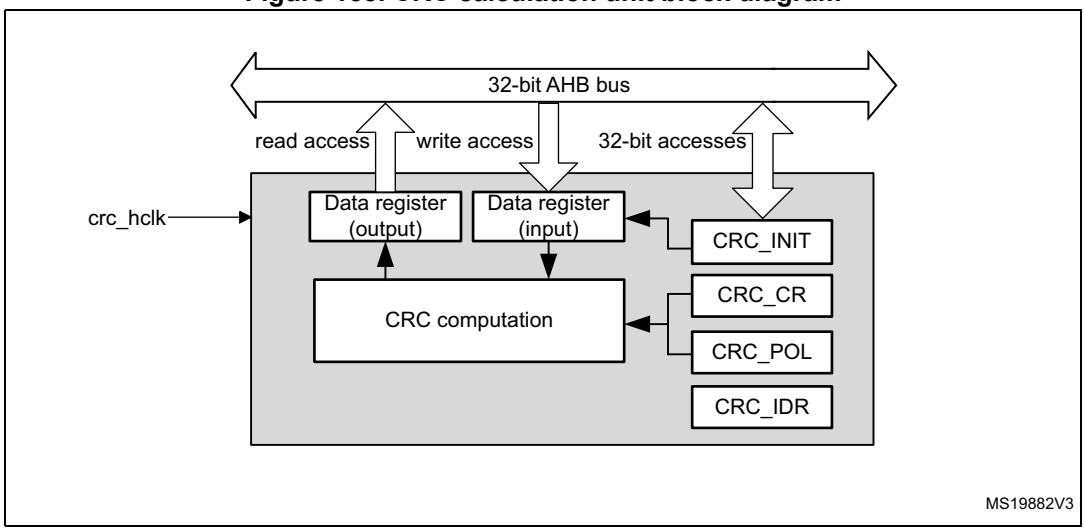
26.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility options on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

26.3 CRC functional description

26.3.1 CRC block diagram

Figure 158. CRC calculation unit block diagram



26.3.2 CRC internal signals

Table 145. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

26.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. When the RTYPE_IN bit is set in CRC_CR, non-word accesses to CRC_DR register are ignored. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register. If RTYPE_IN bit is set in this register, the input reversing operation can be performed with a byte or half-word granularity, but not with single bit granularity.

For example, with RTYPE_IN cleared, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte (REV_IN[1:0] = 01)
- 0xD458B23C with bit-reversal done by half-word (REV_IN[1:0] = 10)
- 0xB23CD458 with bit-reversal done on the full word (REV_IN[1:0] = 11)

With RTYPE_IN set, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x3C4D1A2B with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x4D3C2B1A with byte-reversal done by word (REV_IN[1:0] = 10)

The output data can also be reversed by setting the REV_OUT[1:0] bits in the CRC_CR register. If RTYPE_OUT is set in this register, the output reversing operation is performed with a byte or half-word granularity, but not with single bit granularity.

With RTYPE_OUT cleared, the operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

With RTYPE_OUT set, 0x11223344 output data are converted as:

- 0x33441122 with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x44332211 with byte-reversal done by word (REV_IN[1:0] = 10)

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

26.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes when RTYPE bit is cleared in CRC_CR. When RTYPE is set, only word accesses are allowed. For the other registers only 32-bit accesses are allowed.

26.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

26.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

26.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

					rw	rw	rw	rw	rw	rw	rw	rw			rs

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **RTYPE_OUT**: Reverse type output
This bit controls the reversal granularity of the output data.
0: Bit level output
1: Byte or half-word level output

Bit 9 **RTYPE_IN**: Reverse type input
This bit controls the reversal granularity of the input data.
0: Bit level input
1: Byte or half-word level input

Bits 8:7 **REV_OUT[1:0]**: Reverse output data
This bitfield controls the reversal of the bit order of the output data.
00: Bit order not affected (RTYPE_OUT = 0 or 1)
01: Bit-reversed output format (RTYPE_OUT = 0) or half-word reversal done by word (RTYPE_OUT = 1)
10: Bit order not affected (RTYPE_OUT = 0) or byte reversal done by word (RTYPE_OUT = 1)
11: Bit order not affected (RTYPE_OUT = 0 or 1)

Bits 6:5 **REV_IN[1:0]**: Reverse input data
This bitfield controls the reversal of the bit order of the input data
00: Bit order not affected (RTYPE_IN = 0 or 1)
01: Bit reversal done by byte (RTYPE_IN = 0) or half-word reversal done by word (RTYPE_IN = 1)
10: Bit reversal done by half-word (RTYPE_IN = 0) or byte reversal done by word (RTYPE_IN = 1)
11: Bit reversal done by word (RTYPE_IN = 0) or bit order is not affected (RTYPE_IN = 1)

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.

00: 32 bit polynomial

01: 16 bit polynomial

10: 8 bit polynomial

11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware

26.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CRC_INIT[31:0]**: Programmable initial CRC value

This register is used to write the CRC initial value.

26.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
POL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **POL[31:0]**: Programmable polynomial

This register is used to write the coefficients of the polynomial to be used for CRC calculation.

If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

26.4.6 CRC register map

Table 146. CRC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

27 Flexible memory controller (FMC)

The flexible memory controller (FMC) includes three memory controllers:

- the NOR/PSRAM memory controller
- the NAND memory controller
- the synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) controller

27.1 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND flash memory. Its main purposes are:

- to translate AXI transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique Chip Select. The FMC performs only one access at a time to an external device.

The main features of the FMC are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR flash memory/One NAND flash memory
  - PSRAM (4 memory subregions)
  - Ferroelectric RAM (FRAM)
  - NAND flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) memories
- Burst mode support for faster access to synchronous devices such as NOR flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16- or 32-bit wide data bus
- Independent chip-select control for each memory region
- Independent configuration for each memory region
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control

At startup the FMC pins must be configured by the user application. The FMC input/output pins which are not used by the application can be used for other purposes.

After reset, the FMC is disabled. Once all the used memory controllers are configured, the FMC must be enabled by setting the FMCEN bit.

The FMC registers that define the external device type and associated characteristics are set at boot time and do not change until the next reset or power-up. If some registers have to be re-configured, the FMC must be disabled (FMCEN bit set to 0x0). However, only few bits can be changed on the fly:

- FMCEN bit
- ECCEN and PBEN bits in FMC_PCR register
- FMC_CSQICR and FMC_CSQIER register bits
- FMC command sequencer registers and FMC BCH registers
- WEN bit in the FMC_PCR register
- MODE[2:0], DS1/DS2, NRFS[3:0] and MRD[13:0] bits in FMC_SDCMR register
- REIE and CRE bits in the FMC_SDRTR register.

If some parameters have to be modified while the FMC is enabled, the FMC must be first disabled so that no further access is allowed to any memory controller during register modification. Once all needed configurations are updated, enable the FMC as follows:

1. Disable FMC by resetting the FMCEN bit.
2. Wait ISOST[1:0] bits in FMC_SR register to be set to 0b11.
3. Wait until PEF flag is set in the FMC_SR register.
4. Program the registers with new values.
5. Enable the FMC by setting the FMCEN bit.

When the SDRAM controller is available, if the SDCLK clock ratio or refresh rate has to be modified after the initialization phase, the following procedure must be followed.

1. Stop by software, the AXI traffic from/to the SDRAM devices only.
2. Put all the SDRAM devices in self refresh and wait for the CMDOK command completion flag.
3. Change the clock ratio to the new value.
4. Send a normal mode command (NRM) to exit from SR and wait for the CMDOK command completion flag.
5. Send a load mode register command (LMR) as needed to update devices timing (optional)
6. Resume the AXI traffic to SDRAM devices.

27.2 FMC implementation

Table 147. FMC features

Modes/features	FMC
NAND flash chip-select outputs	4
NAND flash ready/busy	1
NAND/NOR flash with common WAIT pin	No

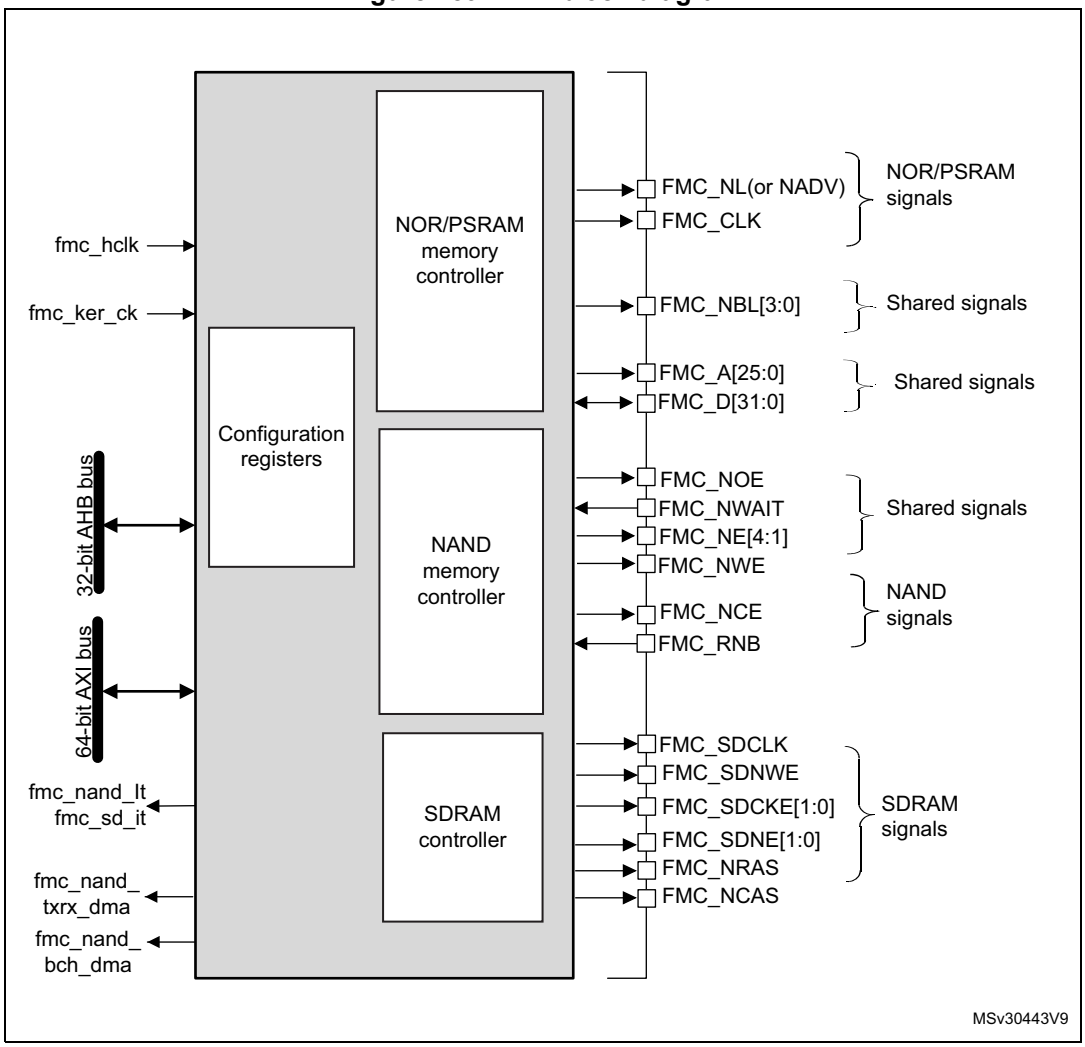
27.3 FMC block diagram

The FMC consists of the following main blocks:

- The NOR flash/PSRAM/SRAM controller
- The NAND controller
- The SDRAM controller
- The AXI interface
- The AHB interface (including the FMC configuration registers)

The block diagram is shown in the below figure.

Figure 159. FMC block diagram



27.4 FMC internal signals

Table 148 gives the list of FMC internal signals. FMC pins (or external signals) are described in *Section 27.8.1: External memory interface signals*.

Table 148. FMC internal signals

Names	Signal type	Description
fmc_nand_it	Digital output	FMC NAND flash interrupt
fmc_sd_it	Digital output	FMC SDRAM interrupt
fmc_ker_ck	Digital input	FMC kernel clock
fmc_hclk	Digital input	FMC interface clock
fmc_nand_txrx_dma	Digital output	DMA request for reading or writing data from/to NAND flash memory
fmc_nand_bch_dma	Digital output	DMA request for BCH results

27.5 AHB interface

The AHB slave interface allows internal CPUs to configure the FMC registers.

The AHB clock (HCLK) is the reference clock for the FMC register accesses.

The FMC registers must be accessed by words (32 bits). For non 32-bit AHB accesses, FMC does not return an AHB bus error and the register value can be corrupted.

27.6 AXI interface

The AXI slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AXI transactions are translated into the external device protocol. As the AXI data bus is 64-bit wide, the AXI transactions might be split into several consecutive 32- or 16- or 8-bit accesses according to data size accesses.

The FMC generates an AXI slave error when one of the following conditions is met:

- When reading or writing to an FMC memory region (memory region 1 to 4) which is not enabled
- When reading or writing to any FMC memory region while the FMC is disabled (FMCEN bit is reset)
- When reading or writing by the command sequencer to NAND memory region while it is disabled
- When reading or writing to the NOR flash memory region while the MBKEN bit is reset in the FMC_BCRx register
- When writing to a write-protected SDRAM device (WP bit set in the SDRAM_SDCRx register)
- When the SDRAM address range is violated (access to a reserved address range)
- When reading or writing to an SDRAM device with the SDEN bit cleared in the FMC_SDCRx register

The FMC generates an AXI decoder error in the following conditions:

- When ADDR[31:28] address bits are not supported by the FMC memory region base address following the BMAP[1:0] bits configuration
- and when an access to an SDRAM or a NAND memory region is performed while the SDRAM or the NAND controller is not present.

The kernel clock for the FMC is the asynchronous fmc_ker_ck clock (refer the Reset and Clock control (RCC) section for details on fmc_ker_ck clock source selection).

27.6.1 Supported memories and transactions

General transaction rules

The requested AXI transaction data size can be 8-, 16-, 32- or 64-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:

- AXI transaction size and memory data size must be equal to prevent issues from occurring.
- AXI transaction size is greater than the memory size:

  In this case, the FMC splits the AXI transaction into smaller consecutive memory accesses to meet the external data width.
- AXI transaction size is smaller than the memory size:

  The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM, SDRAM)

    In this case, the FMC allows read/write transactions and accesses the right data through its byte lanes NBL[3:0].

    Bytes to be written are addressed by NBL[3:0].

    All memory bytes are read (NBL[3:0] are driven low during read transaction) and the useless ones are discarded.
  - Accesses to devices that do not have the byte select feature (NOR and NAND flash memories)

    This situation occurs when a byte access is requested to a 16-bit wide flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the flash memory), write transactions are not allowed while read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

Wrap support for NOR flash/PSRAM

Synchronous memories must be configured in Linear burst mode of undefined length as not all masters can issue wrap transactions.

If a master generates a wrap transaction:

- The read operation is split into two linear burst transactions.
- The write operation is split into two linear burst transactions.

Configuration registers

The FMC can be configured through a set of registers. Refer to *Section 27.8.6*, for a detailed description of the NOR flash/PSRAM controller registers. Refer to *Section 27.9.9*, for a detailed description of the NAND flash registers and to *Section 27.10.5* for a detailed description of the SDRAM controller registers.

27.7 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size memory regions of 256 Mbytes each (see *Table 149*):

- Memory region 1 is used to address up to 4 NOR flash memories or PSRAM devices. This region is split into four NOR/PSRAM subregions with four dedicated Chip Selects, as follows:
  - Subregion 1 - NOR/PSRAM 1
  - Subregion 2 - NOR/PSRAM 2
  - Subregion 3- NOR/PSRAM 3
  - Subregion 4 - NOR/PSRAM 4

Note: The Memory region 1 type attribute must be declared as 'device'.

- Memory region 5 and 6 are used to address SDRAM devices (one device per region).

For each memory region, the type of memory to be used can be configured by the user application through the Configuration register.

Table 149. FMC memory regions (default mapping)

Address	Memory region	Supported memory type
0x6000 0000 - 0x6FFF FFFF	Memory region 1	NOR flash memory/PSRAM/SRAM
0xC000 0000 - 0xCFFF FFFF	Memory region 5	SDRAM device 1
0xD000 0000 - 0xDFFF FFFF	Memory region 6	SDRAM device 2

The mapping of FMC memory regions can be modified through the BMAP[1:0] bits in FMC_BCR1 register. *Table 150* shows the configuration to swap the NOR/PSRAM and SDRAM memory regions or remap SDRAM device 1 and 2. Thus allowing to access the SDRAM devices at two different address mapping.

Table 150. FMC memory region remap using BMAP[1:0]

FMC memory region	BMAP[1:0] = 00 (Default mapping)	BMAP[1:0] = 01	BMAP[1:0] = 10
Memory region 1	NOR/PSRAM/SRAM	SDRAM device 1	NOR/PSRAM/SRAM
Memory region 5	SDRAM device 1	NOR/PSRAM/SRAM	SDRAM device 1
Memory region 6	SDRAM device 2	SDRAM device 2	SDRAM device 2

27.7.1 NOR/PSRAM address mapping

ADDR[27:26] bits are used to select one of the four memory subregions as shown in *Table 151*.

Table 151. NOR/PSRAM subregion selection

ADDR[27:26](1)	Selected subregion
00	Subregion 1 - NOR/PSRAM 1
01	Subregion 2 - NOR/PSRAM 2
10	Subregion 3- NOR/PSRAM 3
11	Subregion 4- NOR/PSRAM 4

1. ADDR are internal address lines that are translated to external memory.

The ADDR[25:0] bits contain the external memory address. Since ADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 152. NOR/PSRAM External memory address

Memory width(1)	Data address issued to the memory	Maximum memory capacity (bits)
8-bit	ADDR[25:0]	64 Mbytes * 8 = 512 Mbit
16-bit	ADDR[25:1] >> 1	64 Mbytes/2 * 16 = 512 Mbit
32-bit	ADDR[25:2] >> 2	64 Mbytes/4 * 32 = 512 Mbit

1. In case of a 16-bit external memory width, the FMC internally uses ADDR[25:1] to generate the address for external memory FMC_A[24:0]. In case of a 32-bit memory width, the FMC internally uses ADDR[25:2] to generate the external address.
Whatever the external memory width, FMC_A[0] must be connected to external memory address A[0].

27.7.2 NAND flash memory address mapping

The 4 Kbyte NAND flash address bits are mapped according to *Table 153*.

Table 153. NAND access memory map

Address field	FMC signal name	Function	Detailed description
ADDR[10]	NCE	NAND chip enable selection	00: NCE1
ADDR[9:8]	-	Reserved	-
ADDR[7]	-	Timing selection	0: Common space, timing defined by FMC_PMEM 1: Attribute space, timing defined by FMC_PATT
ADDR[6]	-	Reserved	-
ADDR[5]	A[17]	Address (ALE)	00: Data section 01: Command section 10: Address section 11: reserved
ADDR[4](1)	A[16]	Command (CLE)	

1. Four address LSBs are don't care: each section has 16 bytes mapped to the alias region.

The application software uses the 3 sections to access the NAND flash memory:

- **To send a command to NAND flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data,** the software reads or writes the data from/to any memory location in the data section.

Since the NAND flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

Note: The NAND region has to be accessed as a device and not as memory. Write accesses to command and address sections must be done in Byte mode and aligned with the section base address (offset = 0).

Read and Write accesses to NAND data section must be in Byte mode for 8-bit NAND flash memories and Byte or Half-word mode for 16-bit NAND flash memories.

Read and Write bursts must start at section base address (offset = 0) and must not cross the 16-byte section boundary.

27.7.3 SDRAM address mapping

Two SDRAM regions are available as indicated in *Table 154*.

Table 154. SDRAM device selection

Selected device	Control register	Timing register
SDRAM device 1	FMC_SDCR1	FMC_SDTR
SDRAM device 2	FMC_SDCR2	

The following table shows SDRAM mapping for an 13-bit row, a 11-bit column and 4 internal bank configuration.

Table 155. SDRAM address mapping

Memory width(1)	Internal bank	Row address	Column address(2)	Maximum memory capacity (Mbytes)
8-bit	ADDR[25:24]	ADDR[23:11]	ADDR[10:0]	64 Mbytes: 4 * 8K * 2K
16-bit	ADDR[26:25]	ADDR[24:12]	ADDR[11:1]	128 Mbytes: 4 * 8K * 2K * 2
32-bit	ADDR[27:26]	ADDR[25:13]	ADDR[12:2]	256 Mbytes: 4 * 8K * 2K * 4

1. When interfacing with a 16-bit memory, the FMC internally uses the ADDR[11:1] internal address lines to generate the external address. When interfacing with a 32-bit memory, the FMC internally uses ADDR[12:2] lines to generate the external address. Whatever the memory width, FMC_A[0] has to be connected to the SDRAM A[0].
2. The AutoPrecharge is not supported. However, FMC_A[10] must be connected to SDRAM A[0].

The ADDR[27:0] bits are translated to external SDRAM address depending on the SDRAM controller configuration:

- Row size:11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

Table 156. SDRAM address mapping with 8-bit data bus width(1)(2)

Row size configuration	ADDR (Internal address lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.							Bank [1:0]		Row[10:0]											Column[7:0]							
	Res.						Bank [1:0]			Row[10:0]											Column[8:0]							
	Res.					Bank [1:0]				Row[10:0]											Column[9:0]							
	Res.				Bank [1:0]					Row[10:0]											Column[10:0]							
12-bit row size configuration	Res.						Bank [1:0]			Row[11:0]											Column[7:0]							
	Res.					Bank [1:0]				Row[11:0]											Column[8:0]							
	Res.				Bank [1:0]					Row[11:0]											Column[9:0]							
	Res.			Bank [1:0]						Row[11:0]											Column[10:0]							
13-bit row size configuration	Res.					Bank [1:0]				Row[12:0]											Column[7:0]							
	Res.				Bank [1:0]					Row[12:0]											Column[8:0]							
	Res.			Bank [1:0]						Row[12:0]											Column[9:0]							
	Res.		Bank [1:0]							Row[12:0]											Column[10:0]							

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be cleared.
2. Access to Reserved (Res.) address range generates an AXI slave error.

Table 157. SDRAM address mapping with 16-bit data bus width(1)(2)

Row size Configuration	ADDR (address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.						Bank [1:0]		Row[10:0]										Column[7:0]									BM0(3)
	Res.							Bank [1:0]		Row[10:0]										Column[8:0]								BM0
	Res.								Bank [1:0]		Row[10:0]										Column[9:0]							BM0
	Res.									Bank [1:0]		Row[10:0]										Column[10:0]						BM0
12-bit row size configuration	Res.							Bank [1:0]		Row[11:0]										Column[7:0]								BM0
	Res.								Bank [1:0]		Row[11:0]										Column[8:0]							BM0
	Res.									Bank [1:0]		Row[11:0]										Column[9:0]						BM0
	Res.										Bank [1:0]		Row[11:0]									Column[10:0]						BM0
13-bit row size configuration	Res.								Bank [1:0]		Row[12:0]										Column[7:0]							BM0
	Res.									Bank [1:0]		Row[12:0]										Column[8:0]						BM0
	Res.										Bank [1:0]		Row[12:0]									Column[9:0]						BM0
	Res.											Bank [1:0]		Row[12:0]								Column[10:0]						BM0

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be cleared.
2. Access to Reserved space (Res.) generates an AXI Slave error.
3. BM0: is the byte mask for 16-bit access.

Table 158. SDRAM address mapping with 32-bit data bus width(1)(2)

Row size configuration	ADDR (address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Res.							Bank [1:0]		Row[10:0]										Column[8:0]							BM[1:0	
	Res.								Bank [1:0]		Row[10:0]										Column[9:0]						BM[1:0	
	Res.									Bank [1:0]		Row[10:0]										Column[10:0]						BM[1:0	

Table 158. SDRAM address mapping with 32-bit data bus width(1)(2) (continued)

Row size configuration	ADDR (address Lines)																											
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
12-bit row size configuration	Res.				Bank [1:0]		Row[11:0]												Column[7:0]								BM[1:0	
	Res.			Bank [1:0]			Row[11:0]												Column[8:0]								BM[1:0	
	Res.		Bank [1:0]				Row[11:0]												Column[9:0]								BM[1:0	
	Res.	Bank [1:0]					Row[11:0]												Column[10:0]								BM[1:0	
13-bit row size configuration	Res.			Bank [1:0]			Row[12:0]												Column[7:0]								BM[1:0	
	Res.		Bank [1:0]				Row[12:0]												Column[8:0]								BM[1:0	
	Res.	Bank [1:0]					Row[12:0]												Column[9:0]								BM[1:0	
	Bank [1:0]						Row[12:0]												Column[10:0]								BM[1:0	

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be cleared.
2. Access to Reserved space (Res.) generates an AXI slave error.
3. BM[1:0]: is the byte mask for 32-bit access.

27.8 NOR flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM, FRAM and ROM
  - 8 bits
  - 16 bits
  - 32 bits
- PSRAM (CellularRAM™)
  - Asynchronous mode
  - Burst mode for synchronous accesses with configurable option to split burst access when crossing boundary page for CRAM 1.5.
  - Multiplexed or non-multiplexed
- NOR flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique Chip Select signal, NE[4:1], per memory region. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait-states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC output Clock (FMC_CLK) is a submultiple of the fmc_ker_ck clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (FMC_CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, memory region 1 must be configured in synchronous mode (see *Section 27.8.6: NOR/PSRAM controller registers*). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AXI data size has to be the same as the memory data width (MWID[1:0]) otherwise the FMC_CLK frequency is changed depending on AXI data transaction (refer to *Section 27.8.5: Synchronous transactions* for FMC_CLK divider ratio formula).

The size of each memory region is fixed and equal to 64 Mbytes. Each memory region is configured through dedicated registers (see *Section 27.8.6: NOR/PSRAM controller registers*).

The programmable memory parameters include access times (see *Table 159*) and support for wait management (for PSRAM and NOR flash accessed in burst mode).

Table 159. Programmable NOR/PSRAM access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Address setup	Duration of the address setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	0	15
Address hold	Duration of the address hold phase	Asynchronous, muxed I/Os	FMC clock cycle (fmc_ker_ck)	1	15
NBL setup	Duration of the Byte lanes setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	0	3
Data setup	Duration of the data setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	1	256
Data hold	Duration of the data hold phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	0	3
Bust turn	Duration of the bus turnaround phase	Asynchronous and synchronous read	FMC clock cycle (fmc_ker_ck)	0	15

Table 159. Programmable NOR/PSRAM access parameters (continued)

Parameter	Function	Access mode	Unit	Min.	Max.
Clock divide ratio	Number of FMC clock cycles (fmc_ker_ck) to build one memory clock cycle (CLK)	Synchronous	FMC clock cycle (fmc_ker_ck)	2	16
Data latency	Number of clock cycles to issue to the memory before the first data of the burst	Synchronous	Memory clock cycle (fmc_ker_ck)	2	17

27.8.1 External memory interface signals

Table 160, *Table 161* and *Table 162* list the signals that are typically used to interface with NOR flash memory, SRAM and PSRAM.

Note: The prefix "N" identifies the signals which are active low.

NOR flash memory, non-multiplexed I/Os

Table 160. Non-multiplexed I/O NOR flash memory

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:0]	O	Address bus
D[31:0]	I/O	Bidirectional data bus
NE[x]	O	Chip Select, x = 1 to 4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits (26 address lines).

NOR flash memory, 16-bit multiplexed I/Os

Table 161. 16-bit multiplexed I/O NOR flash memory

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip Select, x = 1 to 4
NOE	O	Output enable
NWE	O	Write enable

Table 161. 16-bit multiplexed I/O NOR flash memory (continued)

FMC signal name	I/O	Function
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits.

PSRAM/SRAM/FRAM, non-multiplexed I/Os

Table 162. Non-multiplexed I/Os PSRAM/SRAM

FMC signal name	I/O	Function
CLK	O	Clock (only for PSRAM synchronous access)
A[25:0]	O	Address bus
D[31:0]	I/O	Data bidirectional bus
NE[x]	O	Chip Select, x = 1 to 4 (called NCE by PSRAM (CellularRAM™, CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid only for PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[3:0]	O	Byte lane output (upper and lower byte enable)

The maximum capacity is 512 Mbits.

PSRAM, 16-bit multiplexed I/Os

Table 163. 16-bit multiplexed I/O PSRAM

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip Select, x = 1 to 4 (called NCE by PSRAM (CellularRAM™, CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[3:0]	O	Byte lane output (upper and lower byte enable)

The maximum capacity is 512 Mbits (26 address lines).

27.8.2 Supported memories and transactions

Table 164 below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

Table 164. NOR flash/PSRAM: Example of supported memories and transactions

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NOR flash (muxed I/Os and non-muxed I/Os)	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	-
	Synchronous	R	16	16	Y	-
	Synchronous	R	32	16	Y	-
	Synchronous	R	64	16	Y	Split into 4 FMC accesses

Table 164. NOR flash/PSRAM: Example of supported memories and transactions

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
PSRAM (multiplexed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	Y	Use of byte lanes NBL[3:0]
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	-
	Synchronous	R	16	16	Y	-
	Synchronous	R	32/64	16	Y	-
	Synchronous	W	8	16	Y	Use of byte lanes NBL[3:0]
	Synchronous	W	16/32/64	16	Y	-
SRAM and ROM	Asynchronous	R	8 / 16	16	Y	-
	Asynchronous	W	8 / 16	16	Y	Use of byte lanes NBL[3:0]
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses

27.8.3 General timing rules

Signals synchronization

- All controller output signals change on the rising edge of the fmc_ker_ck clock
- In synchronous mode (read or write), all output signals change on the rising edge of fmc_ker_ck clock.
- NBL signals

  They are applicable to memories which support byte enable.
  - The NBL signals are driven low:

    from the start of a read memory transfer and optionally earlier according to NBLSET, when the device requires some setup time from NBL to NCE,

    for bytes to be written during data transfer and according to the first data bytes during the address transfer.
  - The NBL signals are driven high two FMC_CLK clock cycles after the completion of the read or write transfer.

27.8.4 NOR flash/PSRAM controller asynchronous transactions

Asynchronous static memories (NOR flash, PSRAM, SRAM, FRAM)

- Signals are synchronized by the internal clock fmc_ker_ck. This clock is not issued to the memory.
- The FMC always samples the data before deasserting the Chip Select signal NE. This guarantees that the memory data hold timing constraint is met (minimum chip enable high to data transition is usually 0 ns).
- If the extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B. The extended mode is not compatible with the muxed mode (EXTMOD bit must be kept cleared in muxed mode).
- If the extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in mode 1 or mode 2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP[1:0] = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP[1:0] = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/FRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

Figure 160. Mode 1 read access waveforms

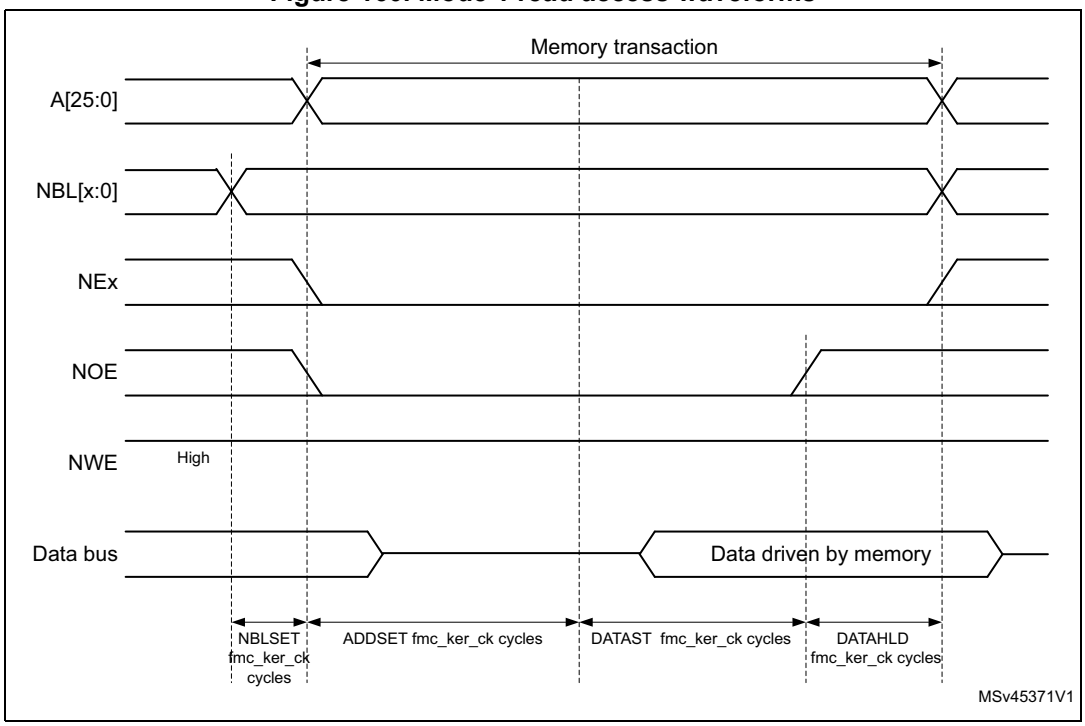

Figure 161. Mode 1 write access waveforms

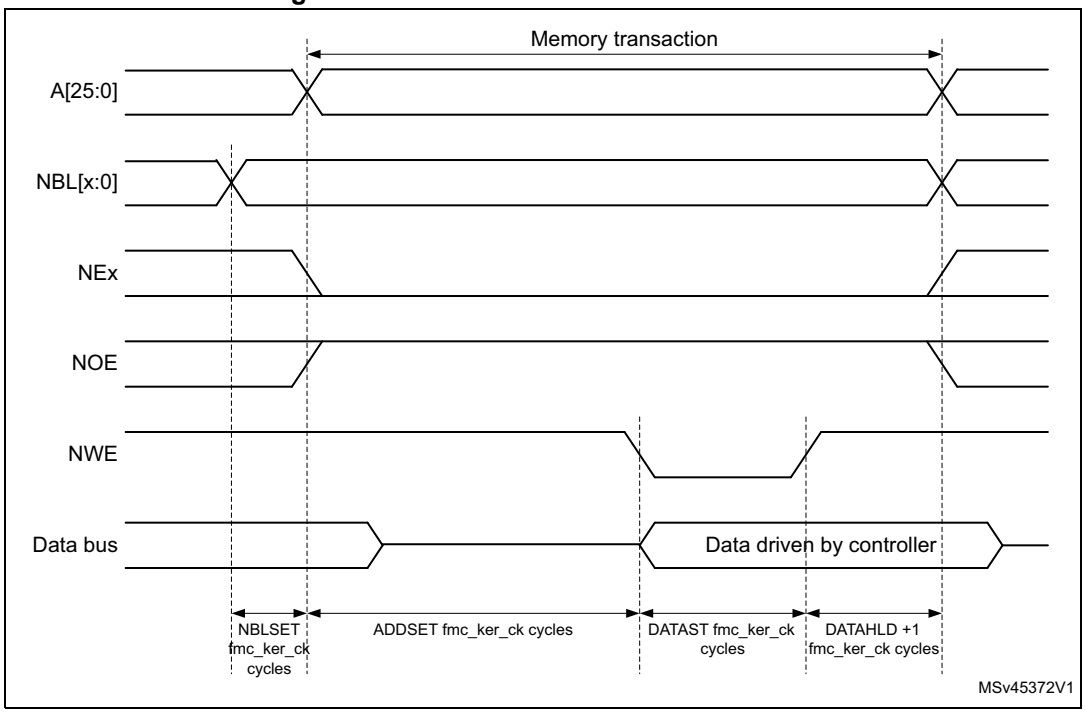

The DATAHLD time at the end of the read and write transaction guarantee the address and data hold time after the NOE/NWE rising edge. For write, the DATAST value must be greater than zero (DATAST > 0).

Table 165. FMC_BCRx bitfields (mode 1)

Bit number	Bit name	Value to set
31	Reserved	0x0
30-24	Reserved	0x00
23:22	NBLSET[1:0]	As needed
21:20	CSCOUNT	As needed
19	CBURSTRW	0x0 (no effect in asynchronous mode)
18:16	CPSIZE	0x0 (no effect in asynchronous mode)
15	ASYNCWAIT	Set if the memory supports this feature. Otherwise keep cleared.
14	EXTMOD	0x0
13	WAITEN	0x0 (no effect in asynchronous mode)
12	WREN	As needed
11	WAITCFG	Don’t care
10	Reserved	0x0
9	WAITPOL	Meaningful only if bit 15 is 1
8	BURSTEN	0x0
7	Reserved	0x1
6	Reserved	0x0
5-4	MWID[1:0]	As needed
3-2	MTYP	As needed, exclude 0x2 (NOR flash memory)
1	MUXE	0x0
0	MBKEN	0x1

Table 166. FMC_BTRx bitfields (mode 1)

Bit number	Bit name	Value to set
31:30	DATAHLD	Duration of the Data hold phase (DATAHLD fmc_ker_ck cycles) for read accesses.
29-28	ACCMOD	Don’t care
27-24	DATLAT	Don’t care
23-20	CLKDIV	Don’t care
19-16	BUSTURN	Time between NEx high to NEx low (BUSTURN fmc_ker_ck)
15-8	DATAST	Duration of the second access phase (DATAST fmc_ker_ck cycles).

Table 166. FMC_BTRx bitfields (mode 1) (continued)

Bit number	Bit name	Value to set
7-4	ADDHLD	Don’t care
3-0	ADDSET	Duration of the first access phase (ADDSET fmc_ker_ck cycles). Minimum value for ADDSET is 0.

Mode A - SRAM/FRAM/PSRAM (CRAM) OE toggling

Figure 162. Mode A read access waveforms

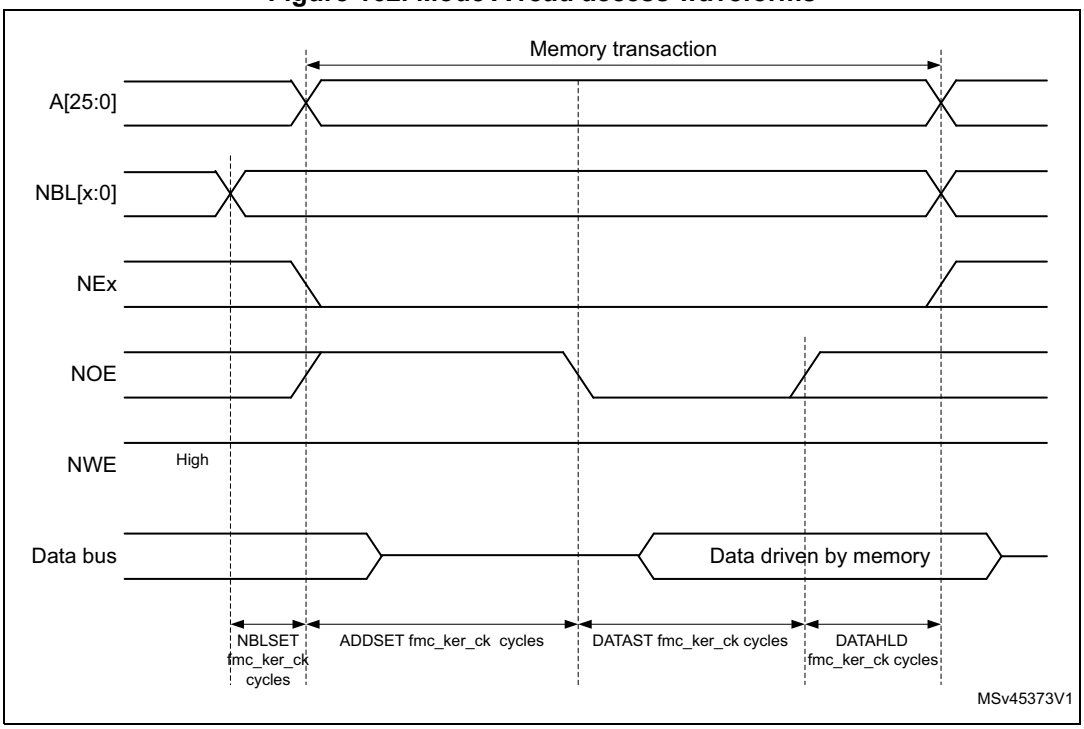

Figure 163. Mode A write access waveforms

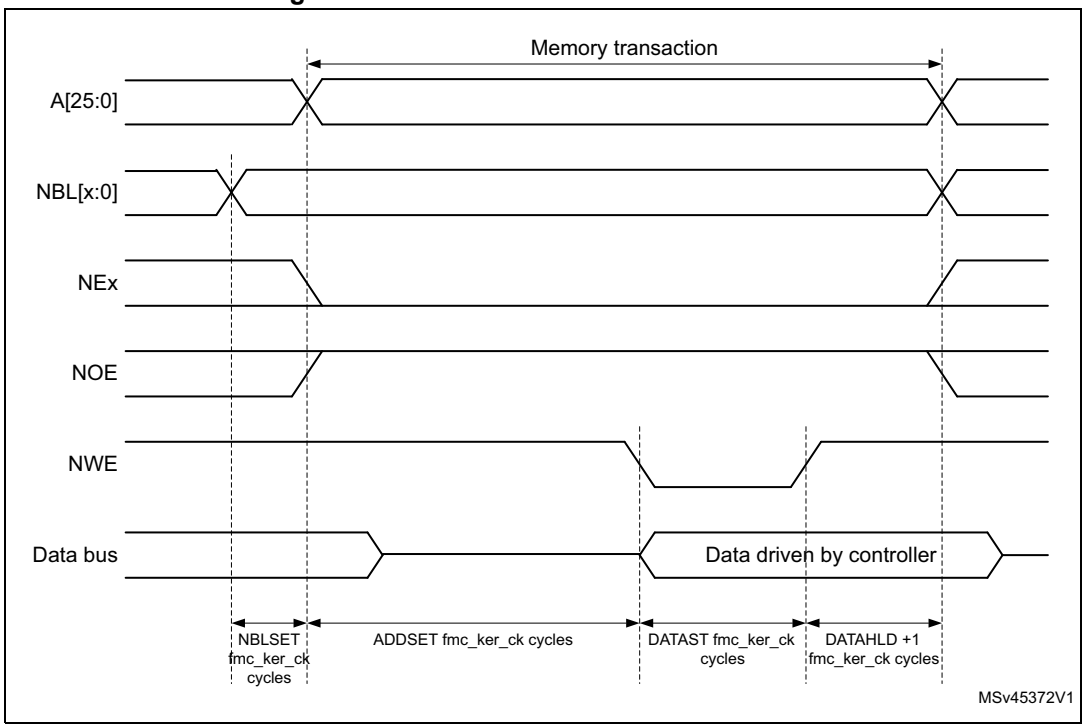

The differences compared with mode 1 are the toggling of NOE and the independent read and write timings.

Table 167. FMC_BCRx bitfields (mode A)

Bit number	Bit name	Value to set
31	Reserved	0x0
30-24	Reserved	0x00
23:22	NBLSET[1:0]	As needed
21:20	CSCOUNT	As needed
19	CBURSTRW	0x0 (no effect in asynchronous mode)

23-20	CLKDIV	Don’t care
19-16	BUSTURN	Time between NEx high to NEx low (BUSTURN fmc_ker_ck)
15-8	DATAST	Duration of the second access phase (DATAST fmc_ker_ck cycles for read accesses and DATAST+1 fmc_ker_ck cycles for write accesses).
7-4	ADDHLD	Duration of the middle phase of the access (ADDHLD fmc_ker_ck cycles).
3-0	ADDSET	Duration of the first access phase (ADDSET fmc_ker_ck cycles). Minimum value for ADDSET is 1.

WAIT management for asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 fmc_ker_ck cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$DATAST \geq (4 \times FMCCLK) + max_wait_assertion_time$$

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   if

$$max_wait_assertion_time > address_phase + hold_phase$$

   then:

$$DATAST \geq (4 \times FMCCLK) + (max_wait_assertion_time - address_phase - hold_phase$$

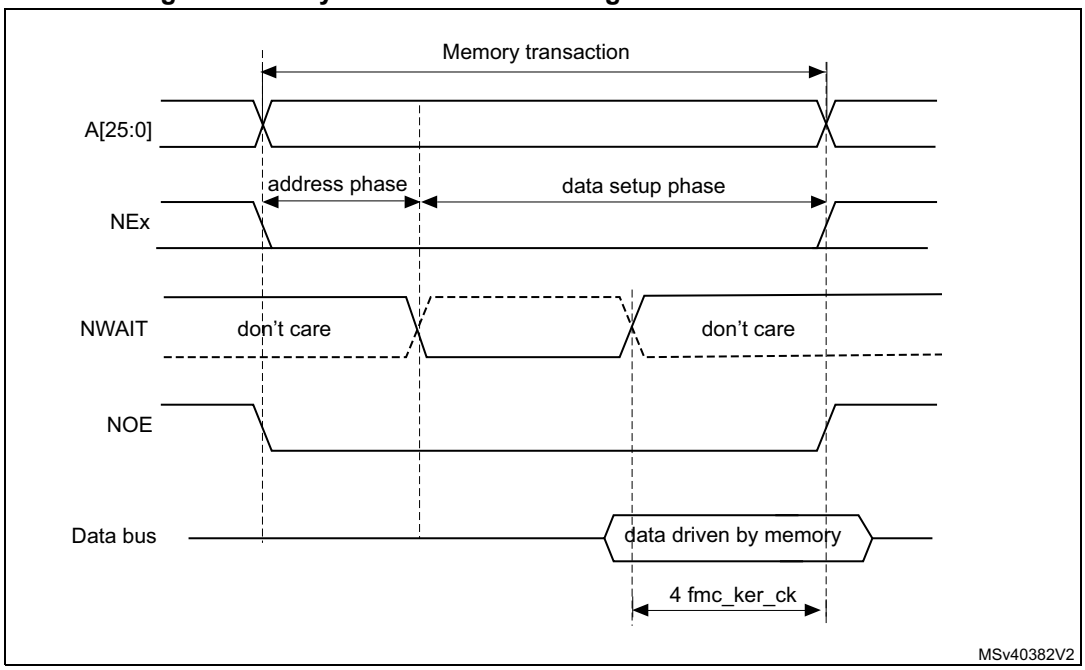
   otherwise

$$DATAST \geq 4 \times FMCCLK$$

   where max_wait_assertion_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

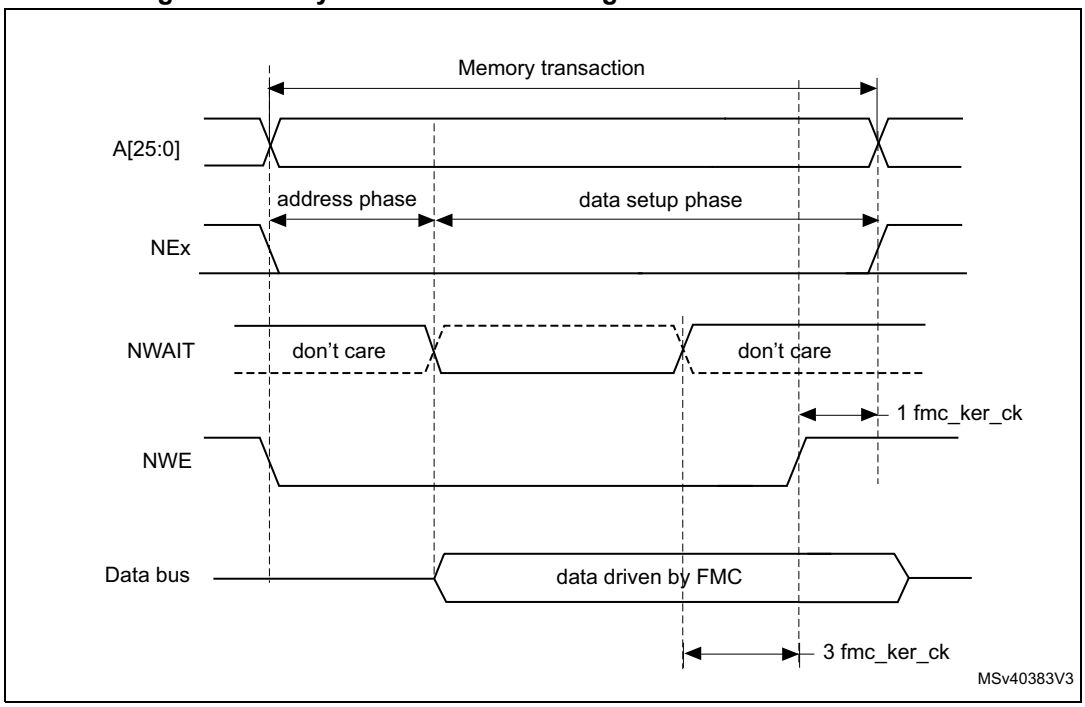
Figure 173 and *Figure 174* show the number of fmc_ker_ck clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

Figure 173. Asynchronous wait during a read access waveforms



1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

Figure 174. Asynchronous wait during a write access waveforms



1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

CellularRAM™ (PSRAM) refresh management

The CellularRAM™ does not allow maintaining the chip select signal (NE) low for longer than the t_{CEM} timing specified in memory device. This timing can be programmed in the FMC_CFGR register. It defines the maximum duration of the NE low pulse (expressed in fmc_ker_ck cycles) in synchronous mode for PSRAM read or write accesses.

27.8.5 Synchronous transactions

The memory clock, FMC_CLK, is a submultiple of fmc_ker_ck. It depends on the value of CLKDIV.

NOR flash memories specify a minimum time from NADV assertion to FMC_CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR flash latency and the FMC DATLAT parameter can be either:

- NOR flash latency = (DATLAT + 2) CLK clock cycles
- or NOR flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

Single-burst transfer

When the selected memory region is configured in burst mode for synchronous accesses, if for example a single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AXI transfer is 16 bits), or length 2 (if the AXI transfer is 32 bits) and deassert the Chip Select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for CellularRAM™ 1.5

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) FMC_CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait-states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the Chip Select and output enable signals valid. It does not consider the data as valid.

In burst mode, there are two timing configurations for the NOR flash NWAIT signal:

- The flash memory asserts the NWAIT signal one data cycle before the wait-state (default after reset).
- The flash memory asserts the NWAIT signal during the wait-state

The FMC supports both NOR flash wait-state configurations, for each Chip Select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0 to 3).

27.8.6 NOR/PSRAM controller registers

The peripheral registers have to be accessed by words (32-bit)

SRAM/NOR flash chip-select control register for memory region x (FMC_BCRx)

Address offset: 0x00 + 0x08 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 30DB, 0x0000 30D2, 0x0000 30D2, 0x0000 30D2

This register contains the control information of each memory region, used for SRAMs, PSRAM, FRAM and NOR flash memories.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NBLSET[1:0]		CSCOUNT1	CSCOUNT0	CBURSTRW	CPSIZE[2:0]		
								rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw		rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 Reserved, must be kept at reset value.

Bits 23:22 **NBLSET[1:0]**: Byte lane (NBL) setup

These bits configure the NBL setup timing from NBLx low to Chip select NEx low.
00: NBL setup time is 0 fmc_ker_ck clock cycle.
01: NBL setup time is 1 fmc_ker_ck clock cycle.
10: NBL setup time is 2 fmc_ker_ck clock cycles.
11: NBL setup time is 3 fmc_ker_ck clock cycles.

Bits 21:20 **CSCOUNT[1:0]:** Chip Select (CS) counter

These bits define the maximum duration of Chip Select low for PSRAM synchronous mode and for each memory region.
The Chip Select counter is loaded into a timer which is decremented using the KCK_FMC while the NE is maintained low during PSRAM read or write access.
When the timer reaches 0, the PSRAM controller splits the current access and toggles NE to allow PSRAM device refresh.
The programmed counter value guarantees a maximum NE pulse width (t_{CEM}) as specified for PSRAM devices.
The counter is reloaded and starts decrementing each time a new access is triggered by a transition of NE from high to low.
0b00: Counter disabled
0b01: NEx deasserted after fmc_ker_ck clock cycle
0b10: NEx deasserted after 64 fmc_ker_ck clock cycles
0b11: NEx deasserted after 256 fmc_ker_ck clock cycles

Note: Most PSRAMs manage refresh transparently and do not require access split. CSCOUNT[1:0] must consequently be left at its default value (counter disabled), otherwise CSCOUNT[1:0] value and access split impact must be checked according to PSRAM timing parameters.

Bit 19 **CBURSTRW:** Write burst enable

For PSRAM (CRAM) operating in burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.
0: Write operations are always performed in asynchronous mode
1: Write operations are performed in synchronous mode.

Bits 18:16 **CPSIZE[2:0]:** CRAM page size

These bits are used for CellularRAM™ 1.5 which does not allow burst accesses to cross the address boundaries between pages. When these bits are configured, the FMC automatically splits the burst access when the memory page size is reached (refer to memory datasheet for page size).
000: No burst split when crossing page boundary. (default after reset).
001: 128 bytes
010: 256 bytes
011: 512 bytes
100: 1024 bytes
Others: Reserved.

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers

This bit enables/disables wait signal usage by the FMC even during asynchronous transfers.
0: NWAIT signal not taken in to account during asynchronous transfers (default after reset)
1: NWAIT signal taken in to account during asynchronous transfers

Bit 14 **EXTMOD:** Extended mode enable

This bit enables write timing programming for asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.

0: Values inside FMC_BWTR register not taken into account (default after reset)

1: Values inside FMC_BWTR register taken into account

Note: When the extended mode is disabled, the FMC can operate in mode 1 or mode 2 as follows:

- *Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP[1:0] =0x0 or 0x01)*
- *Mode 2 is the default mode when the NOR memory type is selected (MTYP[1:0] = 0x10).*

Bit 13 **WAITEN:** Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in synchronous mode.

0: NWAIT signal disabled (its level not taken into account, no wait-state inserted after the programmed flash latency period)

1: NWAIT signal enabled (its level is taken into account after the programmed latency period to insert wait-states if asserted) (default after reset)

Bit 12 **WREN:** Write enable bit

This bit indicates whether write operations to the memory region by the FMC are enabled/disabled:

0: Write operations to the memory region by the FMC disabled. An AXI slave error is reported,

1: Write operations to the memory region by the FMC enabled (default after reset).

Bit 11 **WAITCFG:** Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait-state must be inserted when accessing the memory in synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait-state or during the wait-state:

0: NWAIT signal active one data cycle before wait-state (default after reset),

1: NWAIT signal active during wait-state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL:** Wait signal polarity bit

This bit defines the polarity of the wait signal from memory used for either in synchronous or asynchronous mode:

0: NWAIT active low (default after reset),

1: NWAIT active high.

Bit 8 **BURSTEN:** Burst enable bit

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in burst mode:

0: Burst mode disabled (default after reset). Read accesses are performed in asynchronous mode.

1: Burst mode enable. Read accesses are performed in synchronous mode.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MWID[1:0]:** Memory data bus width

This bit defines the external memory device width, valid for all type of memories.

00: 8 bits

01: 16 bits (default after reset)

10: 32 bits

11: Reserved.

Bits 3:2 **MTYP[1:0]:** Memory type

This bit defines the type of external memory attached to the corresponding memory region:

00: SRAM/ FRAM (default after reset for memory region 2...4)

01: PSRAM (CRAM)/FRAM

10: NOR flash/OneNAND flash (default after reset for memory region 1)

11: Reserved.

Bit 1 **MUXEN:** Address/data multiplexing enable bit

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:

0: Address/Data non-multiplexed

1: Address/Data multiplexed on databus (default after reset)

Bit 0 **MBKEN:** Memory region enable bit

This bit enables the memory region. After reset memory region 1 is enabled, all others are disabled. Accessing a disabled memory region causes an ERROR on AXI bus.

0: Corresponding memory region is disabled

1: Corresponding memory region is enabled

SRAM/NOR flash chip-select timing registers for memory region x (FMC_BTRx)

Address offset: 0x04 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory region, used for SRAMs, PSRAM and NOR flash memories.If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, two registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATAHLD[1:0]		ACCMOD[1:0]		DATLAT[3:0]				CLKDIV[3:0]				BUSTURN[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **DATAHLD[1:0]:** Data Hold phase duration

These bits are written by software to define the duration of the *data hold* phase in fmc_ker_ck cycles (refer to *Figure 173* to *Figure 174*), used in asynchronous accesses:
For read/write accesses:
00: DATAHLD phase duration = fmc_ker_ck clock cycle * 0 (default, read)/1 (default, write)
01: DATAHLD phase duration = fmc_ker_ck clock cycle * 1 (read)/2 (write)
10: DATAHLD phase duration = fmc_ker_ck clock cycle * 2 (read)/3 (write)
11: DATAHLD phase duration = fmc_ker_ck clock cycle * 3 (read)/4 (write)

Bits 29:28 **ACCMOD[1:0]:** Access mode

These bits specify the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.
00: Access mode A
01: Access mode B
10: Access mode C
11: Access mode D

Bits 27:24 **DATLAT[3:0]:** Data latency for synchronous memory (see note below bit descriptions)

For synchronous access with read/write burst mode enabled (BURSTEN / CBURSTRW bits set), these bits define the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data.
This timing parameter is not expressed in fmc_ker_ck periods, but in FMC_CLK periods.
For asynchronous access, this value is don't care.
0000: Data latency of 2 FMC_CLK clock cycles for first burst access
1111: Data latency of 17 FMC_CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)

These bits define FMC_CLK clock output signal period, expressed in fmc_ker_ck cycles:
0000: FMC_CLK period= 1x fmc_ker_ck period
0001: FMC_CLK period = 2 × fmc_ker_ck periods
0010: FMC_CLK period = 3 × fmc_ker_ck periods
1111: FMC_CLK period = 16 × fmc_ker_ck periods (default value after reset)
This value is don't care when accessing NOR flash memories, SRAM and PSRAM in asynchronous mode.

Note: Refer to Section 27.8.5: Synchronous transactions for FMC_CLK *divider ratio formula).*

Note: CLKDIV[3:0] bits are don't care when CCLKEN bit of FMC_CFGR is set. In this case FMC_CLK clock output is controlled by CLKDIV of FMC_CFGR.

Bits 19:16 **BUSTURN[3:0]:** Bus turnaround phase duration

These bits are written by software to add a delay between the end of current read or write transaction and the next transaction on the same memory region.

This delay allows matching the minimum time between consecutive transactions (t_{EHEL} from NEx high to NEx low) and the maximum time required by the memory to free the data bus after a read access ($t_{EHQZ\ f}$from chip enable high to output Hi-Z). This delay is recommended for mode D and muxed mode. For non-muxed memory, the bus turnaround delay can be set to a minimum value that respects the following condition:

(BUSTRUN + 1)fmc_ker_ck period ≥ $t_{EHELmin}$ max ($t_{EHELmin}$, $t_{EHQZmax)}$

For FRAMs, the bus turnaround delay must be configured to match the minimum precharge time (t_{PC}). This delay is inserted between all consecutive transactions on the same memory region (read/read, write/write, read/write and write/read) to match the t_{PC} memory timing, and the Chip select toggles between consecutive accesses.

(BUSTRUN + 1) fmc_ker_ck period >= t_{PCmin}

0000: BUSTURN phase duration = 1 * fmc_ker_ck clock cycle added

...

1111: BUSTURN phase duration = 16 * fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration

These bits are written by software to define the duration of the data phase (refer to *Figure 173* to *Figure 174*) used in asynchronous accesses:

0000 0000: Reserved.

0000 0001: DATAST phase duration = 1 * fmc_ker_ck clock cycles

0000 0010: DATAST phase duration = 2 * fmc_ker_ck clock cycles

...

1111 1111: DATAST phase duration = 255 * fmc_ker_ck clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure (*Figure 173* to *Figure 174*).

Example of mode 1, write access, DATAST=1:

Data-phase duration= DATAST+1 = 2 *fmc_ker_ck clock cycles.

Note: This value is don't care in synchronous accesses.

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 169* to *Figure 172*) used in mode D or multiplexed accesses:

0000: Reserved.

0001: ADDHLD phase duration =1 * fmc_ker_ck clock cycle

0010: ADDHLD phase duration = 2 * fmc_ker_ck clock cycle

...

1111: ADDHLD phase duration = 15 * fmc_ker_ck clock cycles (default value after reset)

For each access mode address-hold phase duration, refer to the respective figure (*Figure 169* to *Figure 172*).

Note: This value is not used in synchronous accesses, and the address hold phase lasts always 1 memory clock period.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to *Figure 173* to *Figure 174*), used in SRAMs, ROMs and asynchronous NOR flash memories:

0000: ADDSET phase duration = 0 * fmc_ker_ck clock cycle

...

1111: ADDSET phase duration = 15 * fmc_ker_ck clock cycles (default value after reset)

For each access mode address setup phase duration, refer to the respective figure (refer to *Figure 173* to *Figure 174*).

Note: This value is don't care in synchronous accesses.

In muxed mode or mode D, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to extend the latency as needed.

On PSRAMs (CRAMs), DATLAT must be configured to 0 so that the FMC quickly exits its latency phase, starts sampling NWAIT from memory, and starts read or write operations when the memory is ready.

This method can be used also with the latest generation of synchronous flash memories, which, unlike older flash memories, issue the NWAIT signal (check the corresponding flash memory datasheet).

SRAM/NOR-flash write timing registers for memory region x (FMC_BWTRx)

Address offset: 0x104 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x000F FFFF

This register contains the control information of each memory region. It is used for SRAMs, FRAMs, PSRAMs and NOR flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATAHLD[1:0]		ACCMOD[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BUSTURN[3:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **DATAHLD[1:0]:** Data Hold phase duration

These bits are written by software to define the duration of the *data hold* phase in fmc_ker_ck cycles (refer to *Figure 174*), used in asynchronous write accesses:

00: DATAHLD phase duration = 1 * fmc_ker_ck clock cycle (default)

01: DATAHLD phase duration = 2 * fmc_ker_ck clock cycle

10: DATAHLD phase duration = 3 * fmc_ker_ck clock cycle

11: DATAHLD phase duration = 4 * fmc_ker_ck clock cycle

Bits 29:28 **ACCMOD[1:0]:** Access mode.

These bits specify the asynchronous access modes as shown in the next timing diagrams.These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: Access mode A

01: Access mode B

10: Access mode C

11: Access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay between the end of current write transaction and the next transaction on the same memory region.

For FRAMs, the bus turnaround delay must be configured to match the minimum precharge time (t_{PC}). The bus turnaround delay is inserted between all consecutive transactions on the same memory region (read/read, write/write, read/write and write/read), and the Chip select toggles between consecutive accesses.

(BUSTRUN + 1) fmc_ker_ck period >= t_{PCmin}

0000: BUSTURN phase duration = 1 * fmc_ker_ck clock cycle added

...

1111: BUSTURN phase duration = 16 * fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration.

These bits are written by software to define the data phase duration (refer to *Figure 173* to *Figure 174*) used in asynchronous SRAM, PSRAM and NOR flash memory accesses:
0000 0000: Reserved.
0000 0001: DATAST phase duration = 1 * fmc_ker_ck clock cycles
0000 0010: DATAST phase duration = 2 * fmc_ker_ck clock cycles
...
1111 1111: DATAST phase duration = 255 * fmc_ker_ck clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration.

These bits are written by software to define the duration of the address hold phase (refer to *Figure 171* to *Figure 172*) used in asynchronous multiplexed accesses:
0000: Reserved.
0001: ADDHLD phase duration = 1 * fmc_ker_ck clock cycle
0010: ADDHLD phase duration = 2 * fmc_ker_ck clock cycle
...
1111: ADDHLD phase duration = 15 * fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous NOR flash accesses, this value is not used, and the address hold phase always lasts 1 flash clock period.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration.

These bits are written by software to define the duration of the address setup phase in fmc_ker_ck cycles (refer to *Figure 173* to *Figure 174*) used in asynchronous accesses:
0000: ADDSET phase duration = 0 * fmc_ker_ck clock cycle
...
1111: ADDSET phase duration = 15 * fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous accesses, this value is not used, and the address setup phase always lasts 1 flash clock period. In muxed mode, the minimum ADDSET value is 1.

FMC common configuration register (FMC_CFGR)

Address offset: 0x020

Reset value: 0x0000 0000

This register is user to set configuration common to all controllers

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FMCEN	Res.	Res.	Res.	Res.	Res.	BMAP1	BMAP0	Res.	Res.	Res.	CCLKEN	CLKDIV[3:0]			
rw						rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 **FMCEN:** FMC enable
This bit enables/disables the FMC.
0: FMC disabled
1: FMC enabled

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:24 **BMAP[1:0]:** FMC memory region mapping
These bits allow the remapping of SDRAM device 2 or the swapping of FMC NOR/PSRAM and SDRAM memory regions.
00: Default mapping (refer to *Table 149*)
01: Devices are remapped (refer to *Table 150*)
10: Devices are remapped (refer to *Table 150*)
11: All memory region accesses are ignored. A bus error is generated.

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **CCLKEN:** Continuous clock enable
This bit enables the FMC_CLK clock output to external memory devices.
0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is defined by the programmed CLKDIV value in the FMC_BCRx register (default after reset).
1: The FMC_CLK is generated continuously during asynchronous and synchronous access.
If continuous clock mode is enabled, the synchronous memories connected to all memory regions are clocked by the same clock with the clock ratio defined by CLKDIV in FMC_CFGR. The CLKDIV value in FMC_BWTRx are don't care.

Bits 19:16 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)
These bits define the FMC_CLK clock output signal period, expressed in number of fmc_ker_ck cycles:
0000: FMC_CLK period= 1x fmc_ker_ck period
0001: FMC_CLK period = 2 × fmc_ker_ck periods
0010: FMC_CLK period = 3 × fmc_ker_ck periods
1111: FMC_CLK period = 16 × fmc_ker_ck periods (default value after reset)
This value is don't care when accessing NOR flash memories, SRAM and PSRAM in asynchronous mode.
Note: Refer to Section 27.8.5: Synchronous transactions for FMC_CLK divider ratio formula.

Bits 15:0 Reserved, must be kept at reset value.

27.9 NAND flash controller

The FMC generates the appropriate signal timings to drive 8- and 16-bit NAND flash memories

The NAND memory region is configured through dedicated registers (*Section 27.9.9*). The programmable memory parameters include access timings (shown in *Table 185*) and ECC configuration.

The NAND controller supports the following features:

- Programmable page size of 256, 512, 1024, 2048, 4096 or 8192 bytes
- Programmable memory timings
- Programmable Error Correction Capability using BCH code or Hamming code
- Command sequencer: a hardware accelerator for read/write accesses within a page or within a block of configurable size.

  This feature is useful when ECC computation is performed.
- Programmable address offset for ECC bytes programming using the command sequencer
- Interrupt generation on ECC error detection and page or sector transfer complete

Table 185. Programmable NAND flash access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Memory setup time	Number of clock cycles (fmc_ker_ck) required to set up the address before the command assertion	Read/Write	FMC clock cycle (fmc_ker_ck)	1	256
Memory wait	Minimum duration (in fmc_ker_ck clock cycles) of the command assertion	Read/Write	FMC clock cycle (fmc_ker_ck)	1	256
Memory hold	Number of clock cycles (fmc_ker_ck) during which the address must be held (as well as the data if a write access is performed) after the command deassertion	Read/Write	FMC clock cycle (fmc_ker_ck)	1	256
Memory databus high-Z	Number of clock cycles (fmc_ker_ck) during which the data bus is kept in high-Z state after a write access has started	Write	FMC clock cycle (fmc_ker_ck)	1	256

27.9.1 External memory interface signals

The following tables list the typical signals that are used to interface NAND flash memory.

Note: The “N” prefix identifies the signals which are active low.

8-bit NAND flash memory

Table 186. 8-bit NAND flash memory

FMC signal name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[7:0]	I/O	8-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)

Table 186. 8-bit NAND flash memory (continued)

FMC signal name	I/O	Function
NWE	O	Write enable
RNB	I	NAND flash Ready/Busy (RNB) input signal to the FMC

Note: Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

16-bit NAND flash memory

Table 187. 16-bit NAND flash memory

FMC signal name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
RNB	I	NAND flash Ready/Busy (RNB) input signal to the FMC

Note: Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

27.9.2 NAND flash supported memories and transactions

Table 188 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND flash controller are shown in gray.

Table 188. Supported memories and transactions

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 8-bit	Asynchronous	R	8	8	Y	
	Asynchronous	W	8	8	Y	
	Asynchronous	R	16	8	Y	Split into 2 FMC accesses
	Asynchronous	W	16	8	Y	Split into 2 FMC accesses
	Asynchronous	R	32	8	Y	Split into 4 FMC accesses
	Asynchronous	W	32	8	Y	Split into 4 FMC accesses
	Asynchronous	R	64	8	Y	Split into 8 FMC accesses
	Asynchronous	W	64	8	Y	Split into 8 FMC accesses

Table 188. Supported memories and transactions (continued)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 16-bit	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	N	
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses

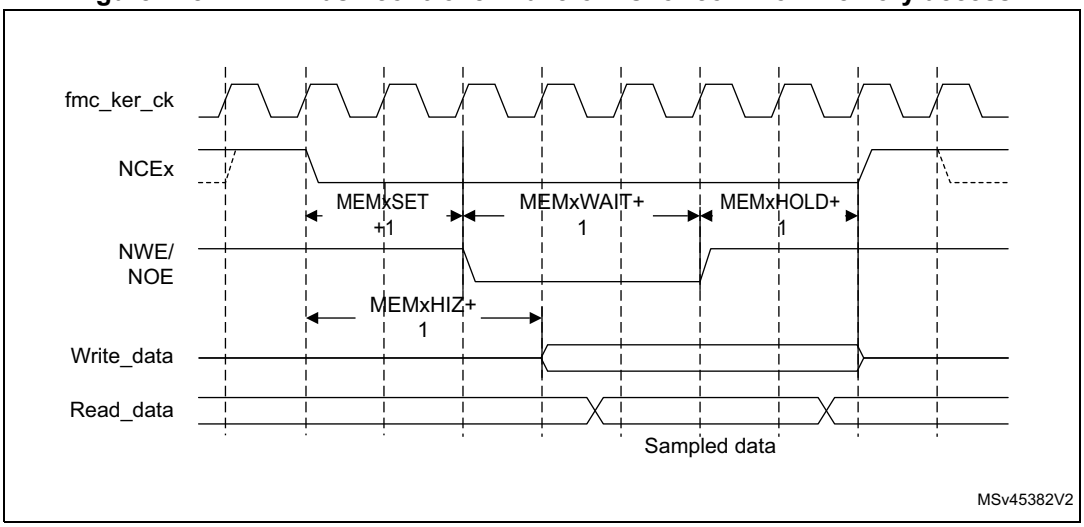
27.9.3 Timing diagrams for NAND flash memory

The NAND flash memory region is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_HECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

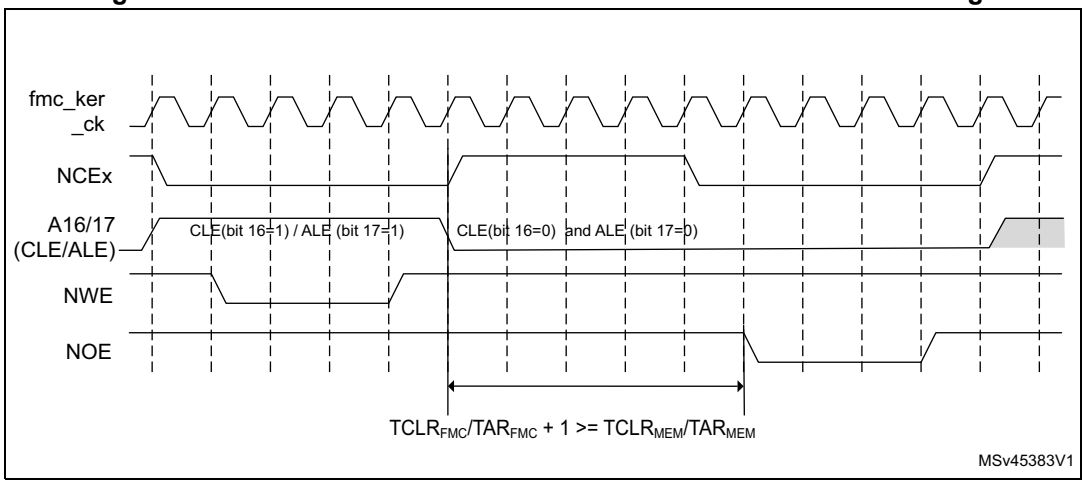
Each timing configuration register contains three parameters used to define the number of fmc_ker_ck cycles for the different phases of any NAND flash access, plus one parameter that defines the timing to start driving the data bus when a write access is performed. *Figure 178* shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 178. NAND flash controller waveforms for common memory access



1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. The programmed values of MEMxSET + MEMxHOLD must be >1.

Figure 179. NAND flash controller waveforms for TCLR and TAR timings



1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.

27.9.4 NAND flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND flash memory device are driven by address signals from the FMC. This means that to send a command or an address to the NAND flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND flash device requires the following steps:

1. Program and enable the NAND memory region by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see *Section 27.9.5: NAND flash prewait function*) registers according to the characteristics of the NAND flash memory (PWID bits to configure NAND flash data bus width, PWAITEN set or cleared as needed, see *Section 27.7.2: NAND flash memory address mapping* for timing configuration).
2. The CPU performs a byte write to the common memory space, with a data byte value equal to one flash command byte (for example 0x00 for Samsung NAND flash devices). The NAND flash CLE input is active during the write strobe (low pulse on NWE), so that the written byte is interpreted as a command by the NAND flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
3. The CPU can send the start address for a read operation by writing a five-byte address to the common memory or the attribute space followed by the second read command. The NAND flash ALE input is active during the write strobe (low pulse on NWE), so that the written bytes are interpreted as the start address for read operations. Using the attribute memory space allows to use a different FMC timing configuration, which can

be used to implement the prewait function required for some NAND flash memories (see details in *Section 27.9.5: NAND flash prewait function*).

4. The controller waits till the NAND flash memory is ready (RNB signal high), before starting a new access to the same memory region or to another memory region.
5. The CPU can then perform byte read operations from the common memory space to read the NAND flash page (data field + Spare field) byte by byte.
6. No CPU command or address write operation is required to read the next NAND flash page. This can be done in three different ways:
   – by simply performing the operation described in step 5,
   – a new random address can be accessed by restarting the operation at step 3,
   – a new command can be sent to the NAND flash device by restarting at step 2.

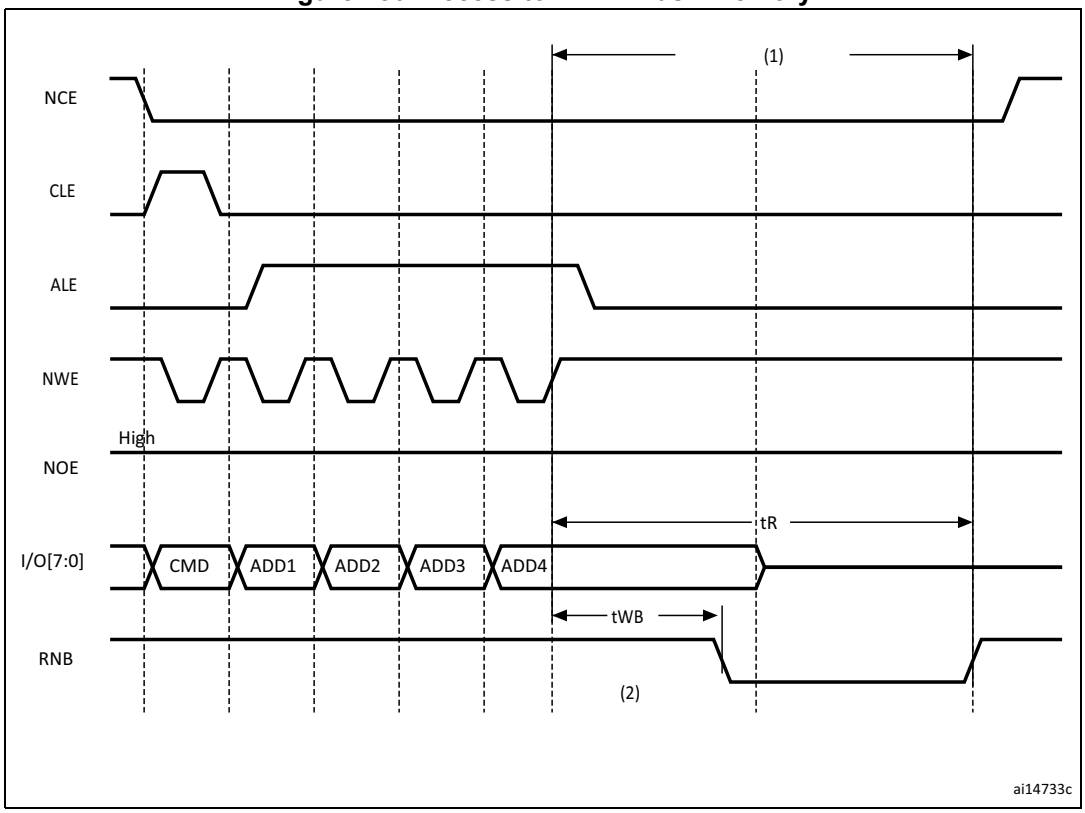
Note: Non-'CE don't care' NAND flash memories are not supported.

ONFI mode 4 and 5 EDO data output cycle timings are not supported.

27.9.5 NAND flash prewait function

The NAND controller must wait for RNB to be asserted low before sending its next command (see *Figure 180*). This timing constraint is set according to t_{WB} using MEMHOLD[7:0] bitfield in FMC_PMEM or ATTHOLD[7:0] in FMC_PATT.

Figure 180. Access to NAND flash memory



1. NCE can be deasserted for NAND flash memories since CE is don't care except for very old NAND flash devices that are not considered in this example.
2. RNB sampling can be delayed after t_{WB} by using ATTHOLD[7:0] bit of FMC_PATT. As an example, if fmc_ker_clk = 14 ns and ATTHOLD[7:0] = 7, the delay is 8*14 = 112 ns. The usual t_{WB} maximum value is 100 ns and the programmed delay must be higher than t_{WB} + 2*fmc_ker_clk.

Any CPU read or write access to the NAND flash memory has a delay of (MEMHOLD[7:0] + 1) * fmc_ker_ck cycles after the NWE signal is asserted.

The ATTHOLD[7:0] bitfield in FMC_PATT register must be determined to satisfy t_{WB} timing constraints and selectively apply larger timing constraints to the last command or address byte in CPU mode. When setting ATTHOLD[7:0], the 2 * fmc_ker_ck delay required for the sampling of RNB by NAND sequencer must also taken into account.

27.9.6 NAND ECC controller

NAND flash memories include a spare memory area (or OOB) at the end of each page. This area is typically used to store some metadata (such as Bad Block Marker information to invalidate the whole page) or for error management functions.

The FMC supports on-the-fly error correction code (ECC) computation during data read/program from/to NAND flash memory. This mechanism reduces the host CPU workload when processing the ECC by software.

The user application can select one out of two algorithms:

- Hamming code algorithm for 1-bit error code correction and 2-bit error detection per 256, 512, 1024, 2048, 4096 or 8192 bytes.
- BCH (Bose, Chaudhuri and Hocquenghem) code for 4-bit error code correction and 8-bit error detection or 8-bit error code correction and 16-bit error detection per 512 bytes.

The principle of both ECC controllers is similar: the ECC modules monitor the NAND flash data bus and read/write signals (NCE and NWE) each time the NAND flash memory region is active. The ECC controllers operate as follows:

- When accessing a NAND flash memory region, the data present on the D[7:0] or D[15:0] bus are latched and used for ECC computation.
- When accessing any other address in NAND flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND flash memory by the host CPU or DMA, the ECC result registers are updated.

Hamming code

The Hamming code implemented can perform 1-bit error correction and 2-bit error detection per 256, 512, 1024, 2048, 4 096 or 8192 bytes read or written from/to the NAND flash memory. It consists in calculating the row and column parity. This algorithm is supported by 8-bit and 16-bit NAND flash memories.

Page write and read sequences with Hamming code are described below.

To perform a page program with Hamming ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND flash memory page. While the NAND page is written, the ECC controller computes the ECC value.
3. Wait until the ECC code is ready (NWRF is set in the FMC_SR register).
4. Read the ECC value available in the FMC_HECCR register and store it in NAND flash spare area.
5. Clear the ECCEN bit and launch the page programming.

To perform a page read with Hamming ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register before reading the NAND page. While the NAND page is read, the ECC block computes the ECC value.
2. Wait until the ECC code is ready (NWRF set in the FMC_SR register).
3. Read the ECC value available in the spare area as well also the ECC value, processed by Hamming controller, available in FMC_HECCR register.
4. If the two ECC values are identical, no correction is required. Otherwise an ECC error occurred, the software correction routine returns information on whether the error can be corrected or not, and corrects it when possible.

Depending on the spare area size, the page can be split into several sectors of identical size. This allows increasing the error correction capability for each page since 1 error can be corrected and 2 errors can be detected for each sector.

Example

For a NAND flash memory with 2 Kbytes + 64 bytes pages, each page can be split into 8 sectors of 256 bytes each. 3 bytes (22 bits) of ECC are required for each sector, which makes 24 bytes (8 * 3 bytes) to be stored in the spare area for the whole page. For the whole 2 Kbyte page, up to 8 errors can be corrected, respectively up to 16 errors detected, provided there is less than 1 error, respectively 2 errors, per sector.

BCH (Bose, Chaudhuri and Hocquenghem) code

To increase the error correction capability, the FMC embeds a BCH (Bose, Chaudhuri and Hocquenghem) encoder and decoder.

It supports 4-bit error code correction and 8-bit error detection or 8-bit error code correction, and 16-bit error detection per sector. BCH encoder/decoder module handles sectors of fixed size, equal to 512 bytes. Each page must consequently be split into 512-byte sectors. The number of parity bytes generated for each sector is given in *Table 189*. For 16-bit NAND flash memories, a padding is added to align parity bytes to an even number (8 bytes and 14 bytes for 4-bit and 8-bit BCH code, respectively).

Table 189. Number of ECC parity bytes per sector

Function	BCH code	
Error correction	4-bit	8-bit
Number of parity bytes	7 bytes	13 bytes

The BCH module detects errors and returns the bit position for each sector. To correct the errors, the software needs to flip the error bits at the provided bit position stored in the FMC_BCHPBRx register.

The BCH ECC controller supports 8-bit and 16-bit NAND flash memories.

During a page program operation, the BCH encoder generates the ECC bytes (7 or 13 bytes) for each sector of 512 bytes that must be written in the NAND flash spare area with a programmable offset. It must take into account some metadata at the beginning of the spare area. This operation must be executed for each sector. The BCH encoder does not process the spare area: metadata must have their own error protection mechanism.

The total number of ECC bytes (N) is given by the below equation:

$$N = \text{Number of ECC bytes /sector} \times \text{Number of sector/page}$$

Example

For an 8-bit NAND flash with 4096-byte pages and an error correction capability of 4-bit per 512 bytes, the number of sector per page is 8 (4096 / 512). The total number of ECC bytes is consequently:

$$N = 7 \times 8 = 56 \text{ bytes}$$

The user application has to make sure that the spare area is large enough to store the metadata and parity bytes.

Page program and read sequences with BCH code are described below.

To perform a page program:

1. Enable write access by setting the WEN bit in the FMC_PCR register.
2. Enable the ECC by setting the ECCEN bit in FMC_PCR register.
3. Write 512 data bytes to the sector in the NAND flash memory page. While the sector is written, the BCH encoder computes the ECC value.
4. Wait until the BCH encoder parity bits are available by monitoring EPBRF bit of FMC_BCHISR register.
5. Read the ECC value available in the FMC_BCHPBRx registers and store it in the NAND flash spare area.
6. Disable ECC by resetting the ECCEN bit in FMC_PCR register.
7. Execute again step 2 to 6 for all sectors to be written in NAND flash memory.
8. Launch the page programming.

To perform a page read:

1. Enable read access by resetting the WEN bit in the FMC_PCR register.
2. Enable the ECC by stetting the ECCEN bit in FMC_PCR register.
3. Read the NAND page sector (512 bytes).
4. Read the corresponding ECC bytes (7 or 13 bytes) from the NAND flash spare area.
5. During the read of data and parity bits, the syndrome is calculated. Then the error location search is launched.
6. Wait until the decoding error is ready (DERF bit set in the FMC_BCHISR register), then read the decoding results (errors detected if any, correctable or not, number of errors, bit position) in FMC_BCHDSR0 and FMC_BCHDSRx registers.
7. Thanks to the decoding results, the software can correct the errors in the sector (when possible).
8. Disable ECC by resetting the ECCEN bit in FMC_PCR register.
9. Execute again step 2 to 7 for all relevant sectors of the page.

27.9.7 FMC command sequencer

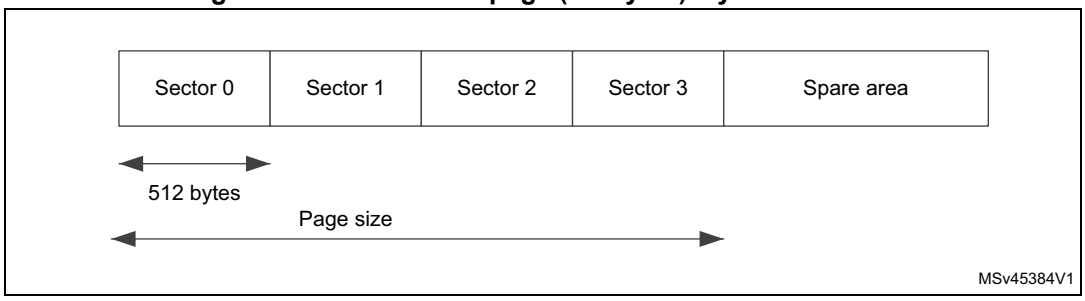
NAND flash page programming and reading can be performed by the CPU as described in the above sections.
Data sector programming/reading as well as ECC byte programming/reading can also be managed automatically by the FMC command sequencer for command and address transfers, and by DMA for data transfers.

The purpose of the command sequencer is to ease the programming/reading of NAND flash pages with ECC computation as well as free the CPU of sequencing tasks. The command sequencer enables the software to work on full NAND flash pages instead of sectors, which is more efficient and essential to achieve high throughput. The sequencer handles all the sectors in the page. It does not support sub-page read or program operations.

One DMA channel is required for write operations and two DMA channels for read operations.

A specific NAND flash page layout must be respected when using the BCH algorithm. See *Figure 181* for an example of 2Kbyte page BCH layout.

Figure 181. NAND flash page (2 Kbytes) layout with BCH



Page program sequence

1. A data buffer located in SRAM has to be initialized with the data to be written to the NAND flash page.
2. The CPU configures the FMC command sequencer registers: page program command (0x80), address bytes, change write column command (0x85), ECC address offset, page size, sector size and sector number.

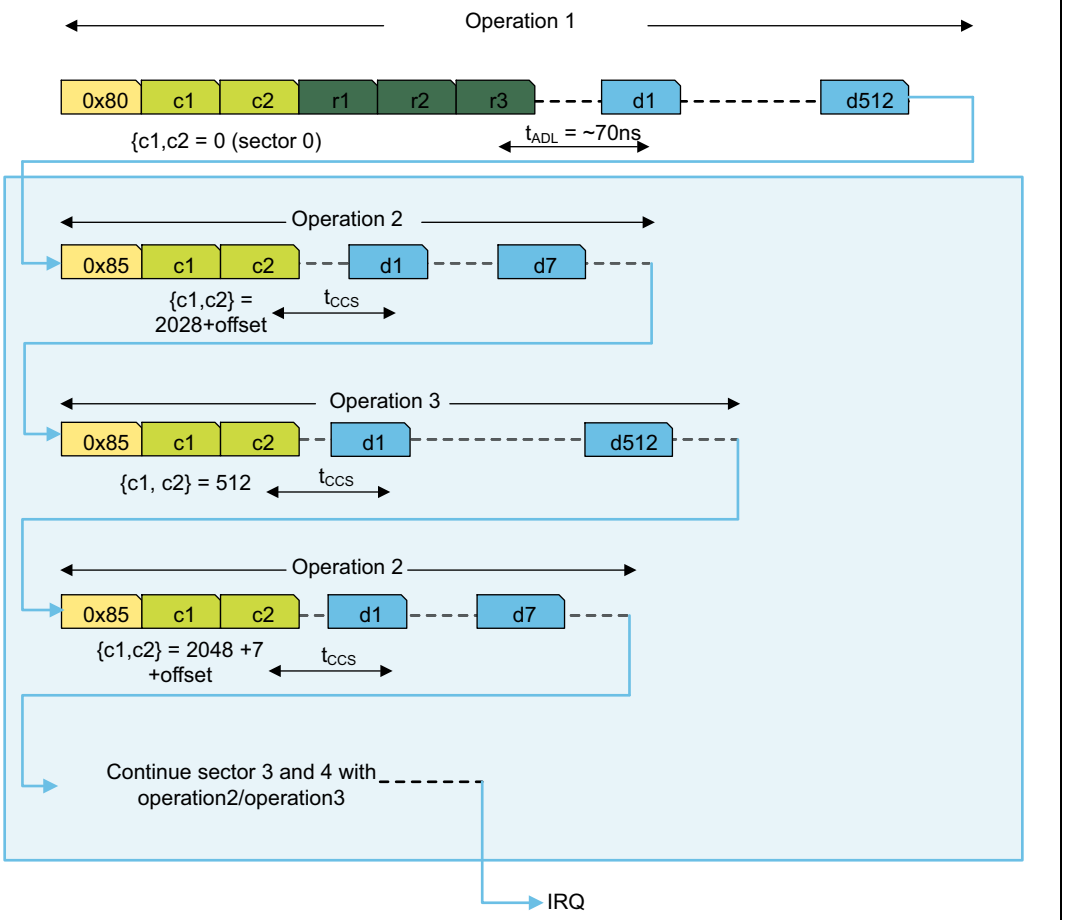
   It also selects the ECC algorithm (Hamming or BCH) and configures one DMA channel to transfer data from the buffer to the NAND flash page.
3. The CPU then launches the sequencer by setting the CSQSTART bit in the FMC_CSQCR register.
4. The command sequencer automatically generates the control and address cycles to the NAND flash memory, following the programmed timings configured either in FMC_PMEM or FMC_PATT register.
5. A DMA request is issued to start data transfer from the data buffer to NAND flash memory.
6. When the full sector is programmed, go to step 7 if ECC is enabled. Otherwise, jump to step 9.
7. The FMC command sequencer automatically issues a change write column command (0x85) followed by two address cycles. The command to be issued and the number of

address cycles are programmed in FMC_CSQCFGR2 register. The address is automatically generated from the programmed ECC address offset.

8. Once the parity bytes are available in ECC encoder (Hamming or BCH) module, they are automatically transferred to the NAND flash spare area. The FMC command sequencer can generate a sector transfer complete interrupt if it has been previously enabled.
9. The sequencer then repeats step 4 (except that it performs only a change write column command instead of a page program command) to step 8 to program the following sectors and their corresponding ECC parity bytes. The ECC address offset is automatically incremented for each sector transfer. When ECC is disabled, the sequencer repeats step 5.
10. The FMC command sequencer can generate a transfer complete interrupt or a transfer complete error interrupt by sector or when all sectors are written.
11. The CPU can program any further metadata in the NAND flash area, taking care not to overwrite parity bytes.
12. The program command (0x10) can then be written to the command section to program the NAND flash memory.
13. An interrupt, if enabled, is generated on the rising edge of the Ready/Busy (RNB) signal to indicate that the page program operation is complete.

Refer to *Figure 182* for an overview of the page program sequence with BCH.

Figure 182. Example of 2 Kbyte page program sequence with 4-bit BCH



Operation 1: Program first sector
Operation 2: Program sector data ECC
Operation 3: Program next sector

MSv45393V3

Page read sequence

1. A data buffer is allocated in SRAM to store the NAND flash page data. A decoding status buffer is also allocated to store result of ECC decoding.
2. The CPU programs the command sequencer registers: the page read first cycle command (0x00), address bytes, the page read second cycle command (0x30), change read column command (0x05), spare area offset, page size, sector size and sector number.

   It configures the ECC algorithm if required (Hamming or BCH), one DMA channel to handle data transfers from the NAND flash page to the data buffer, and a second DMA

channel to transfer ECC decoding results from ECC status registers to the RAM decoding status buffer.

3. The CPU then launches the FMC sequencer by setting the CSQSTART bit in the FMC_CSQCR register.
4. The FMC command sequencer issues the command and address cycles to the NAND flash memory.
5. The command sequencer waits for a Ready/Busy (RNB) rising edge to start data transfer.
6. It sends a DMA request to launch the data transfer from the NAND flash page to the data buffer.
7. When all sector data are read, go to step 8 if ECC is enabled, otherwise go to step 9. The FMC command sequencer can generate a sector transfer complete interrupt if it has been previously enabled.
8. When ECC status registers are empty (because the Hamming error code or the BCH error position bits of previous sector have already been read), the ECC command sequencer automatically issues a change read column command (0xE0) followed by two address cycles and by the 0xE0 command, to read ECC bytes from NAND flash memory and store them in ECC registers. These commands as well as the number of address cycles are programmed in the FMC_CSQCFGR2 register (see *Figure 183*).

   The address in spare area is extracted from the programmed ECC address offset.

   When the Hamming algorithm is used, a DMA request to the second DMA channel is send to transfer ECC codes (FMC_HPR and FMC_HECCR registers) to the decoding status buffer.

   When BCH algorithm is used, once all the parity bytes have been read, the BCH decoder first processes the syndrome to detect errors and then searches for error positions if any.

   As the BCH decoder is pipelined, it is possible to start reading a sector even if the decoding of the previous sector is not complete.

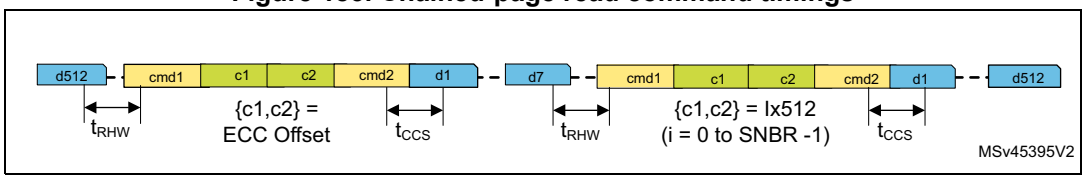
   In parallel of the following steps, when BCH sector decoding is complete, the new error status is stored in the ECC status registers (FMC_BCHDSR0) and a DMA request to the second DMA channel is sent to transfer data from the status registers to the decoding status buffer located in RAM.
9. The FMC command sequencer then repeats step 4 (except that a change read column command is issued instead of the page read first cycle command) to step 8 to read the other sectors and their corresponding ECC bytes. The addresses are issued and incremented following the page size, number of sectors, spare area address offset address and BCH code selection. When the read sequence is complete, the command sequencer waits for t_{RHWL} before issuing a new command sequence (refer to *Figure 182*). When ECC is disabled, the sequencer repeats step 6.
10. Once all sectors within a page and the status registers (FMC_BCHDSRx) are transferred by the command sequencer, the ECC controller can generate the transfer complete interrupt or transfer complete error (when enabled).
11. By reading the decoding status buffer, the CPU can start processing the errors corresponding to each sector. If no error has been detected, the page stored in RAM is validated. Otherwise the CPU corrects the error(s) before validating the page buffer in RAM. If there are too many errors, the CPU can detect the page cannot be corrected and invalidate the data buffer.

Following the selected BCH code, if the number of detected errors exceeds the number of correctable errors, this bit is not significant and the DUE bit is set. If the number of errors the detected by the BCH decoder exceeds the maximum number of detectable errors, DEN and DUE bits are not significant.

The DMA channels can also send interrupts each time a data transfer is complete. This allows the CPU to process error(s) in a sector as soon as it is available.

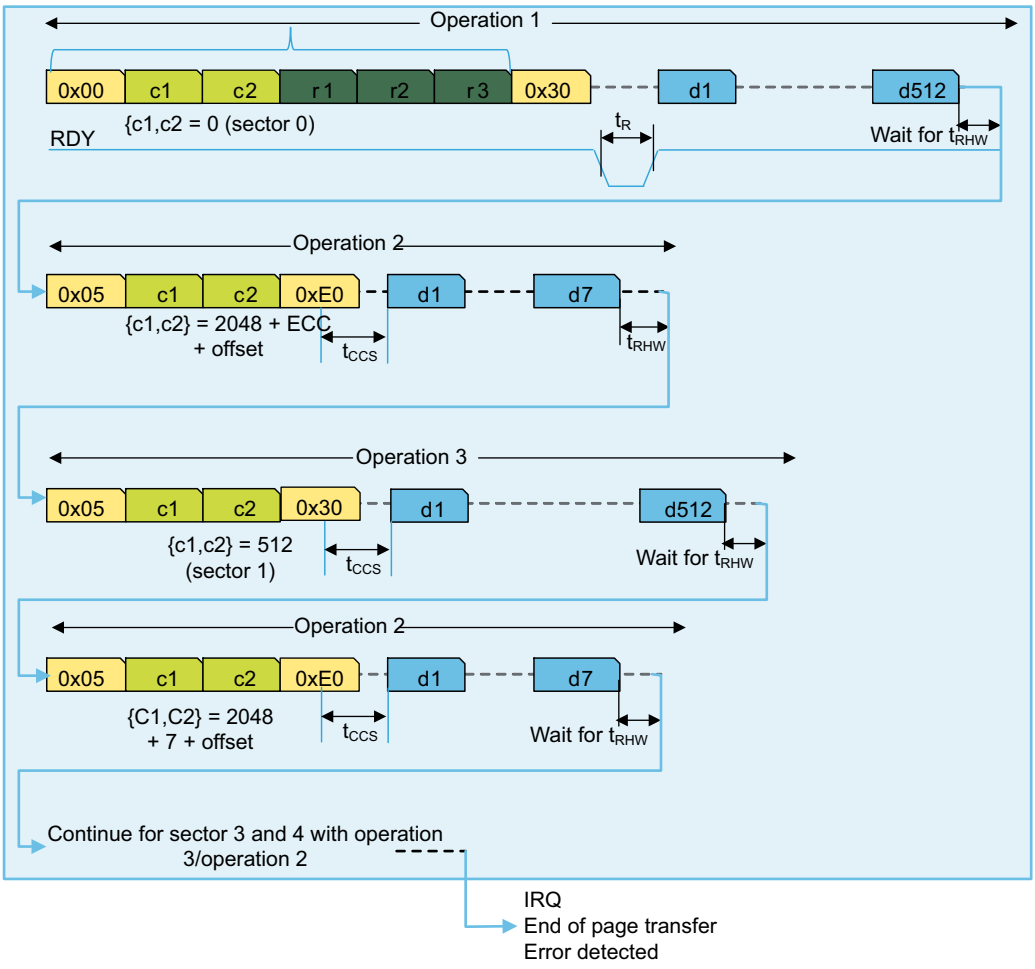
Note: When using the sequencer and DMA channels, the CPU must not read the FMC_BCHPBRx and FMC_BCHDSRx registers before data of all sectors are transferred, that is when TCF flag is set in the FMC_CSQISR register.

Figure 183. Chained-page read command timings



An example of 2 Kbyte page read sequence with BCH is described in *Figure 184*. This example corresponds to four 512-byte sectors and 7 ECC bytes per data 512 bytes.

Figure 184. Example of 2-Kbyte page read sequence with 4-bit BCH



The BCH controller resets the ECC computation whenever a page read (0x00), a page program (0x80), a random read (0x05) or a random program command ((0x85) is issued.

When only part of a page is written/read using the BCH, the command sequencer issues a random read/write command sequence only for the number of sectors to be read/written. This is done by programming the number of sector to be processed.

FMC command sequencer configuration

1. Configure the FMC_CSQCFGR1 register: program the command1 and the command 2 (in case of read access), the number of address cycles to be issued, configure the read or write sequence, and select the timings to be used.
2. Configure the address bytes in FMC_CSQAR1 and FMC_CSQAR2 register.
3. In the FMC_CSQCFGR2 register, configure the change write or change read column commands and the timings to be used for ECC. Program the address offset for the random columns in the FMC_CSQAR2 register. Enable the DMA if it is needed for ECC status register transfer.
4. Configure the number of sectors and the address cycle timings in the FMC_CSQCFGR3 register.
5. Configure the ECC sector size, and select read or write access in the FMC_PCR register.
6. Enable the SQSDTEN bit in the FMC_CSQFCGR2 register. The ECCEN bit in the FMC_PCR register kept at 0.
7. Transfer complete, and transfer error complete or sector transfer complete can be enabled through the FMC_CSQIER register.

27.9.8 NAND flash controller interrupt

An interrupt can be generated on the following events:

- RNB rising edge: an interrupt is generated when a rising edge is detected on RNB NAND flash signal
- RNB falling edge: an interrupt is generated when a falling edge is detected on RNB NAND flash signal
- RNB high-level: an interrupt is generated when a high-level is detected on RNB NAND flash signal.
- Transfer complete: an interrupt is generated when the FMC command sequencer has completed all data transfers for all sectors or when the command sequencer was aborted.
- Sector complete interrupt: an interrupt is generated when the FMC command sequencer has completed all data transfers for one sector.
- Sector error interrupt: an interrupt is generated when the FMC command sequencer has completed a sector transfer with at least one error detected.
- Sector uncorrectable error interrupt: an interrupt is generated when the FMC command sequencer has completed a sector transfer and detected an uncorrectable error.
- Command transfer complete: the command sequencer has completed the transfer of programmed commands and addresses.
- BCH encoder parity bits ready: an interrupt is generated when the BCH encoder has finished processing parity bits.
- BCH decoder syndrome ready: an interrupt is generated when the BCH decoder has finished processing the syndrome and knows if errors have been detected or not.
- BCH decoder error found: an interrupt is generated when the BCH decoder has detected an error.
- BCH decoder error ready: an interrupt is generated when the BCH decoder has finished processing errors, has identified error locations and can then correct them.
- BCH decoder uncorrectable error: an interrupt is generated when the BCH decoder has detected that the errors cannot be corrected (more than four or eight errors according to BCH error correction capability configuration).

The interrupt source can be enabled or disabled separately through the FMC_ IER, FMC_CSQIER and FMC_BCHIER registers.

Table 190. FMC NAND controller Interrupt request

Interrupt event	Event Flag	Enable control bit
Transfer complete	TCF in FMC_CSQISR	TCIE in FMC_CSQIER
Sector complete	SCF in FMC_CSQISR	SCIE in FMC_CSQIER
Sector error	SEF in FMC_CSQISR	SEIE in FMC_CSQIER
Sector uncorrectable error	SUEF in FMC_CSQISR	SUEIE in FMC_CSQIER
Command transfer complete	CMDTCF in FMC_CSQISR	CMDTCIE in FMC_CSQIER
BCH encoder parity bits ready	EPBRF in FMC_BCHISR	EPBRIE in FMC_BCHIER
BCH decoder syndrome ready	DSRF in FMC_BCHISR	DSRIE in FMC_BCHIER
BCH decoder error found	DEFF in FMC_BCHISR	DEFIE in FMC_BCHIER

Table 190. FMC NAND controller Interrupt request (continued)

Interrupt event	Event Flag	Enable control bit
BCH decoder error ready	DERF in FMC_BCHISR	DERIE in FMC_BCHIER
BCH decoder uncorrectable error	DUEF in FMC_BCHISR	DUEIE in FMC_BCHIER

27.9.9 NAND flash controller registers

NAND flash programmable control register (FMC_PCR)

Address offset: 0x80

Reset value: 0x0007 FE08

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	WEN	BCHECC	Res.	Res.	Res.	Res.	ECCSS[2:0]			TAR [3]
						rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAR[2:0]			TCLR[3:0]				ECCALG	Res.	ECCEN	PWID[1:0]		Res.	PBKEN	PWAITEN	Res.
rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw		rw	rw	

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **WEN:** Write enable

This bit enables read or write access. It must be configured when using the FMC sequencer or when the ECC with BCH code is enabled. It can only be modified when ECCEN bit is reset.

0: Read access enabled

1: Write access enabled

Bit 24 **BCHECC:** BCH error correction capability

0: 4-bit BCH (4-bit error correction and 8-bit error detection per 512 bytes)

1: 8-bit BCH (8-bit error correction and 16-bit error detection per 512 bytes)

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCSS[2:0]:** ECC sector size (used to access spare area)

These bits define the sector size used for the ECC:

000: 256 bytes

001: 512 bytes

010: 1024 bytes

011: 2048 bytes (default)

100: 4096 bytes

101: Reserved.

11X: Reserved.

When the ECC is enabled with BCH code, the sector size must be programmed to 512 bytes.

Bits 16:13 **TAR[3:0]:** ALE to RE delay.

These bits define the time from ALE low to RE low in number of fmc_ker_ck clock cycles:
t_ar ≤ (TAR +1) × $t_{fmc_ker_ck}$
where $t_{fmc_ker_ck}$ is the FMC clock period and *t*_ar is the ALE to RE timing of NAND flash memories.
0000: 1 * fmc_ker_ck cycle
1111: 16 * fmc_ker_ck cycles (default)

Bits 12:9 **TCLR[3:0]:** CLE to RE delay.

These bits define the time from CLE low to RE low in number of fmc_ker_ck clock cycles:
t_clr ≤ (TCLR +1) × $t_{fmc_ker_ck}$
where $t_{fmc_ker_ck}$ is the FMC clock period and *t*_clr is the CLE to RE timing of NAND flash memories.
0000: 1 * fmc_ker_ck cycle
1111: 16 * fmc_ker_ck cycles (default)

Bit 8 **ECCALG:** ECC algorithm

0: Hamming code is selected (default).
1: BCH code is selected.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ECCEN:** ECC computation logic enable bit

0: ECC logic is disabled and reset (default after reset),
1: ECC logic is enabled.
This bit must be kept reset when using the FMC sequencer

Bits 5:4 **PWID[1:0]:** Data bus width

These bits define the external memory device width.
00: 8 bits (default after reset).
01: 16 bits
1X: Reserved.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **PBKEN:** NAND flash memory region enable bit

This bit enables the memory region. Accessing a disabled memory region causes an AXI bus error.
0: Corresponding memory region is disabled (default after reset)
1: Corresponding memory region is enabled.

Note: The NAND flash memory region must be disabled only when all NAND flash controller commands are complete.

Bit 1 **PWAITEN:** Wait feature enable bit

This bit enables the Wait feature for the NAND flash memory region:
0: disabled (default)
1: enabled

Bit 0 Reserved, must be kept at reset value.

FMC status register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0053

This register contains information about the AXI interface isolation status and the NAND write requests status. The FMC has to be disabled before modifying some registers. As requests might be pending, it is necessary to wait till the AXI interface is stable and the core of the block is totally isolated from its AXI interface before reconfiguring the registers.

The PEF and NWEF bits indicate the status of the pipe. If Hamming algorithm is used, the ECC is calculated while data are written to the memory. To read the correct ECC, the software must consequently wait until no write request to the NAND controller are pending, by polling PEF and NWRF bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NWRF	Res.	PEF	Res.	Res.	ISOST[1:0]	
									r		r			r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **NWRF:** NAND write request flag

This bit provides the status of the write request issued to the NAND flash memory. When this bit is set, all write requests to the NAND controller are served.

0: NAND flash write requests are pending

1: No NAND flash write requests pending

Bit 5 Reserved, must be kept at reset value.

Bit 4 **PEF:** Pipe Empty Flag

This bit indicates if the pipe contains requests.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **ISOST[1:0]:** FMC isolation state with respect to the AXI interface

00: FMC is not isolated; AXI transactions are treated by the FMC and its controllers.

01: FMC has been enabled (FMCEN = 1) and waits for the end of pending AXI transactions (which leads to error responses) before going to “non-isolated” state.

10: FMC has been disabled (FMCEN = 0) and waits for the end of pending AXI transactions before going to isolation state.

11: FMC is isolated from its AXI interface. All AXI requests lead to error responses.

FMC common memory space timing register (FMC_PMEM)

Address offset: 0x88

Reset value: 0x0A0A 0A0A

The FMC_PMEM read/write register contains NAND flash memory region timing information. This information is used to access the NAND flash common memory space for command, address write accesses or data read/write accesses.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEMHIZ[7:0]								MEMHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEMWAIT[7:0]								MEMSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **MEMHIZ[7:0]:** Common memory data bus Hi-Z time

These bits define the number of fmc_ker_ck clock cycles (+1) during which the data bus is kept Hi-Z after starting a NAND flash write access to the common memory space. This is only valid for write transactions:

0000 0000: 1 * fmc_ker_ck cycle

0000 0001: 2 * fmc_ker_ck cycles

.....

1111 1111: 256 * fmc_ker_ck cycles

Bits 23:16 **MEMHOLD[7:0]:** Common memory hold time

These bits define the number of fmc_ker_ck clock cycles (+1) during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), during NAND flash read or write accesses to the common memory space:

0000 0000: 1 * fmc_ker_ck cycle

0000 0001: 2 * fmc_ker_ck cycles

.....

1111 1111: 256 * fmc_ker_ck cycles

Bits 15:8 **MEMWAIT[7:0]:** Common memory wait time

These bits define the minimum number of fmc_ker_ck clock cycles (+1) to assert the command (NWE, NOE), during NAND flash read or write accesses to the common memory space. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:

0000 0000: 1 * fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)

0000 0001: 2 * fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)

.....

1111 1111: 256 * fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)

Bits 7:0 **MEMSET[7:0]:** Common memory setup time

These bits define the number of fmc_ker_ck clock cycles (+1) to set up the address before the command assertion (NWE, NOE), during NAND flash read or write accesses to the common memory space:

0000 0000: 1 * fmc_ker_ck cycles

0000 0001: 2 * fmc_ker_ck cycles

.....

1111 1111: 256 * fmc_ker_ck cycles

FMC attribute memory space timing registers (FMC_PATT)

Address offset: 0x8C

Reset value: 0x0A0A 0A0A

The FMC_PATT read/write register contains NAND flash memory region timing information. It is used for 8-bit accesses to the NAND flash attribute memory space during the last address write access when the timing differs from previous accesses (for Ready/Busy management, refer to *Section 27.9.5: NAND flash prewait function*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ATTHIZ[7:0]								ATTHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ATTWAIT[7:0]								ATTSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ATTHIZ[7:0]:** Attribute memory data bus Hi-Z time

These bits define the number of fmc_ker_ck clock cycles (+1) during which the data bus is kept in Hi-Z after starting a NAND flash write access to the attribute memory space. These bits are only valid for write transactions:
0000 0000: 1 * fmc_ker_ck cycle
0000 0001: 2 * fmc_ker_ck cycle
.....
1111 1111:256 * fmc_ker_ck cycles

Bits 23:16 **ATTHOLD[7:0]:** Attribute memory hold time

These bits define the number of fmc_ker_ck clock cycles (+1) during which the address is held (and data for write access) after the command deassertion (NWE, NOE), during NAND flash read or write accesses to the attribute memory space:
0000 0000: 1 * fmc_ker_ck cycle
0000 0001: 2 * fmc_ker_ck cycle
.....
1111 1111:256 * fmc_ker_ck cycles.

Bits 15:8 **ATTWAIT[7:0]:** Attribute memory wait time

These bits define the minimum number of x fmc_ker_ck (+1) clock cycles to assert the command (NWE, NOE), during NAND flash read or write accesses to the attribute memory space. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:
0000 0000: 1 * fmc_ker_ck cycle (+ wait cycle introduced by deassertion of NWAIT)
0000 0001: 2 * fmc_ker_ck cycles (+ wait cycle introduced by deassertion of NWAIT)
.....
1111 1111: 256 * fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)

Bits 7:0 **ATTSET[7:0]:** Attribute memory setup time

These bits define the number of fmc_ker_ck clock cycles (+1) for address set up before the command assertion (NWE, NOE), during NAND flash read or write accesses to the attribute memory space:
0000 0000: 1 * fmc_ker_ck cycle
0000 0001: 2 * fmc_ker_ck cycle
.....
1111 1111:256 * fmc_ker_ck cycles.

FMC Hamming parity result registers (FMC_HPR)

Address offset: 0x90

Reset value: 0x0000 0000

This register is used during read accesses in conjunction with the FMC sequencer. It contains the current error correction code value computed by the FMC NAND controller Hamming module. When the FMC sequencer reads data from a NAND flash memory page at the correct address, the data read are automatically processed by the Hamming computation module. When X bytes have been read (according to the sector size ECCSS field in the FMC_PCR register), the CPU must read the computed ECC value from the FMC_HECCR register. It then verifies if these computed parity data are the same as the parity value recorded in the spare area and stored in the and the FMC_HPR, to determine whether a page is valid, and to correct it otherwise. The FMC_HPR register must be cleared after being read by setting the ECCEN bit to 0. To compute a new data block, the ECCEN bit must be set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HPR[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

HPR[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **HPR[31:0]:** Hamming parity result

This field contains the parity value computed by the Hamming ECC computation module. *Table 191* describes the contents of these bitfields.

Table 191. HPR relevant bits

ECCSS[2:0]	Sector size in bytes	HPR bits
000	256	HPR[21:0]
001	512	HPR[23:0]
010	1024	HPR[25:0]
011	2048	HPR[27:0]
100	4096	HPR[29:0]
101	8192	HPR[31:0]

FMC Hamming code ECC result register (FMC_HECCR)

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the FMC NAND controller Hamming module.When the CPU reads/writes data from/to a NAND flash memory page at the correct address (refer to *Section 27.9.6: NAND ECC controller*), the data read/written from/to the NAND flash memory are automatically processed by the Hamming computation module. When X bytes have been read (according to the sector size ECCSS

field in the FMC_PCR register), the CPU must read the computed ECC value from the FMC_HECCR register. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and to correct it otherwise. The FMC_HECCR register must be cleared after being read by setting the ECCEN bit to 0. To compute a new data block, the ECCEN bit must be set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HECC[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

HECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **HECC[31:0]:** ECC result

This field contains the value computed by the Hamming ECC computation logic. *Table 192* describes the contents of these bitfields.

Table 192. ECC result relevant bits(1)

ECCSS[2:0]	Sector size in bytes	HECC bits
000	256	HECC[21:0]
001	512	HECC[23:0]
010	1024	HECC[25:0]
011	2048	HECC[27:0]
100	4096	HECC[29:0]
101	8192	HECC[31:0]

1. Only the relevant bits according to the sector size are valid.

FMC NAND interrupt enable register (FMC_IER)

Address offset: 0x180

Reset value: 0x0000 0000

This register configures the interrupt capability generation when the RNB signal is connected on FMC interrupt pin. An interrupt can be generated on the rising edge, falling edge or high level detected on the RNB signal.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IFEE	IHLE	IREE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **IFEE:** Interrupt falling edge detection enable bit
0: Interrupt falling edge detection request disabled
1: Interrupt falling edge detection request enabled

Bit 1 **IHLE:** Interrupt high-level detection enable bit
0: Interrupt high-level detection request disabled
1: Interrupt high-level detection request enabled

Bit 0 **IREE:** Interrupt rising edge detection enable bit
0: Interrupt rising edge detection request disabled
1: Interrupt rising edge detection request enabled

FMC interrupt status register (FMC_ISR)

Address offset: 0x184

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IFEF	IHLF	IREF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **IFEF:** Interrupt falling edge flag
The flag is set by hardware and cleared by setting the CFEIF bit.
0: No interrupt falling edge occurred
1: Interrupt falling edge occurred

Bit 1 **IHLF:** Interrupt high-level flag
The flag is set by hardware and cleared by setting the CHLIF bit.
0: No Interrupt high-level occurred
1: Interrupt high-level occurred

Bit 0 **IREF:** Interrupt rising edge flag
The flag is set by hardware and cleared by setting the CREIF bit.
0: No interrupt rising edge occurred
1: Interrupt rising edge occurred

FMC NAND controller interrupt clear register (FMC_ICR)

Address offset: 0x188

Reset value: 0x0000 0000

Writing 1 in one of these bits clears the corresponding flag in the interrupt status register (FMC_ISR).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CIFEF	CIHLF	CIREF
													w	w	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CIFEF:** Clear Interrupt falling edge flag
0: No effect
1: Clears the IFEF flag in the FMC_ISR register

Bit 1 **CIHLF:** Clear Interrupt high-level flag
0: No effect
1: Clears the IHLF flag in the FMC_ISR register

Bit 0 **CIREF:** Clear Interrupt rising edge flag
0: No effect
1:Clear the IREF flag in the FMC_ISR register

FMC NAND command sequencer control register (FMC_CSQCR)

Address offset: 0x200

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSQSTART
															w

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **CSQSTART**: Command Sequencer Enable
Writing 1 starts the Command sequencer.
Writing 0 has no effect.

Note: Write this bit to 1 to start the sequencer only when the FMC is enabled by setting FMCEN bit of FMC_CFGR to 1 and the NAND flash controller is activated by setting PBKEN bit of FMC_PCR to 1.

FMC NAND command sequencer configuration register 1 (FMC_CSQCFGR1)

Address offset: 0x204

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	CMD2T	CMD1T	CMD2[7:0]							
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMD1[7:0]								Res.	ACYNBR[2:0]			Res.	DMADEN	CMD2EN	Res.
rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw		rw	rw	

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **CMD2T:** Command 2 Sequencer timings

This bit specifies if the Command 2 (CMD2) is issued to the NAND flash memory with the timings defined in FMC_PMEM or FMC_PATT register.

0: CMD2 issued with the timings programmed in FMC_PMEM

1: CMD2 issued with the timings programmed in FMC_PATT

Bit 24 **CMD1T:** Command 1 Sequencer timings

This bit specifies if the Command 1 (CMD1) is issued to the NAND flash memory with the timings programmed in FMC_PMEM or FMC_PATT register.

0: CMD1 issued with the timings programmed in FMC_PMEM

1: CMD1 issued with the timings programmed in FMC_PATT

Bits 23:16 **CMD2[7:0]:** Command 2 sequencer

These bits specify if the Command 2 is issued by the command sequencer for the command second cycle during read operations.This command is only issued when the CMD2EN bit is set.

Example: CMD2[7:0] bits must be programmed to 0x30 to issue the read column command.

Bits 15:8 **CMD1[7:0]:** Command 1 sequencer

These bits specify if the Command 1 is issued by the command sequencer for the first cycle during read or write operations.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACYNBR[2:0]:** Address Cycle number

These bits define the number of address cycles to be generated by the command sequencer when issuing the command programmed in the registers.

000: No address cycle.

001: 1 address cycle

010: 2 address cycles

011: 3 address cycles

100: 4 address cycles

101: 5 address cycles

Others: Reserved.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DMADEN:** Command sequencer DMA request data enable

When this bit is set, the command sequencer generates a DMA request to the first DMA channel, to transfer data from/to NAND flash memory.

0: No DMA request transfer

1: A DMA request transfer

Bit 1 **CMD2EN:** Command cycle 2 Enable

This bit specifies that the command cycle 2 has to be generated by the command sequencer.

0: Command cycle 2 not issued.

1: Command cycle 2 (programmed CMD2[7:0]) sent by the command sequencer to the NAND flash memory after the address cycles.

Bit 0 Reserved, must be kept at reset value.

FMC NAND command sequencer configuration register 2 (FMC_CSQCFGR2)

Address offset:0x208

Reset value: 0x0000 0000

This register is used to configure the command sequencer to issue random read/ write commands to read/ write data by sector and automatically read/write data from NAND flash memory at a programmable address offset. This is useful when performing a sector read/write operation followed by an ECC read/write operation in the NAND flash spare area.The command sequencer generates the random commands until all the sectors are read/written.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	RCMD2T	RCMD1T	RCMD2[7:0]

RCMD1[7:0]								Res.	Res.	Res.	Res.	Res.	DMASEN	RCMD2EN	SQSDTEN
rw	rw	rw	rw	rw	rw	rw	rw						rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **RCMD2T:** Command 1 sequencer timings

This bit specifies if the CMD1 is issued to the NAND flash memory with the timings programmed in FMC_PMEM or FMC_PATT register.

0: CMD1 issued with the timings programmed in FMC_PMEM

1: CMD1 issued with the timings programmed in FMC_PATT

Bit 24 **RCMD1T:** Command 1 sequencer timings

This bit specifies if the CMD1 is issued to the NAND flash memory with the timings flash memory in FMC_PMEM or FMC_PATT register.

0: CMD1 issued with the timings programmed in FMC_PMEM

1: CMD1 issued with the timings programmed in FMC_PATT

Bits 23:16 **RCMD2[7:0]:** Random Command 2 sequencer

These bits specify that the command 2 is issued by the command sequencer for the second cycle during read operations.This command is only issued when the RCMD2EN bit is set.
Example: the RCMD2 (0xE0) is required to issue the random read column command.

Bits 15:8 **RCMD1[7:0]:** Random Command 1 sequencer

These bits specify that the command 1 value is issued by the command sequencer for the first cycle during read or write accesses.

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **DMASEN:** Command sequencer DMA request decoding status enable

When this bit is set, the command sequencer generates a DMA request to the second DMA channel when valid bits are available in the ECC status register at the end of ECC processing (decoding).
0: No DMA request used for ECC status registers transfer
1: A DMA request used for ECC status registers transfer

Note: This bit must be set only during a page read sequence to offload the saving of the ECC results between sectors by using a second DMA channel.

Bit 1 **RCMD2EN:** Random Command 2 sequencer enable

This bit enables the command 2 to be issued by the command sequencer during read accesses. This command is issued only when the CMD2SQEN bit is set.
0: Command 2 not issued.
1: Command 2 (CMD2SQ[7:0]) issued by the command sequencer to NAND flash memory after the address cycle.

Bit 0 **SQSDTEN:** Sequencer spare data transfer enable

This bit enables the sequencer to access the spare data area after each sector transfer. It also enables the ECC when using the sequencer. ECCEN bit in FMC_PCR register must be reset.
0: ECC disabled and spare data area not accessed by the sequencer
1: ECC enabled and spare data area read or programmed by the sequencer after each sector transfer

FMC NAND sequencer configuration register 3 (FMC_CSQCFGR3)

Address offset: 0x20C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RAC2T	RAC1T	SDT	AC5T	AC4T	AC3T	AC2T	AC1T
								rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	SNBR[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
		rw	rw	rw	rw	rw	rw								

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **RAC2T:** Random Address cycle 2 sequencer timings

This bit specifies if the random Address cycle 2 (ADDC2) is issued to the NAND flash memory with the timings programmed in FMC_PMEM or in FMC_PATT register.

0: Random ADDC2 issued with the timings programmed in FMC_PMEM

1: Random ADDC2 issued with the timings programmed in FMC_PATT

Bit 22 **RAC1T:** Random Address cycle 1 sequencer timings

This bit specifies if the random Address cycle 1 (ADDC1) is issued to the NAND flash memory with the timings programmed in FMC_PMEM or in FMC_PATT register.

0: Random ADDC1 issued with the timings programmed in FMC_PMEM

1: Random ADDC1 issued with the timings programmed in FMC_PATT

Bit 21 **SDT:** Spare data transfer sequencer timings

This bit specifies if the spare data transfer for read and write operations from/to the NAND flash memory are performed with the timings programmed in FMC_PMEM or FMC_PATT register.

0: Spare data transfer issued with the timings programmed in FMC_PMEM

1: Spare data transfer issued with the timings programmed in FMC_PATT

Bit 20 **AC5T:** Address cycle 5 sequencer timings

This bit defines if the Address cycle 5(ADDC1) is issued to the NAND flash memory with the timings programmed in FMC_PMEM or FMC_PATT register.

0: ADDC5 issued with the timings programmed in FMC_PMEM

1: ADDC5 issued with the timings programmed in FMC_PATT

Bit 19 **AC4T:** Address cycle 4sequencer timings

This bit defines if the Address cycle 4 (ADDC4) is issued to the NAND flash memory with the timings programmed in FMC_PMEM or FMC_PATT register.

0: ADDC4 issued with the timings programmed in FMC_PMEM

1: ADDC4 issued with the timings programmed in FMC_PATT

Bit 18 **AC3T:** Address cycle 3 sequencer timings

This bit defines if the Address cycle 3 (ADDC3) is issued to the NAND flash memory with the timings programmed in FMC_PMEM or FMC_PATT register.

0: ADDC3 issued with the timings programmed in FMC_PMEM

1: ADDC3 issued with the timings programmed in FMC_PATT

Bit 17 **AC2T:** Address cycle 2 sequencer timings

This bit defines if the Address cycle 2 (ADDC2) is issued to the NAND flash memory with the timings programmed in FMC_PMEM or FMC_PATT register.

0: ADDC2 issued with the timings programmed in FMC_PMEM

1: ADDC2 issued with the timings programmed in FMC_PATT

Bit 16 **AC1T:** Address cycle 1 sequencer timings

This bit defines if the Address cycle 1 (ADDC1) is issued to the NAND flash memory with the timings programmed in FMC_PMEM or FMC_PATT register.

0: ADDC1 issued with the timings programmed in FMC_PMEM

1: ADDC1 issued with the timings programmed in FMC_PATT

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **SNBR[5:0]:** Number of sectors to be read/written

These bits define the number of sectors that are processed by the sequencer.
They are used to read/write part of a page or to use the ECC (in particular with the BCH code which requires 512-byte sectors):
000000: 1 sector
000001: 2 sectors
...
111111: 16 sectors
Others: Reserved.

Bits 7:0 Reserved, must be kept at reset value.

FMC NAND command sequencer address register 1 (FMC_CSQAR1)

Address offset: 0x210

Reset value: 0x0000 0000

This register is used to define the value of address cycles 1 to 4 to be issued by the command sequencer.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDC4[7:0]								ADDC3[7:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDC2[7:0]								ADDC1[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ADDC4[7:0]:** Address Cycle 4

These bits define the value of address cycle 4 to be issued by the command sequencer during read or write accesses.

Bits 23:16 **ADDC3[7:0]:** Address Cycle 3

These bits define the value of address cycle 2 to be issued by the command sequencer during read or write accesses.

Bits 15:8 **ADDC2[7:0]:** Address Cycle 2

These bits define the value of address cycle 2 to be issued by the command sequencer during read or write accesses.

Bits 7:0 **ADDC1[7:0]:** Address Cycle 1

These bits define the value of address cycle 1 to be issued by the command sequencer during read or write accesses.

FMC NAND command sequencer address register 2 (FMC_CSQAR2)

Address offset: 0x214

Reset value: 0x0000 0000

This register is used to program the fifth address cycle and the address offset in spare area.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADDC5[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **SAO[15:0]:** Spare Area Address Offset

These bits define the offset of the first ECC byte in the spare area for the program sequence.

Note: The minimum SAQ value is 2 since the first two bytes of the spare area are reserved for Bad block marking and metadata.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 Reserved, must be kept at reset value.

Bits 7:0 **ADDC5[7:0]:** Address Cycle 5

These bits define the value of address cycle 5 to be issued by the command sequencer during read or write accesses.

FMC NAND command sequencer interrupt enable register (FMC_CSQIER)

Address offset: 0x220

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDTCIE	SUEIE	SEIE	SCIE	TCIE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CMDTCIE:** Command Transfer Complete interrupt enable

0: Command Transfer Complete Interrupt disable

1: Command Transfer Complete Interrupt enable

Bit 3 **SUEIE:** Sector Uncorrectable Error interrupt enable

0: Command Transfer Complete Interrupt disable

1: Command Transfer Complete Interrupt enable

Bit 2 **SEIE:** Sector Error interrupt enable
0: Sector Error Interrupt disable
1: Sector Error Interrupt enable

Bit 1 **SCIE:** Sector Complete interrupt enable
0: Sector Complete Interrupt disable
1: Sector Complete Interrupt enable

Bit 0 **TCIE:** Transfer Complete Interrupt enable
0: Transfer Complete Interrupt disable
1: Transfer Complete Interrupt enable

FMC NAND command sequencer interrupt status register (FMC_CSQISR)

Address offset: 0x224

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDTCF	SUEF	SEF	SCF	TCF
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CMDTCF:** Command Transfer Complete flag
This bit is set when the command sequencer has completed the transfer of programmed commands and addresses.
This bit is cleared by setting CCMDTCF bit. An interrupt can be generated if the CMDTCIE bit is set in the FMC_CSQICR register.

Note: The Sector Transfer Complete interrupt is not needed in sequencer mode.

Bit 3 **SUEF:** Sector Uncorrectable Error flag
This bit is set by hardware and cleared by writing 1 to the CSUEF bit in FMC_CSQICR.
When this bit is set, it indicates that the command sequencer detected an uncorrectable error when decoding a sector. An interrupt can be generated if the SUEIE bit is set in the FMC_CSQICR register.

Note: The SUEF bit is relevant only for BCH code to indicate uncorrectable errors. It must be ignored for Hamming code.

Bit 2 **SEF:** Sector Error flag

This bit is set by hardware and cleared by writing 1 to the CSEF bit in FMC_CSQICR.

This bit is set when the command sequencer has completed the sector data transfer with at least one error detection. An interrupt can be generated if the SEIE bit is set in the FMC_CSQICR register.

Note: The SEF bit is relevant only for BCH code to indicate that errors are present. It must be ignored for Hamming code.

Bit 1 **SCF:** Sector Complete flag

This bit is set by hardware and cleared by writing 1 to the CSCF bit in FMC_CSQICR.

This bit is set when the command sequencer has completed the sector data transfer. An interrupt can be generated if the SCIE bit is set in the FMC_CSQICR register.

Bit 0 **TCF:** Transfer Complete flag

This bit is set by hardware and cleared by writing 1 to the CTCF bit in FMC_CSQICR.

This bit is set when the command sequencer has transferred all the data for all sectors or when the command sequencer was aborted. An interrupt can be generated if the TCIE bit is set in the FMC_CSQICR register.

FMC NAND command sequencer interrupt clear register (FMC_CSQICR)

Address offset: 0x228

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCMDTCF	CSUEF	CSEF	CSCF	CTCF
											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CCMDTCF:** Clear Command Transfer Complete flag

Writing one clears the CMTCF flag in the FMC_CSQISR register

Bit 3 **CSUEF:** Clear Sector uncorrectable Error flag

Writing one clears the SUEF flag in the FMC_CSQISR register

Bit 2 **CSEF:** Clear Sector Error flag

Writing one clears the SEF flag in the FMC_CSQISR register

Bit 1 **CSCF:** Clear Sector Complete flag

Writing one clears the SCF flag in the FMC_CSQISR register

Bit 0 **CTCF**: Clear Transfer Complete flag

Writing one clears the TCF flag in the FMC_CSQISR register

FMC command sequencer error mapping status register (FMC_CSQEMSR)

Address offset: 0x230

Reset value: 0x0000 0000

This register holds a sector error mapping status when the whole transfer is complete.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

SEM[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SEM[15:0]:** Sector Error mapping
When SEM[i] bit (0 ≤ i ≤ 15) is set, at least one error has been detected on sector i+1.
As an example, SEM[2] and SEM[1] bits are set when errors are detected in sector 3 and 2.

FMC BCH interrupt enable register (FMC_BCHIER)

Address offset: 0x250

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EPBRIE	DSRIE	DEFIE	DERIE	DUEIE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **EPBRIE:** Decoder Parity Bits Ready Interrupt enable
0: Decoder Parity Bits Ready Interrupt disable
1: Decoder Parity Bits Ready Interrupt enable

Bit 3 **DSRIE:** Decoder Syndrome Ready Interrupt enable
0: Decoder Syndrome Ready Interrupt disable
1: Decoder Syndrome Ready Interrupt enable

Bit 2 **DEFIE:** Decoder Error Found Interrupt enable
0: Decoder Error Found Interrupt disable
1: Decoder Error Found Interrupt enable

Bit 1 **DERIE:** Decoder Error Ready Interrupt enable
0: Decoder Error Ready Interrupt disable
1: Decoder Error Ready Interrupt enable

Bit 0 **DUEIE:** Decoder Uncorrectable Errors Interrupt enable
0: Decoder Uncorrectable Errors Interrupt disable
1: Decoder Uncorrectable Errors Interrupt enable

FMC BCH interrupt and status register (FMC_BCHISR)

Address offset: 0x254

Reset value: 0x0000 0000

This register holds the status of BCH encoder/decoder after processing each sector. When the sequencer is used, this register is automatically cleared and the corresponding interrupt must not be enabled through FMC_BCHIER register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EPBRF	DSRF	DEFF	DERF	DUEF
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **EPBRF:** Encoder Parity Bits Ready flag
This bit is set when the BCH encoder parity bits are available in FMC_BCHPBR1 to 4.

Bit 3 **DSRF:** Decoder Syndrome Ready flag
This bit is set when the syndrome is ready and DEFF is a valid field.

Bit 2 **DEFF:** Decoder Error Found flag
This bit is set by hardware and cleared by writing 1 to CDEFF.
This bit indicates that at least one error has been detected in the sector.

Bit 1 **DERF:** Decoder Error Ready flag
This bit indicates that the decoder has finished searching errors and identifying their location. The number of errors and their location are available in FMC_BCHDSR0 and FMC_BCHDSR1 to 4, respectively.

Bit 0 **DUEF:** Decoder Uncorrectable Errors flag
This field indicates that too many errors have been detected in the sector during the BCH decoding and that the sector is uncorrectable.

FMC BCH interrupt clear register (FMC_BCHICR)

Address offset: 0x258

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CEPBRF	CDSRF	CDEFF	CDERF	CDUEF
											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CEPBRF:** Clear Encoder Parity Bits Ready flag
Writing 1 clears the EPBRF flag in FMC_BCHISR.

Bit 3 **CDSRF:** Clear Decoder Syndrome Ready flag
Writing 1 clears the DSRF flag in FMC_BCHISR.

Bit 2 **CDEFF:** Clear Decoder Error Found flag
Writing 1 clears the DEFF flag in FMC_BCHISR.

Bit 1 **CDERF:** Clear Decoder Error ready flag
Writing 1 clears the DERF flag in FMC_BCHISR.

Bit 0 **CDUEF:** Clear Decoder Uncorrectable Error flag
Writing 1 clears the DUEF flag in FMC_BCHISR.

FMC BCH parity bits register 1 (FMC_BCHPBR1)

Address offset: 0x260

Reset value: 0x0000 0000

These registers contain the BCH parity bits (BCHPB). For the BCH 4-bit, only BCHPB[51:0] are significant and for the BCH 8-bit BCHPB[103:0] are significant.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 7:0 **BCHPB[103:96]:** BCH parity bits

FMC BCH decoder status register 0 (FMC_BCHDSR0)

Address offset: 0x27C

Reset value: 0x0000 0000

This register contains some fields already available in other registers but that require to be saved when error correction is performed on several sectors at a time (for example a whole NAND flash page). This allows a DMA channel to transfer the content of FMC_BCHDSR0 to 4 to a decoding status buffer.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DEN[3:0]				Res.	Res.	DEF	DUE
								r	r	r	r			r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **DEN[3:0]:** Decoder error number

When DEF bit is set, this field indicates the number of errors detected by the BCH decoder.
Following the selected BCH code, if the number of detected errors exceeds the number of correctable errors, this bit is not significant and DUE bit is set.
If the BCH decoder detects a number of errors that exceeds the maximum number of detectable errors, DEN is not significant.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **DEF:** Decoder error found

This field indicates that the decoder has finished searching errors and identifying their location.
The number of errors and their location are available in FMC_BCHDSR0 and FMC_BCHDSR1 to 4, respectively.

Bit 0 **DUE:** Decoder uncorrectable error

This field indicates that too many errors have been detected in the sector during the BCH decoding and that the sector is uncorrectable.
If the BCH decoder detects a number of errors that exceeds the maximum number of detectable errors, DUE is not significant.

FMC BCH decoder status register for memory region 1 (FMC_BCHDSR1)

Address offset: 0x280

Reset value: 0x0000 0000

The maximum error correction capability of the BCH block embedded in the FMC is 8 errors. This register contains the positions of the 1st and 2nd error bits in EBP1 and EPB2 fields, respectively. If less than 8 errors are detected, the useless EPBx fields (x = 1 to 8) are “don’t care”.

27.10 SDRAM controller

27.10.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM devices with control registers
- 8-bit, 16-bit, 32-bit data bus width with narrow width support using DQM byte masking
- 11- to 13-bit Address Row, 8- to 11-bit Address Column, 2 to 4 internal banks
  Maximum supported device configurations: 4 x 16 M x 32 bits (256 Mbytes), 4 x 16 M x 16 bits (128 Mbytes), 4 x 16 M x 8 bits (64 Mbytes)
- 64-bit AXI interface with word, half-word or byte access
- SDRAM clock ratio programmable to 1, 2 or 3 (fmc_ker_ck, fmc_ker_ck/2 or fmc_ker_ck/3)
- Automatic row and bank boundary crossing management
- Multibank back-to-back access
- Programmable timing parameters
- Automatic refresh operation with programmable refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3

27.10.2 SDRAM External memory interface signals

Table 193. SDRAM signals

SDRAM signal	I/O type	Description	Alternate function
SDCLK	O	SDRAM clock	
SDCKE[1:0]	O	SDCKE0: SDRAM Bank 1 Clock Enable SDCKE1: SDRAM Bank 2 Clock Enable	
SDNE[1:0]	O	SDNE0: SDRAM Bank 1 chip enable SDNE1: SDRAM Bank 2 chip enable	
A[13:0](1)	O	Address	FMC_A[13:0]
D[31:0]	I/O	Bidirectional data bus	FMC_D[31:0]
BA[1:0]	O	Bank Address	FMC_A[15:14]
NRAS	O	Row Address Strobe	
NCAS	O	Column Address Strobe	
SDNWE	O	Write Enable	
NBL[3:0]	O	Output byte mask for write accesses (memory signal name: DQM[3:0]	FMC_NBL[3:0]

1. A[13:0] address depends on the number of row address bits (NR) and the number of column address bits (NC).
   A[10] is also used as a command parameter.
   A[12] is asserted only when NR = 13.
   A[13] is never asserted.

27.10.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (SDCLK).

SDRAM initialization

The initialization sequence is managed by software. If the two devices are used, the initialization sequence must be generated simultaneously to device 1 and device 2 by setting DS1 and DS2 bits in the FMC_SDCMR register:

1. Program the memory device features into the FMC_SDCRx register.The SDRAM clock and RPIPE[1:0] must be programmed in the FMC_SDCR1 register.
2. Program the memory device timing into the FMC_SDTR register.
3. Enable each SDRAM device by setting the corresponding SDEN bit in FMC_SDCRx register.
4. Set the FMCEN bit. The SDRAM clock starts when this step is complete.
5. Wait during the recommended delay period (100 µs). Refer to the SDRAM datasheet for the required delay after power-up.
6. Set the MODE[2:0] bitfield to 0x2 and configure the device select bits (DS1 and DS2) in the FMC_SDCMR register to issue a Precharge all banks (PALL) command.
7. Set the MODE[2:0] bitfield to 0x3 (Auto-refresh) and configure the device select bits (DS1 and DS2). The user application can either generate Auto-refresh commands by burst (NRFS[3:0]) in the FMC_SDCMR register or generate consecutive single Auto-refresh commands. Refer to the SDRAM datasheet for the number of Auto-refresh commands that must be issued during the initialization phase.
8. Perform load mode register: configure the MRD[13:0] bitfield in the FMC_SDCMR register, set the MODE[2:0] bitfield to 0x4, and configure the device select bits (DS1 and DS2) in the FMC_SDCMR register to issue a load mode register command to the memory devices. In particular, the burst length (BL) has to be set.

   If the mode register value is not the same for both SDRAM devices, this step must be repeated twice, once for each device, and the device select bit has to be set accordingly. For mobile SDRAM devices, the MRD[13:0] bitfield is also used to configure the extended mode register while performing the load mode register.
9. Program the refresh rate in the FMC_SDRTR register. The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted depending on the SDRAM device.
10. Set the SDINIT bit for all the enabled devices in the FMC_SDCRx register, to indicate to the hardware that the initialization procedure has been completed for all the enabled devices.

    At the end of this step, the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device.

    Therefore, the SDRAM device must be first initialized again after reset before issuing any new access by the NOR flash/PSRAM/SRAM or NAND flash controller.

    Any AXI request to SDRAM that is occurring before the end of SDRAM initialization returns a bus error and the request is lost.

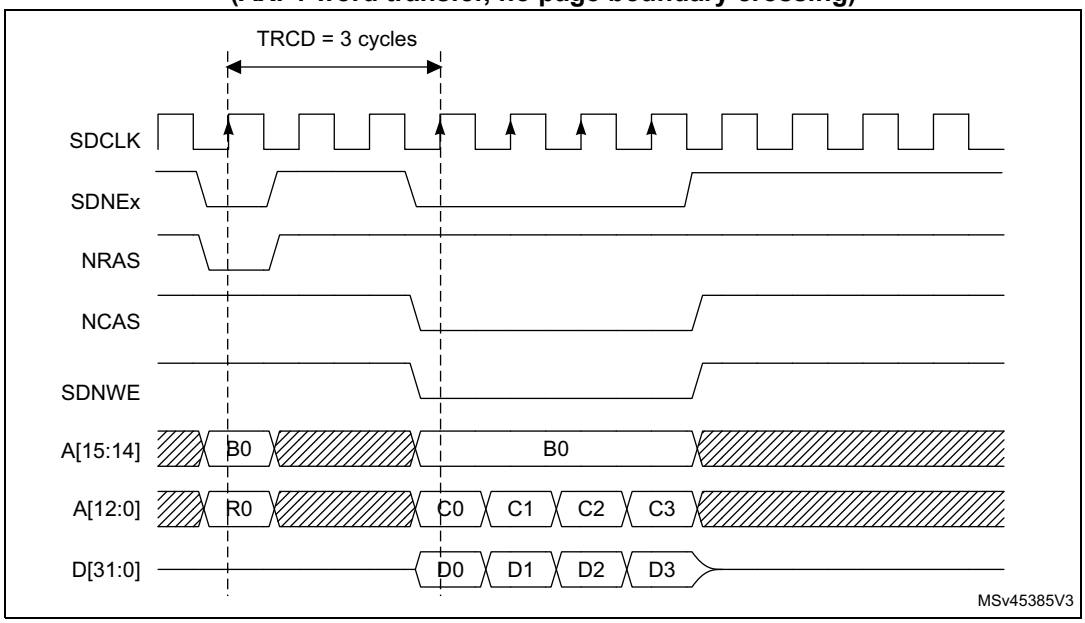
During Initialization, only the commands PALL, AR and LMR are accepted, the other commands are ignored.

SDRAM controller write cycle

The SDRAM controller converts AXI single and burst write transfers into single memory accesses. Consecutive write transfers to the same page or to open pages in different banks can be presented as back-to-back write operations to the SDRAM.

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC_SDCRx register.

Figure 185. SDRAM burst write waveforms (AXI 4-word transfer, no page boundary crossing)



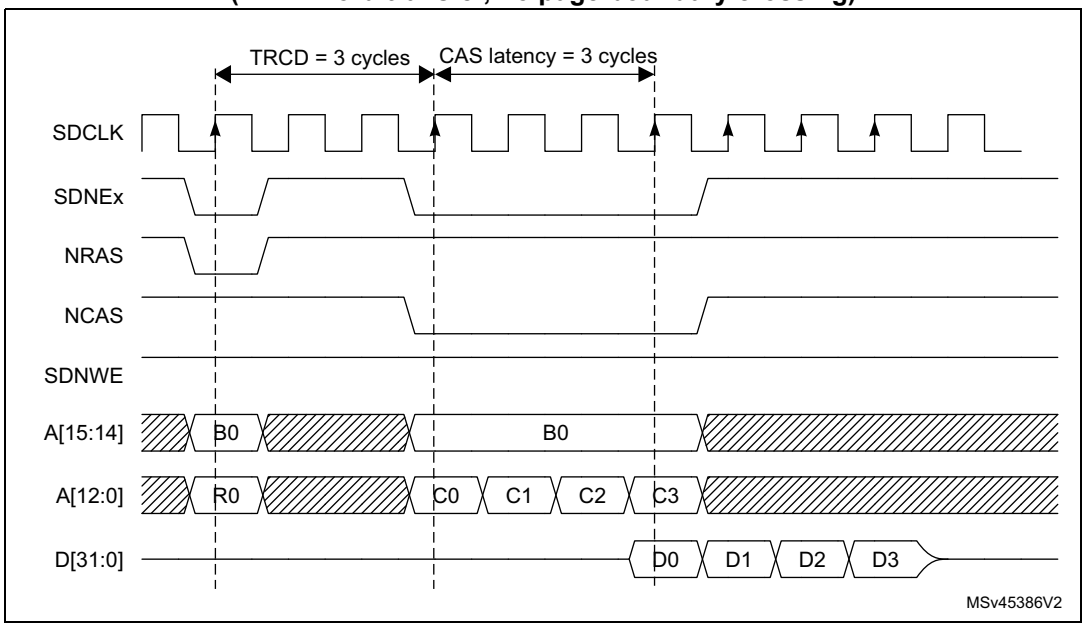
The SDRAM controller always checks the next access.

- If the next access is in the same row or in another active row, the write operation is carried out, and write commands can be back-to-back.
- if the next access targets another row (not active), the SDRAM controller generates a Bank precharge command (PRE), activates the new row and initiates a write command.

SDRAM controller read cycle

The SDRAM controller converts single and burst read transfers into single memory accesses. Consecutive read transfers to the same page or to open pages in different banks can be presented as back-to-back read operations from the SDRAM.

Figure 186. SDRAM burst read waveforms (AXI 4-word transfer, no page boundary crossing)



The address management depends on the next AXI request:

- Next request is performed at sequential address (burst access)

  In this case, the SDRAM controller increments the address.
- Next request is not performed at sequential address
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  - If the new read request does not target an active row, the SDRAM controller generates a Bank precharge command (PRE), activates the new row, and initiates a read command.

Row and bank boundary management

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row, using the Bank precharge command (PRE)
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP[3:0] parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD[3:0] parameter.

These parameters are defined into the FMC_SDTR register.

Refer to *Figure 187* and *Figure 188* for read and burst write access crossing a row boundary.

Figure 187. SDRAM burst read crossing a row boundary

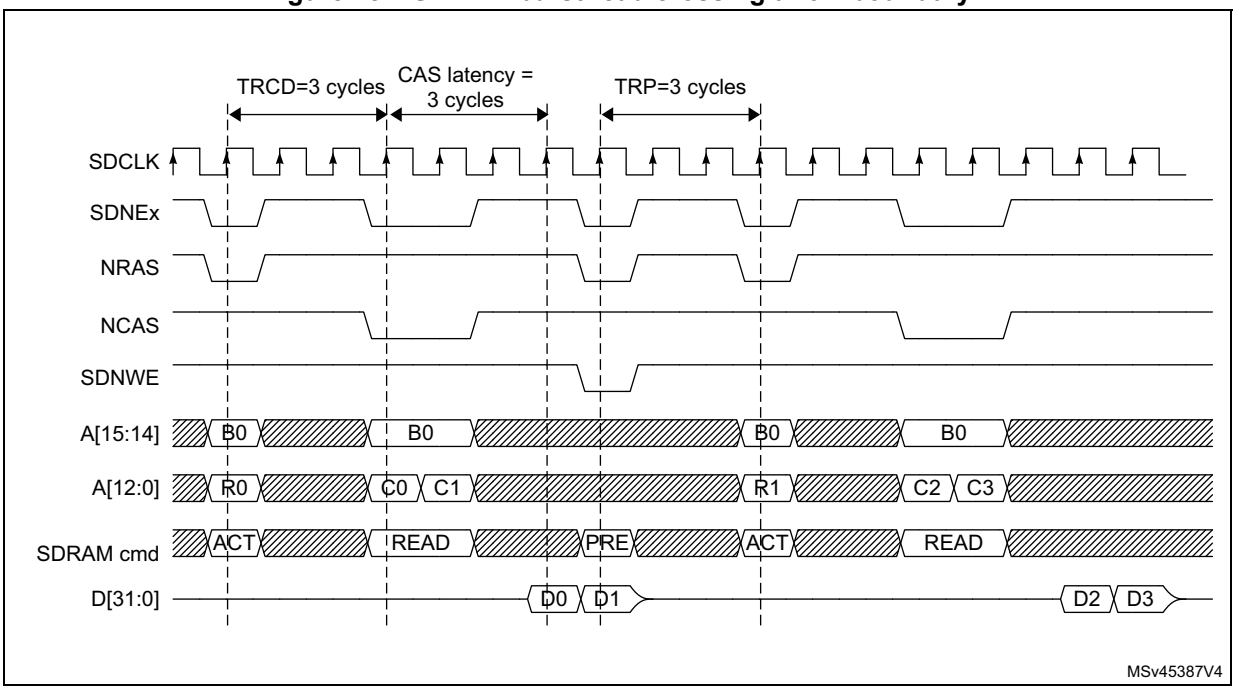


Figure 188. SDRAM burst write crossing a row boundary

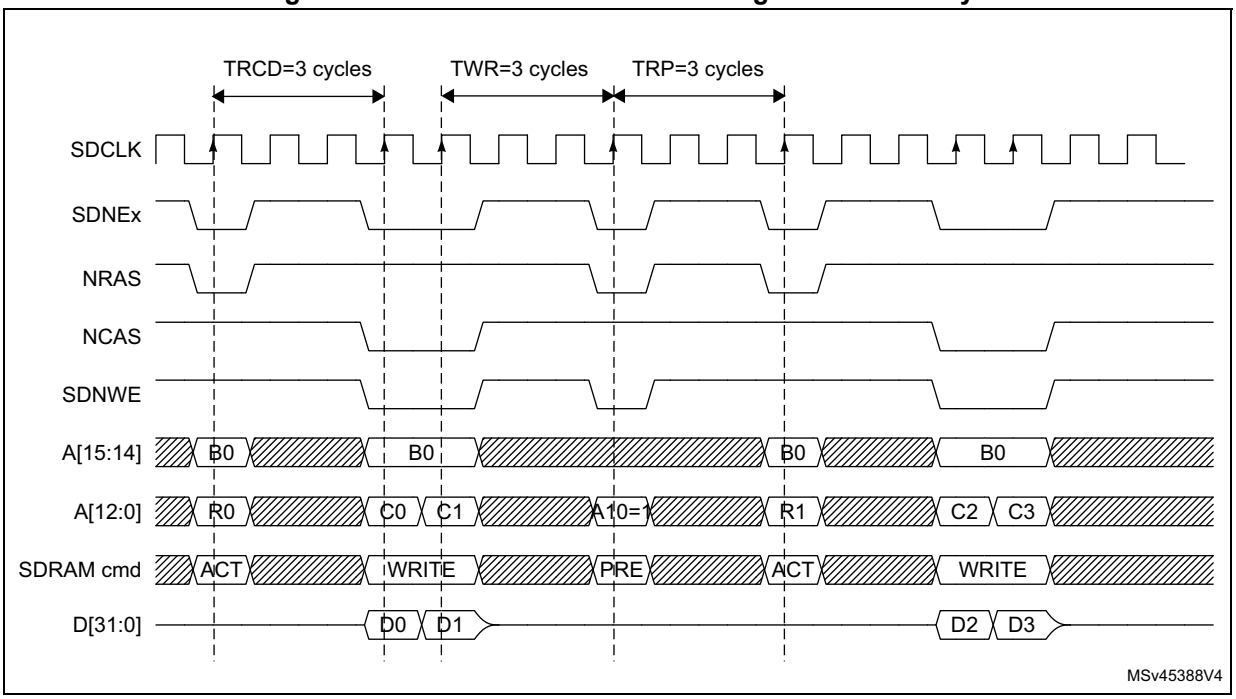

An AXI burst operation crossing a row boundary between different banks is automatically split by AXI interconnect because the boundary address is a multiple of 4 Kbytes.

Consecutive read and write operations to the same SDRAM page are back-to-back as shown in *Figure 189* and *Figure 190*.

Figure 189. Read followed by write operation

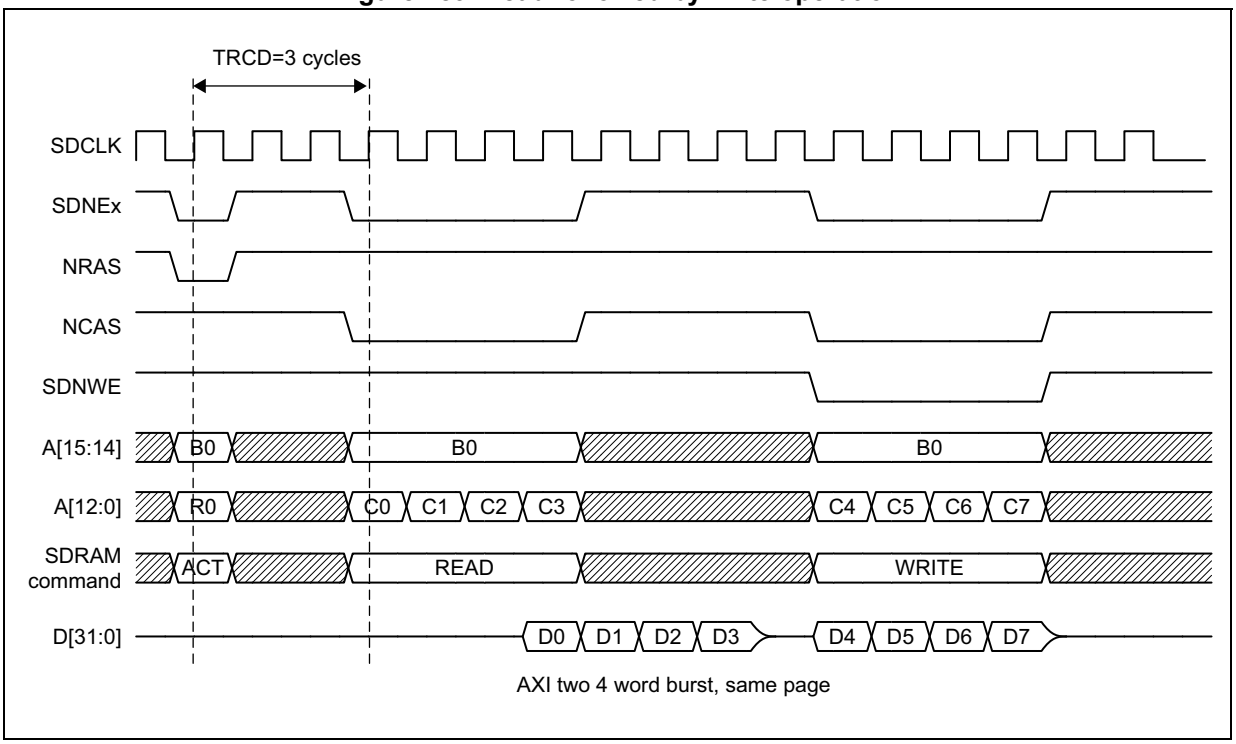

Figure 190. Write followed by read operation

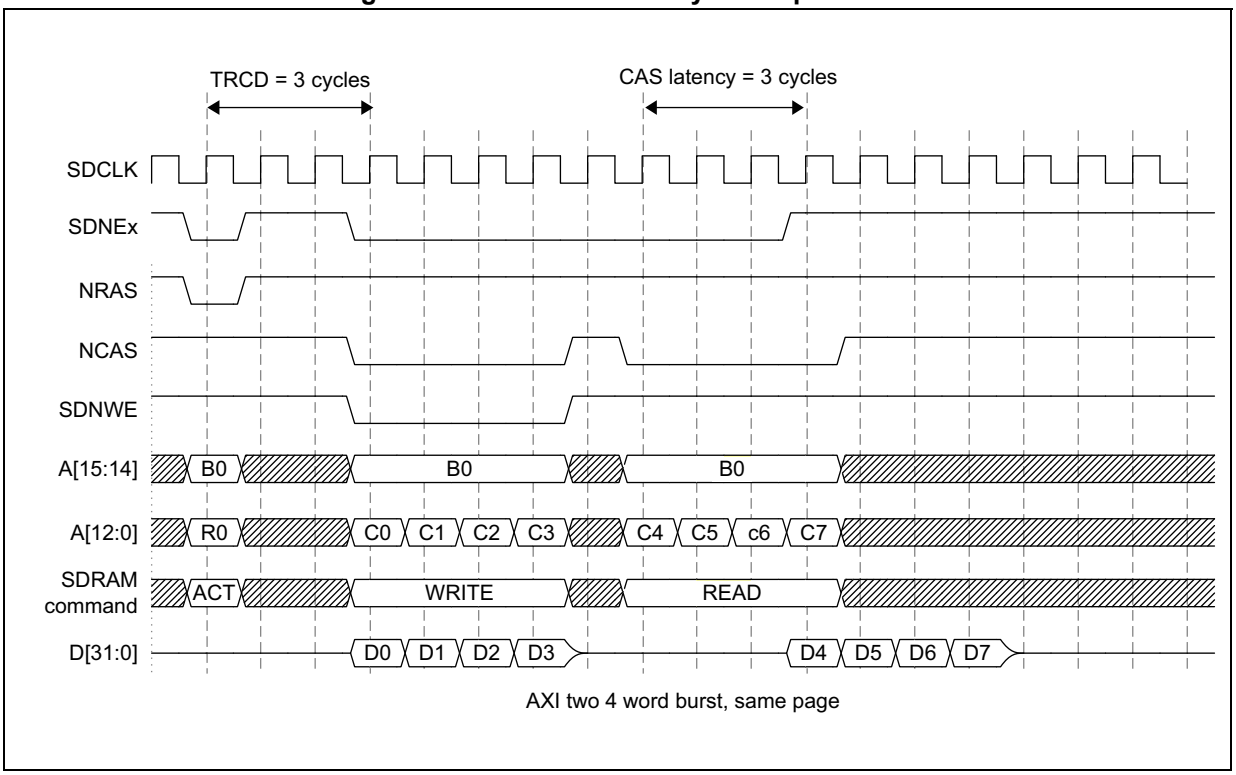


SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues Auto-refresh commands. An internal counter is loaded with the RFSCNT[12:0] value in the register FMC_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, a refresh command is generated.

The Auto-refresh command is applied on SDRAM device that are enabled (SDEN = 1) and that are not in Self-refresh mode.

If a memory access is in progress, the Auto-refresh request is delayed until the end of the AXI transfer. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. In addition, an Auto-refresh request does not suspend consecutive Read or Write commands from an AXI burst. An AXI burst transfer is not interrupted by an Auto-refresh request, except when the Auto-refresh crosses a row or bank boundary. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

If a new Auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = 1).

If the SDRAM is not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge all banks) command before the Auto-refresh.

If the Auto-refresh command is generated by the FMC_SDCMR register, a PALL command is generated by the SDRAM controller as it is keeping track of the SDRAM opened pages.

27.10.4 Low-power modes

Two low-power modes are available:

- Self-refresh mode

  The Auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.
- Power-down mode

  The Auto-refresh cycles are performed by the SDRAM controller.

Self-refresh mode

SDRAM devices can be forced into Self-refresh by software according to the MODE[2:0], DS1, DS2 bits of the FMC_SDCMR register.

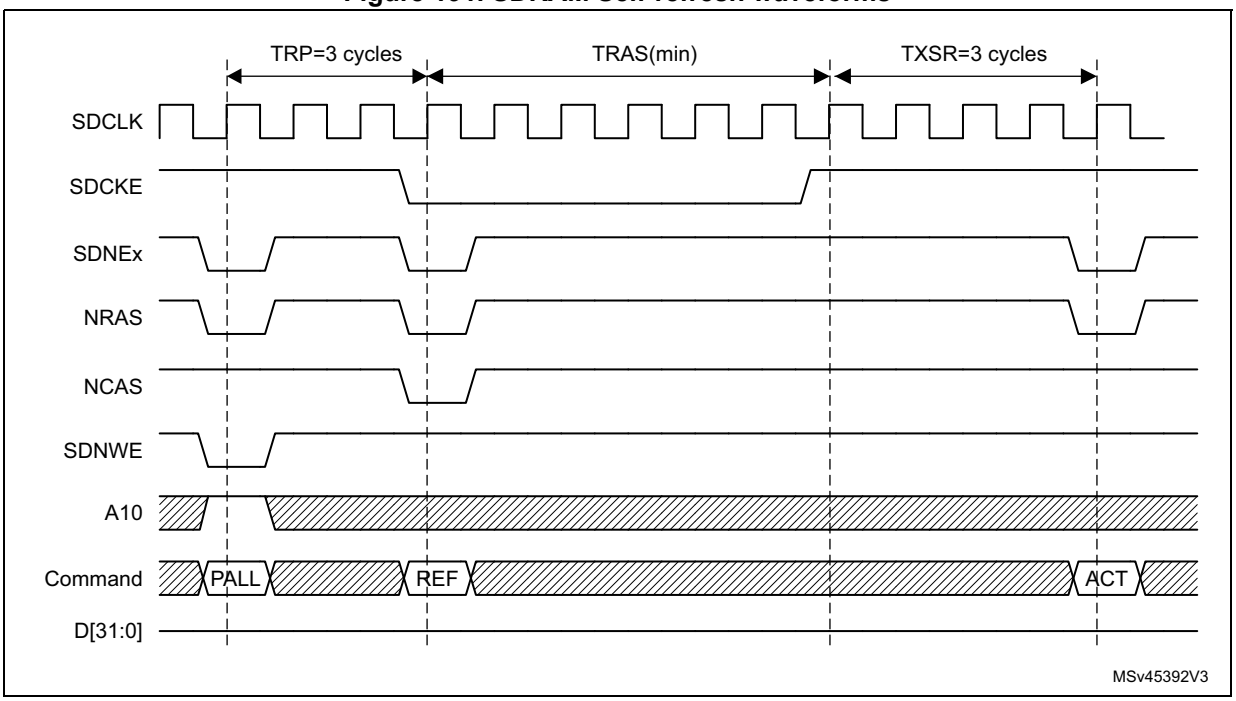
SDRAM devices exit Self-refresh either by a normal mode command from the FMC_SDCMR register (according to DS1 and DS2 bits), or upon the arrival of an AXI request (according to the device enabled through SDEN bit in the FMC_SDCRx).

Note: Exiting Self-refresh by software using FMC_SDCMR is defined on a per-device basis, while the Self-refresh exit upon receiving an AXI transfer is applicable to all devices, irrespectively of the AXI target controller, including NOR flash/PSRAM and NAND flash memories.

Changing the SDRAM frequency is possible only during Self-Refresh: RPIPE[1:0] and SDCLK[1:0] of a device FMC_SDCRx register must not be modified when the device is not in Self-Refresh mode.

Note: During Self-Refresh, any command other than normal mode configured in the FMC_SDCMR register, is ignored by the SDRAM controller.

Figure 191. SDRAM Self-refresh waveforms

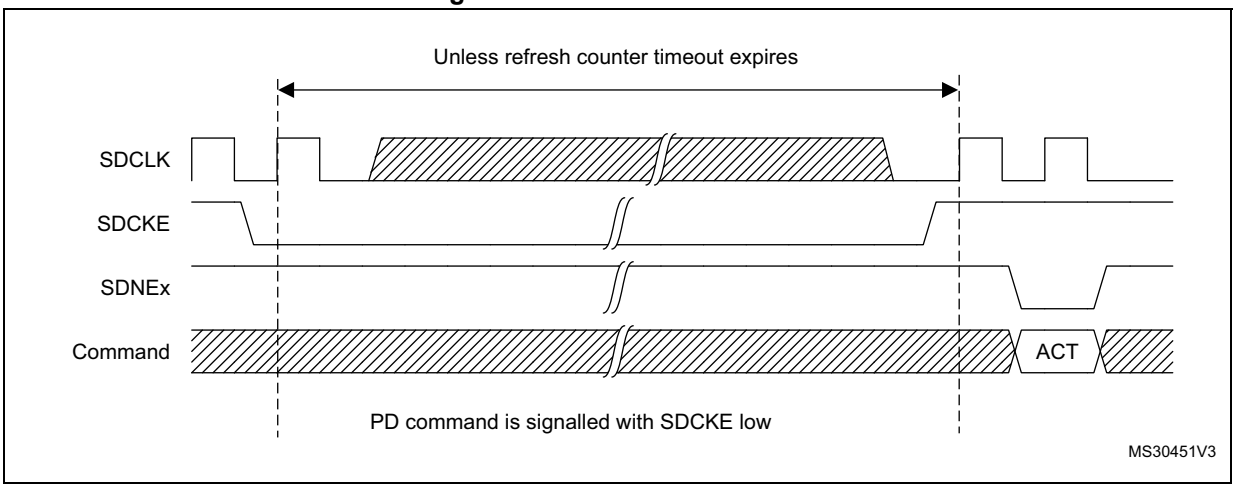


Power-down mode

SDRAM devices can be forced into Power-down by software according to the MODE[2:0], DS1, DS2 bits of the FMC_SDCMR register.
SDRAM devices exit Power-down either by a normal mode command from the FMC_SDCMR register (according to DS1 and DS2 bits) or upon the arrival of an AXI request (according to the device enabled through SDEN bit in the FMC_SDCRx).

Note: During Power-down, any command other than normal mode configured in the FMC_SDCMR register, is ignored by SDRAM controller.

Figure 192. Power-down mode

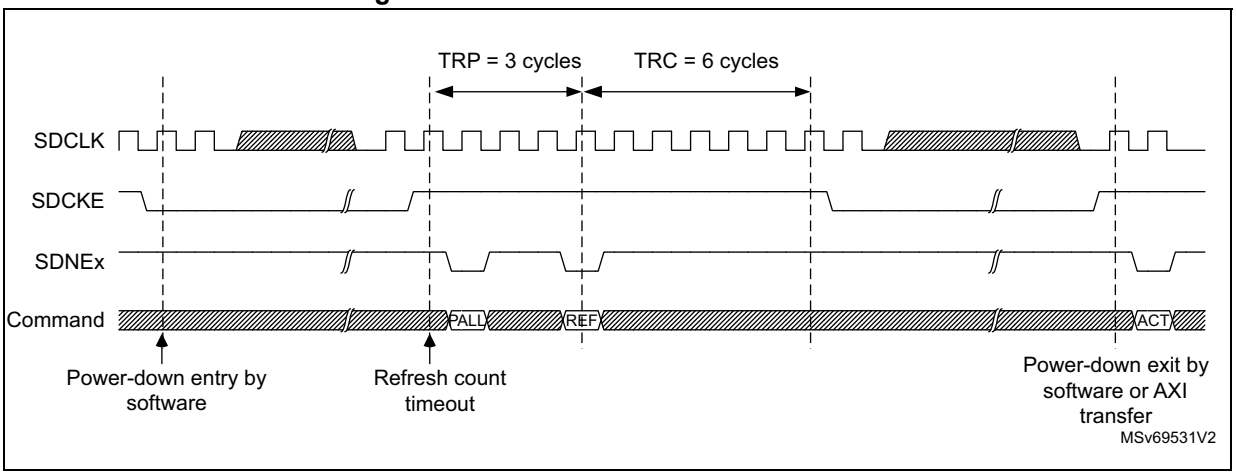


During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the Auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

Figure 193. Power-down with Auto-refresh



Clock stop during low-power modes

If all SDRAM devices are simultaneously in low-power mode, the controller stops the SDRAM clock generation. The clock is resumed when at least one device exits from low-power mode.

27.10.5 SDRAM controller registers

SDRAM control registers for SDRAM device 1 (FMC_SDCR1)

Address offset: 0x140

Reset value: 0x0000 02D0

This register contains the control parameters for SDRAM device 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDINIT	SDEN
														rw	rw

Res.	RPIPE[1:0]		Res.	SDCLK[1:0]		WP	CAS[1:0]		NB	MWID[1:0]		NR[1:0]		NC[1:0]	
	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SDINIT:** SDRAM device initialization
1: Initialization is complete and the device is ready to be accessed
0: Initialization is not complete, the AXI accesses are rejected and an AXI slave error is generated.

Bit 16 **SDEN**: SDRAM device enable
1: SDRAM device enabled
0: SDRAM disabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **RPIPE[1:0]:** Read pipe

These bits define the delay, in fmc_ker_ck clock cycles, for reading data after CAS latency, and for both SDRAM devices.

00: No fmc_ker_ck clock cycle delay (default value)

01: One fmc_ker_ck clock cycle delay

10: Two fmc_ker_ck clock cycle delay

11: Reserved.

Bit 12 Reserved, must be kept at reset value.

Bits 11:10 **SDCLK[1:0]**: SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM devices and allow disabling the clock before changing the frequency.

00: SDCLK clock disabled

01: SDCLK period = 1 * fmc_ker_ck period

10: SDCLK period = 2 * fmc_ker_ck periods

11: SDCLK period = 3 * fmc_ker_ck periods

Note: SDRAM devices must be in Self-refresh mode before a clock frequency change, then all timing parameters are reprogrammed through FMC_SDTR, FMC SDCRx, FMC_SDCMR and load mode register according to CAS latency.

Bit 9 **WP**: Write protection

This bit enables write mode access to the SDRAM bank.

0: Write accesses allowed

1: Write accesses ignored

Bits 8:7 **CAS[1:0]:** CAS Latency

These bits set the SDRAM CAS latency in number of memory clock cycles

00: Reserved.

01: 1 cycle

10: 2 cycles

11: 3 cycles

Note: CAS latency must have the same value for both devices as they operate on the same frequency.

Bit 6 **NB:** Number of banks

This bit sets the number of SDRAM banks.

0: Two banks

1: Four banks

Bits 5:4 **MWID[1:0]:** Memory data bus width.
These bits define the memory device width.
00: 8 bits
01: 16 bits
10: 32 bits
11: Reserved.

Bits 3:2 **NR[1:0]:** Number of row address bits
These bits define the number of bits of a row address.
00: 11 bit
01: 12 bits
10: 13 bits
11: Reserved.

Bits 1:0 **NC[1:0]:** Number of column address bits
These bits define the number of bits of a column address.
00: 8 bits
01: 9 bits
10: 10 bits
11: 11 bits.

SDRAM control registers for SDRAM device 2 (FMC_SDCR2)

Address offset: 0x144

Reset value: 0x0000 02D0

This register contains the control parameters for SDRAM device 2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SDINIT:** SDRAM device initialization
1: Initialization is complete and the device is ready to be accessed
0: Initialization is not complete, the AXI accesses are rejected and an AXI slave error is generated.

Bit 16 **SDEN**: SDRAM device enable
1: SDRAM device enabled
0: SDRAM disabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **WP**: Write protection
This bit enables write mode access to the SDRAM bank.
0: Write accesses allowed
1: Write accesses ignored

Bits 8:7 **CAS[1:0]:** CAS Latency
These bits set the SDRAM CAS latency in number of memory clock cycles
00: Reserved.
01: 1 cycle
10: 2 cycles
11: 3 cycles
Note: CAS latency must have the same value for both devices as they operate on the same frequency.

Bit 6 **NB:** Number of banks
This bit sets the number of SDRAM banks.
0: Two banks
1: Four banks

Bits 5:4 **MWID[1:0]:** Memory data bus width.
These bits define the memory device width.
00: 8 bits
01: 16 bits
10: 32 bits
11: Reserved.

Bits 3:2 **NR[1:0]:** Number of row address bits
These bits define the number of bits of a row address.
00: 11 bit
01: 12 bits
10: 13 bits
11: Reserved.

Bits 1:0 **NC[1:0]:** Number of column address bits
These bits define the number of bits of a column address.
00: 8 bits
01: 9 bits
10: 10 bits
11: 11 bits.

SDRAM timing register (FMC_SDTR)

Address offset: 0x148

Reset value: 0x0FFF FFFF

This register contains the timing parameters. It is common to both SDRAM banks.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TRCD[3:0]				TRP[3:0]				TWR[3:0]			
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRC[3:0]				TRAS[3:0]				TXSR[3:0]				TMRD[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TRCD[3:0]:** Row to column delay

This bitfield defines the number of SDRAM clock cycles between an Active command and a Read or Write command. Its value must meet the SDRAM TRCD timing requirement.

0000: 1 cycle.

0001: 2 cycles

....

1111: 16 cycles

Bits 23:20 **TRP[3:0]:** Row precharge delay

This bitfield defines the number of SDRAM clock cycles between a Precharge command and an Active or Refresh command. Its value must meet the SDRAM TRP timing requirement.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 19:16 **TWR[3:0]:** Recovery delay

This bitfield defines the number of SDRAM clock cycles between a Write command and a Precharge command. Its value must meet the SDRAM TWR timing requirement.

These bits define the delay between a Write and a Precharge command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: The SDRAM write recovery (t_{WR}) can be determined as the highest of the three timings requirements, TWR, TRAS – TRCD and TRC – TRP – TRCD.

Bits 15:12 **TRC[3:0]:** Row cycle delay

This bitfield defines the number of SDRAM clock cycles between two Active commands or between two Refresh commands. Its value must meet both SDRAM TRC and TRFC timing requirements.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 11:8 **TRAS[3:0]:** Self-refresh time

This bitfield defines the number of SDRAM clock cycles between an Active command and a Precharge command. Its value must meet the SDRAM TRAS timing requirement.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 7:4 **TXSR[3:0]:** Exit self-refresh delay

This bitfield defines the number of SDRAM clock cycles between a Self-refresh exit and an Active command. Its value must meet the SDRAM TXSR timing requirement.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 3:0 **TMRD[3:0]:** Load mode register to active

This bitfield defines the number of SDRAM clock cycles between a load mode register command and an Active or Refresh command. Its value must meet the SDRAM TMRD timing requirement.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

SDRAM command mode register (FMC_SDCMR)

Address offset: 0x150

Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE[2:0] bitfield is written, the command is issued only to one or to both SDRAM banks according to DS1 and DS2 command bits. This register is the same for both SDRAM banks.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MRD[13:7]						
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MRD[6:0]							NRFS[3:0]				DS1	DS2	MODE[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w	w	w	w	w

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:9 **MRD[13:0]:** Mode register definition

The two MSBs, bits 13 and 12, are applied to BA[1:0] to support mode and extended mode register selection by LMR command.

The LSBs, bits 11 to 0, are applied to A[11:0] and define the value programmed by LMR command.

Bits 8:5 **NRFS[3:0]:** Number of Refresh commands

These bits define the number of consecutive Refresh commands.

0000: 1 Refresh cycle

0001: 2 Refresh cycles

....

1110: 15 Refresh cycles

1111: 16 Refresh cycles

Bit 4 **DS1:** Command targeting SDRAM device 1

0: Command not issued to SDRAM device 1

1: Command issued to SDRAM device 1

Bit 3 **DS2:** Command targeting SDRAM device 2

0: Command not issued to SDRAM device 2

1: Command issued to SDRAM device 2

Bits 2:0 **MODE[2:0]:** Command mode

These bits define the command issued to the SDRAM device.

000: Normal mode command (NRM)

010: Precharge all banks command (PALL)

011: Refresh command (REF)

100: Load mode register command (LMR)

101: Self-refresh command (SR)

110: Power-down command (PD)

Others: Reserved, must not be used.

Note: When a command is issued, at least one DSx must be set otherwise the command is ignored.

If two SDRAM devices are used, the Refresh and PALL command must be issued simultaneously to the two devices with DS1 and DS2 bits set.

If only one SDRAM device is used and a command is issued with the associated DSx bit set, the other DSx bit of the unused bank must be kept to 0.

When a device has been put in low-power mode following either a SR or a PD command, only a NRM command can exit it from this mode.

SDRAM refresh timer register (FMC_SDRTR)

Address offset: 0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the Refresh commands to meet the SDRAM refresh rate.

Example

$$\text{Refresh rate} = 64\ \text{ms} / (8196\text{rows}) = 7.81\mu\text{s}$$

where 64 ms is the SDRAM refresh period.

The refresh rate must be increased to obtain a safe margin.

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a Refresh command when zero is reached. The RFSCNT[12:0] value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is 0, no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, RFSCNT[12:0] bitfield is reloaded into the counter.

This register is common to SDRAM bank 1 and bank 2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	REIE	RFSCNT[12:0]													CRE
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **REIE:** RES Interrupt Enable
0: Interrupt is disabled
1: An Interrupt is generated if RE = 1

Bits 13:1 **RFSCNT[12:0]:** Refresh Timer Count
This bitfield defines the number of SDRAM clock cycles between Refresh commands. Its value must meet the SDRAM Refresh timing requirement. For example an 8192-cycle refresh every 64 ms requires a 7.8 µs interval between Refresh commands. It is recommended to round down RFSCNT[12:0] to optimize the refresh rate.

Bit 0 **CRE:** Clear Refresh error flag
This bit is used to clear the Refresh Error Flag (RE) in the Status Register.
0: no effect
1: Refresh Error flag is cleared

Note: The programmed RFSCNT[12:0] value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles.

SDRAM status register (FMC_SDSR)

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDOK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODES2[1:0]		MODES1[1:0]		RE
r											r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **CMDOK:** Previous command status

This bit defines the status of the previous command.

0: Command not complete

1: Command complete in the SDRAM clock domain

Note: In case of command chaining, CMDOK must be polled between commands, to insure correct command chaining.

Bits 14:5 Reserved, must be kept at reset value.

Bits 4:3 **MODES2[1:0]:** Status mode for SDRAM device 2

This bit defines the status mode of SDRAM device 2.

00: Normal mode, devices are not in Self-refresh or power-down

01: Self-refresh

10: Power-down

Bits 2:1 **MODES1[1:0]:** Status mode for SDRAM device 1

This bit defines the status mode of SDRAM device 1.

00: Normal mode, devices are not in Self-refresh or power-down

01: Self-refresh

10: Power-down

Bit 0 **RE:** Refresh error flag

0: No refresh error has been detected

1: A refresh error has been detected

An interrupt is generated if REIE = 1 and RE = 1

28 Extended-SPI interface (XSPI)

28.1 Introduction

The XSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the XSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The XSPI supports the following protocols with associated frame formats:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

28.2 XSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- Support for single, dual, quad, and octal communication
- Dual-memory configuration, where 8 bits can be sent/received simultaneously by accessing two quad or two octal memories in parallel
- XSPI mode accessing a single 16-bit memory
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AXI acceptance 2: acceptance is offered based on a read transaction followed by a second write or read request (acknowledged on the bus), while the first one is being processed.
- Dual chip select support (NCS1 and NCS2)
- Extended external memory support: if two same size external memories (extmem1 and extmem2) are connected to the same I/O port, contiguously in the memory map and

driven by a single XSPI. This XSPI automatically switches CS to extmem1 or extmem2, according to the address on interconnect side.

28.3 XSPI implementation

Table 195. XSPI implementation

Feature	XSPI1/2/3
HyperBus standard compliant	X
Xccela standard compliant	X
XSPI (JDES251C) standard compliant	X
AMBA® AXI compliant data interface	X

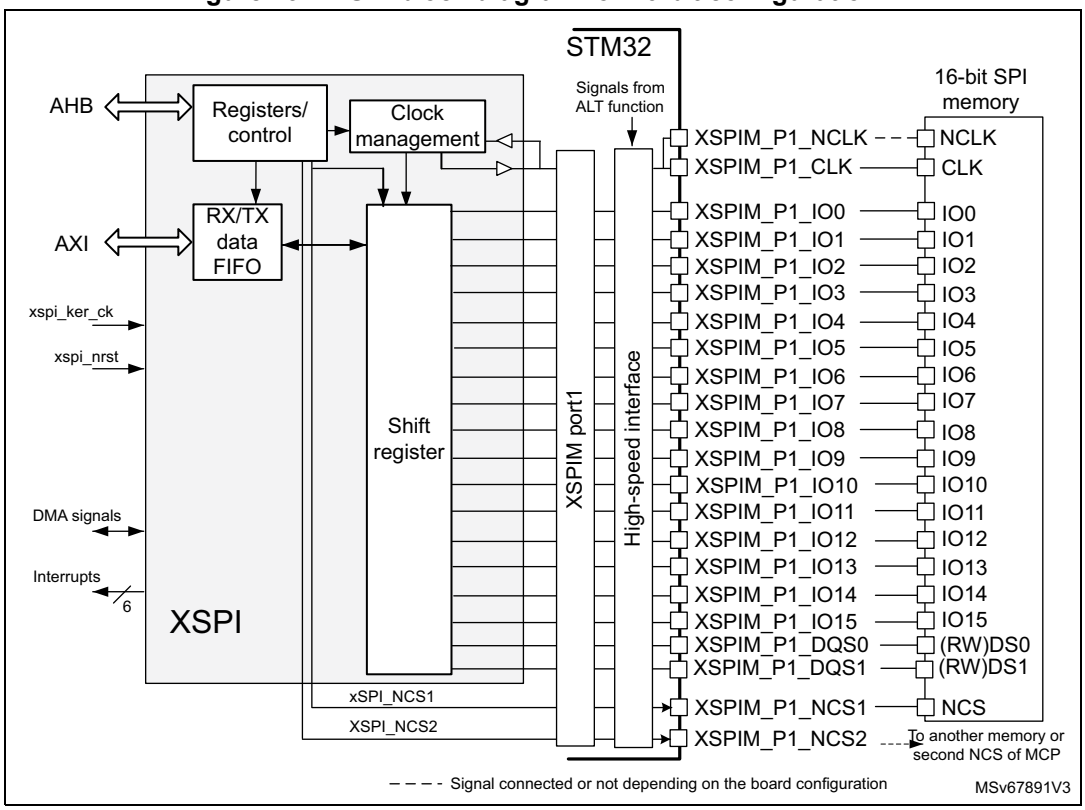
28.4 XSPI functional description

28.4.1 XSPI block diagram

The block diagrams provided below correspond to a single XSPI connected to the I/O ports.

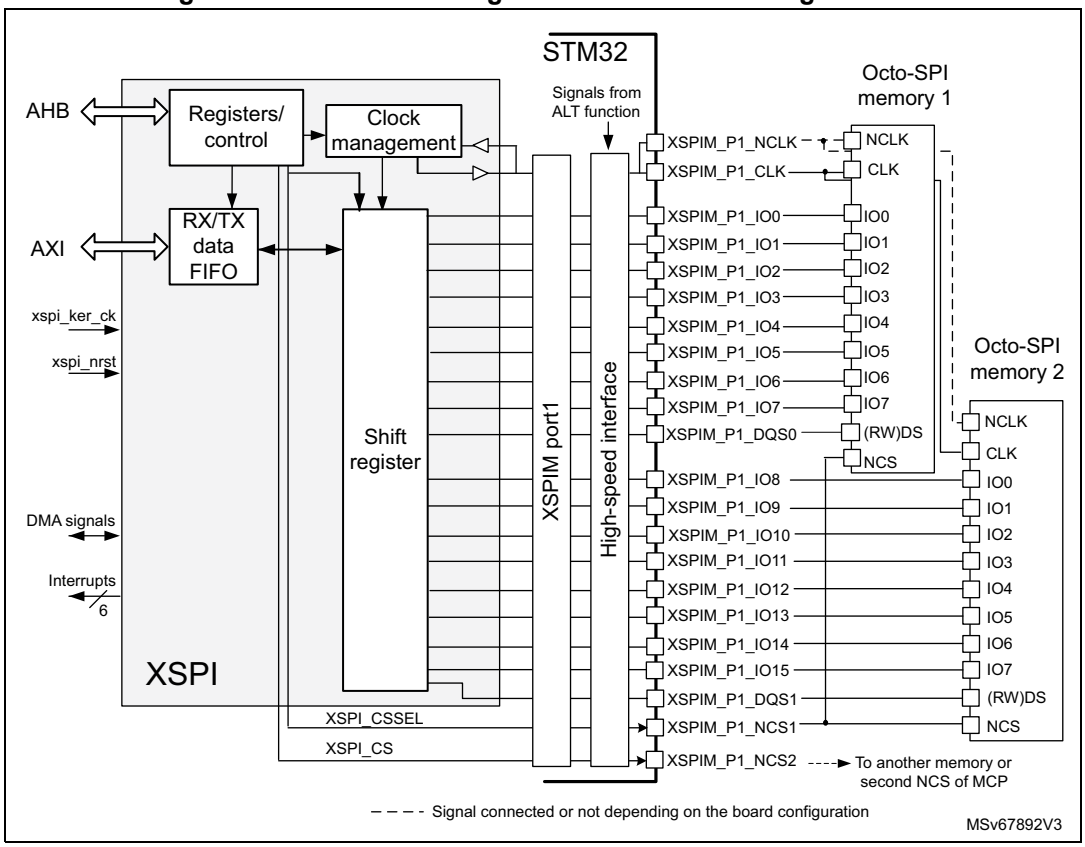
In case several XSPIs are connected to the I/O ports through the XSPIM I/O manager, refer to *Section 29: XSPI I/O manager (XSPIM)* for more details.

Figure 194. XSPI block diagram for 16-bit configuration(1)



1. The configuration depends on the package (see the datasheet for more details).

Figure 195. XSPI block diagram for dual-octal configuration(1)



1. The configuration depends on the package (see the datasheet for more details).

Figure 196. XSPI block diagram for octal configuration

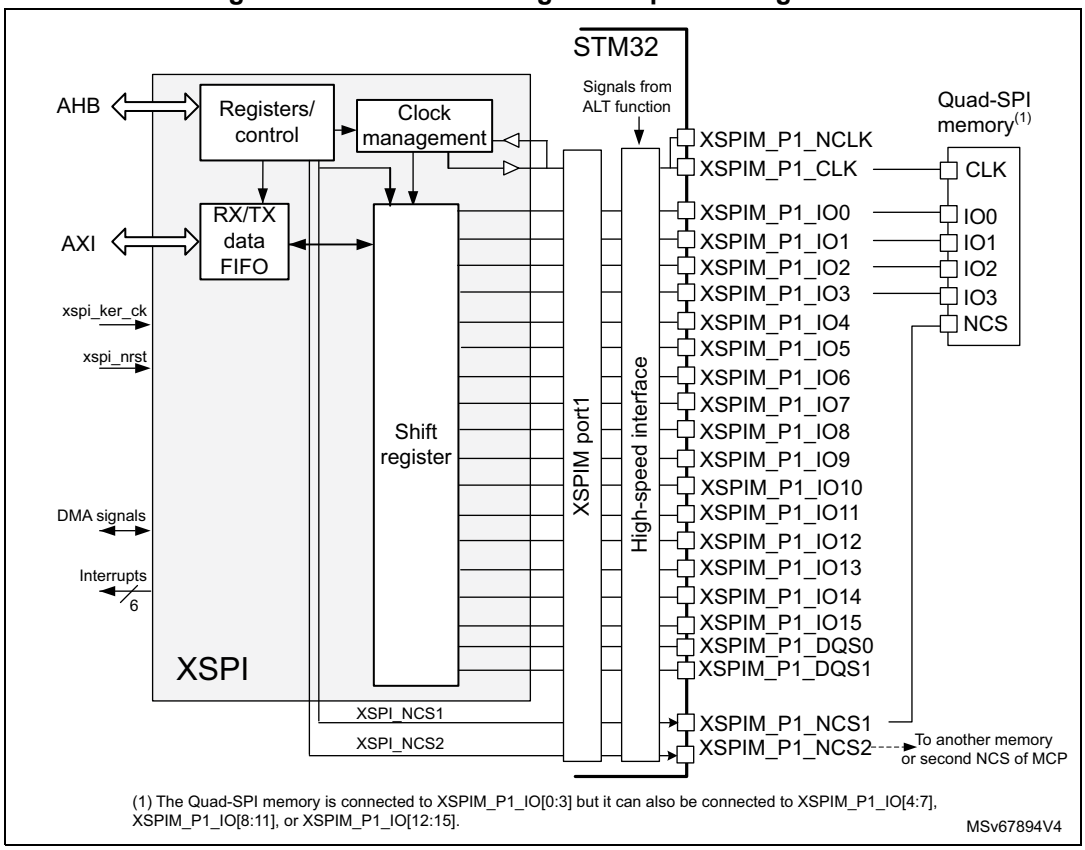

Figure 198. XSPI block diagram for dual-quad configuration

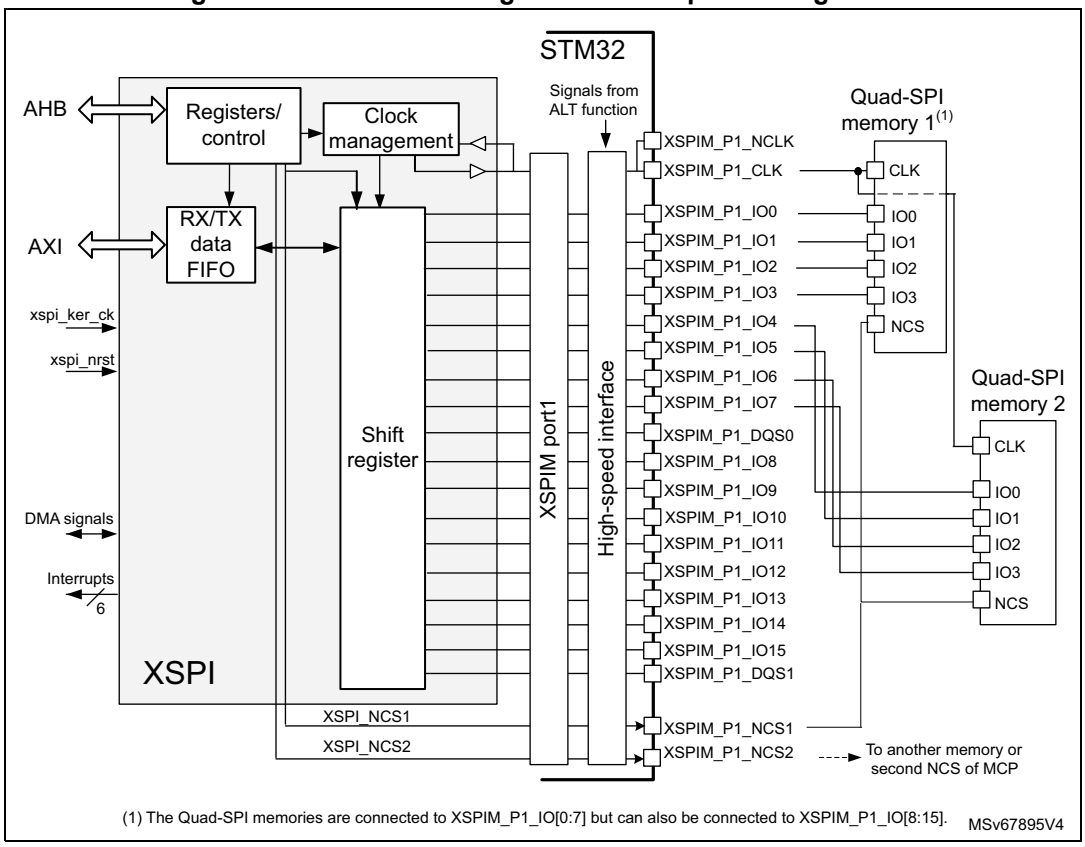


28.4.2 XSPI pins and internal signals

Table 196. XSPI input/output pins(1)

Pin name	Type	Description
XSPIM_Px_NCLK	Output	XSPI inverted clock to support 1.8 V HyperBus protocol.
XSPIM_Px_CLK	Output	XSPI clock
XSPIM_Px_IOn (n = 0 to 15)	Input/output	XSPI data pins
XSPIM_Px_NCS1,2	Output	Chip select for the memory
XSPIM_Px_DQS0,1	Input/output	Data strobe/write mask signal from/to the memory

1. x = 1 to 2.

Caution: Use the same configuration (output speed, HSLV) for all XSPI input/output pins to avoid any data corruption.

Table 197. XSPI internal signals

Signal name	Type	Description
xspi_hclk	Input	XSPI AHB clock
xspi_aclk	Input	XSPI AXI clock

Table 197. XSPI internal signals

Signal name	Type	Description
xspi_ker_ck	Input	XSPI kernel clock
xspi_dma	N/A	DMA request signal
xspi_it	Output	Global interrupt line (see *Table 201* for the multiple sources of interrupt)

28.4.3 Clock constraints

The XSPI AXI clock (xspi_aclk) has to be greater or equal than the XSPI kernel clock (xspi_ker_ck).

28.4.4 XSPI interface to memory modes

The XSPI supports the following protocols:

- regular-command protocol
- HyperBus protocol

The XSPI uses from 6 to 21 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select (in the following sections, unless otherwise specified, NCS applies for NCS1 or NCS2. Only one of these two signals is active at a given moment in time).
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS0, DQS1: data strobe used only in regular-command protocol
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus used as possible remap for quad-SPI mode
- IO[15:8]:
  - data bus MSB used in dual-quad, dual-octal and 16-bit configurations
  - data bus used as possible remap for octal-SPI mode
  - IO[15:12] and IO[11:8] can also be used as possible remap for quad-SPI mode

28.4.5 XSPI regular-command protocol

When in regular-command protocol, the XSPI communicates with the external device using commands. Each command can include the following phases:

- instruction phase
- address phase
- alternate-byte phase
- dummy-cycle phase
- data phase

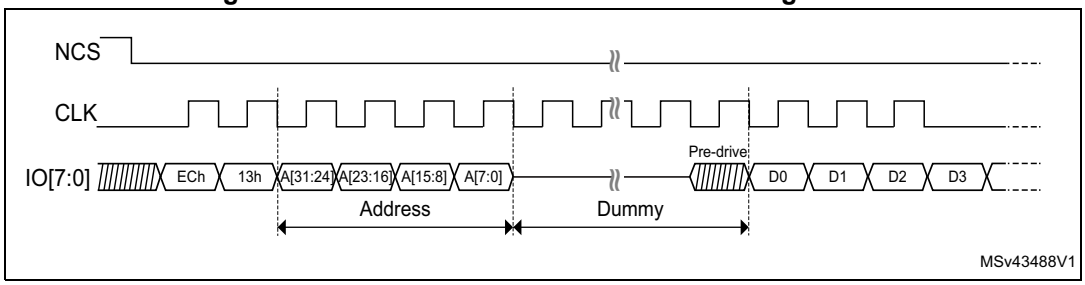
Only the data phase uses 16 bits. Instruction, address, and alternate phases use only the eight LSB of the bus as for octal configuration.

Any of these phases can be configured to be skipped, but single-phase commands supported are only those with instruction phase.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operation are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 199. SDR read command in 16-bit configuration



1. Data (such as D0, D1, D2) are sent in 16-bit configuration mode over IO[15:0]. Only the command and address are sent over IO[7:0] as for octal mode.

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of XSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of XSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using IMODE[2:0] of XSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in XSPI_CCR.

When IMODE[2:0] = 000 in XSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

When in memory-mapped mode, the instruction used for the write operation is specified in XSPI_WIR and the instruction format is specified in XSPI_WCCR. The instruction used for the read operation and the instruction format are specified in XSPI_IR and XSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of XSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of XSPI_AR. In memory-mapped mode, the address is given directly via the AXI (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using ADMODE[2:0] of XSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in XSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in XSPI_WCCR. The address format for the read operation is specified in XSPI_CCR.

Warning: Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value.So the software needs to multiply the address by two when accessing the memory registers.

Alternate-byte phase

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of XSPI_CCR. The bytes to be sent are specified in XSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using ABMODE[2:0] of XSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of XSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

Only a single nibble may need to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011), and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in XSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0], while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in XSPI_WABR, and the alternate byte format is specified in XSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in XSPI_ABR and XSPI_CCR.

Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of XSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-, quad-, octal-, or 16-bit SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in XSPI_WTCR. The dummy cycles for the read operation are specified in XSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in XSPI_DLR. In this mode, the data to be sent to the external device must be written to XSPI_DR. In indirect-read mode, the data received from the external device is obtained by reading XSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in XSPI_DLR, and the data received from the external device can be obtained by reading XSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AXI to the Cortex core or to a DMA.

The data phase can send/receive:

- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)
- 16 bits at a time (over IO0 to IO15 in 16-bit SPI mode)

This can be configured using DMODE[2:0] of XSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of XSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.

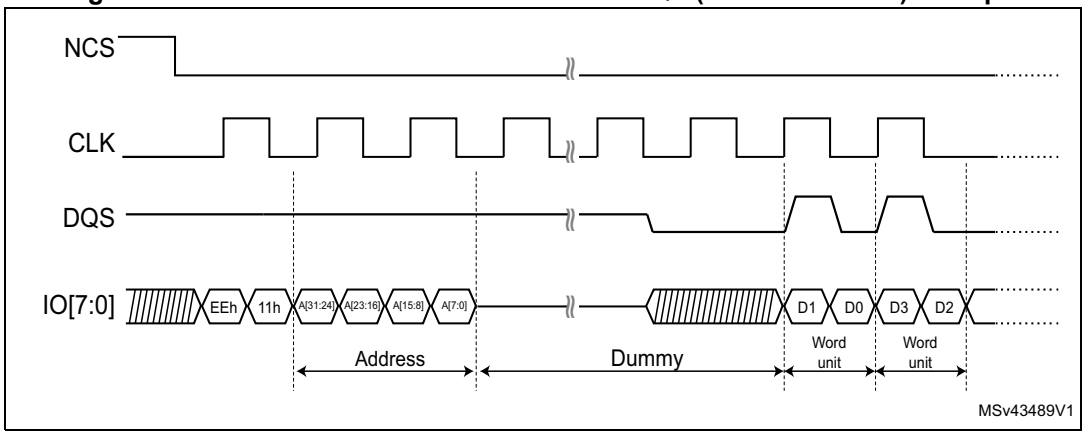
In memory-mapped mode, the data format for the write operation is specified in XSPI_WCCR. The data format for the read operation is specified in XSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE of XSPI_CCR.

Figure 200. DTR read in octal-SPI mode with DQS (Macronix mode) example



28.4.6 XSPI regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (Single-SPI Output) (whose I/Os are shared with IO0). The data received from the external device arrives via SI (Single-SPI Input) (whose I/Os are shared with IO1).

Compared to the SPI legacy mode, I0/SO and I1/SI are respectively equivalent to MOSI and MISO, having the XSPI generating the clock.

The different phases can each be configured separately to use this single-bit mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO15 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO15 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO15 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

XSPI mode

In XSPI mode, the 16 bits are sent/received simultaneously over the IO[0:15] signals during the data phase.

The following phases must be configured separately to use the XSPI mode:

1. Set to 100 the IMODE, ADMODE, and ABMODE fields (in XSPI_CCR and XSPI_WCCR).
2. Set to 101 the DMODE fields (in XSPI_CCR and XSPI_WCCR).

In each phase that is configured in XSPI mode, IO[0:15] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 101, IO[0:15] are all high-impedance.

IO[8:15] are used only in XSPI mode. If none of the phases are configured to use this mode, then the pins corresponding to IO[8:15] can be used for other functions, even while the XSPI is active.

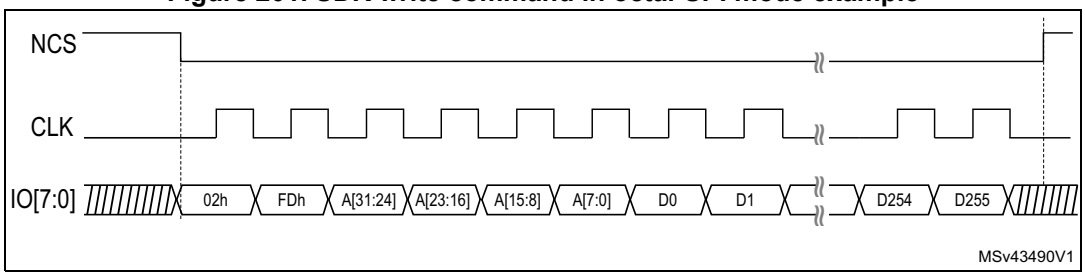
Single-data rate (SDR) mode

By default, all the phases operate in single-data rate (SDR) mode.

In SDR mode, when the XSPI drives the IO0/SO and IO1 to IO15 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the XSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in XSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

Figure 201. SDR write command in octal-SPI mode example



Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in XSPI_CCR.

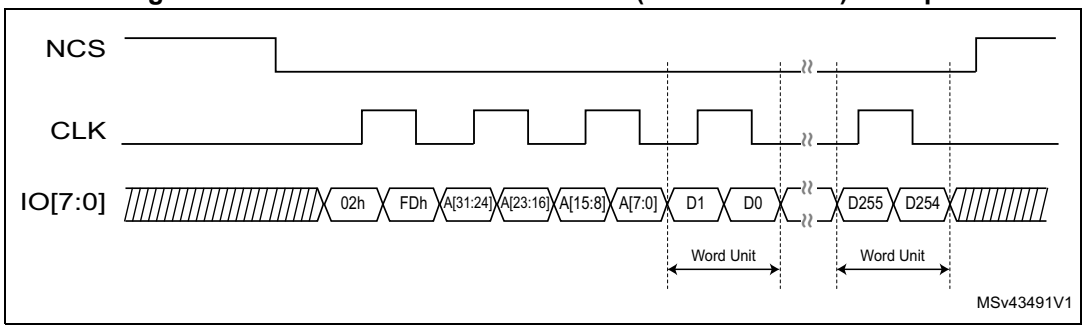
In memory-mapped mode, the DTR mode for each phase of the write operations is specified in XSPI_WCCR. The DTR mode for each phase of the read operations is specified in XSPI_CCR.

In DTR mode, when the XSPI drives the IO0/SO and IO1to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

In DTR mode, when the XSPI drives the IO0 to IO15 signals in the data phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the XSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in XSPI_CCR, the software must clear SSHIFT in XSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

Figure 202. DTR write in octal-SPI mode (Macronix mode) example



Dual-quad configuration

When DMM = 1 in XSPI_CR, the XSPI is in dual-memory configuration: if DMODE = 011, two external quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either SDR or DTR mode.

The device size, as specified in DEVSIZE[4:0] of XSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the XSPI gives for address X is the byte at the address X/2 of device A, and the byte that the XSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 2 bytes (16 bits), and the XSPI receives one byte from each device.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in XSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

Dual-octal configuration

When DMM = 1 in XSPI_CR, the XSPI is in dual-memory configuration: when DMODE = 100, two external octal-SPI devices (device A and device B) are used in order to receive 32 bits in DTR mode every cycle, effectively doubling the throughput as well as the capacity.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO7 signals.

The dual-octal configuration can be used in DTR mode exclusively in conjunction with the single-SPI, dual-SPI, quad-SPI and octal-SPI modes.

The device size, as specified in DEVSIZE[4:0] of XSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the XSPI gives for address X is the byte at the address X/2 of device A, and the byte that the XSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-octal DTR mode, twice as many bytes must be read compared to the same read in regular DTR mode: if each device gives twice eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 4 bytes. The LSB is the LSB of device A, and the third byte is the LSB of device B.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-octal DTR mode. In such case, the order of retrieved status bits is as follows:

- first byte: LSB of device A
- second byte: second byte of device A
- third byte: LSB of device B
- fourth byte: second byte of device B

In indirect mode using DTR mode, a number of bytes multiple of four must always be accessed in XSPI mode. For this reason, bit 0 and bit 1 of the DL[31:0] bitfield in XSPI_DLR are stuck at 0 when DMODE[2:0] = 101.

In dual-octal configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

Note: The variable latency is not supported in dual-octal configuration.

XSPI mode

When DMODE[2:0] = 0b101 in XSPI_CCR, the XSPI is in single 16-bit-memory configuration: when DMODE[2:0] = 0b101 with DMM value ignored in that case. A single external XSPI device is used in order to send/receive 16 bits (or 32 bits in DTR mode) every cycle, effectively doubling the throughput.

The device provides/receives two separate DQS signals: DQS0 for the eight LSBs and DQS1 for the eight MSBs.

The XSPI mode can be used in conjunction with the single-SPI, dual-SPI, quad-SPI and octal-SPI modes, as well as with either the SDR or the DTR mode.

The device size, as specified in DEVSIZE[4:0] of XSPI_DCR1, must reflect the total external device capacity.

In SDR mode, a number of bytes multiple of two must always be accessed in XSPI mode. For this reason, bit 0 of DL[31:0] in XSPI_DLR is stuck at 0 when DMODE = 101.

In DTR mode, a number of bytes multiple of four must always be accessed in XSPI mode. For this reason, bit 0 and 1 of DL[31:0] in XSPI_DLR are stuck at 0 when DMODE = 101.

28.4.7 HyperBus protocol

The XSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins in 8-bit data mode, or 19 to 20 pins in 16-bit data mode depending on the operating voltage:

- IO[7:0] as bidirectional data bus for 8-bit data mode and IO[15:0] as bidirectional data bus for 16-bit data mode
- DQS for read and write data strobe and latency insertion
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)

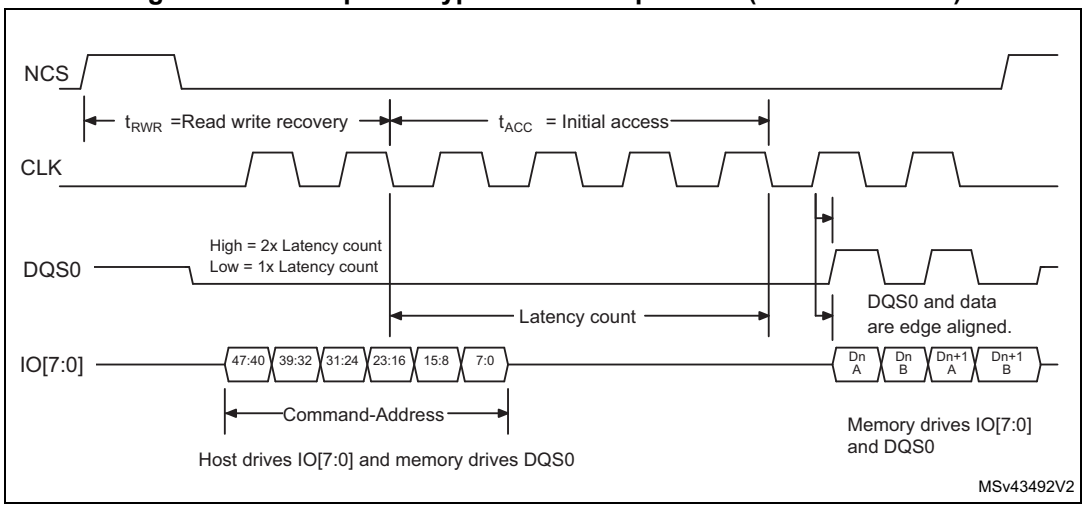
The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- command/address phase
- data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 203. Example of HyperBus read operation (8-bit data mode)



The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the XSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 198. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write
46	Address space	Indicates if the transaction accesses the memory or the register space
45	Burst type	Indicates if the burst is linear or wrapped
44-16	Row and upper column address	Selects the row and the upper column addresses
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page

The address space is configured through the memory type MTYP[2:0] of XSPI_DCR1.

The total size of the device must be considered through DEVSIZE[4:0] of XSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Warning: Some memory specifications consider that each address corresponds to a 16-bit value. The XSPI considers that each address corresponds to an 8-bit value. So, the software needs to multiple the address by two when accessing the memory registers.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined by TRWR[7:0] in XSPI_HLCR)
- t_{ACC}: access time for the device (defined in TACC[7:0] of XSPI_HLCR) according to the memory latency

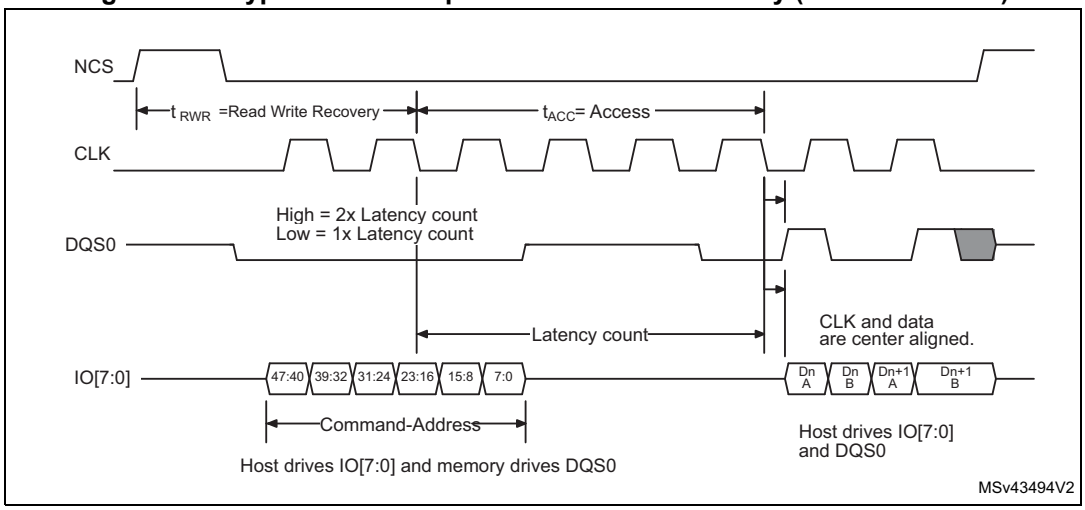
During the read operation, the DQS0/1 is used by the device, in two ways (see *Figure 203*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the DQS0/1 is used:

- by the device, during the command/address phase, to request an additional latency.
- by the XSPI, during the data phase, for write data masking.

Figure 204. HyperBus write operation with initial latency (8-bit data mode)



Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), DQS0/1 must be tied to one during one of the DQS signals, during the command/address phase.

An additional t_{ACC} duration is added by the XSPI to meet the device request.

Figure 205. HyperBus read operation with additional latency (8-bit data mode)

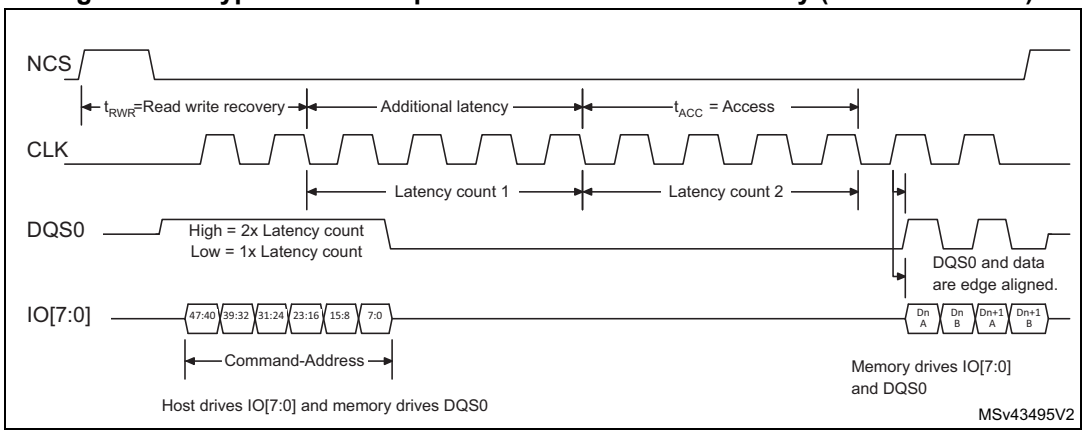


Figure 206. HyperBus write operation with additional latency (8-bit data mode)

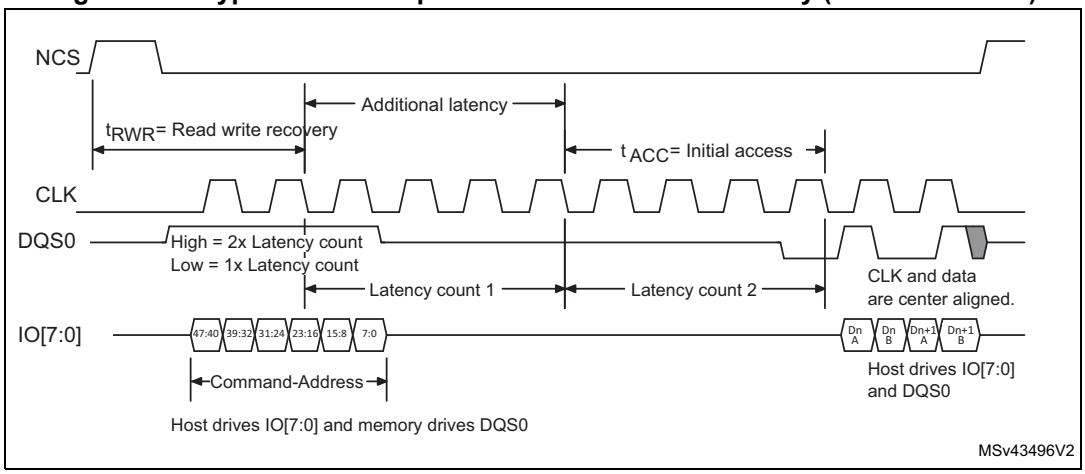


Fixed latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

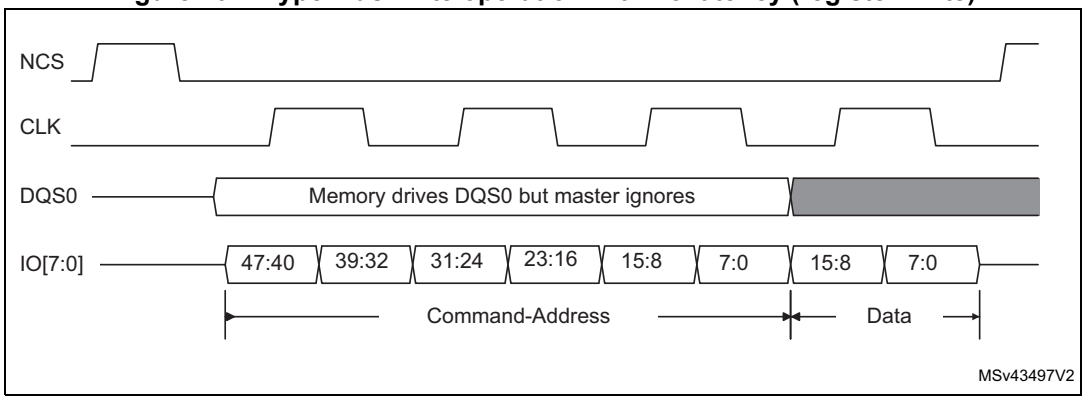
The latency can be forced to 2 x t_{ACC} by setting LM of XSPI_HLCR.

In this XSPI latency mode, the state of the DQS signal is not taken into account by the XSPI and an additional latency is always added leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in XSPI_HLCR.

Figure 207. HyperBus write operation with no latency (register write)

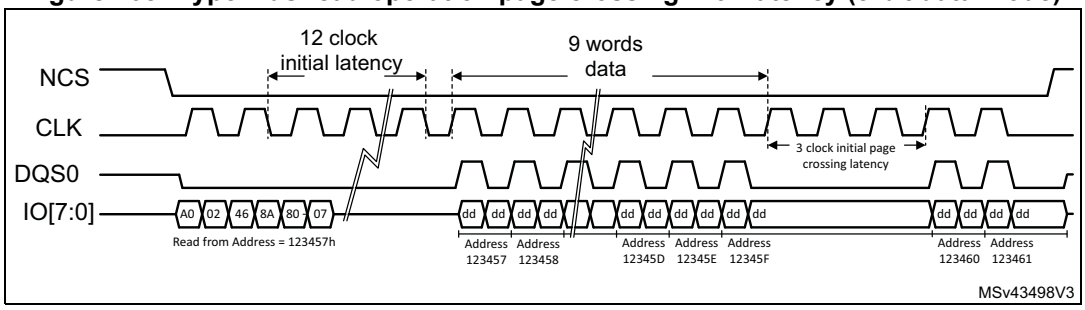


Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 208. HyperBus read operation page crossing with latency (8-bit data mode)



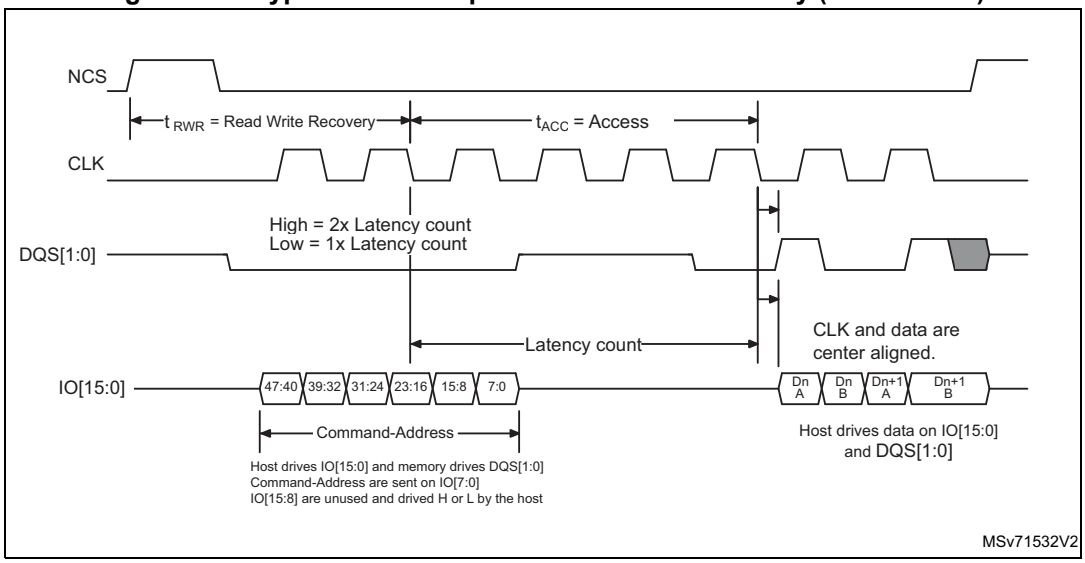
16-bit data transfer using HyperBus

In HyperBus protocol, the XSPI supports a dual-octal configuration (16-bit data transfers) when DMM = 1 in XSPI_CR: one octal HyperBus memory is connected to IO0-IO7 and another is connected to IO8-IO15. These memories share all signals except DQS that are dedicated.

For 16-bit data transfers, DMODE[2:0] must be to equal to 101. Any other value in DMODE[2:0] correspond to 8-bit data transfer (quad-, dual-, and single-bit data transfer do not exist in HyperBus protocol). Command-address phase is always using 8 bits in HyperBus protocol (from IO8-IO15). Only the data is on 16-bit for write or read operations accessing the memory space (from IO0-IO15) as shown for instance in *Figure 209*. For the memory register accesses, the data is on 8-bit (from IO0 to IO7, IO8 to IO15 being not used but driven by the controller) as shown in *Figure 207*.

The behavior of the interface at protocol-level is exactly the same as for HyperBus octal configuration, as described above, except that the variable latency is not supported in dual-octal HyperBus configuration. LM in XSPI_HLCR must be set.

Figure 209. HyperBus write operation with initial latency (16-bit mode)



28.4.8 Specific features

The XSPI supports some specific features, such as:

- wrap support
- NCS boundary and refresh
- communication regulation

Wrap support

The XSPI supports an hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in XSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 8 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated registers XSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated XSPI_WPxxx registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: Hybrid wrap requires that the nonwrapped registers (XSPI_CCR, XSPI_TCR, XSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the XSPI transactions:

- NCS boundary
- refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with is configured in CSBOUND[4:0] of XSPI_DCR3 and it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF, and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of XSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Communication regulation

The communication regulation feature is useful in case two or more XSPIs share access to the same I/O port through an I/O manager. This feature limits the maximum length of a transaction to the value programmed in MAXTRAN[7:0] of XSPI_DCR3.

If the number of clock cycles of XSPI1 for example reach the MAXTRAN + 1 value, and if the second interface connected to the I/O manager requests an access, the NCS is released, and a new transaction is issued. If the second interface connected to the I/O manager does not request an access, the transaction is not stopped, and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.

Note: The communication regulation feature cannot be used in write mode for the flash memory devices that require extra command to reenable the write operation after the NCS is active again.

If NCS boundary, refresh and communication regulation are enabled at the same time, the NCS is released on the first condition met.

Restarting after an interrupted transfer

When a read or write operation is interrupted by a timeout, the XSPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

28.4.9 XSPI operating modes introduction

The XSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

28.4.10 XSPI indirect mode

In indirect mode, the commands are started by writing to the XSPI registers, and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in XSPI_CR, the XSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to XSPI_DR.

When FMODE[1:0] = 01, the XSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading XSPI_DR.

In indirect mode, when the XSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The XSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in XSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the XSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in XSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the XSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in XSPI_SR and an interrupt is generated if TCIE = 1 in XSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in XSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the XSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in XSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in XSPI_AR

- if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in XSPI_DR

A write to XSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in XSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the XSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (XSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01)
- when a write is performed to DATA[31:0] (XSPI_DR) in indirect-write mode (when FMODE = 00)
- when a (dummy) write is performed to INSTRUCTION[31:0] (XSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01)

As soon as a transfer is started, the BUSY bit (XSPI_SR[5]) is automatically set.

FIFO and data management

Data in indirect mode pass through a 64-byte FIFO that is internal to the XSPI. FLEVEL in XSPI_SR indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in the XSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to the XSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

In indirect-read mode, when the FIFO becomes full, the XSPI temporarily stops reading bytes from the external device to avoid an overrun.

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

28.4.11 XSPI automatic status-polling mode

In automatic status-polling mode, the XSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in XSPI_SR goes high at this point, and stays high even between the periodic accesses.

The content of MASK[31:0] in XSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in XSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in XSPI_CR, the AND-match mode is activated: SMF is set in XSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in XSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in XSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the XSPI is disabled (EN = 0).

XSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in XSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

28.4.12 XSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256-Mbyte range, then an AXI error is given. The effect of this error depends on the AXI master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the XSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the XSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time. This prefetch feature can be disabled by setting the NOPREF bit in XSPI_DCR1. Disabling the prefetch can be beneficial for performance when the transfer requests are short and jumping frequently between non-consecutive addresses.

Since external devices tend to consume more power when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in XSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in XSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes. The indirect-write mode fulfills this operation.

However, if the application requires the use of the MCE for encryption (check MCE product availability), the memory-mapped write mode may be used to program encrypted data to external flash memory under the following conditions:

- Prefetch must be enabled.
- In block cipher mode, the CPU must write a complete 128-bit data block to prevent the MCE from initiating read-modify-write operations when only a few bytes need to be programmed. This precaution avoids incorrect programming operations. There are no specific constraints to respect if the MCE is used in stream cipher mode.
- Apply the abort sequence to exit memory-mapped mode when the data linked to the page has been written in the external memory buffers. The abort sequence triggers the start of the page programming.
- Switch to the automatic status-polling mode to monitor the completion of the page programing phase.
- Relaunch the write enable command in indirect mode, then switch back to the memory-mapped mode configuration to continue to program additional pages if any.

It is recommended to add a synchronization barrier between the end of the controller registers configuration and the first memory-mapped access to the external memory when the controller is configured in memory-mapped mode.

28.4.13 XSPI configuration introduction

The XSPI configuration is done in three steps:

1. XSPI system configuration
2. XSPI device configuration
3. XSPI mode configuration

28.4.14 XSPI system configuration

The XSPI is configured using XSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- DMA use with DMAEN

- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in XSPI_LPTR.

The DMA channel must not be enabled during the XSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and XSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

28.4.15 XSPI device configuration

The parameters related to the external device targeted are configured through XSPI_DCR1 and XSPI_DCR2.The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the device frequency with PRESCALER[7:0]

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{[\text{DEVSIZE}+1]}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

When the XSPI executes two commands, one immediately after the other, it raises the NCS high between the two commands, at least one CLK cycle by default.

If the external device requires more time between commands, CSHT[5:0] can be used to specify the minimum number of CLK cycles (up to 64) for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the Latency mode must be configured in XSPI_HLCR.

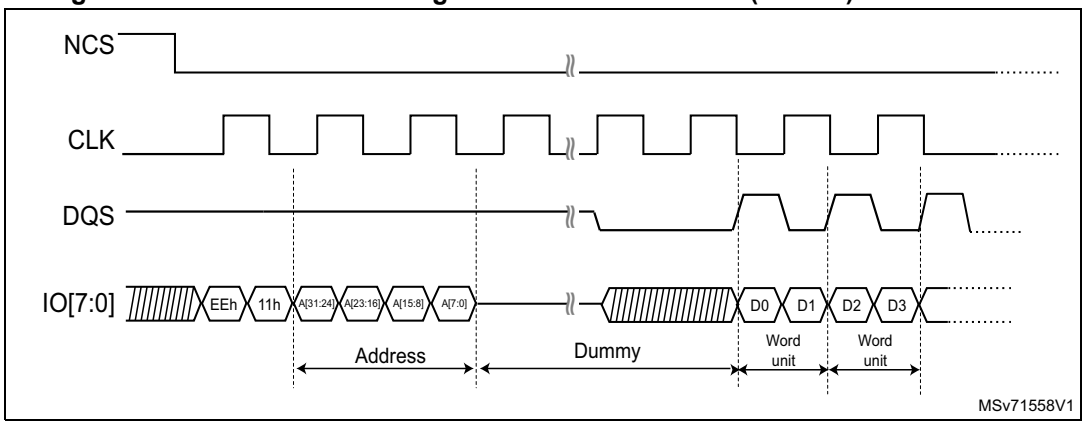
Memory types

External memory providers may present some architecture and slight data formatting differences between them. The bitfield MTYP[2:0] into the XSPI_CR register allows targeting the right controller configuration depending on the associated memory type selected in the application. This is the responsibility of the software developer to align the controller configuration to fit with the targeted memory type.

The memory types are grouped in a such way:

- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 000. For instance, Micron is using such data ordering. In this configuration, the DQS is sent with a polarity inverted respect to the clock polarity.

Figure 210. D0/D1 data ordering in octal-SPI DTR mode (Micron) - Read access



- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 001. For instance, Macronix is using this reverse data ordering in its Octaflash portfolio (this configuration is not adapted to its OctaRAM™ memories). DQS is keeping the same polarity as the clock when reading data from the memory. Refer to *Figure 200: DTR read in octal-SPI mode with DQS (Macronix mode) example*.
- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 011 with specific address phase built with row and column to fit with Macronix OctaRAM™ memories requirement (refer to *Table 199: OctaRAM command address bit assignment (based on 64 Mb OctaRAM)*. This is the controller which translates internally the targeted address provided by the software in row/column address formatting to sent to the memory. DQS is keeping the same polarity as the clock when reading data from the memory.

Figure 211. OctaRAM read operation with reverse data ordering D1/D0

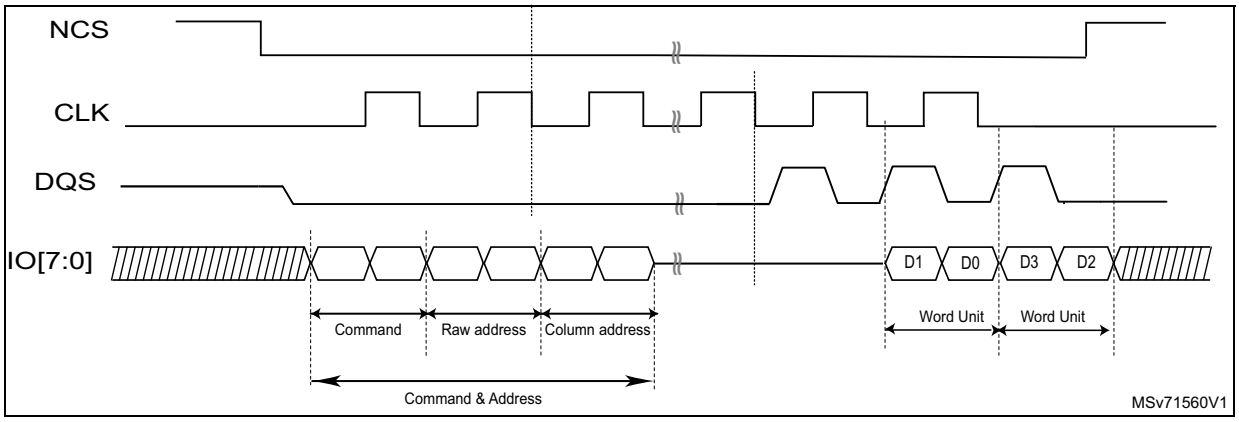


Table 199. OctaRAM command address bit assignment (based on 64 Mb(1) OctaRAM)

Clock	1st clock	2nd clock		3rd clock	
Function	Command	Row address		Column address	
SIO[7]	Command	Reserved	RA7	CA9	Reserved
SIO[6]		Reserved	RA6	CA8	Reserved
SIO[5]		Reserved	RA5	CA7	Reserved
SIO[4]		RA12	RA4	CA6	Reserved
SIO[3]		RA11	RA3	CA5	CA3
SIO[2]		RA10	RA2	CA4	CA2
SIO[1]		RA9	RA1	Reserved	CA1
SIO[0]		RA8	RA0	Reserved	CA0(2)

1. Example of 64 Mb OctaRAM address assignment:
Row Address [RA12:RA0]: 8K. Column address [CA9:CA0]: 1K. 64 Mb density = 8K x 1K x 8 bits
2. Column address A0 must be always 0.

- HyperBus memories need to be selected when targeted by the application. The configuration to set depends on the access type:
  - HyperBus memory mode: The protocol follows the HyperBus specification. MTYP[2:0] = 100 is the configuration to use to access the memory space.
  - HyperBus register mode (addressing register space): the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes must be used. The configuration to be set for this particular register space access is MTYP[2:0] = 101.
- The software must configure MTYP[2:0] = 110 when the memory targeted comes from APmemory and DMODE[2:0] = 101 to fit with the memory provider requirements concerning the address formating.
- Standard mode. It is the mode to use whenever the targeted memory is not corresponding to any others configurations described in this section. MTYP[2:0] = 010 for this standard mode.

28.4.16 XSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected and data can be read from the external device.

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the frame timing in XSPI_TCR.
3. Specify the frame format in XSPI_CCR.
4. Specify the instruction in XSPI_IR.

5. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
6. Specify the targeted address in XSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

If neither the address register (XSPI_AR) nor the data register (XSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as XSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through XSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in XSPI_DLR, it is ignored, and only 4 bytes are read.The periodicity is specified in XSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in XSPI_PSMKR, and can be ORed or ANDed with the value stored in XSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The XSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in XSPI_DR.

When the XSPI is used in automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in XSPI_PSMKR.
2. Specify the comparison value in XSPI_PSMAR.
3. Specify the read period in XSPI_PIR.
4. Specify a number of data bytes to read in XSPI_DLR.
5. Specify the frame timing in XSPI_TCR.
6. Specify the frame format in XSPI_CCR.
7. Specify the instruction in XSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
9. Specify the optional targeted address in XSPI_AR.

If the address register (XSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as XSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in XSPI_CR.

The programmed instruction and frame are sent when an AXI master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

When the XSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in XSPI_TCR for read operation.
2. Specify the frame format in XSPI_CCR for read operation.
3. Specify the instruction in XSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR for read operation.
5. Specify the frame timing in XSPI_WTCR for write operation.
6. Specify the frame format in XSPI_WCCR for write operation.
7. Specify the instruction in XSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_WABR for write operation.

All the configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 have no effect and is not signaled with an error response. On the first access, the XSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

Memory-mapped write operations are not supported without write strobe.

XSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the XSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in XSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

XSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it is shifted precisely by one quarter of the SPI clock cycle, for all frequencies above freq_min, to compensate the data propagation delay in the “high-speed interface” when the product embeds one.

28.4.17 XSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the targeted address in XSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through XSPI_DR.

Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AXI master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the XSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

28.4.18 XSPI error management

The following errors set the TEF flag in XSPI_SR and generates an interrupt if enabled (TEIE = 1 in XSPI_CR):

- in indirect or automatic status-polling mode, when a wrong address has been programmed in XSPI_AR (according to the device size defined by DEVSIZE[4:0]).

- in indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.

In memory-mapped mode, the XSPI generates an AXI slave error in the following situations:

- The memory-mapped mode is disabled and an AXI read or write request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing when the abort condition is present at the moment of transfer phases preceding the data phase (In incremental or wrap burst type modes). To avoid the error, refer to *Section 28.4.20: XSPI BUSY and ABORT*.
- The XSPI is disabled while a read or write burst is requested.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in XSPI_WCCR in octal DTR mode, in dual-memory configuration, in hyperbus mode or 16-bit mode.
- A read or write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means AXI Bus transfer size (ARSIZE) is different from 8 bytes (only for memory-mapped mode).
- Bit DMM is set in XSPI_CR (dual-memory configuration) and 16-bit mode is set.

28.4.19 XSPI high-speed interface and calibration

To reach higher frequencies, a dedicated high-speed interface is inserted between the XSPI (or the I/O manager in case the product embeds one), and the I/O pads.

The following is valid for all data bus sizes 1, 2, 4, 8 or 16 bits.

The high-speed interface block embeds resynchronization registers that are clocked by a delayed clock created from a DLL (delay locked loop) also located in the high-speed interface. The high-speed interface features are controlled by registers located in the XSPI.

The purpose of resynchronization is primary to shift data or data strobe by one quarter of controller bus clock period, with a correct timing accuracy. DLL must be calibrated versus this clock period.

The calibration process is automatically enabled when one of the three conditions below is met:

- The XSPI exits reset state.
- A value is written in PRESCALER[7:0] of XSPI_DCR2.
- A value is written in XSPI_CCR.

The calibration process starts when the two following conditions are **both** met:

- The calibration has been enabled by one of the three conditions above.
- An action that sets BUSY = 1 is performed. For example the first transfer to memory after calibration is enabled. When the calibration is completed, BUSY returns to 0.

In case a periodic recalibration is needed (for example to take in account possible variations in temperature or power supply on a long duration), this recalibration must be triggered by writing periodically in PRESCALER[7:0] of XSPI_DCR2, while BUSY = 0.

Once the calibration is completed, the value of the SPI bus clock period, expressed in number of unitary delay, is available to user in COARSE[5:0] and FINE[6:0] of XSPI_CALFCR.

After auto-calibration, XSPI_CALSOR and XSPI_CALSIR are automatically loaded with the same value that corresponds to the delay for a quarter cycle.

The automatic calibration is not executed if at least one of both registers XSPI_CALSOR/XSPI_CALSIR is written between the last write operation on XSPI_DCR2 or XSPI_CCR and the next transfer start. In such case, the calibration values must be set by the software code into XSPI_CALSOR and XSPI_CALSIR registers. It may improve the flash programming time without relaunching the automatic calibration processing between two programming pages.

When the memory is not supporting DQS (DQSE = 0), the automatic calibration is not used in reception. The DLL Master is used instead for delaying the feedback clock (XSPI_CALMR). This delay needs to be adjusted by the application itself, using a software sequence that determines which delay is optimal to guarantee the correct read operations.

When the clock is divided in DTR transmission mode, the quarter cycle delays on DQS/data are not inserted by the DLLs themselves, but by internal flops design scheme. In SDR transmission mode, the DLLs are not used and this, whatever the clock prescaler value.

In case of DTR mode and prescaler bypassed (PRESCALER[7:0] = 0), the kernel clock provided to interface must have a 50 % duty-cycle.

When using the high-speed-interface, the system clock (AXI clock) must be at least as fast as the SPI clock.

28.4.20 XSPI BUSY and ABORT

Once the XSPI starts an operation with the external device, BUSY is automatically set in XSPI_SR.

In indirect mode, BUSY is reset once the XSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in XSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in XSPI_DR, it is recommended to disable the DMA channel before aborting the XSPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

28.4.21 XSPI reconfiguration or deactivation

Before any XSPI reconfiguration, the software must ensure that all the transactions are completed:

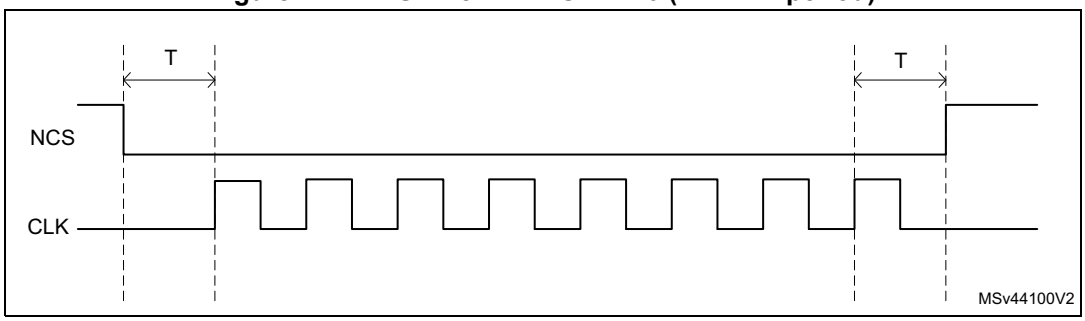
- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier then an abort.

28.4.22 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 212. NCS when CKMODE = 0 (T = CLK period)



Note: Clock mode 3 is not supported.

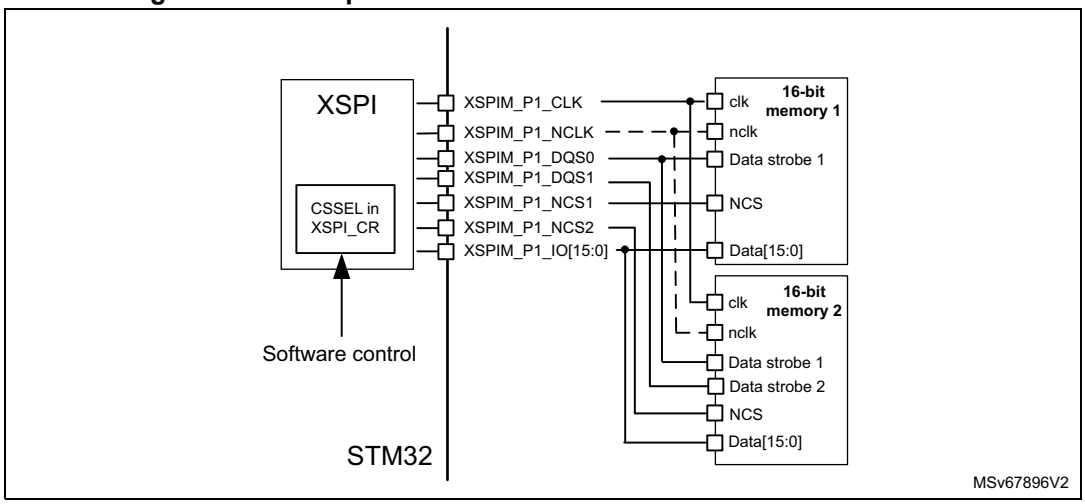
In dual-memory configuration, the NCS2 behaves exactly the same as the NCS1. The quad-SPI/octal-SPI memory 2 can then use the NCS1, and the NCS2 pin can be used for other functions.

28.4.23 Software control of two external memories

One XSPI instance is able to control the generation of the two chip-select signals (NCS1 and NCS2). This allows two external memories to be connected to the same I/O port driven by the XSPI.

The XSPI generates one NCS signal and the user defines how the NCS is directed to NCS1 or NCS2, by setting the CSSEL bit in XSPI_CR. Intended operation is semistatic commutation, such as starting an application reading an external flash memory and then, for the rest of the application, use an external SRAM connected to the same I/O bus.
From a memory-map point of view, these two memories are located in the same address range.

Figure 213. Example of software control of two external memories



28.4.24 Hardware-controlled extended memory support

One XSPI instance is able to control autonomously the generation of the two chip-select signals (NCS1 and NCS2). This feature is activated by setting EXTENDMEM in XSPI_DCR1 and allows two external memories to be connected to the same I/O port driven by the XSPI.

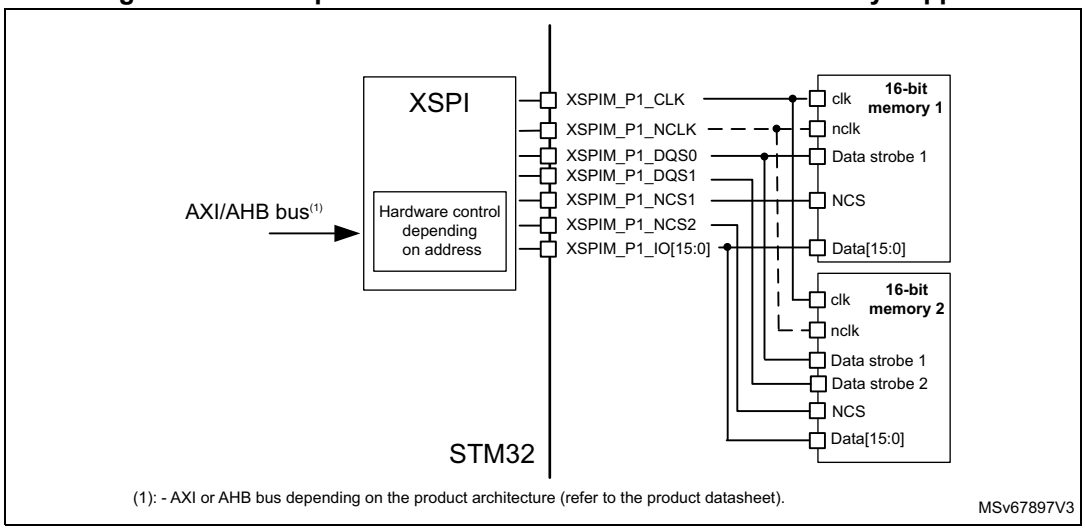
The aim is to extend by a factor two, the available external memory size. Both memories must be contiguous in the memory map. Both external memories must be of the same type and size. The size of one external memory must be set in the DEVSIZE bitfield in XSPI_CR.

- When the address presented on the interconnect bus in memory-mapped mode or in XSPI_AR register in indirect mode is in the range [XSPI_base_address : XSPI_base_address + $2^{DEVSIZE}$ - 1], NCS1 is generated.
- When the address presented on the interconnect bus in memory-mapped mode or in XSPI_AR register in indirect mode is in the range [XSPI_base_address + $2^{DEVSIZE}$:XSPI_base_address + 2 * $2^{DEVSIZE}$-1], NCS2 is generated.

Note: If the access crosses the middle boundary of the external memory, CS changes automatically (no write into XSPI_AR in indirect mode, or new memory access in memory-mapped mode is needed).

The EXTENDMEM feature (set in bit 21 of XSPI*_DCR1) and the Dual-memory mode (set in bit 6 of* XSPI*_CR) are exclusive. It is not possible to set both EXTENDMEM to 1 and DMM to 1 as this configuration is not supported.*

Figure 214. Example of hardware-controlled extended memory support



28.5 Address alignment and data number

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 200. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				
Single, dual, quad flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				
Octal memory in DTR mode without WDM(6), or 16-bit memory in SDR mode without WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.

Table 200. Address alignment cases (continued)

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
16-bit or dual-octal memory in DTR mode without WDM	IND read 32-bit	Aligned	ADDR[1:0] is assumed to be 00.(4)	N × 4	DLR[1:0] is assumed to be 11.(5)
	MM read	None	None	None	None
	IND write	Aligned	ADDR[1:0] is assumed to be 00.(4)	N × 4	DLR[1:0] is assumed to be 11.(5)
	MM write	Aligned	Slave error	N × 4	Last byte is lost.
Octal flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				
HyperBus	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				
16-bit data bus memory or dual-octal memory with WDM	IND read 32-bit	Aligned	ADDR[1:0] is assumed to be 00.(4)	N × 4	DLR[1:0] is assumed to be 11.(5)
	MM read	None	None	None	None
	IND write(8)				
	MM write				
16-bit HyperBus	IND read 32-bit	Aligned	ADDR[1:0] is assumed to be 00.(4)	N × 4	DLR[1:0] is assumed to be 11.(5)
	MM read	None	None	None	None
	IND write(9)				
	MM write				

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode.
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.
7. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 2 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.
8. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 4 aligned in DTR mode or modulo 2 in SDR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.
9. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 4 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

28.6 XSPI interrupts

An interrupt can be produced on the following events:

- timeout
- status match
- FIFO threshold
- transfer complete
- transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 201. XSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

28.7 XSPI registers

28.7.1 XSPI control register (XSPI_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSEL[1:0]		FMODE[1:0]		Res.	NOPREF_AXI	NOPREF	CSSEL	PMM	APMS	Res.	TOIE	SMIE	FTIE	TCIE	TEIE
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FTHRES[5:0]						Res.	DMM	Res.	Res.	TCEN	DMAEN	ABORT	EN
		rw	rw	rw	rw	rw	rw		rw			rw	rw	rw	rw

Bits 31:30 **MSEL[1:0]**: Flash select

These bits select the memory to be addressed in single-, dual-, quad-, or octal-SPI mode in single-memory configuration (when DMM = 0).

- when in quad-SPI mode:

00: Data exchanged over IO[3:0]

01: Data exchanged over IO[7:4]

10: Data exchanged over IO[11:8]

11: Data exchanged over IO[15:12]

- when in octal-SPI mode or dual-quad configuration:

0x: Data exchanged over IO[7:0]

1x: Data exchanged over IO[15:8]

These bits are ignored when in dual-octal configuration (data on 8 bits and DMM = 1) or 16-bit configuration (data exchanged over IO[15:0]).

Note: This bitfield can be modified only when BUSY = 0.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the XSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode (relevant in regular-command protocol only)

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value.

Note: This bitfield can be modified only when BUSY = 0.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **NOPREF_AXI**: No prefetch for signaled AXI transactions

This bit disables the automatic prefetch in the external memory when the corresponding AXI transaction is signaled as not-prefetchable.

0: Prefetch is enabled, whatever the AXI prefetch transaction request.

1: Prefetch is disabled when the AXI transaction is signaled as not-prefetchable.

This bit has no effect when NOPREF = 1.

Bit 25 **NOPREF**: No prefetch data

This bit disables the automatic prefetch in the external memory.

0: Automatic prefetch enabled

1: Automatic prefetch disabled

Bit 24 **CSSEL**: chip select selection

This bit indicates if the XSPI must activate NCS1 or NCS2.

0: NCS1 active

1: NCS2 active

Note: This bit can be modified only when BUSY = 0.

Bit 23 **PMM**: Polling match mode

This bit indicates which method must be used to determine a match during the automatic status-polling mode.

0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.

1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop
This bit determines if the automatic status-polling mode is stopped after a match.
0: Automatic status-polling mode is stopped only by abort or by disabling the XSPI.
1: Automatic status-polling mode stops as soon as there is a match.
Note: This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 19 **SMIE**: Status match interrupt enable
This bit enables the status match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **FTHRES[5:0]**: FIFO threshold level
This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in XSPI_SR, to be set.
000000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.
000001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.
...
111111: FTF is set if there are 64 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 64 valid bytes can be read from the FIFO in indirect-read mode.
Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[5:0] value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity.

0: Dual-memory configuration disabled

1: Dual-memory configuration enabled

Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.

1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In indirect mode, the DMA can be used to input or output data via XSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for indirect mode

1: DMA enabled for indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

0: No abort requested

1: Abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the XSPI.

0: XSPI disabled

1: XSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation. In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

28.7.2 XSPI device configuration register 1 (XSPI_DCR1)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	MTYP[2:0]			Res.	Res.	EXTENDMEM	DEVSIZE[4:0]				
					rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CSHT[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	FRCK	CKMODE
		rw	rw	rw	rw	rw	rw							rw	r

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bitfield indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes. In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes.

010: Standard mode

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping (address is built with row and column to fit with Macronix requirements).

100: HyperBus memory mode, the protocol follows the HyperBus specification.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be noncacheable, or indirect read/write modes must be used.

110: APmemory mode. If DMODE = 101, there is a special hardware operation on address word from the bit 10 and above to fit the provider requirement (shift operation on the left from the address bit 10, keeping this last at 0).

Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **EXTENDMEM**: Extended memory support

This bit is only relevant when one XSPI drives two same size external memories located in contiguous places in the memory map. In this case, DEVSIZE[4:0] represents the size of each external memory.

When this bit is set, the XSPI automatically controls which of NCS1 or NCS2 is active.

0: NCS1 and NCS2 values depend from CSSEL bit in XSPI_CR (software controlled).

1: NCS1 and NCS2 values depend from the address of transfer (hardware controlled).

Bits 20:16 **DEVSIZE[4:0]**: Device size

This bitfield defines the size of the external device using the following formula:
Number of bytes in device = $2^{[DEVSIZE+1]}$.
DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.
In regular-command protocol, if DMM = 1 or EXTENDMEM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.
0x0: NCS stays high for at least 1 cycle between external device commands.
0x1: NCS stays high for at least 2 cycles between external device commands.
...
0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.
0: CLK is not free running.
1: CLK is free running (always provided).

Note: Once the bit has been set to 1, the BSY bit is set, the NCS signal remains set to 1 and the clock is sent. The only way to stop the clock is to perform an abort (which clears the BSY bit). Then, the FRCK bit must be cleared by software to allow controller transactions to take place with the external memory.

Bit 0 **CKMODE**: Clock mode 0

This bit is read-only and is read as zero.

28.7.3 XSPI device configuration register 2 (XSPI_DCR2)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories, which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in XSPI_WPIR.

000: Wrapped reads are not supported by the memory.

010: External memory supports wrap size of 16 bytes.

011: External memory supports wrap size of 32 bytes.

100: External memory supports wrap size of 64 bytes.

101: External memory supports wrap size of 128 bytes.

Others: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as XSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the XSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.

Writing this bitfield automatically starts a new calibration of high-speed interface DLL at the start of next transfer, except in case XSPI_CALSOR or XSPI_CALSIR have been written in the meantime. BUSY stays high during the whole calibration execution.

28.7.4 XSPI device configuration register 3 (XSPI_DCR3)

Address offset: 0x010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAXTRAN[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of three is recommended.

The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Others: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **MAXTRAN[7:0]**: Maximum transfer

This bitfield enables the communication regulation feature.
The NCS is released every MAXTRAN+1 clock cycles when the other XSPI request the access to the bus.
0: Maximum communication disabled
Others: Maximum communication is set to (MAXTRAN + 1) bytes.

28.7.5 XSPI device configuration register 4 (XSPI_DCR4)

Address offset: 0x014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual-, or quad-SPI mode, because the byte transmission must be completed.
0: Refresh disabled
Others: Maximum communication length is set to REFRESH + 1 clock cycles.

28.7.6 XSPI status register (XSPI_SR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	FLEVEL[6:0]							Res.	Res.	BUSY	TOF	SMF	FTF	TCF	TEF
	r	r	r	r	r	r	r			r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 **FLEVEL[6:0]**: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO.FLEVEL = 0 when the FIFO is empty, and 64 when it is full. In automatic-status polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (XSPI_PSMAR).
It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.
It is cleared automatically as soon as the threshold condition is no longer true.
In automatic status-polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag

This bit is set in indirect mode when an invalid address is being accessed in indirect mode.
It is cleared by writing 1 to CTEF.

28.7.7 XSPI flag clear register (XSPI_FCR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTOF	CSMF	Res.	CTCF	CTEF
											w	w		w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag

Writing 1 clears the TOF flag in the XSPI_SR register.

Bit 3 **CSMF**: Clear status match flag

Writing 1 clears the SMF flag in the XSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag

Writing 1 clears the TCF flag in the XSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag

Writing 1 clears the TEF flag in the XSPI_SR register.

28.7.8 XSPI data length register (XSPI_DLR)

Address offset: 0x040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value + 1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1's in indirect mode means undefined length, where XSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect when in memory-mapped mode.

28.7.9 XSPI address register (XSPI_AR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In HyperBus protocol, this bitfield must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 0.

Caution: Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value. So the software needs to multiply the address by two when accessing the memory registers.

28.7.10 XSPI data register (XSPI_DR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

28.7.11 XSPI polling status mask register (XSPI_PSMKR)

Address offset: 0x080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

28.7.12 XSPI polling status match register (XSPI_PSMAR)

Address offset: 0x088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31:0]**: Status match

Value to be compared with the masked status register to get a match

28.7.13 XSPI polling interval register (XSPI_PIR)

Address offset: 0x090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval

Number of CLK cycles between a read during the automatic status-polling phases

28.7.14 XSPI communication configuration register (XSPI_CCR)

Address offset: 0x100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]		
		rw		rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled

1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate

This bit sets the DTR mode for the data phase.

0: DTR mode disabled for the data phase

1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101: Data on 16 lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

28.7.15 XSPI timing configuration register (XSPI_TCR)

Address offset: 0x108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bits 29:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

28.7.16 XSPI instruction register (XSPI_IR)

Address offset: 0x110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

28.7.17 XSPI alternate bytes register (XSPI_ABR)

Address offset: 0x120

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address.

28.7.18 XSPI low-power timeout register (XSPI_LPTR)

Address offset: 0x130

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period

After each access in memory-mapped mode, the XSPI prefetches the subsequent bytes and hold them in the FIFO.

This bitfield indicates how many CLK cycles the XSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

28.7.19 XSPI wrap communication configuration register (XSPI_WPCCR)

Address offset: 0x140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled

1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate

This bit sets the DTR mode for the data phase.

0: DTR mode disabled for the data phase

1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode

This bitfield defines the data phase mode of operation.

000: No data

001: Data on a single line

010: Data on two lines

011: Data on four lines

100: Data on eight lines

101: Data on 16 lines

Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size

This bitfield defines the alternate-byte size.

00: 8-bit alternate bytes

01: 16-bit alternate bytes

10: 24-bit alternate bytes

11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

28.7.20 XSPI wrap timing configuration register (XSPI_WPTCR)

Address offset: 0x148

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1).

Bits 29:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

28.7.21 XSPI wrap instruction register (XSPI_WPIR)

Address offset: 0x150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address

28.7.23 XSPI write communication configuration register (XSPI_WCCR)

Address offset: 0x180

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101: Data on 16 lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size:
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double-transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size:
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

28.7.24 XSPI write timing configuration register (XSPI_WTCR)

Address offset: 0x188

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency. In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

28.7.25 XSPI write instruction register (XSPI_WIR)

Address offset: 0x190

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address

28.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR)

Address offset: 0x200

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRWR[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

TACC[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	WZL	LM
rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read-write minimum recovery time

Device Read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7:0]**: Access time

Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.

0: Latency on write accesses

1: No latency on write accesses

Bit 0 **LM:** Latency mode

This bit selects the latency mode.

0: Variable initial latency

1: Fixed latency

Note: This bit must be set when using the dual-octal HyperBus configuration.

28.7.28 XSPI full-cycle calibration configuration (XSPI_CALFCR)

Address offset: 0x210

Reset value: 0x0000 0000

This read-only register gives the calibration code needed by the DLL master so that its delay is equivalent to a full memory-clock cycle. The value of this register is updated every time that auto-calibration finishes.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CALMAX	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COARSE[4:0]				
r											r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FINE[6:0]						
									r	r	r	r	r	r	r

Bit 31 **CALMAX:** Max value
This bit gets set when the memory-clock period is outside the range of DLL master, in which case XSPI_CALFCR and XSPI_CALSR are updated with the values for the maximum delay.

Bits 30:21 Reserved, must be kept at reset value.

Bits 20:16 **COARSE[4:0]**: Coarse calibration
The delay unitary value for this bitfield depends on product technology (see the datasheet).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **FINE[6:0]**: Fine calibration
The delay unitary value for this bitfield depends on product technology (see the datasheet).

28.7.29 XSPI DLL master calibration configuration (XSPI_CALMR)

Address offset: 0x218

Reset value: 0x0000 0000

The DLL Master is used for delaying the feedback clock when reading without DQS.
The delay of the master DLL is determined by the value in this register.

This register can always be read by software and can be modified only when BUSY = 0.

This register never gets updated automatically by hardware.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COARSE[4:0]				
											rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FINE[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **COARSE[4:0]**: Coarse calibration
The delay unitary value for this bitfield depends on product technology (see the datasheet).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **FINE[6:0]**: Fine calibration
The delay unitary value for this bitfield depends on product technology (see the datasheet).

28.7.30 XSPI DLL slave output calibration configuration (XSPI_CALSOR)

Address offset: 0x220

Reset value: 0x0000 0000

The DLL output slave is used to delay the output data in DDR mode for write operations. The delay of the output slave DLL is determined by the value in this register.

This register is updated automatically by hardware at the end of calibration (at the same moment that XSPI_CALFCR is updated).

If this register is written after the last write to XSPI_DCR2 or XSPI_CCR, then auto-calibration is not executed on the next transfer (auto-calibration is not performed for XSPI_CALSIR as well).

This register can always be read by software and can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COARSE[4:0]				
											rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FINE[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **COARSE[4:0]**: Coarse calibration
The delay unitary value for this bitfield depends on product technology.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **FINE[6:0]**: Fine calibration
The delay unitary value for this bitfield depends on product technology.

28.7.31 XSPI DLL slave input calibration configuration (XSPI_CALSIR)

Address offset: 0x228

Reset value: 0x0000 0000

The DLL input slave is used to delay the DQS input for sampling the data when DQS is enabled for read operations. The delay of the input slave DLL is determined by the value in this register.

This register is updated automatically by hardware at the end of calibration (at the same moment that XSPI_CALFCR is updated).

If this register is written after the last write to XSPI_DCR2 or XSPI_CCR, then auto-calibration is not executed on the next transfer (auto-calibration is not performed for XSPI_CALSOR as well).

This register can always be read by software and can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

29 XSPI I/O manager (XSPIM)

29.1 Introduction

The XSPI I/O manager is a low-level interface, enabling an efficient XSPI pin assignment with a full I/O matrix (before alternate function map), and multiplex of single/dual/quad/octal/16-bit SPI interfaces over the same bus.

29.2 XSPIM main features

- Supports up to two single/dual/quad/octal/16-bit SPI interfaces
- Supports up to two ports for pin assignment
- Supports high-speed interfaces
- Manages up to three XSPIs

29.3 XSPIM implementation

Table 203 describes the XSPIM implementation.

Table 203. XSPIM implementation

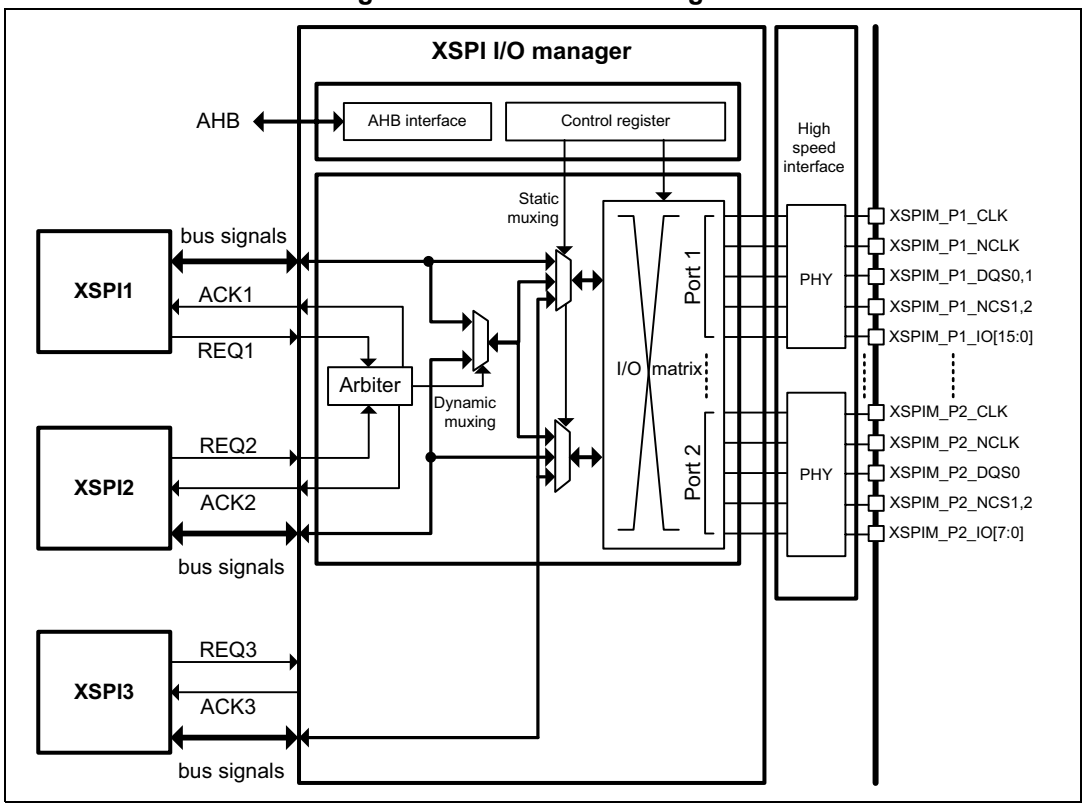
XSPI feature	Available on the devices
Supports up to two single/dual/quad interfaces	X
Fully I/O multiplexing capability	X
Supports time-multiplexed mode	X
Supports high-speed interface	X
Chip select selection if XSPI provides dual chip select	X
Supports 16-bit data interface and dual-octal mode	X
Supports up to three XSPIs	X

29.4 XSPIM functional description

29.4.1 XSPIM block diagram

The block diagram of the XSPI I/O manager is shown in *Figure 215*.

Figure 215. XSPIM block diagram



29.4.2 XSPIM input/output pins

Table 204. XSPIM input/output pins

Pin name(1)	Signal type	Description
XSPIM_Px_NCLK	Output	XSPI inverted clock to support 1.8 V HyperBus protocol. The inversion must be activated only in this case, setting bit INVCLK in the advanced I/O configuration section.
XSPIM_Px_CLK		XSPI clock
XSPIM_Px_IOn (n = 0 to 15)	Input/output	XSPI data pins
XSPIM_Px_NCS1,2	Output	Chip select for the memory
XSPIM_Px_DQS0,1	Input/output	Data strobe/write mask signals from/to the memory

1. x = 1 to 2.

29.4.3 XSPIM matrix

The XSPI I/O manager matrix allows the user to set a premapping of functions:

- XSPI1 mapped to Port 1, with XSPI2 mapped to Port 2 (direct mode)
- XSPI1 mapped to Port 2, with XSPI2 mapped to Port 1 (swapped mode)
- XSPI1 and XSPI2 both mapped to Port 1, with arbitration (multiplexed mode), and XSPI3 mapped to Port 2
- XSPI1 and XSPI2 both mapped to Port 2, with arbitration (multiplexed mode), and XSPI3 mapped to Port 1

Note: There is no possibility to use mixed combinations of signals (like NCS of XSPI1 with data of XSPI2).

When several I/O pins have the same configuration and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, all the XSPI1 and XSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The configuration can be changed only when all XSPIs are disabled.

29.4.4 XSPIM multiplexed mode

When this mode is set, the XSPIs are time-multiplexed over the same bus. They get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit in the configuration register XSPIM_CR.

The fairness counter (MAXTRAN) of each XSPI can be used to manage the maximum duration for which a given XSPI takes the bus: this feature ensures the maximum bus access latency for the other XSPI(s). When one XSPI releases the bus, a round-robin arbitration phase occurs: when another XSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both XSPI interfaces must be activated.

Each XSPI delivers two NCS signals (NCS1, NCS2). In multiplexed modes, the active NCS signal is the one of the XSPI owning the bus. Only XSPIn_IOs, XSPIn_DQS and XSPIn_CLK / XSPIn_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the XSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the XSPI, when used, can be increased.

Minimum switching duration

The minimum number of cycles needed to switch from an XSPI to another can be configured. This guarantees a latency between the falling edge of the REQ signal of the active XSPI (the active one releases the bus), and the rising edge of the ACK signal to the requesting XSPI (the bus is granted to the requesting one).

The duration is defined by the REQ2ACK_TIME field in the XSPIM_CR register.

29.5 Use cases description

The following table summarizes the use cases corresponding to IO manager modes.

Table 205. Use cases

IO manager mode	MUXEN	Mode	Reference
Direct (XSPI1 to Port1, XSPI2 to Port2, XSPI3 not used)	0	0	*Section 29.5.1* *Section 29.5.2*
Swapped (XSPI1 to Port2, XSPI2 to Port1, XSPI3 not used)	0	1	*Section 29.5.4*
Multiplexed to Port1 (XSPI1 and XSPI2 to Port1, XSPI3 to Port2)	1	0	*Section 29.5.5*
Multiplexed to Port2 (XSPI1 and XSPI2 to Port2, XSPI3 to Port1)	1	1	*Section 29.5.6*
XSPI1 and 2 drive a single external memory connected to Port1 or Port2, and XSPI3 drives one external memory connected to the other port	1	0 or 1, depending upon the port connected to the memory	*Section 29.5.7*
XSPI1 or 2 drives two external memories connected to Port1 or Port2, and XSPI3 drives one external memory connected to the other port	0	0 with CS selection command from XSPI1/2.	*Section 29.5.8*

29.5.1 XSPIs direct octal mode

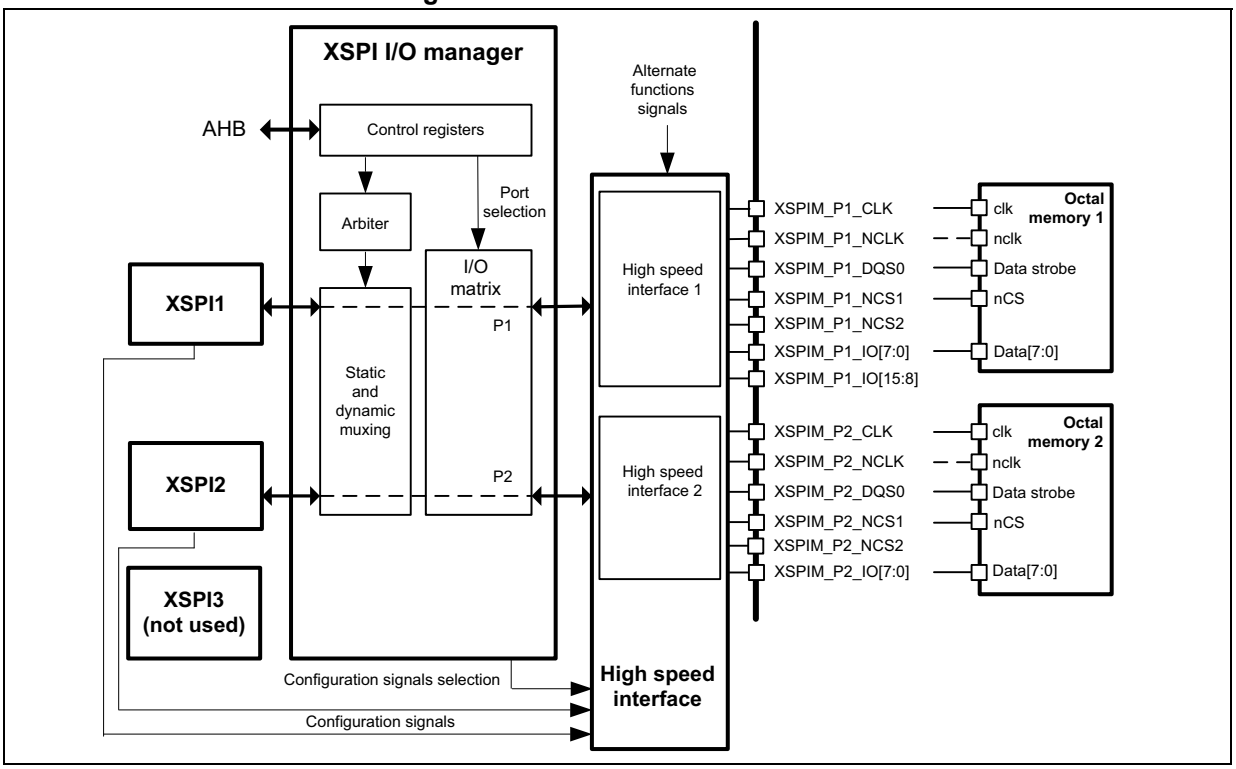
This is the baseline mode: each XSPI independently drives the corresponding port and high-speed interface. There is no multiplexing.

The configuration selection signal selects the signals used for each high speed interface. These signals come from the XSPI_CR and XSPI_CALxxx register outputs.

Alternate function signals can be routed on NCS2 pins (they are not used for the XSPI bus), nclk clocks are requested in case of 1.8 V HyperBus memory type.

This mode is selected by default through bits XSPIM_CR[1:0].

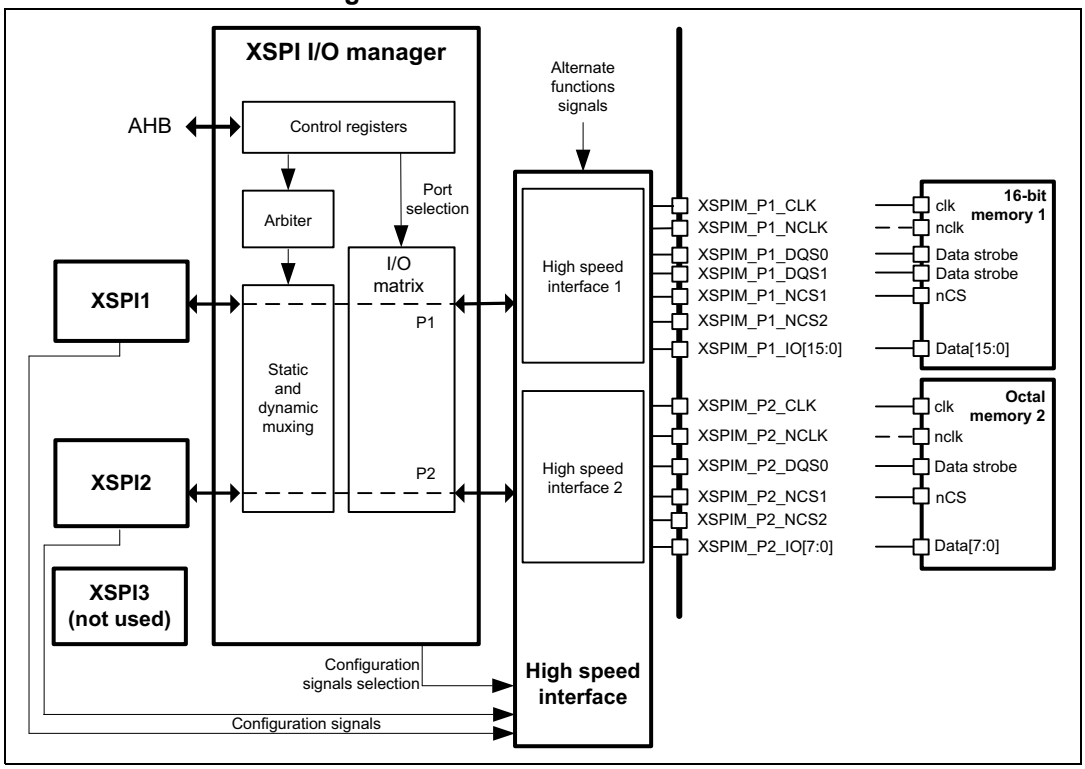
Figure 216. XSPI direct octal mode



29.5.2 XSPI direct 16-bit mode

This is the baseline mode, completely similar to XSPI octal direct mode, where each XSPI directly drives the corresponding port (XSPI1 connected to Port 1, XSPI2 connected to Port 2). Two DQS (1 per byte) are needed for each 16-bit port, when available.

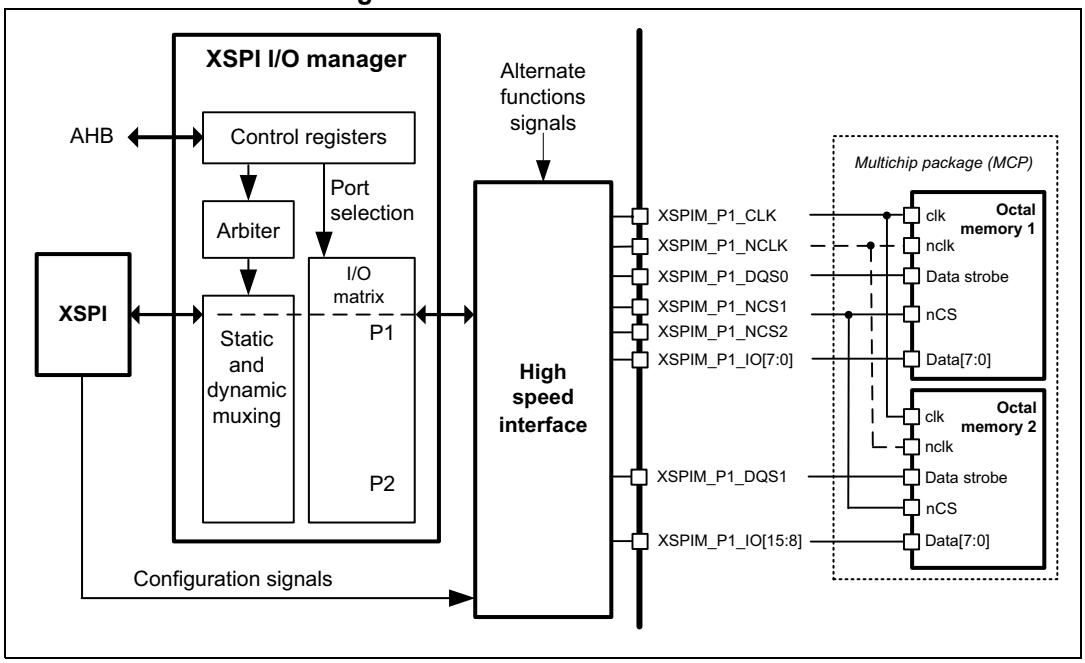
Figure 217. XSPI direct 16-bit mode



29.5.3 XSPI dual-octal mode

This mode is equivalent to XSPI direct mode, but, for simplicity, only one XSPI interface is represented. Two external octal memories are accessed in parallel, similarly to the dual-quad mode implemented with octal interfaces.

Figure 218. XSPI dual-octal mode



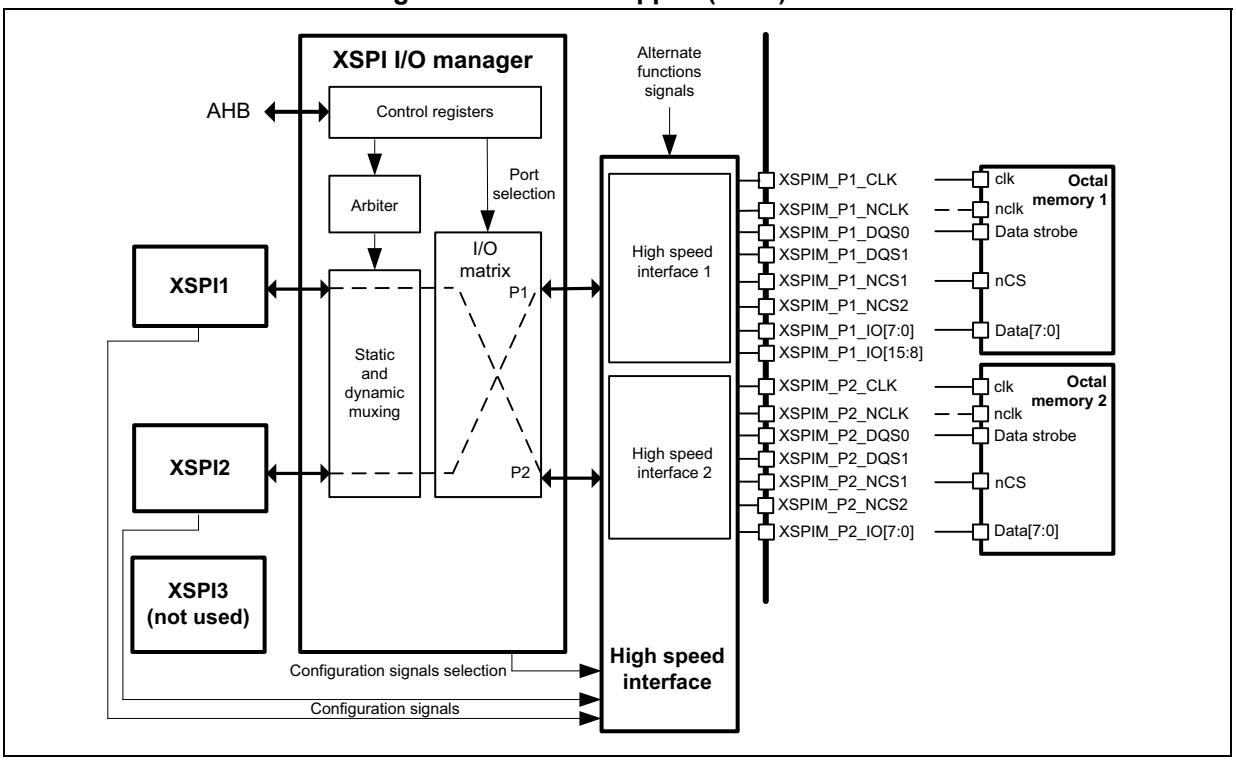
29.5.4 XSPI swapped mode

This mode is similar to XSPI direct mode, but the ports are swapped, to help I/O mapping. The mode is selected by bits XSPIM_CR[1:0].

If XSPIM.CR[0] or XSPIM.CR[1] is toggled in application, XSPI DCR2 or XSPI.CCR must be written, so that the calibration of the high speed interface is launched according to the new XSPI using it.

Note: In swapped mode, the XSPI2 can be configured in 16-bit mode, and the XSPI1 can be configured in octal mode, to connect an external 16-bit memory on Port 1, and to connect in a concurrent way an octal external memory connected to Port 2 of the I/O manager.

Figure 219. XSPI swapped (octal) mode



29.5.5 Two XSPIs multiplexed mode to Port 1 accessing two external memories, and the third XSPI accessing Port 2

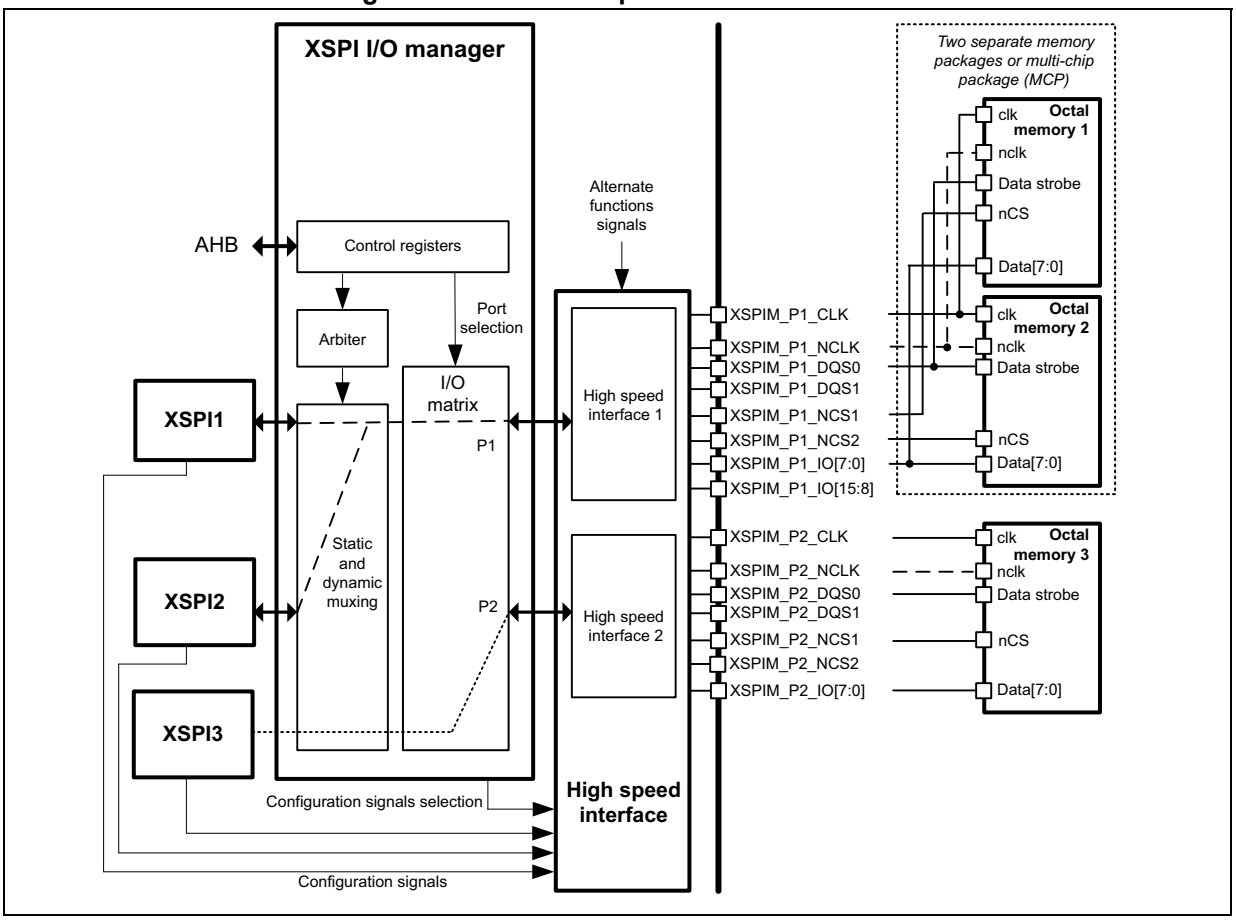
If only one output port is used to access two memories, alternate function signals can be routed to pins corresponding to the other port. This mode is selected by bits XSPIM_CR[1:0].

The arbiter in the IO manager selects XSPI1 or XSPI2 to own the octal-SPI bus according to the existing transfer requests and status of the two MAXTRAN fairness counters.

The external memories can be on separate chips, or embedded in a single multichip package. In this case, each memory requests a dedicated Chip select, selected according to the CSSEL control of the XSPI currently owning the bus.

The configuration signals of the high speed interface toggle when the corresponding XSPI is selected, because the timing characteristics of the two memories can be different.

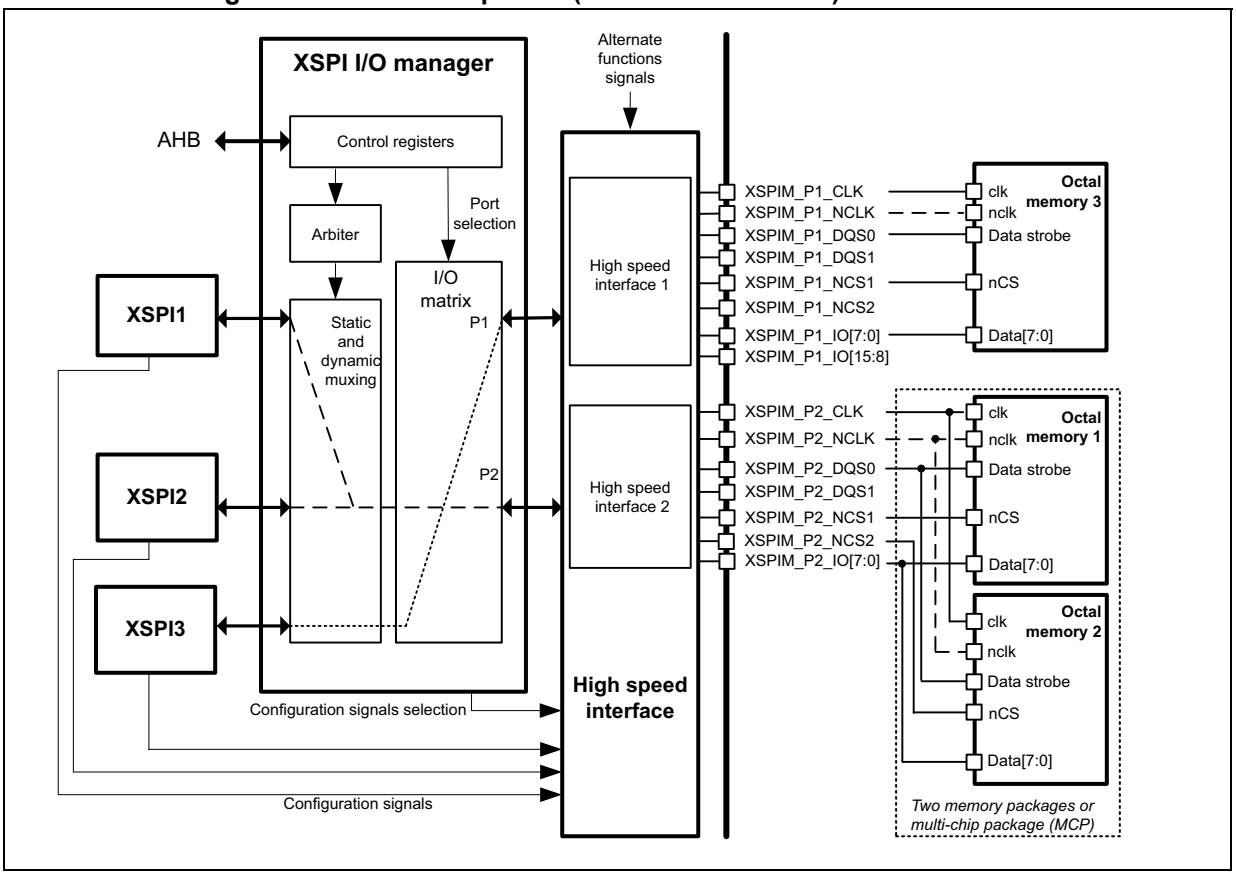
Figure 220. XSPI multiplexed mode to Port 1



29.5.6 Two XSPIs multiplexed mode to Port 2 accessing two external memories and the third XSPI accessing Port 1

This is similar to XSPI multiplexed mode to Port 1, but the target is Port 2. This mode is selected by bits XSPIM_CR[2:1].

Figure 221. XSPI multiplexed (octal and dual-octal) mode to Port 2

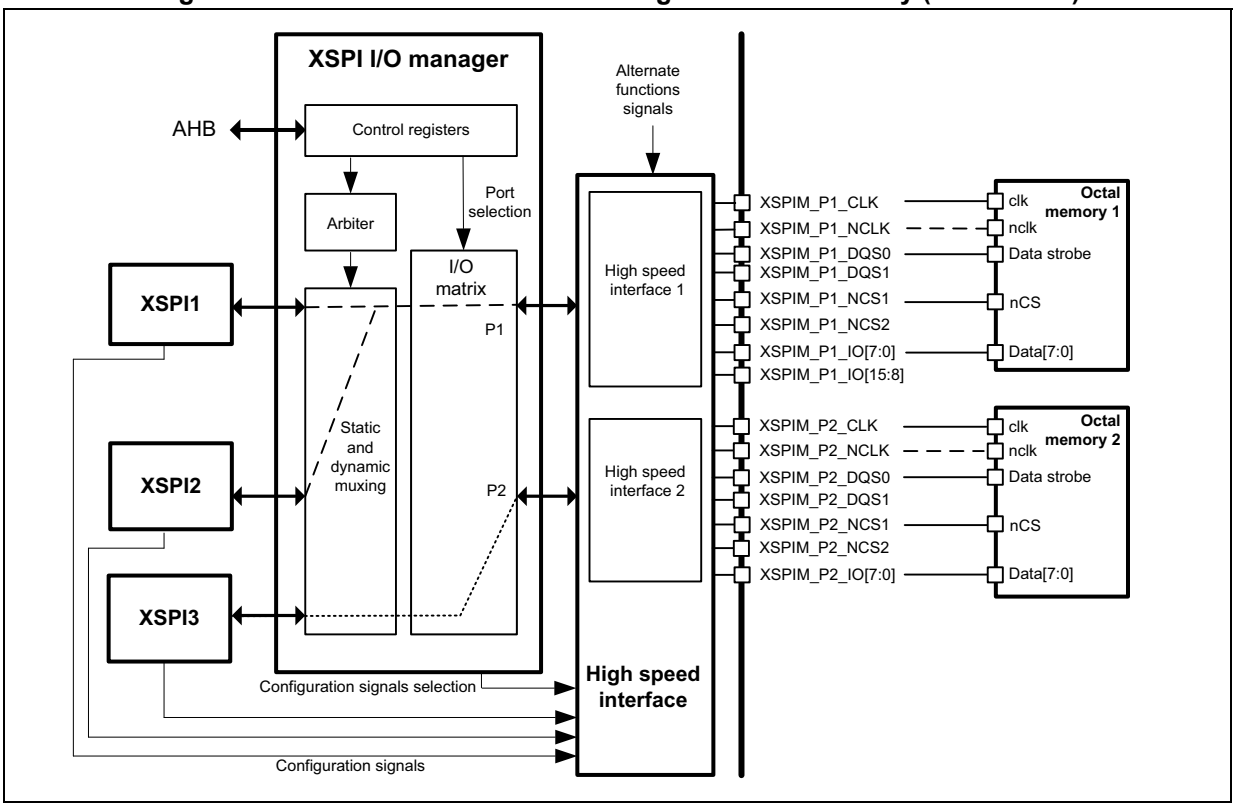


Note: It is possible to connect a 16-bit memory on Port 1, whereas Port 2 uses multiplexing mode on two octal memories.

29.5.7 XSPI1 and XSPI2 drive a single external memory

This is similar to XSPIs multiplexed mode to Port 1, but in this case only one external memory is present. Both CSSEL controls must target the same NCS (NCS1 in *Figure 222*).

Figure 222. XSPI1 and XSPI2 drive a single external memory (octal mode)



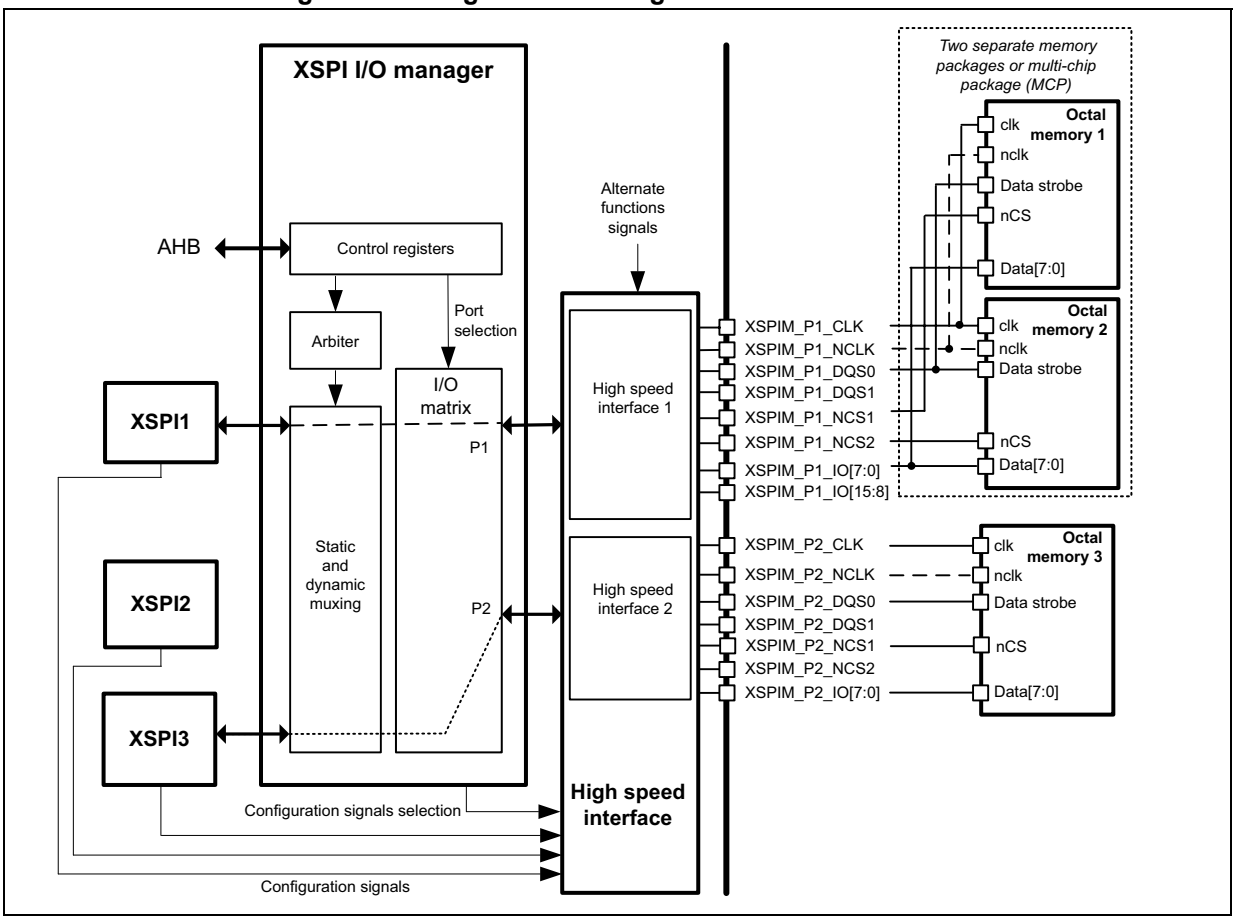
This use case is valid even when Port 2 is used instead of Port 1, and also possible with XSPI1 and XSPI2 interfacing a 16-bit memory (connecting XSPIM_P1_DQS1 to the memory).

29.5.8 A single XSPI drives two external memories

This is a subset of direct mode and corresponds to semi-dynamic switching. There are two target memories, but the arbiter is not used. The software must set the XSPI1 chip selector (bit 24 of the XSPI_CR register) each time the target memory changes.

The baseline use case boots on flash (memory1) and then switches to SRAM (memory2) for the rest of the application.

Figure 223. Single XSPI driving two external memories



This use case is valid even when Port 2 is used instead of Port 1, and also with XSPI3 interfacing two 16-bit memories (connecting XSPIM_P1_DQS1 to the memory).

29.6 XSPIM registers

29.6.1 XSPIM control register (XSPIM_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REQ2ACK_TIME[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSSEL_OVR_O2	CSSEL_OVR_O1	CSSEL_OVR_EN	Res.	Res.	MODE	MUXEN
									rw	rw	rw			rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **REQ2ACK_TIME[7:0]**: REQ to ACK time

In Multiplexed mode (MUXEN = 1), this field defines the time between two transactions. The value is the number of XSPI clock cycles - 1

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **CSSEL_OVR_O2**: Chip select selector override setting for XSPI2

0: XSPI2 can only use NCS1 (accesses using NCS2 are ignored)

1: XSPI2 can only use NCS2 (accesses using NCS1 are ignored)

Bit 5 **CSSEL_OVR_O1**: Chip select selector override setting for XSPI1

0: XSPI1 can only use NCS1 (accesses using NCS2 are ignored)

1: XSPI1 can only use NCS2 (accesses using NCS1 are ignored)

Bit 4 **CSSEL_OVR_EN**: Chip select selector override enable

0: CSSEL_OVR_O1 and CSSEL_OVR_O2 bit values are ignored, the chip select signals from OCTOSPIs or XSPIs are transmitted unconditionally

1: CSSEL_OVR_O1 and CSSEL_OVR_O2 bit values are taken into account

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **MODE**: XSPI multiplexing mode

0: if MUXEN = 0 direct mode, if MUXEN = 1 arbitration mode to output Port 1

1: if MUXEN = 0 swapped mode, if MUXEN = 1 arbitration mode to output Port 2

Bit 0 **MUXEN**: Multiplexed mode enable

This bit enables the multiplexing of the two XSPIs.

0: No multiplexing, hence no arbitration

1: XSPI1 and XSPI2 are multiplexed over the same bus

29.6.2 XSPIM register map

Table 206. XSPIM register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 162* for the register boundary addresses.

30 Secure digital input/output MultiMediaCard interface (SDMMC)

30.1 SDMMC main features

The SD/SDIO, embedded MultiMediaCard (*e*•MMC) host interface (SDMMC) provides an interface between the AHB bus and SD memory cards, SDIO cards and *e*•MMC devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at www.jedec.org, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at www.sdcard.org.

The SDMMC features include the following:

- Compliance with *Embedded MultiMediaCard System Specification Version 5.1*. Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit. (HS200 SDMMC_CK speed limited to maximum allowed I/O speed)(HS400 is not supported).
- Full compatibility with previous versions of MultiMediaCards (backward compatibility).
- Full compliance with *SD memory card specifications version 6.0*. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Full compliance with *SDIO card specification version 4.0.* Card support for two different databus modes: 1-bit (default) and 4-bit. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Data transfer up to 208 Mbyte/s for the 8-bit mode. (depending maximum allowed I/O speed).
- Data and command output enable signals to control external bidirectional drivers.
- IDMA linked list support

The MultiMediaCard/SD bus connects cards to the host.

The current version of the SDMMC supports only one SD/SDIO/*e*•MMC card at any one time and a stack of *e*•MMC.

30.2 SDMMC implementation

Table 207. SDMMC features

SDMMC modes/features(1)	SDMMC1	SDMMC2
Variable delay	X	X
SDMMC_CKIN	X	-
SDMMC_CDIR, SDMMC_D0DIR	X	-
SDMMC_D123DIR	X	-

1. X = supported.

30.3 SDMMC bus topology

Communication over the bus is based on command/response and data transfers.

The basic transaction on the SD/SDIO/*e*•MMC bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers are done in the following ways:

- Block mode: data block(s) with block size 2^N bytes with N in the range 0-14
- SDIO multibyte mode: single data block with block size range 1-512 bytes
- *e*•MMC Stream mode: continuous data stream

Data transfers to/from *e*•MMC cards are done in data blocks or streams.

Figure 224. SDMMC "no response" and "no data" operations

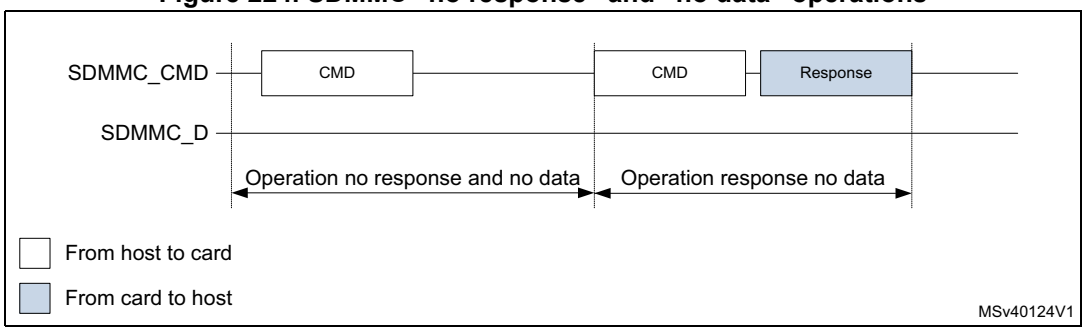

Figure 225. SDMMC (multiple) block read operation

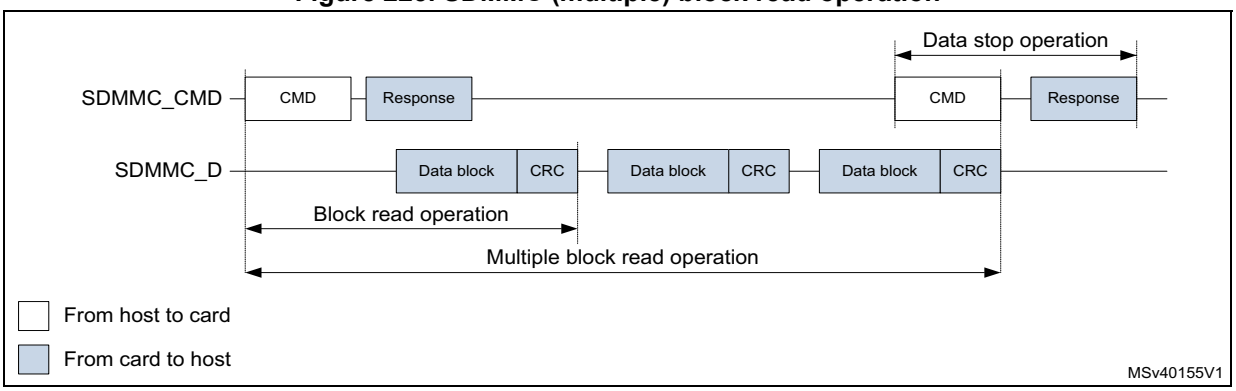
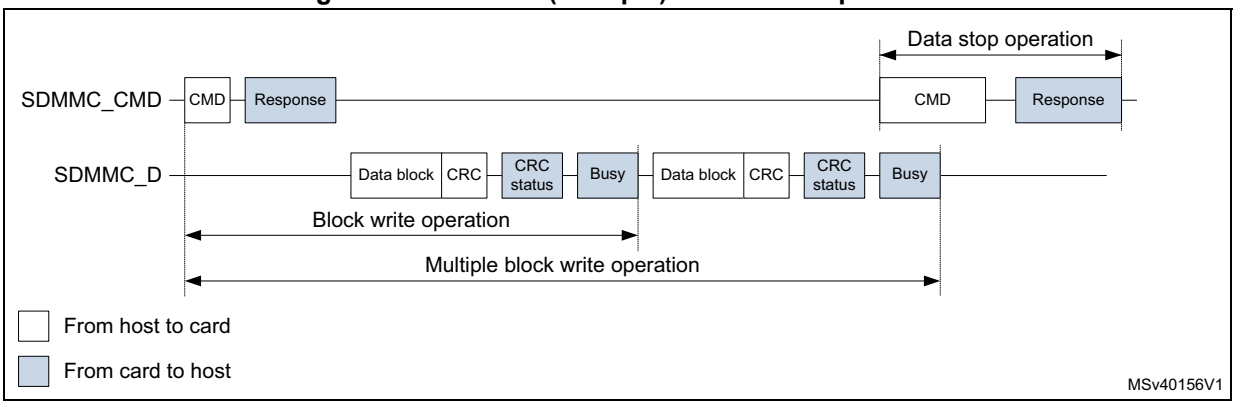


Note: The Stop Transmission command is not required at the end of a e•MMC multiple block read with predefined block count.

Figure 226. SDMMC (multiple) block write operation



Note: The Stop Transmission command is not required at the end of an e•MMC multiple block write with predefined block count.

The SDMMC does not send any data as long as the Busy signal is asserted (SDMMC_D0 pulled low).

Figure 227. SDMMC (sequential) stream read operation

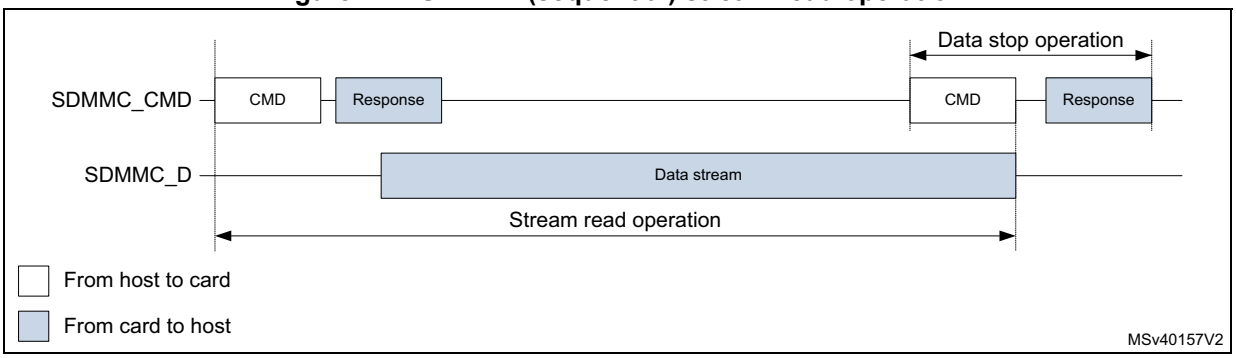


Figure 228. SDMMC (sequential) stream write operation

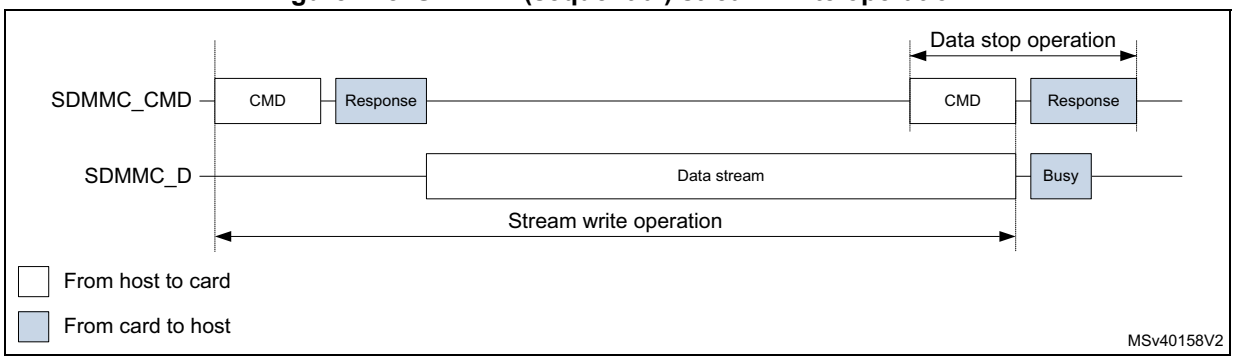


Stream data transfer operates only in a 1-bit wide bit bus configuration on SDMMC_D0 in single data rate modes (DS, HS, and SDR).

30.4 SDMMC operation modes

Table 208. SDMMC operation modes SD and SDIO

SDIO bus speed modes(1)(2)	Max bus speed (3) [Mbyte/s]	Max clock frequency [MHz](4)	Signal voltage [V]
DS (default speed)	12.5	25	3.3
HS (high speed)	25	50	3.3
SDR12	12.5	25	1.8
SDR25	25	50	1.8
DDR50	50	50	1.8
SDR50	50	100	1.8
SDR104	104	208	1.8

1. SDR single data rate signaling.
2. DDR double data rate signaling (data is sampled on both SDMMC_CK clock edges).
3. SDIO bus speed with 4-bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.

SDR104 mode requires variable delay support using sampling point tuning. The use of variable delay is optional for SDR50 mode.

Table 209. SDMMC operation modes *e*•MMC

e•MMC bus speed modes (1)(2)	Max bus speed (3) [Mbyte/s]	Max clock frequency [MHz](4)	Signal voltage [V](5)
Legacy compatible	26	26	3/1.8/1.2V
High speed SDR	52	52	3/1.8/1.2V
High speed DDR	104	52	3/1.8/1.2V
High speed HS200	200	200	1.8/1.2V

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. *e*•MMC bus speed with 8-bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.
5. Supported signal voltage level depends on I/O port characteristics, refer to device datasheet.

HS200 mode requires variable delay support using sampling point tuning.

30.5 SDMMC functional description

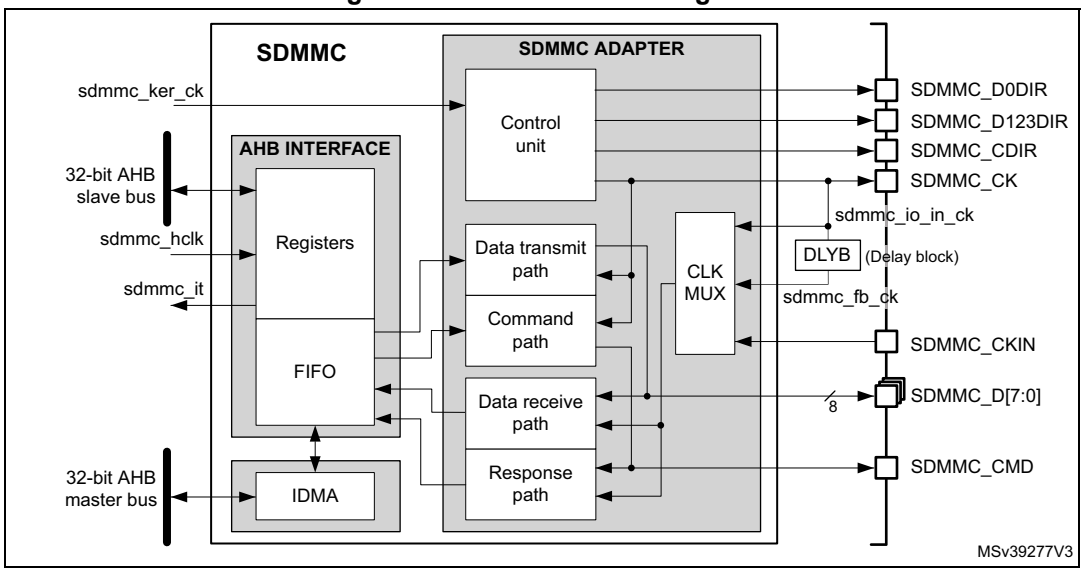
The SDMMC consists of four parts:

- The AHB slave interface accesses the SDMMC adapter registers, and generates interrupt signals and IDMA control signals.
- The SDMMC adapter block provides all functions specific to the *e*•MMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The internal DMA (IDMA) block with its AHB master interface.
- A delay block (DLYB) taking care of the receive data sample clock alignment. The delay block is NOT part of the SDMMC. A delay block is mandatory when supporting SDR104 or HS200.

30.5.1 SDMMC block diagram

Figure 229 shows the SDMMC block diagram.

Figure 229. SDMMC block diagram



30.5.2 SDMMC pins and internal signals

Table 210 lists the SDMMC internal input/output signals, *Table 211* the SDMMC pins (alternate functions).

Table 210. SDMMC internal input/output signals

Signal name	Signal type	Description
sdmmc_ker_ck	Digital input	SDMMC kernel clock
sdmmc_hclk	Digital input	AHB clock
sdmmc_it	Digital output	SDMMC global interrupt

Table 210. SDMMC internal input/output signals (continued)

Signal name	Signal type	Description
sdmmc_io_in_ck	Digital input	SD/SDIO/*e*•MMC card feedback clock. This signal is internally connected to the SDMMC_CK pin (for DS and HS modes).
sdmmc_fb_ck	Digital input	SD/SDIO/*e*•MMC card tuned feedback clock after DLYB delay block (for SDR50, DDR50, SDR104, HS200)

Table 211. SDMMC pins

Pin name	Pin type	Description
SDMMC_CK	Digital output	Clock to SD/SDIO/*e*•MMC card
SDMMC_CKIN	Digital input	Clock feedback from an external driver for SD/SDIO/*e*•MMC card. (for SDR12, SDR25, SDR50, DDR50)
SDMMC_CMD	Digital input/output	SD/SDIO/*e*•MMC card bidirectional command/response signal.
SDMMC_CDIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the SDMMC_CMD signal.
SDMMC_D[7:0]	Digital input/output	SD/SDIO/*e*•MMC card bidirectional data lines.
SDMMC_D0DIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the SDMMC_D0 data line.
SDMMC_D123DIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the data lines SDMMC_D[3:1].

30.5.3 General description

The **SDMMC_D[7:0]** lines have different operating modes:

- By default, SDMMC_D0 line is used for data transfer. After initialization, the host can change the databus width.
- For an *e*•MMC, 1-bit (SDMMC_D0), 4-bit (SDMMC_D[3:0]) or 8-bit (SDMMC_D[7:0]) data bus widths can be used.
- For an SD or an SDIO card, 1-bit (SDMMC_D0) or 4-bit (SDMMC_D[3:0]) can be used. All data lines operate in push-pull mode.

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the data lines is indicated with I/O direction signals. The **SDMMC_D0DIR** signal indicates the I/O direction for the SDMMC_D0 data line, the **SDMMC_D123DIR** for the SDMMC_D[3:1] data lines.

SDMMC_CMD only operates in push-pull mode:

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the SDMMC_CMD line is indicated with the I/O direction signal **SDMMC_CDIR**.

SDMMC_CK clock to the card originates from **sdmmc_ker_ck**:

- When the sdmmc_ker_ck clock has 50 % duty cycle, it can be used even in bypass mode (CLKDIV = 0).
- When the sdmmc_ker_ck duty cycle is not 50 %, the CLKDIV must be used to divide it by 2 or more (CLKDIV > 0).
- The phase relation between the SDMMC_CMD / SDMMC_D[7:0] outputs and the SDMMC_CK can be selected through the NEGEDGE bit. The phase relation depends on the CLKDIV, NEGEDGE, and DDR settings. See *Figure 230*.

Figure 230. SDMMC Command and data phase relation

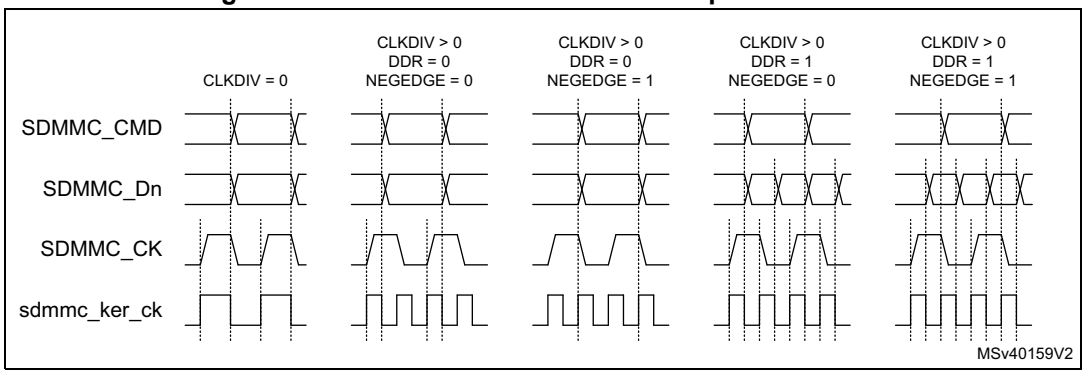


Table 212. SDMMC Command and data phase selection

CLKDIV	DDR	NEGEDGE	SDMMC_CK	Command out	Data out
0	x	x	= sdmmc_ker_ck	Generated on sdmmc_ker_ck falling edge	
>0	0	0	Generated on sdmmc_ker_ck rising edge	Generated on sdmmc_ker_ck falling edge succeeding the SDMMC_CK rising edge.	
		1		Generated on the same sdmmc_ker_ck rising edge that generates the SDMMC_CK falling edge.	
	1	0		Generated on sdmmc_ker_ck falling edge succeeding the SDMMC_CK rising edge.	Generated on sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
		1		Generated on the same sdmmc_ker_ck rising edge that generates the SDMMC_CK falling edge.	

By default, the **sdmmc_io_in_ck** feedback clock input is selected for sampling incoming data in the SDMMC receive path. It is derived from the SDMMC_CK pin.

For tuning the phase of the sampling clock to accommodate the receive data timing, the DLYB delay block available on the device can be connected between **sdmmc_io_in_ck** signal (DLYB input dlyb_in_ck) and **sdmmc_fb_ck** clock input of SDMMC (DLYB output dlyb_out_ck). Selecting the **sdmmc_fb_ck** clock input in the receive path then enables using the phase-tuned sampling clock for the incoming data. This is required for SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

When using an external driver (a voltage switch transceiver), the SDMMC_CKIN feedback clock input can be selected to sample the receive data.

For an SD/SDIO/*e*•MMC card, the clock frequency can vary between 0 and 208 MHz (limited by maximum I/O speed).

Depending on the selected bus mode (SDR or DDR), one bit or two bits are transferred on SDMMC_D[7:0] lines with each clock cycle. The SDMMC_CMD line transfers only one bit per clock cycle.

30.5.4 SDMMC adapter

The SDMMC adapter (see *Figure 229: SDMMC block diagram*) is a multimedia/secure digital memory card bus master that provides an interface to a MultiMediaCard stack or to a secure digital memory card. It consists of the following subunits:

- Control unit
- Data transmit path
- Command path
- Data receive path
- Response path
- Receive data path clock multiplexer
- Delay block (DLYB), external to the SDMMC
- Adapter register block
- Data FIFO
- Internal DMA (IDMA)

Note: The adapter registers and FIFO use the AHB clock domain (sdmmc_hclk). The control unit, command path and data transmit path use the SDMMC adapter clock domain (sdmmc_ker_ck). The response path and data receive path use the SDMMC adapter feedback clock domain from the sdmmc_io_in_ck, or SDMMC_CKIN, or from the sdmmc_fb_ck generated by DLYB.

The DLYB delay block on the device can be used in conjunction with the SDMMC adapter, to tune the phase of the sampling clock for incoming data in SDMMC receive mode. It is required for the SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

Adapter register block

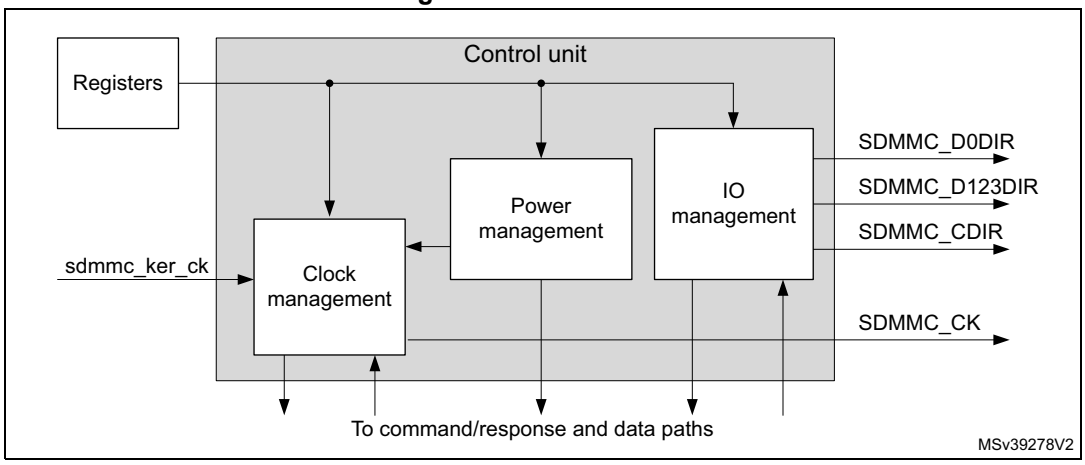
The adapter register block contains all system control registers, the SDMMC command and response registers and the data FIFO.

This block also generates the signals from the corresponding bit location in the SDMMC Clear register that clear the static flags in the SDMMC adapter.

Control unit

The control unit illustrated in *Figure 231*, contains the power management functions, the SDMMC_CK clock management with divider, and the I/O direction management.

Figure 231. Control unit



The power management subunit disables the card bus output signals during the power-off and power-up phases.

There are three power phases:

- power-off
- power-up
- power-on

The clock management subunit uses the sdmmc_ker_ck to generate the SDMMC_CK and provides the division control. It also takes care of stopping the SDMMC_CK for flow control, for example.

The clock outputs are inactive:

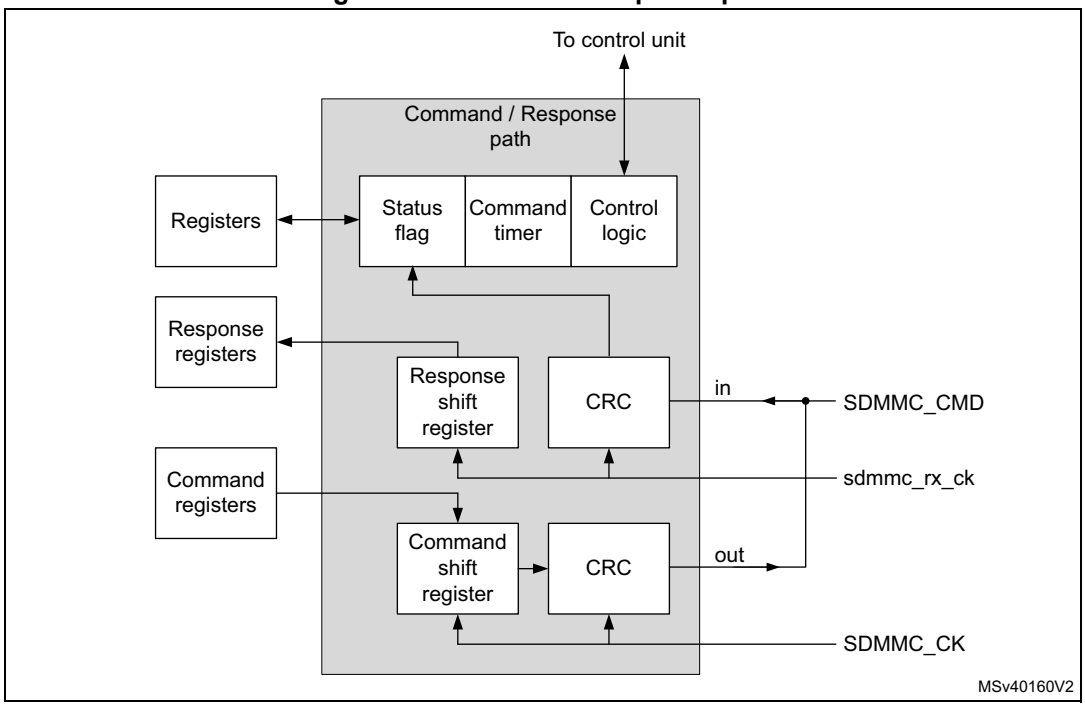
- after reset
- during the power-off or power-up phases
- if the power saving mode (register bit PWRSAV) is enabled and the card bus is in the Idle state for eight clock periods. The clock is stopped eight cycles after both the command/response CPSM and data path DPSM subunits have enter the Idle phase. The clock is restarted when the command/response CPSM or data path DPSM is activated (enabled).

The I/O management subunit takes care of the SDMMC_Dn and SDMMC_CMD I/O direction signals, which controls the external voltage transceiver.

Command/response path

The command/response path subunit transfers commands and responses on the SDMMC_CMD line. The command path is clocked on the SDMMC_CK and sends commands to the card,. The response path is clocked on the sdmmc_rx_ck and receives responses from the card.

Figure 232. Command/response path

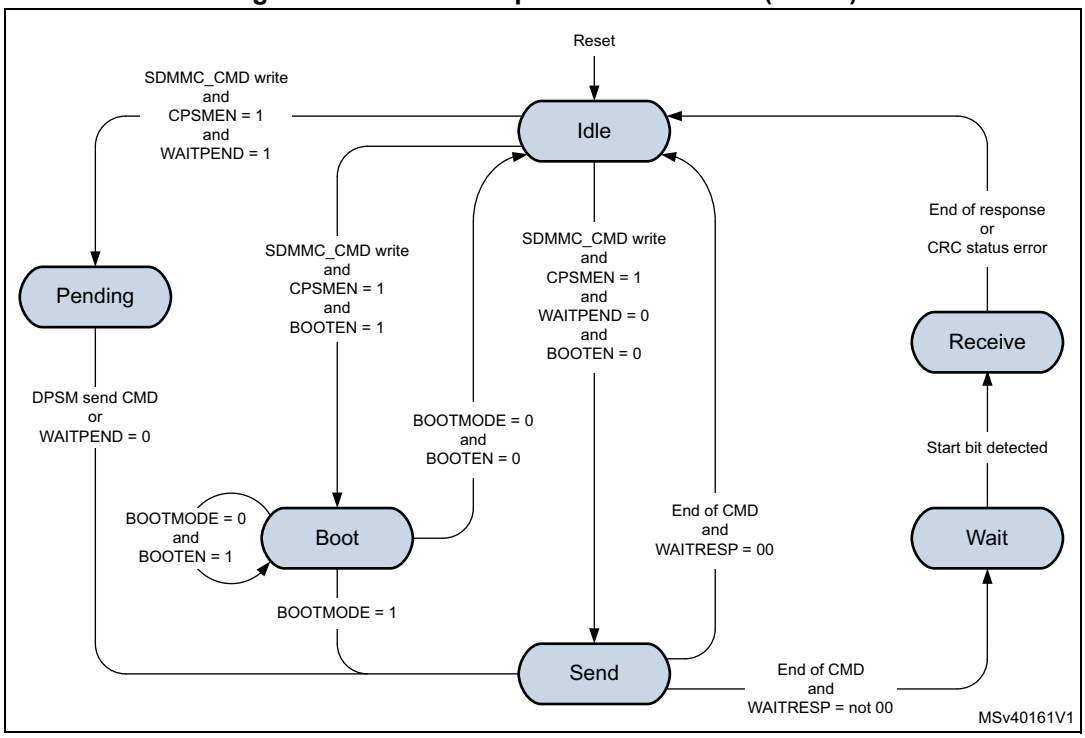


Command/response path state machine (CPSM):

- When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent the CRC is appended and the command path state machine (CPSM) sets the status flags and:
  - if a response is not required enters the Idle state.
  - If a response is required, it waits for the response.
- When the response is received,
  - for a response with CRC, the received CRC code and the internally generated code are compared, and the appropriate status flag is set according the result.
  - for a response without CRC, no CRC is checked, and the appropriate status flag is not set.

When ever the CPSM is active (not in the Idle state), the CPSMACT bit is set.

Figure 233. Command path state machine (CPSM)



- **Idle**: The command path is inactive. When the command control register is written and the enable bit (CPSMEN) is set, the CPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit) and moves
  - to the Send state when WAITPEND = 0 and BOOTEN = 0.
  - to the Pending state when WAITPEND = 1.
  - to the Boot state when BOOTEN = 1.
- **Send**: The command is sent and the CRC is appended.
  - When CMDTRANS bit is set or when BOOTEN bit is set and BOOTMODE is alternative boot, and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM at the end of the command.
  - When the CMDTRANS bit is set and the CMDSUSPEND bit is 0 the interrupt period is terminated at the end of the command.
  - When CMDSTOP bit is set the CPSM Abort signal is issued to the DPSM at the end of the command.
  - If no response is expected (WAITRESP = 00) the CPSM moves to the Idle state and the CMDSENT flag is set. When BOOTMODE = 1 and BOOTEN = 0 the CMDSENT flag is delayed 56 cycles after the command end bit, otherwise the

CMDSENT flag is generated immediately after the command end bit.
The RESPCMDR and RESPxR registers are not modified.

– If a command response is expected (WAITRESP = not 00) the CPSM moves to the Wait state and start the response timeout.

- **Wait**: The command path waits for a response.
  – When WAITINT bit is 0 the command timer starts running and the CPSM waits for a start bit.
  a) If a start bit is detected before the timeout the CPSM moves to the Receive state.
  b) If the timeout is reached before the CPSM detect a response start bit, the timeout flag (CTIMEOUT) is set and the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are not modified.
  – When WAITINT bit is 1, the timer is disabled and the CPSM waits for an interrupt request (response start bit) from one of the cards.
  a) When a start bit is detected the CPSM moves to the Receive state.
  b) When writing WAITINT to 0 (interrupt mode abort), the host sends a response by its self and on detecting the start bit the CPSM move to the Receive state.
- **Receive**: The command response is received. Depending the response mode bits WAITRESP in the command control register, the response can be either short or long, with CRC or without CRC. The received CRC code when present is verified against the internally generated CRC code.
  – When the CMDSUSPEND bit is set and the SDIO Response bit BS = 0 (response bit [39]), the interrupt period is started after the response.
  When the CMDSUSPEND bit is cleared, or the CMDSUSPEND bit is 1 and the SDIO Response bit BS = 1 (response bit [39]), there is no interrupt period started.
  – When the CMDTRANS bit is set and the CMDSUSPEND bit is set and the SDIO Response bit DF= 1 (response bit [32]) the interrupt period is terminated after the response.
  – When the CRC status passes or no CRC is present the CMDREND flag is set, the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are updated with received response.
  - When BOOTMODE = 1 and BOOTEN = 0 the CMDREND flag is delayed 56 cycles after the response end bit, otherwise the CMDREND flag is generated immediately after the response end bit.
  - When CMDTRANS bit is set and the DTDIR = transmit, the CPSM DataEnable signal is issued to the DPSM at the end of the command response.
  – When the CRC status fails the CCRCFAIL flag is set and the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are updated with received response.
- **Pending**: According the pending WAITPEND bit in the command register, the CPSM enters the pending state.
  – When DATALENGTH ≤ 5 bytes the CPSM moves to the Sent state and generates the DataEnable signal to start the data transfer aligned with the CMD12 Stop Transmission command.
  – When DATALENGTH > 5 bytes, the CPSM DataEnable signal is issued to the DPSM to start the data transfer. The CPSM waits for a send CMD signal from the

DPSM before moving to the Send state. This enables, for example, the CMD12 Stop Transmission command to be sent aligned with the data.

– When writing WAITPEND to 0, the CPSM moves to the Send state.

- **Boot**: If the BOOTEN bit is set in the command register, the CPSM enters the Boot state, and when:
  – BOOTMODE = 0 the SDMMC_CMD line is driven low and when CMDTRANS bit is set and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM. This enables normal boot operation. This state is left at the end of the boot procedure by clearing the register bit BOOTEN, which cause the SDMMC_CMD line to be driven high and the CPSM Abort signal is issued to the DPSM, before moving to the Idle state. The CMDSENT flag is generated 56 cycles after SDMMC_CMD line is high.
  – BOOTMODE = 1, move to the Send state. This enables sending of the CMD0 (boot). Clearing BOOTEN has no effect.

Note: The CPSM remains in the Idle state for at least eight SDMMC_CK periods to meet the N_{CC} and N_{RC} timing constraints. N_{CC} is the minimum delay between two host commands, and N_{RC} is the minimum delay between the host command and the card response.

The response timeout has a fixed value of 64 SDMMC_CK clock periods.

A command is a token that starts an operation. Commands are sent from the host to either a single card (addressed command) or all connected cards (broadcast command are available for *e*•MMC V3.31 or previous). Commands are transferred serially on the SDMMC_CMD line. All commands have a fixed length of 48 bits. The general format for a command token for SD-Memory cards, SDIO cards, and *e*•MMC cards is shown in *Table 213.*

The command token data is taken from two registers, one containing a 32-bit argument and the other containing the 6-bit command index (six bits sent to a card).

Table 213. Command token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	1	Transmission bit
[45:40]	6	x	Command index
[39:8]	32	x	Argument
[7:1]	7	x	CRC7
0	1	1	End bit

Next to the command data there are command type (WAITRESP) bits controlling the command path state machine (CPSM). These bits also determine whether the command requires a response, and whether the response is short (48 bit) or long (136 bits) long, and if a CRC is present or not.

A response is a token that is sent from an addressed card or synchronously from all connected cards to the host as an answer to a previous received command. All responses are sent via the command line SDMMC_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type. Response tokens R1, R2, R3, R4, R5, and R6 have various

coding schemes, depending on their content. The general formats for the response tokens for SD-Memory cards, SDIO cards, and *e*•MMC cards are shown in *Table 214*, *Table 215* and *Table 216*.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. Most responses, except some, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

The response token data is stored in five registers, four containing the 32-bits card status, OCR register, argument or 127-bits CID or CSD register including internal CRC, and one register containing the 6-bits command index.

Table 214. Short response with CRC token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	0	Transmission bit
[45:40]	6	x	Command index (or reserved 111111)
[39:8]	32	x	Argument
[7:1]	7	x	CRC7
0	1	1	End bit

Table 215. Short response without CRC token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	0	Transmission bit
[45:40]	6	x	Command index (or reserved 111111)
[39:8]	32	x	Argument
[7:1]	7	1111111	(reserved 1111111)
0	1	1	End bit

Table 216. Long response with CRC token format

Bit position	Width	Value	Description
135	1	0	Start bit
134	1	0	Transmission bit
[133:128]	6	111111	Reserved
[127:1]	127:8	x	CID or CSD slices
	7:1	x	CRC7 (included in CID or CSD)
0	1	1	End bit

The command/response path operates in a half-duplex mode, so that either commands can be sent or responses can be received. If the CPSM is not in the Send state, the

SDMMC_CMD output is in the Hi-Z state. Data sent on SDMMC_CMD are synchronous with the SDMMC_CK according the NEGEDGE register bit see *Figure 230*.

The command and short response with CRC, the CRC generator calculates the CRC checksum for all 40 bits before the CRC code. This includes the start bit, transmission bit, command index, and command argument (or card status).

For the long response the CRC checksum is calculated only over the 120 bits of R2 CID or CSD. Note that the start bit, transmission bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:

CRC[6:0] = remainder $[(M(x) * x^7) / G(x)]$

$G(x) = x^7 + x^3 + 1$

$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit before CRC}) * x^0$

Where n = 39 or 119.

The CPSM can send a number of specific commands to handle various operating modes when CPSMEN is set, see *Table 217*.

Table 217. Specific Commands overview

VSWITCH	BOOTEN	BOOTMOD	CMDTRAN	WAITPEND	CMDSTOP	WAITINT	Description
1	x	x	x	x	x	x	Start voltage switch sequence
0	1	x	x	x	x	x	Start normal boot
0	1	1	x	x	x	x	Start alternative boot
0	0	1	x	x	x	x	Stop alternative boot.
0	0	0	1	x	x	x	Send command with associated data transfer.
0	0	0	0	1	1	x	*e*•MMC stream data transfer, command (STOP_TRANSMISSION) pending until end of data transfer.
0	0	0	0	1	0	x	*e*•MMC stream data transfer, command different from (STOP_TRANSMISSION) pending until end of data transfer.
0	0	0	0	0	1	x	Send command (STOP_TRANSMISSION), stopping any ongoing data transmission.
0	0	0	0	0	0	1	Enter *e*•MMC wait interrupt (Wait-IRQ) mode.
0	0	0	0	0	0	0	Any other none specific command

The command/response path implements the status flags and associated clear bits shown in *Table 218*:

Table 218. Command path status flags

Flag	Description
CMDSENT	Set at the end of the command without response (CPSM moves from Send to Idle).
CMDREND	Set at the end of the command response when the CRC is OK (CPSM moves from Receive to Idle).
CCRCFAIL	Set at the end of the command response when the CRC is FAIL (CPSM moves from Receive to Idle).
CTIMEOUT	Set after the command when no response start bit received before the timeout (CPSM moves from Wait to Idle).
CKSTOP	Set after the voltage switch (VSWITCHEN = 1) command response when the CRC is OK and the SDMMC_CK is stopped (no impact on CPSM).
VSWEND	Set after the voltage switch (VSWITCH = 1) timeout of 5 ms + 1 ms (no impact on CPSM).
CPSMACT	Command transfer in progress (CPSM not in Idle state).

The command path error handling is shown in *Table 219*:

Table 219. Command path error handling

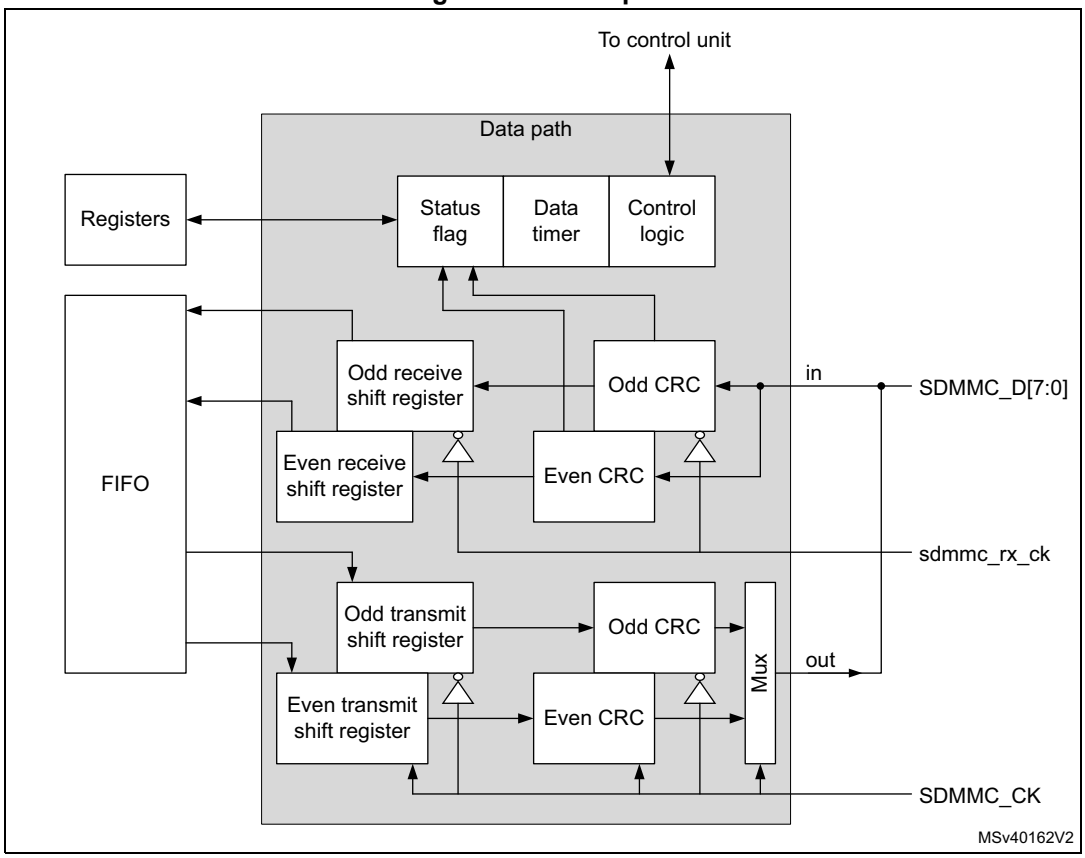
Error	CPSM state	Cause	Card action	Host action	CPSM action
Timeout	Wait	No start bit in time	Unknown	Reset or cycle power card(1)	Move to Idle
CRC status	Receive	Negative status	Command ignored	Resend command(1)	Move to Idle
		Transmission error	Command accepted	Resend command(1)	

1. When CMDTRANS is set, also a stop_transmission command must be send to move the DPSM to Idle.

Data path

The data path subunit transfers data on the SDMMC_D[7:0] lines to and from cards. The data transmit path is clocked on the SDMMC_CK and sends data to the card. The data receive path is clocked on the sdmmc_rx_ck and receives data from the card. *Figure 234* shows the data path block diagram.

Figure 234. Data path



The card data bus width can be programmed in the clock control register bits WIDBUS. The supported data bus width modes are:

- If the wide bus mode is not enabled, only one bit is transferred over SDMMC_D0.
- If the 4-bit wide bus mode is enabled, data is transferred at four bits over SDMMC_D[3:0].
- If the 8-bit wide bus mode is enabled, data is transferred at eight bits over SDMMC_D[7:0].

Next to the data bus width the data sampling mode can be programmed in the clock control register bit DDR. The supported data sampling modes are:

- Single data rate signaling (SDR), data is clocked on the rising edge of the clock.
- Double data rate signaling (DDR), data is clocked on the both edges of the clock. DDR mode is only supported in wide bus mode (4-bit wide and 8-bit wide).

Note: The data sampling mode only applies to the SDMMC_D[7:0] lines. (not applicable to the SDMMC_CMD line.)

In DDR mode, data is sampled on both edges of the SDMMC_CK according the following rules, see also *Figure 235* and *Figure 236*:

- On the rising edge of the clock odd bytes are sampled.
- On the falling edge of the clock even bytes are sampled.
- Data payload size is always a multiple of 2 bytes.
- Two CRC16 are computed per data line
  - Odd bits CRC16 clocked on the falling edge of the clock.
  - Even bits CRC16 clocked on the rising edge of the clock.
- Start, end bits and idle conditions are full cycle.
- CRC status / boot acknowledgment and busy signaling are full cycle and are only sampled on the rising edge of the clock.

In DDR mode, the SDMMC_CK clock division must be ≥ 2.

Figure 235. DDR mode data packet clocking

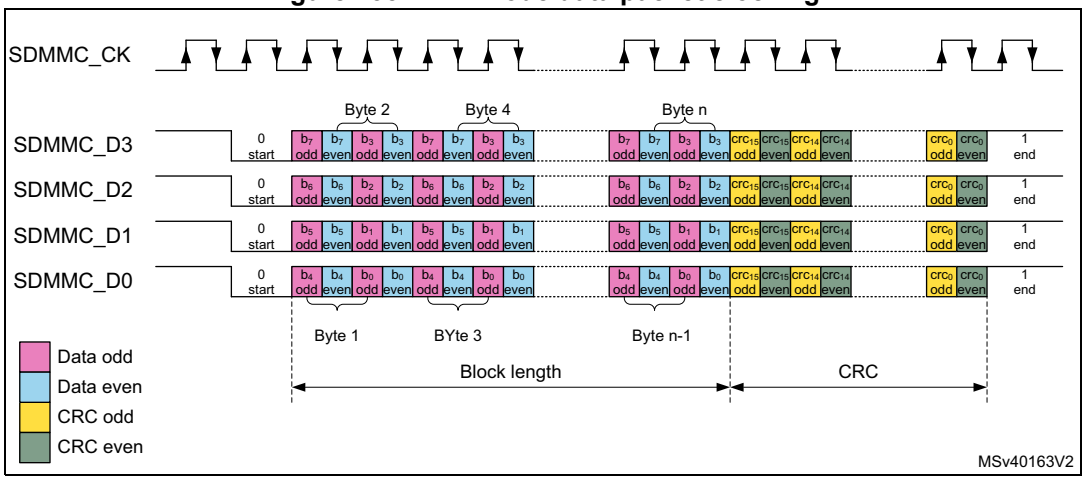


Figure 236. DDR mode CRC status / boot acknowledgment clocking

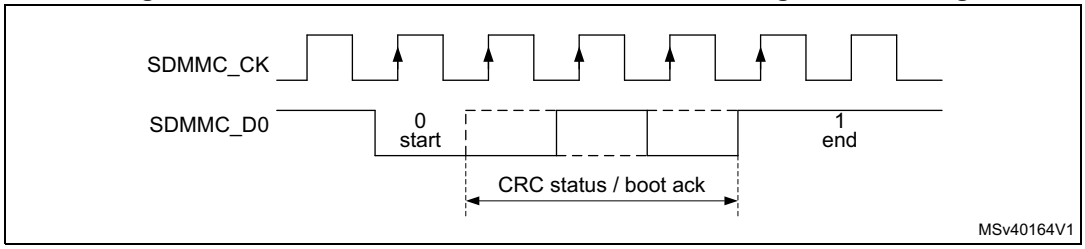


Data path state machine (DPSM)

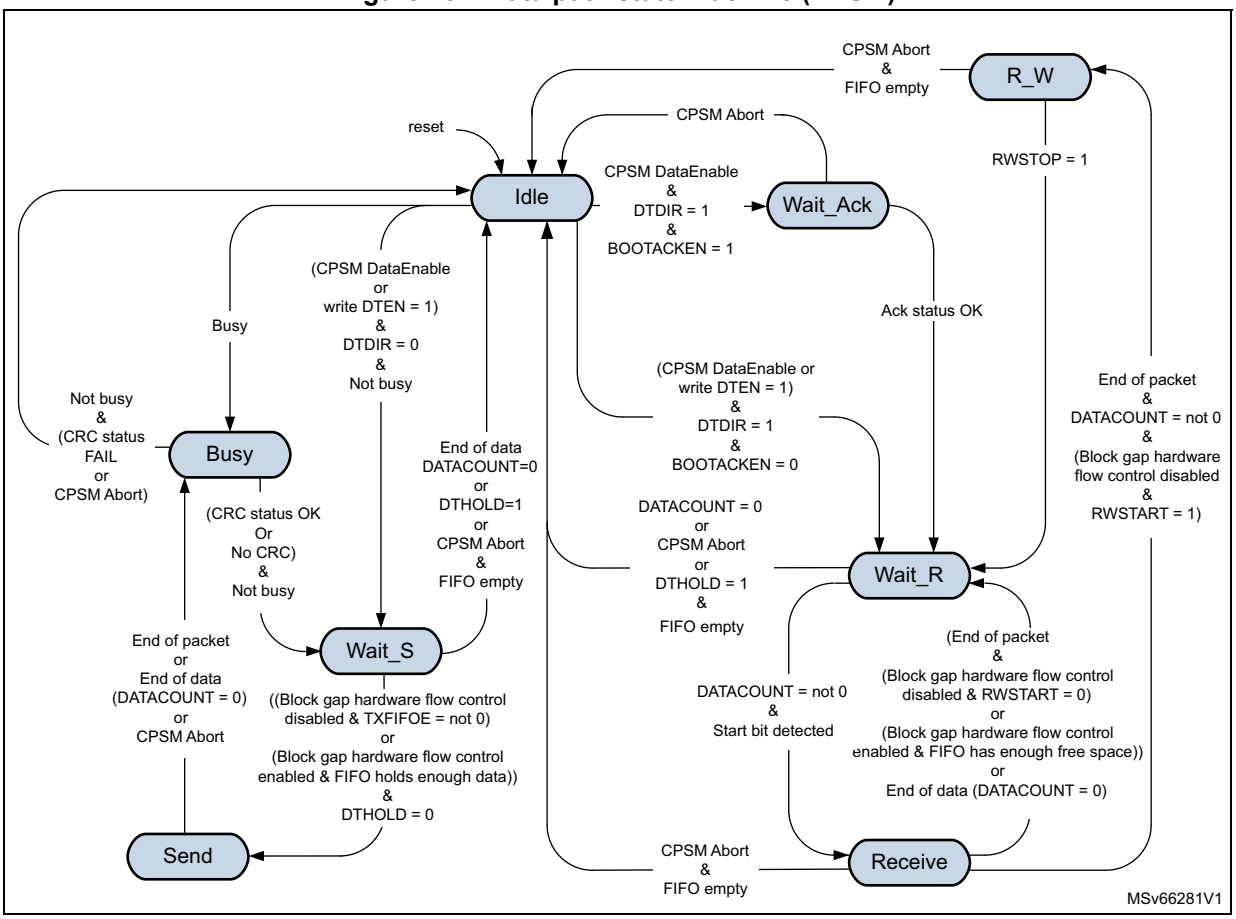
Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait_S or Wait_R state when it is enabled:

- Send: the DPSM moves to the Wait_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.

For boot operation with acknowledgment the DPSM moves to the Wait_Ack state and waits for the boot acknowledgment before moving to the Wait_R state.

The DPSM operates at SDMMC_CK. The DPSM has the following states, as shown in *Figure 237*. When ever the DPSM is active (not in the Idle state), the DPSMACT bit is set.

Figure 237. Data path state machine (DPSM)



- **Idle** state: the data path is inactive, and the SDMMC_D[7:0] outputs are according the PWRCTRL setting. The DPSM is activated either by sending a command with CMDTRANS bit set or by setting the DTEN bit, or by detecting Busy on SDMMC_D0 (that is, after a command with R1b response).

  When not busy, the DPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit), loads the data counter with a new (DATALENGTH) value and:

  – When the data direction bit (DTDIR) indicates send, moves to the Wait_S.

  – When the data direction bit (DTDIR) indicates receive, moves to the
  - Wait_R when BOOTACKEN register bit is clear.
  - Wait_Ack when BOOTACKEN register bit is set and start the acknowledgment timeout.

  When busy the DPSM keeps the SDMMC_CK clock active and move to the Busy state.

Note: DTEN must not be used to start data transfer with SD, SDIO and e•MMC cards.

- **Wait_Ack** state: the data path waits for the boot acknowledgment token.
  - The DPSM moves to the Wait_R state if it receives an error free acknowledgment before a timeout.
  - When a pattern different from the acknowledgment is received an acknowledgment status error is generated, and the ack fail status flag (ACKFAIL) is set. The DPSM stays in Wait_Ack.
  - If it reaches a timeout (ACKTIME) before it detects a start bit, it sets the timeout status flag (ACKTIMEOUT). The DPSM stays in Wait_Ack.
  - When the CPSM Abort signal is set it moves to the Idle state and sets the DABORT flag.
- **Wait_R** state: the data path, if the data counter is not zero and data is not hold, waits for a start bit on SDMMC_D[n:0]. If the data counter is zero or data is hold, wait for the FIFO to be empty.
  - In block mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DBLOCKSIZE.
  - In SDIO multibyte mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DATALENGTH.
  - In stream mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data counter with DATALENGTH.
  - if the data counter (DATACOUNT) equals zero (end of data) the DPSM moves to the Idle state when the receive FIFO is empty and the DATAEND flag is set.
  - If it reaches a timeout (DATATIME) before it detects a start bit, it sets the timeout status flag (DTIMEOUT) and the DPSM stays in the Wait_R state.
  - If the CPSM Abort signal is set:
    If DATACOUNT > 0, the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST, and sets the DABORT flag.
    If DATACOUNT is zero normal operation is continued, there is no DABORT flag since the transfer has completed normally.
  - if the DTHOLD bit is set:
    - When DATACOUNT > 0, the DPSM moves to the Idle state when the receive FIFO is empty and when IDMAEN = 0 reset with FIFORST, and issues the DHOLD flag. When holding the timeout is disabled. When an CPSM Abort signal is received during holding, the transfer is aborted.

- When DATACOUNT = 0, the transfer is completed normally and there is no DHOLD flag.

– When DPSM has been started with DTEN, after an error (DTIMEOUT) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

- **R_W** state: the data path Read Wait the bus.
  – The DPSM moves to the Wait_R state when the Read Wait stop bit (RWSTOP) is set, and start the receive timeout.
  – If the CPSM Abort signal is set, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then moves to the Idle state and sets the DABORT flag.
- **Receive** state: the data path receives serial data from a card. Pack the data in bytes and written it to the data FIFO. Depending on the transfer mode selected in the data control register (DTMODE), the data transfer mode can be either block or stream:
  – In block mode, when the data block size (DBLOCKSIZE) number of data bytes are received, the DPSM waits until it receives the CRC code.
  – In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are received, the DPSM waits until it receives the CRC code.

  a) If the received CRC code matches the internally generated CRC code, the DPSM moves to the
  - R_W state when RWSTART = 1 and DATACOUNT > zero, the DBCKEND flag is set.
  - Wait_R state otherwise, either immediately when block gap hardware flow control is disabled, or after enough free area is available in the FIFO when block gap hardware flow control is enabled.

  b) If the received CRC code fails the internally generated CRC code any further data reception is prevented.
  - When not all data has been received (DATACOUNT > 0), the CRC fail status flag (DCRCFAIL) is set and the DPSM stays in the Receive state.
  - When all data has been received (DATACOUNT = 0), wait for the FIFO to be empty after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.

  – In stream mode, the DPSM receives data while the data counter DATACOUNT > 0. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait_R state.
  – When a FIFO overrun error occurs, the DPSM sets the FIFO overrun error flag (RXOVERR) and any further data reception is prevented. The DPSM stays in the Receive state.
  – When an CPSM Abort signal is received:
  - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted. The remaining data in the shift register is written to the data FIFO, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and the DABORT flag is set.
  - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT = 0, the transfer is completed normally. The DPSM stays in the Receive state no DABORT flag is generated.

  - When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or RXOVERR) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

- **Wait_S** state: the data path waits for data to be available from the FIFO.
  - If the data counter DATACOUNT > 0,
    - When block gap hardware flow control is disabled, waits until the data FIFO empty flag (TXFIFOE) is de-asserted and DTHOLD is not set, and moves to the Send state.
    - When block gap hardware flow control is enabled, waits until the data FIFO hold enough data and DTHOLD is not set, and moves to the Send state.
  - If the data counter (DATACOUNT) = 0 the DPSM moves to the Idle state.
    - When DTHOLD is disabled, the DATAEND flag is set.
    - When DTHOLD is enabled, the DHOLD flag is set.
  - When DTHOLD is set and the DATACOUNT > 0
    - When IDMA is enabled, the DBCKEND flag is set and subsequently the FIFO is flushed, furthermore the DPSM moves to the Idle state and the DHOLD flag is set.
    - When IDMA is disabled the DBCKEND flag is set. Wait for the FIFO to be reset by software with FIFORST, then DPSM moves to the Idle state and issues the DHOLD flag.
  - When DTHOLD is set and DATACOUNT = 0 the transfer is completed normally.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and sets the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT = 0, normal operation is continued, there is no DABORT flag since the transfer has completed normally.

Note: The DPSM remains in the Wait_S state for at least two clock periods to meet the N_{WR} timing requirements, where N_{WR} is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.

- **Send** state: the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block, SDIO multibyte or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In stream mode, the DPSM sends data to a card while the data counter DATACOUNT > 0. When the data counter reaches zero moves to the Busy state and start the transmit timeout.
    Before sending the last stream byte according to DATACOUNT, the DPSM issues

a trigger on the send CMD signal. This signal is used by the CPSM to sent any pending command (CMD12 Stop Transmission command).

– If a FIFO underrun error occurs, the DPSM sets the FIFO underrun error flag (TXUNDERR). The DPSM stays in the Send state.

– When receiving the CPSM Abort signal
- If the CPSM Abort signal is received before the 2 last bits of the transfer with DATACOUNT = 0, the transfer is aborted. The DPSM sends a last data bit followed by an end bit. The FIFO is disabled/flushed, and the DPSM moves to the Busy state to wait for not busy before setting the DABORT flag.
- If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT = 0, the transfer is completed normally, there is no DABORT flag.

- **Busy** state: the DPSM waits for the CRC status token when expected, and wait for a not busy signal:

– If a CRC status token is expected and indicate “non-erroneous transmission” or when there is no CRC expected:
- it moves to the Wait_S state when SDMMC_D0 is not low (the card is not busy).
- When the card is busy SDMMC_D0 is low it remains in the Busy state.

– If a CRC status token is expected and indicates “erroneous transmission”.
- When not all data has been send (DATACOUNT > 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set. The FIFO is disabled/flushed and the DPSM stays in the Busy state.
- When all data has been send (DATACOUNT = 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.

– If a CRC status (Ncrc) timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.

– If a busy timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.

– When receiving the CPSM Abort signal in the Busy state:
- If the CPSM Abort signal is received before the 2 last bits of the CRC response with DATACOUNT > 0, the data transfer is aborted. The DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
- If the CPSM Abort signal is received during or after the 2 last bits of the CRC response when DATACOUNT = 0 or when no CRC is expected and DATACOUNT = 0 and there has been no DTIMEOUT error, the DPSM stays in the Busy state no DABORT flag is generated, since the transfer may completed normally.
- If the CPSM Abort signal is received when a DTIMEOUT error has occurred the DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.

– When entering the Busy state due to an abort in the Send state, the DPSM waits for not busy before moving to the Idle state and the DABORT flag is set.

– When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or DTIMEOUT) the DPSM moves to the Idle state when the FIFO is reset.

– When the DPSM has been started due to Busy on SDMMC_D0, waits for not busy after which the Busy end status flag (BUSYD0END) is set and the DPSM moves to the Idle state.

The data timer (DATATIME) is enabled when the DPSM is in the Wait_R or Busy state 2 cycles after the data block end bit, or data read command end bit, or R1b response, and generates the data timeout error (DTIMEOUT):

- When transmitting data, the timeout occurs
  - when a CRC status is expected and no start bit is received withing 8 SDMMC_CK cycles, the DTIMEOUT flag is set.
  - when the Busy state takes longer than the programmed timeout period., the DTIMEOUT flag is set.
- When receiving data, the timeout occurs
  - when there is still data to be received DATACOUNT > 0 and no start bit is received before the programmed timeout period, the DTIMEOUT flag is set.
- After a R1b response, the timeout occurs
  - when the Busy state takes longer than the programmed timeout period., the DTIMEOUT flag is set.

When DATATIME = 0:

- In receive the start bit must be present 2 cycles after the data block end bit or data read command end bit.
- In transmit busy is timed out 2 cycles after the CRC token end bit or stream data end bit.
- After a R1b response busy is timed out 2 cycles after the response end bit.

Data can be transferred from the card to the host (transmit, send) or vice versa (receive). Data are transferred via the SDMMC_Dn data lines, they are stored in a FIFO.

Table 220. Data token format

Description	Start bit	Data(1)	CRC16	End bit	DTMODE
Block data	0	(DBLOCKSIZE, DATALENGTH)	Yes	1	00
SDIO multibyte	0	(DATALENGTH)	Yes	1	01
e•MMC stream	0	(DATALENGTH)	No	1	10

1. The total amount of data to transfer is given by DATALENGTH. Where for Block data the amount of data in each block is given by DBLOCKSIZE.

The data token format is selected with register bits DTMODE according.

The data path implements the status flags and associated clear bits shown in *Table 221*:

Table 221. Data path status flags and clear bits

Flag		Description
DATAEND	TX	Set at the end of the complete data transfer when the CRC is OK and busy has finished and both DTHOLD = 0 and DATACOUNT = 0. (DPSM moves from Wait_S to Idle)
	RX	Set at the end of the complete data transfer when the CRC is OK and all data has been read, (DATACOUNT = 0 and FIFO is empty). (DPSM moves from Wait_R to Idle)
	Boot	

Table 221. Data path status flags and clear bits (continued)

Flag		Description
DCRCFAIL	TX	Set at the end of the CRC when FAIL and busy has finished. (DPSM stay in Busy when there is still data to send and wait for CPSM Abort) (DPSM moves from Busy to Idle when all data has been sent) or DPSM has been started with DTEN
	RX	Set at the end of the CRC when FAIL and FIFO is empty. (DPSM stays in Receive when there is still data to be received and wait for CPSM Abort) (DPSM moves from Receive to Idle when all data has been received or DPSM has been started with DTEN)
	Boot	
ACKFAIL	Boot	Set at the end of the boot acknowledgment when fail. (DPSM stays in Wait_Ack and wait for CPSM Abort)
DTIMEOUT	CMD R1b	Set after the command response no end of busy received before the timeout. (DPSM stays in Busy and wait for CPSM Abort)
	TX	Set when no CRC token start bit received within Ncrc, or no end of busy received before the timeout. (DPSM stays in Busy and wait for CPSM Abort) (When DPSM has been started with DTEN move to Idle) Note: The DCRCFAIL flag may also be set when CRC failed before the busy timeout.
	RX	Set when no start bit received before the timeout. (DPSM stays in Wait_R and wait for CPSM Abort) (When DPSM has been started with DTEN move to Idle)
	Boot	
ACKTIMEOUT	Boot	Set when no start bit received before the timeout. (DPSM stays in Wait_Ack and wait for CPSM Abort)
DBCKEND	TX	When DTHOLD = 1 and IDMAEN = 0: Set at the end of data block transfer when the CRC is OK and busy has finished, when data transfer is not complete (DATACOUNT >0). (DPSM moves from Busy to Wait_S)
	RX	When RWSTART = 1: Set at the end of data block transfer when the CRC is OK, when data transfer is not complete (DATACOUNT > 0). (DPSM moves from Receive to R_W)
	Boot	
DHOLD	TX	When DTHOLD = 1: Set at the end of data block transfer when the CRC is OK and busy has finished. (DPSM moves from Wait_S to Idle)
	RX	When DTHOLD = 1: Set at the end of data block transfer when the CRC is OK and all data has been read (FIFO is empty), when data transfer is not complete (DATACOUNT >0). (DPSM moves from Wait_R to Idle)
DABORT	CMD R1b	When CPSM Abort event has been sent by the CPSM and busy has finished. (DPSM moves from Busy to Idle)
	TX	When CPSM Abort event has been sent by the CPSM before the 2 last bits of the transfer. (DPSM moves from any state to Idle)
	RX	
	Boot	
BUSYD0END	CMD R1b	Set after the command response when end of busy before the timeout. (DPSM moves from Busy to Idle)
DPSMACT		Data transfer in progress. (DPSM not in Idle state)

The data path error handling is shown in *Table 222*:

Table 222. Data path error handling

Error	DPSM state	Cause	Card action	Host action	DPSM action
Timeout	Wait_Ack	No Ack in time	unknown	Card cycle power	Stay in Wait_Ack (reset the SDMMC with the RCC.SDMMCxRST register bit)
	Wait_R	No start bit in time	unknown	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
			unknown	Stop boot procedure	
	Busy	Busy too long (due to data transfer)	unknown	Stop data reception Send stop transmission command	
		Busy too long (due to R1b)	unknown	Send reset command	
CRC	Receive	transmission error	Send further data	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
CRC status	Busy	Negative status	Ignore further data	Stop data transmission Send stop transmission command	On CPSM Abort move to Idle
		transmission error	wait for further data		
Ack status	Wait_Ack	transmission error	Send boot data	Stop boot procedure	On CPSM Abort move to Idle
Overrun	Receive	FIFO full	Send further data	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
Underrun	Send	FIFO empty	Receive further data	Stop data transmission Send stop transmission command	On CPSM Abort move to Idle

Data FIFO

The data FIFO (first-in-first-out) subunit contains the transmit and receive data buffer. A single FIFO is used for either transmit or receive as selected by the DTDIR bit. The FIFO contain a 32-bit wide, 256-word deep data buffer and control logic. Because the data FIFO operates in the AHB clock domain (sdmmc_hclk), all signals from the subunits in the SDMMC clock domain (SDMMC_CK/sdmmc_rx_ck) are resynchronized.

The FIFO can be in one of the following states:

- The transmit FIFO refers to the transmit logic and data buffer when sending data out to the card. (DTDIR = 0)
- The receive FIFO refers to the receive logic and data buffer when receiving data in from the card. (DTDIR = 1)

The end of a correctly completed SDMMC data transfer from the FIFO is indicated by the DATAEND flags driven by the data path subunit. Any incorrect (aborted) SDMMC data transfer from the FIFO is indicated by one of the error flags (DCRCFAIL, DTIMEOUT, DABORT) driven by the data path subunit, or one of the FIFO error flags (TXUNDERR, RXOVERR) driven by the FIFO control.

The data FIFO can be accessed in the following ways, see *Table 223*.

Table 223. Data FIFO access

Data FIFO access	IDMAEN
From firmware via AHB slave interface	0
From IDMA via AHB master interface	1

Transmit FIFO:

Data can be written to the transmit FIFO when the DPSM has been activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. The transmit FIFO is accessible via sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out. The transmit FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Enable hardware flow control HWFC_EN.
   If bus speed SDR50, SDR104, HS200 or DDR50 is used FIFO threshold can be used to provide flow control at the receive block gap.
3. Set the SDMMC in transmit mode (DTDIR = 0).
   – Configures the FIFO in transmit mode.
4. Enable the data transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit
5. When (DPSMACT = 1) write data to the FIFO.
   – When BUSSPEED = 0: The DPSM stays in the Wait_S state until FIFO is full (TXFIFOF = 1), or the number indicated by DATALENGTH.
   - The SDMMC keeps sending data as long as FIFO is not empty, hardware flow control during data transfer is used to prevent FIFO underrun.
   – When BUSSPEED = 1 and the FIFO threshold is zero: The DPSM reads the transmit data from the FIFO.

- The SDMMC keeps transmitting data as long as FIFO is not empty, hardware flow control during the data transfer is used to prevent FIFO underrun.

– When BUSSPEED = 1 and the FIFO threshold is not zero: The DPSM reads the transmit data from the FIFO.
- The SDMMC only starts sending a new block when there is enough data in the FIFO according the threshold. Block gap hardware flow control is used to prevent FIFO underrun.

6. Write data to the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half empty (TXFIFOHE flag), write data to the FIFO until FIFO is full (TXFIFOF = 1), or last data has been written.
   – When the FIFO is handled by the IDMA, the IDMA transfers the FIFO date.
7. When last data has been written wait for end of data (DATAEND flag)
   – SDMMC has completely sent all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer error or transfer hold when IDMAEN = 0, firmware must stop writing to the FIFO and flush and reset the FIFO with the FIFORST register bit.

The transmit FIFO status flags are listed in *Table 224*.

Table 224. Transmit FIFO status flags

Flag	Description
TXFIFOF	Set to high when all transmit FIFO words contain valid data.
TXFIFOE	Set to high when the transmit FIFO does not contain valid data.
TXFIFOHE	Set to high when half or more transmit FIFO words are empty.
TXUNDERR	Set to high when an underrun error occurs. This flag is cleared by writing to the SDMMC Clear register.

Receive FIFO:

Data can be read from the receive FIFO when the DPSM is activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface.When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. The receive FIFO is accessible via sequential addresses.

The receive FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Enable hardware flow control HWFC_EN.
   – If bus speed SDR50, SDR104, HS200 or DDR50 is used FIFO threshold can be used to provide flow control at the receive block gap.
3. Set the SDMMC in receive mode (DTDIR = 1).
   – Configures the FIFO in receive mode.
4. Enable the DPSM transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit.
5. When (DPSMACT = 1) the FIFO is ready to receive data.
   – When BUSSPEED = 0: The DPSM writes the received data to the FIFO.
   - The SDMMC keeps receiving data as long as FIFO is not full, hardware flow control during the data transfer is used to prevent FIFO overrun.
   – When BUSSPEED = 1 and the FIFO threshold is zero: The DPSM writes the received data to the FIFO.
   - The SDMMC keeps receiving data as long as FIFO is not full, hardware flow control during the data transfer is used to prevent FIFO overrun.
   – When BUSSPEED = 1 and the FIFO threshold is not zero: The DPSM writes the received data to the FIFO.
   - The SDMMC only starts receiving a new block when there is enough free space in the FIFO according the threshold. Block gap hardware flow control is used to prevent FIFO overrun.
6. Read data from the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half full (RXFIFOHF flag), read data from the FIFO until FIFO is empty (RXFIFOE = 1).
   - When last data has been received, read data from the FIFO until FIFO is empty (DATAEND = 1).
   – When the FIFO is handled by the IDMA, the IDMA transfers the FIFO date.
7. SDMMC has completely received all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer hold when IDMAEN = 0, the firmware must read the remaining data until the FIFO is empty and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

In case of a data transfer error when IDMAEN = 0, the firmware must stop reading the FIFO and flush and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

The receive FIFO status flags are listed in *Table 225*.

Table 225. Receive FIFO status flags

Flag	Description
RXFIFOF	Set to high when all receive FIFO words contain valid data
RXFIFOE	Set to high when the receive FIFO does not contain valid data.
RXFIFOHF	Set to high when half or more receive FIFO words contain valid data.
RXOVERR	Set to high when an overrun error occurs. This flag is cleared by writing to the SDMMC Clear register.

CLKMUX unit

The CLKMUX selects the source for clock sdmmc_rx_ck to be used with the received data and command response. The receive data clock source can be selected by the clock control register bit SELCLKRX, between:

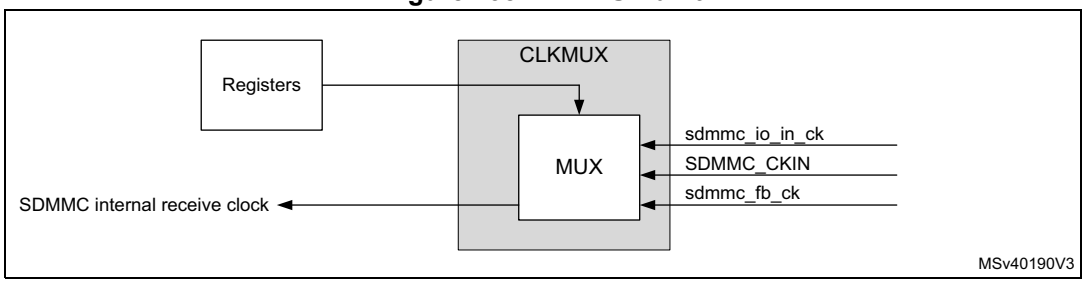
- sdmmc_io_in_ck bus master main feedback clock.
- SDMMC_CKIN external bus feedback clock.
- sdmmc_fb_ck bus tuned feedback clock.

The sdmmc_io_in_ck is selected when there is no external driver, with DS and HS.

The SDMMC_CKIN is selected when there is an external driver with SDR12, SDR25, SDR50 and DDR50.

The sdmmc_fb_ck clock input must be selected when the DLYB block on the device is used with SDR104, HS200 and optionally with SDR50 and DDR50 modes.

Figure 238. CLKMUX unit



The sdmmc_rx_ck source must be changed when the CPSM and DPSM are in the Idle state.

30.5.5 SDMMC AHB slave interface

The AHB slave interface generates the interrupt requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt logic.

SDMMC FIFO

The FIFO access is restricted to word access only:

- In transmit FIFO mode
  - Data are written to the FIFO in words (32-bits) until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer

multiple of 4, the last remaining data (1, 2 or 3 bytes) are written with a word transfer.

- In receive FIFO mode
  - Data are read from the FIFO in words (32-bits) until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are read with a word transfer padded with 0 value bytes.

When accessing the FIFO with half word or byte accesses an AHB bus fault is generated.

SDMMC interrupts

The interrupt logic generates an interrupt request signal that is asserted when at least one of the unmasked status flags is active. A mask register is provided to allow selection of the conditions that generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set. Some status flags require an implicit clear in the clear register.

30.5.6 SDMMC AHB master interface

The AHB master interface is used to transfer the data between a memory and the FIFO using the SDMMC IDMA.

SDMMC IDMA

Direct memory access (DMA) is used to provide high-speed transfer between the SDMMC FIFO and the memory. The AHB master optimizes the bandwidth of the system bus. The SDMMC internal DMA (IDMA) provides one channel to be used either for transmit or receive.

The IDMA is enabled by the IDMAEN bit and supports burst transfers of 16 beats.

- In transmit burst transfer mode:
  - Data are fetched in burst from memory whenever the FIFO is empty for the number of burst transfers, until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of the burst size the remaining, smaller then burst size data is transfered using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are fetched with a word transfer.
- In receive burst transfer mode:
  - Data are stored in burst in to memory whenever the FIFO contains the number of burst transfers, until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of the burst transfer the remaining, smaller then burst size data, is transfered using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are stored with halfword and or byte transfers.

In addition the IDMA provides the following channel configurations selected by bit IDMABMODE:

- single buffered channel
- linked list channel

Single buffered channel

In single buffer configuration the data at the memory side is accessed in a linear matter starting from the base address IDMABASE. When the IDMA has finished transferring all data the and the DPSM has completed the transfer the DATAEND flag is set.

Linked list channel

In linked list configuration, IDMAMODE = 1, the data at the memory side is subsequently accessed from linked buffers, located at base address IDMABASE. The size of the memory buffers is defined by IDMABSIZE. The buffer size must be an integer multiple of the burst size. The bit ULA is used to indicate if a new linked list buffer configuration has to be loaded from the linked list table. A new linked list configuration is loaded when the ULA bit for the current linked list item is set.

The first linked list item configuration is programmed by firmware directly in the SDMMC registers.

When the IDMA has finished transferring all the data of one linked list buffer, according IDMABSIZE, and when the linked list item ULA bit is set, the IDMA loads the new linked list item from the linked list table, and continues transferring data from the next linked list buffer. When the IDMA has finished transferring all data, according IDMABSIZE and ULA, and the DPSM has completed the transfer, according DATALENGHT, the DATAEND flag is set.

In the following cases, the linked list provides more buffer space than the data to transfer which means the current linked list buffer data has not completely be transfered:

- the ULA bit is set, and all SDMMC data according DATALENGTH has been transfered (DATAEND flag)
- a transfer error (DCRCFAIL when DATACOUNT > 0, RXOVERR, TXUNDERR) occurs
- a transfer is hold (DTHOLD)

In all above cases, the IDMA linked list is stopped and the FIFO is flushed/reset. Before starting or restarting a new SDMMC transfer, the software must initialize a new linked list with correct IDMABASE and IDMABSIZE.

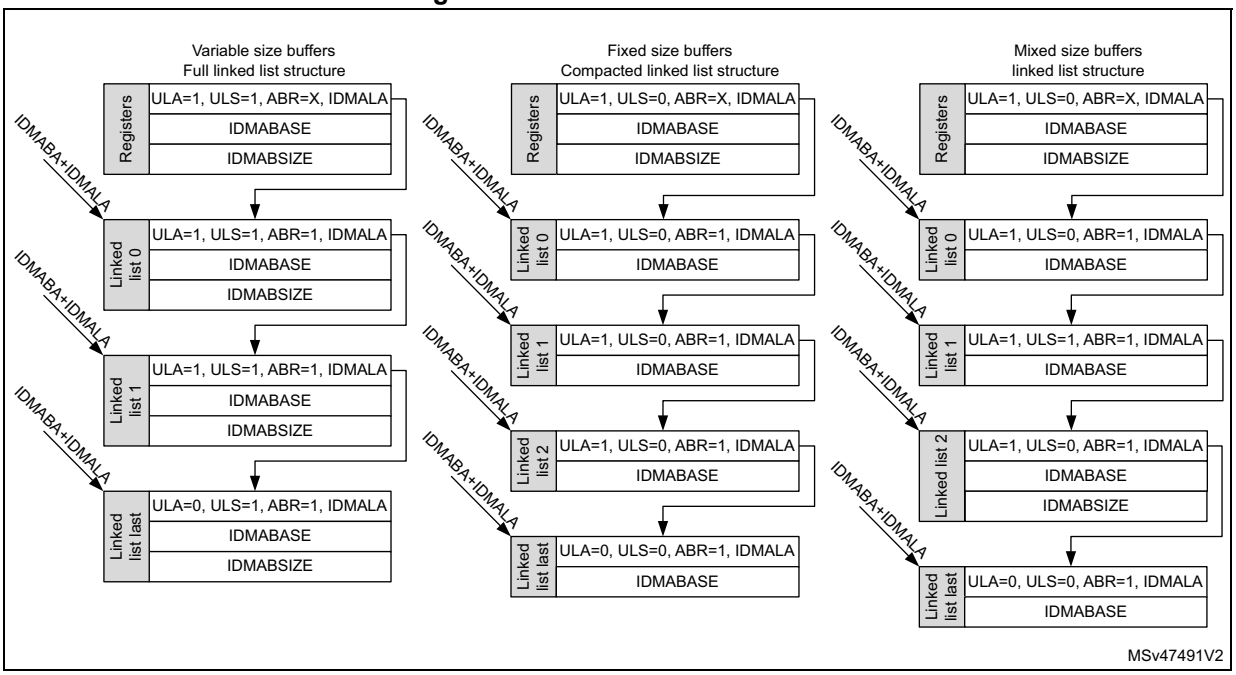
When a IDMA transfer error occurs (see *Section : IDMA transfer error management*) or when the linked list does not provide sufficient buffer space:

- the linked list ends with ULA = 0 and all last linked list buffer data has been transfered, and not all SDMMC data according DATALENGTH has been transfered. The SDMMC transfer is stopped and an IDMA transfer error is generated (see *Section : IDMA transfer error management*).

For a given linked list item, the base address is given by the linked list base IDMABA register value plus the linked list offset IDMALA register value.

The content of each linked list item can be specified by the ULS bit, which makes possible to optionally load the IDMABSIZE, resulting in a 3-word linked list structure. When the IDMABSIZE is not to be loaded (fixed size buffers) a compacted reduced 2-word linked list structure can be used containing only the IDMABASER and the IDMALAR values.

Figure 239. Linked list structures



There is no restriction on mixing both linked list item structures in a single list, this enables the IDMABSIZE to be updated only when needed.

Whenever a linked list buffer has been transfered and the current buffer ULA = 1, an end-of-linked-list-buffer-transfer-complete interrupt (IDMABTC) may be generated (if interrupt is enabled).

Linked list acknowledgment

In the case where software dynamically updates the linked list, during the SDMMC transfer, the availability of a new linked list buffer can be acknowledged by the acknowledge buffer ready (ABR) bit.

When ABR acknowledges that the new linked list buffer is ready, the IDMA continues transferring data from the new linked list buffer.

When ABR indicates that the new linked list buffer is not ready, an IDMA transfer error is generated (see *Section : IDMA transfer error management*). Depending when the IDMA transfer error occurs, it normally causes the generation of an TXUNDERR or RXOVERR error. When a linked list buffer is not acknowledged in time the SDMMC transfer is stopped.

The ABR information is “don't care” when starting the linked list from software programmed register information. The first linked list buffer must be ready to be used before starting the SDMMC transfer.

IDMA transfer error management

An IDMA transfer error can occur:

- When reading or writing a reserved address space (for data or linked list information).
- When there is no more linked list buffer space to store received SDMMC data.
- When all linked list buffer data has been transfered and still more SDMMC data needs to be sent.
- When the availability of a linked list buffer is not acknowledged.

On an IDMA transfer error subsequent IDMA transfers are disabled and an IDMATE flag is set and hardware flow control is disabled. Depending when the IDMA transfer error occurs, it normally causes the generation of a TXUNDERR or RXOVERR error.

The behavior of the IDMATE flag depend on when the IDMA transfer error occurs during the SDMMC transfer:

- An IDMA transfer error is detected before any SDMMC transfer error (TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT):
  - The IDMATE flag is set at the same time as the SDMMC transfer error flag.
  - The TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT interrupt is generated.
- An IDMA transfer error is detected during a STOP_TRANSNMISSION command:
  - The IDMATE flag is set at the same time as the DABORT flag.
  - The DABORT interrupt is generated.
- An IDMA transfer error is detected at the end of the SDMMC transfer (DHOLD, or DATAEND).
  - The IDMATE flag is set at the end of the SDMMC transfer.
  - A SDMMC transfer end interrupt is generated and a DHOLD or DATAEND flag is set.

The IDMATE is generated on an other SDMMC transfer interrupt (TXUNDERR. RXOVERR, DCRCFAIL, DTIMEOUT, DABORT, DHOLD, or DATAEND).

30.5.7 AHB and SDMMC_CK clock relation

The AHB must at least have between 1.72x and 3x more bandwidth than the SDMMC bus bandwidth i.e. for SDR50 4-bit mode (50 Mbyte/s) the minimum sdmmc_hclk frequency is 21.43 MHz (85.72 Mbyte/s).

Table 226. AHB and SDMMC_CK clock frequency relation

SDMMC bus mode	SDMMC bus width	Maximum SDMMC_CK [MHz]	Minimum AHB clock [MHz]
e•MMC DS	8	26	13
e•MMC HS	8	52	26
e•MMC DDR52	8	52	78
e•MMC HS200	8	200	100
SD DS / SDR12	4	25	5.36
SD HS / SDR25	4	50	10.72
SD DDR50	4	50	25

Table 226. AHB and SDMMC_CK clock frequency relation (continued)

SDMMC bus mode	SDMMC bus width	Maximum SDMMC_CK [MHz]	Minimum AHB clock [MHz]
SD SDR50	4	100	21.43
SD SDR104	4	208	44.58

Warning: When minimum HCLK frequency is not respected, overrun or underrun errors may occur even when hardware flow control is enabled.

30.6 Card functional description

30.6.1 SD I/O mode

The following features are SDMMC specific operations:

- SDIO interrupts
- SDIO suspend/resume operation (write and read suspend)
- SDIO Read Wait operation by stopping the clock
- SDIO Read Wait operation by SDMMC_D2 signaling

Table 227. SDIO special operation control

Operation mode	SDIOEN	RWMOD	RWSTOP	RWSTART	DTDIR
Interrupt detection	1	X	X	X	X
Suspend/Resume operation	X	X	X	X	X
Read Wait SDMMC_CK clock stop (START)	X	1	0	1	1
Read Wait SDMMC_CK clock stop (STOP)	X	1	1	1	1
Read Wait SDMMC_D2 signaling (START)	X	0	0	1	1
Read Wait SDMMC_D2 signaling (STOP)	X	0	1	1	1

SD I/O interrupts

To allow the SD I/O card to interrupt the host, an interrupt function is available on pin 8 (shared with SDMMC_D1 in 4-bit mode) on the SD interface. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the host or deasserted due to the end of the interrupt period. After the host has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card internal registers. The interrupt output of all SD I/O cards is active low and the application must provide external pull-up resistors on all data lines (SDMMC_D[3:0]).

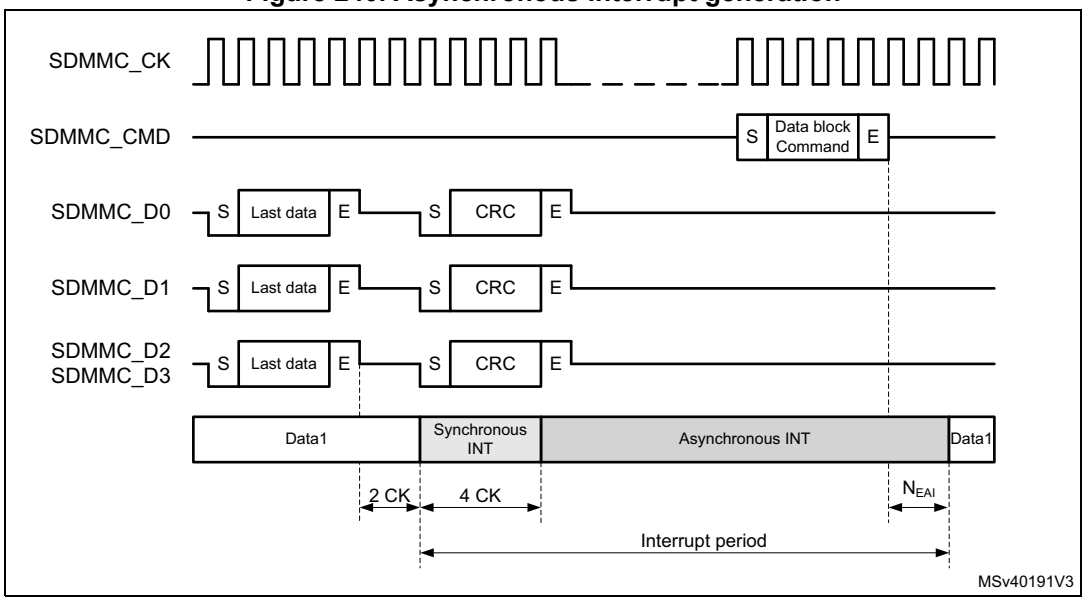
In SD 1-bit mode pin 8 is dedicated to the interrupt function (IRQ), and there are no timing constraints on interrupts.

In SD 4-bit mode the host samples the level of pin 8 (SDMMC_D1/IRQ) into the interrupt detector only during the interrupt period. At all other times, the host interrupt ignores this value. The interrupt period begins when interrupts are enabled at the card and SDIOEN bit is set see register settings in *Table 227*.

In 4-bit mode the card can generate a synchronous or asynchronous interrupt as indicated by the card CCCR register SAI and EAI bits.

- Synchronous interrupt, require the SDMMC_CK to be active.
- Asynchronous interrupt, can be generated when the SDMMC_CK is stopped, 4 cycles after the start of the card interrupt period following the last data block.

Figure 240. Asynchronous interrupt generation



The timing of the interrupt period is depending on the bus speed mode.

In DS, HS, SDR12, and SDR25 mode, selected by register bit BUSSPEED, the interrupt period is synchronous to the SD clock.

- The interrupt period ends at the next clock from the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set.
- The interrupt period resumes 2 SDMMC_CK after the completion of the data block.
- At the data block gap the interrupt period is limited to 2 SDMMC_CK cycles.

Note: DTEN must not be used to start data transfer with SD and e•MMC cards.

Figure 241. Synchronous interrupt period data read

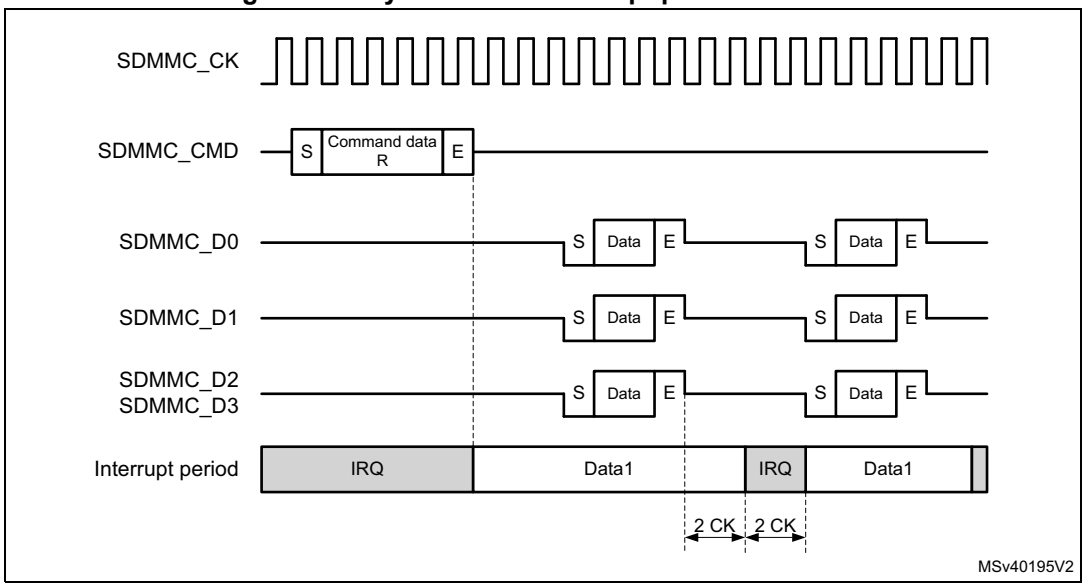


Figure 242. Synchronous interrupt period data write

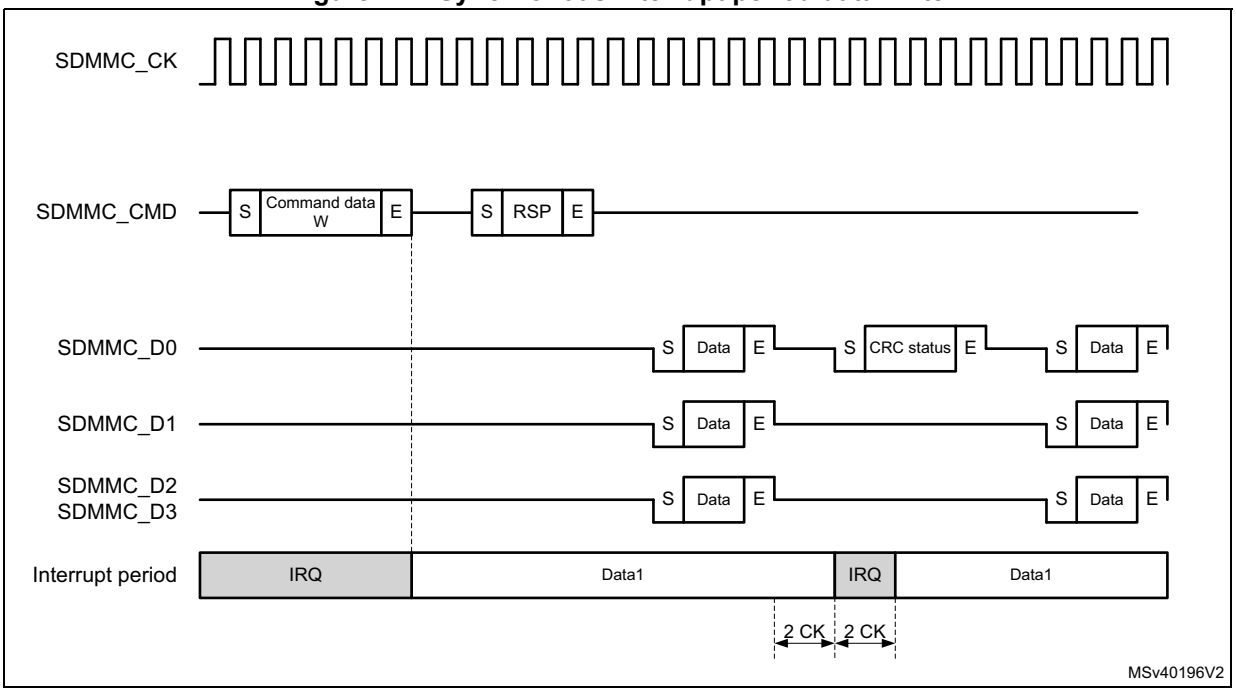

In SDR50, SDR104, and DDR50, selected by register bit BUSSPEED, due to propagation delay from the card to host, the interrupt period is asynchronous.

- The card interrupt period ends after 0 to 2 SDMMC_CK cycles after the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set. At the host the interrupt period ends after the end bit of a

command that transfers data block(s). A card interrupt issued in the 1 to 2 cycles after the command end bit are not detected by the host during this interrupt period.

- The card interrupt period resumes 2 to 4 SDMMC_CK after the completion of the last data block. The host resumes the interrupt period always 2 cycles after the last data block.
- There is NO interrupt period at the data block gap.

Note: DTEN must not be used to start data transfer with SD and e•MMC cards.

Figure 243. Asynchronous interrupt period data read

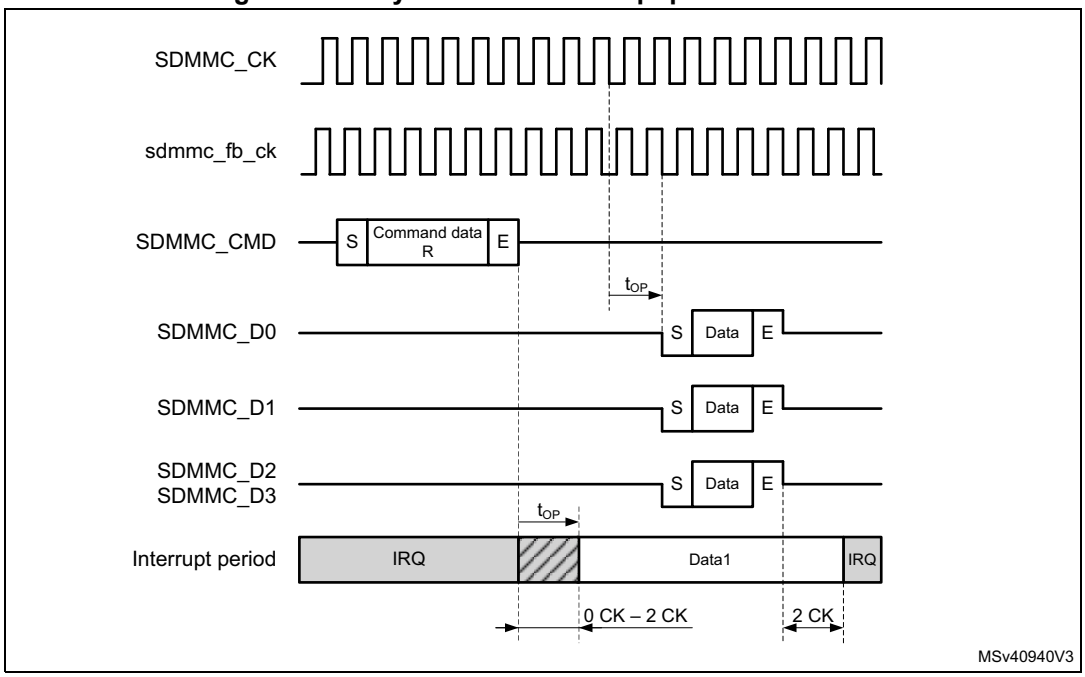

Figure 244. Asynchronous interrupt period data write

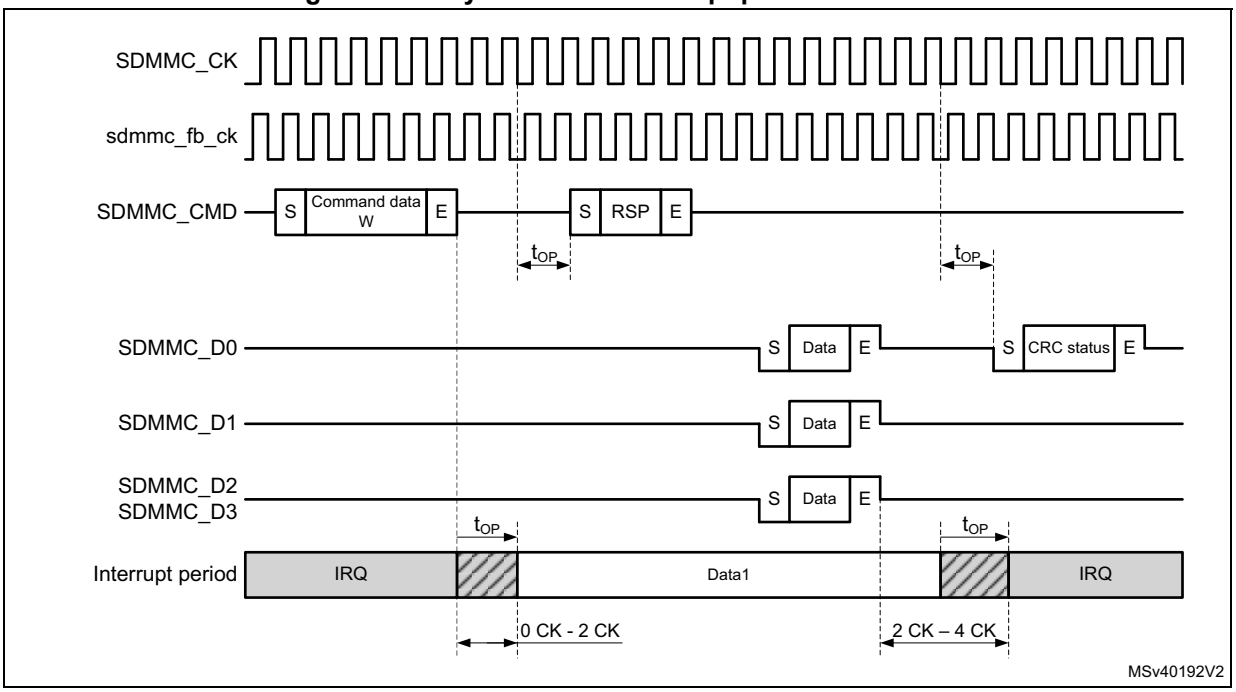


When transferring Open-ended multiple block data and using DTMODE “block data transfer ending with STOP_TRANSMISSION command”, the SDMMC masks the interrupt period after the last data block until the end of the CMD12 STOP_TRANSMISSION command.

The interrupt period is applicable for both memory and I/O operations.

In 4-bit mode interrupts can be differentiated from other signaling according *Table 228*.

Table 228. 4-bit mode Start, interrupt, and CRC-status Signaling detection

SDMMC data line	Start	Interrupt	CRC-status
SDMMC_D0	0	1 or CRC-status	0
SDMMC_D1	0	0	X
SDMMC_D2	0	1 or Read Wait	X
SDMMC_D3	0	1	X

SD I/O suspend and resume

This function is NOT supported in SDIO version 4.00 or later.

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the *e*•MMC/SD bus. To share access to the host among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the host can temporarily halt (suspend) a data transfer operation to one function or memory to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is restarted (resume) where it left off.

To perform the suspend/resume operation on the bus, the host performs the following steps:

1. Determines the function currently using the SDMMC_D[3:0] line(s).
2. Requests the lower-priority or slower transaction to suspend.
3. Waits for the transaction suspension to complete.
4. Begins the higher-priority transaction.
5. Waits for the completion of the higher priority transaction.
6. Restores the suspended transaction.

The card receiving a suspend command responds with its current bus status. Only when the bus has been suspended by the card the bus status indicates suspension completed.

There are different suspend cases conditions:

- Suspend request accepted prior to the start of data transfer.
- Suspend request not accepted, (due to data being transfered at the same time), the host keeps checking the request until it is accepted (data transfer has suspended).
- Suspend request during write busy.
- Suspend request with write multiple.
- Suspend request during Read Wait.

For the host to know if the bus has been released it must check the status of the suspend request, suspension completed.

When the bus status of the suspend request response indicates suspension completed, the card has released the bus. At this time the state of the suspended operation must be saved where after an other operation can start.

The suspend command must be sent with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

The hardware does not save the number of remaining data to be transfered when resuming the suspended operation. It is up to firmware to determine the data that has been transferred and resume with the correct remaining number of data bytes.

While receiving data from the card, the SDMMC can suspend the read operation after the read data block end (DPSM in Wait_R). After receiving the suspend acknowledgment response from the card the following steps must be taken by firmware:

1. The normal receive process must be stopped by setting DTHOLD bit.
   a) The remaining number of data bytes in the FIFO must be read until the receive FIFO is empty (RXFIFOE flag is set), and when IDMAEN = 0 the FIFO must be reset with FIFORST.
2. The confirmation that all data has been read from the FIFO, and that the suspend is completed is indicated by the DHOLD flag.
   a) The remaining number of data bytes (multiple of data blocks) still to be read when resuming the operation must be determined from the remaining number of bytes indicated by the DATACOUNT.

Note: When a DTIMEOUT flag occurs during the suspend procedure, this must be ignored.

To resume receiving data from the card, the following steps must be taken by firmware:

1. The remaining number of data bytes (multiple of data blocks) must be programmed in DATALENGTH.
2. The DPSM must be configured to receive data in the DTDIR bit.
3. The resume command must be sent from the CPSM, with the CMDTRANS bit set and the CMDSUSPEND bit set, which ends the interrupt period when data transfer is resumed (response bit DF = 1) and enabled the DPSM, after which the card resumes sending data.

While sending data to the card, the SDMMC can suspend the write operation after the write data block CRC status end (DPSM in Busy). Before sending the suspend command to the card the following steps must be taken by firmware:

1. Enable DHOLD flag (and DBCKEND flag when IDMAEN = 0)
2. The DPSM must be prevented from start sending a new data block by setting DTHOLD.
3. When IDMAEN = 0: When receiving the DBCKEND flag the data transfer is stopped. Firmware can stop filling the FIFO, after which the FIFO must be reset with FIFORST. Any bytes still in the FIFO need to be rewritten when resuming the operation.
4. When receiving the DHOLD flag the data transfer is stopped. The remaining number of data bytes still to be written when resuming must be determined from the remaining number of bytes indicated by the DATACOUNT.
5. To suspend the card the suspend command must be sent by the CPSM with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

To resume sending data to the card, the following steps must be taken by firmware:

1. The remaining number of data bytes must be programmed in DATALENGTH.
2. The DPSM must be configured for transmission with DTDIR set and enabled by having the CPSM send the resume command with the CMDTRANS bit set and the CMDSUSPEND bit set. This ends the interrupt period and start the data transfer. The DPSM either goes to the Wait_S state when SDMMC_D0 does not signal busy, or goes to the Busy state when busy is signaled.
3. When IDMAEN = 1: The IDMA needs to be reprogrammed for the remaining bytes to be transfered.
4. When IDMAEN = 0: Firmware must start filling the FIFO with the remaining data.

SD I/O Read Wait

There are two methods to pause the data transfer during the block gap:

1. Stopping the SDMMC_CK.
2. Using Read Wait signaling on SDMMC_D2.

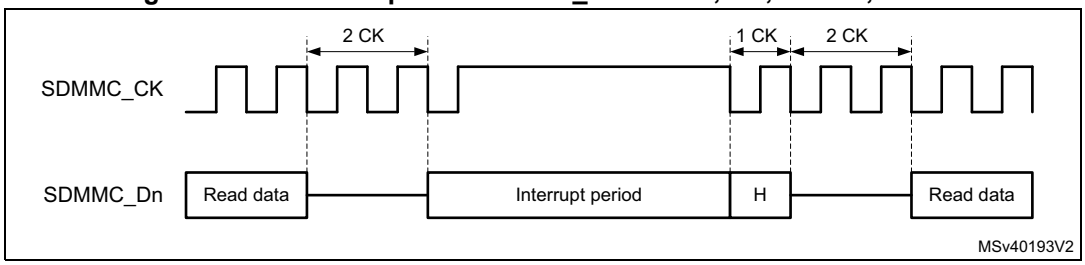
The SDMMC can perform a Read Wait with register settings according *Table 227*.

Read Wait is not available when block gap hardware flow control is enabled. (see *Section 30.7.2: Block gap hardware flow control*)

Depending the SDMMC operation mode (DS, HS, SDR12, SDR25) or (SDR50, SDR104, DDR) each method has a different characteristic.

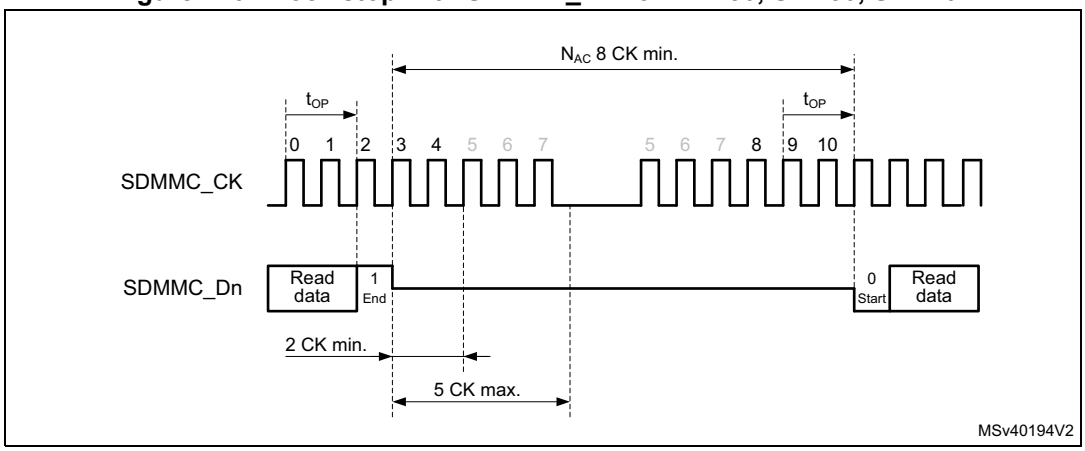
The timing for pause read operation by stopping the SDMMC_CK for DS, HS, SDR12, and SDR25, the SDMMC_CK may be stopped 2 SDMMC_CK cycles after the end bit. When ready the host resumes by restarting clock (see *Figure 245*).

Figure 245. Clock stop with SDMMC_CK for DS, HS, SDR12, SDR25



The timing for pause read operation by stopping the SDMMC_CK for SDR50, SDR104, and DDR50, the SDMMC_CK may be stopped minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, after the end bit. When ready the host resumes by restarting clock, see *Figure 246*. (In DDR50 mode the SDMMC_CK must only be stopped after the falling edge, when the clock line is low.)

Figure 246. Clock stop with SDMMC_CK for DDR50, SDR50, SDR104



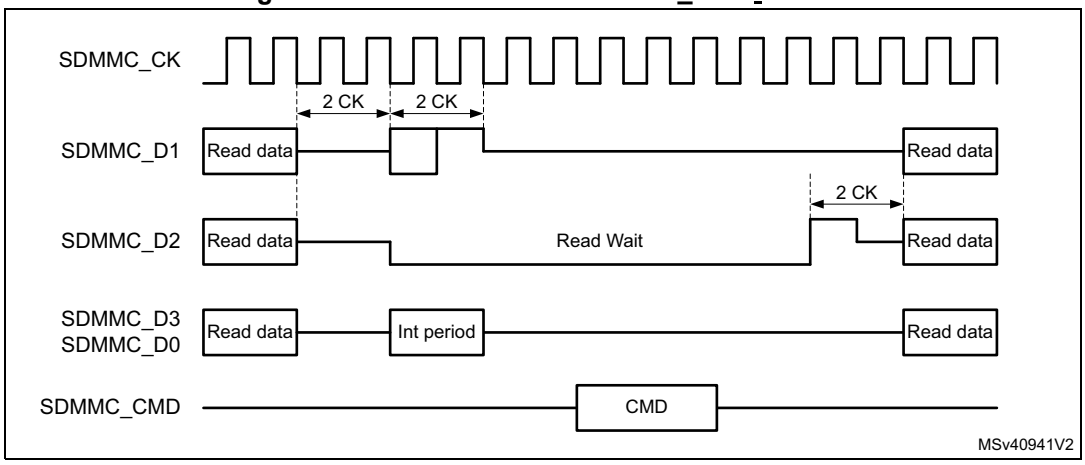
In Read Wait SDMMC_CK clock stopping, when RWSTART is set, the DSPM stops the clock after the end bit of the current received data block CRC. The clock start again after writing 1 to the RWSTOP bit, where after the DPSM waits for a start bit from the card.

As SDMMC_CK is stopped, no command can be issued to the card. During a Read Wait interval, the SDMMC can still detect SDIO interrupts on SDMMC_D1.

The optional Read Wait signaling on SDMMC_D2 (RW) operation is defined only for the SD 1-bit and 4-bit modes. The Read Wait operation enables the host to signal a card that is reading multiple registers (IO_RW_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O device. To determine when a card supports the Read Wait protocol, the host must test capability bits in the internal card registers.

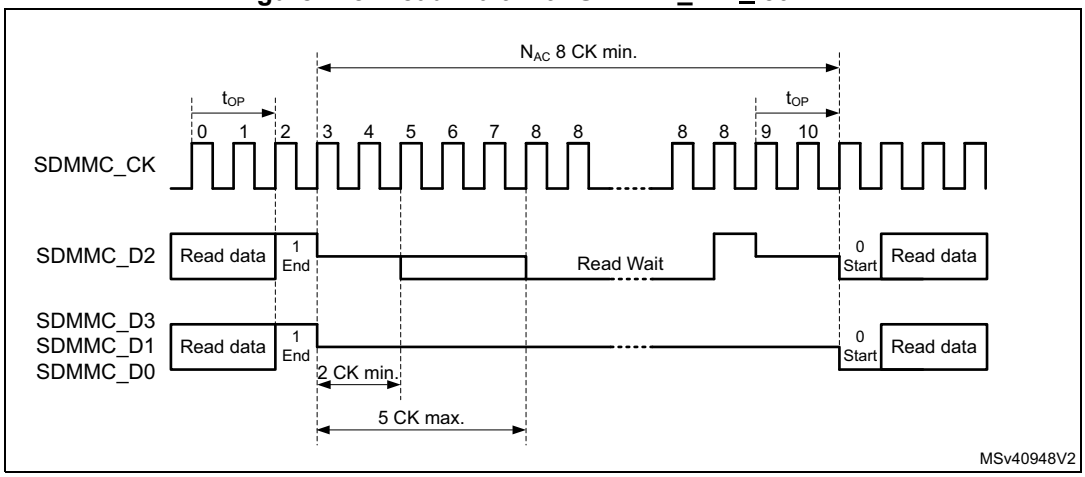
The timing for Read Wait with a SDMMC_CK less then 50MHz (DS, HS, SDR12, SDR25) is based on the interrupt period generated by the card on SDMMC_D1. The host by asserting SDMMC_D2 low during the interrupt period requests the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z, see *Figure 247*.

Figure 247. Read Wait with SDMMC_CK < 50 MHz



For SDR50, SDR104 with a SDMMC_CK more than 50MHz, and DDR50, the card treats the Read Wait request on SDMMC_D2 as an asynchronous event. The host by asserting SDMMC_D2 low after minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, request the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z. The host must raise SDMMC_D2 on the SDMMC_CK clock (see *Figure 248*).

Figure 248. Read Wait with SDMMC_CK ≥ 50 MHz



In Read Wait SDMMC_D2 signaling, when RWSTART is set, the DPSM drives SDMMC_D2 after the end bit of the current received data block CRC. The Read Wait signaling on SDMMC_D2 is removed when writing 1 to the RWSTOP bit. The DPSM remains in R_W state for two more SDMMC_CK clock cycles to drive SDMMC_D2 to 1 for one clock cycle (in accordance with SDIO specification), where after the DPSM waits for a start bit from the card.

During the Read Wait signaling on SDMMC_D2 commands can be issued to the card. During the Read Wait interval, the SDMMC can detect SDIO interrupts on SDMMC_D1.

30.6.2 CMD12 send timing

CMD12 is used to stop/abort the data transfer, the card data transmission is terminated two clock cycles after the end bit of the Stop Transmission command.

Table 229. CMD12 use cases

Data operation	Stop Transmission command CMD12 Description
SDMMC stream write	The data transfer is stopped/aborted by sending the Stop Transmission command.
SDMMC open ended multiple block write	The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC block write with predefined block count	The Stop Transmission command is not required at the end of this type of multiple block write. (sending the Stop Transmission command after the card has received the last block is regarded as an illegal command.) If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC stream read	The data transfer is stopped/aborted by sending the Stop Transmission command.
SDMMC open ended multiple block read	The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC block read with predefined block count	The Stop Transmission command is not required at the end of this type of multiple block read. (sending the Stop Transmission command after the card has transmitted the last block is regarded as an illegal command.) Transaction can be aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.

All data write and read commands can be aborted any time by a Stop Transmission command CMD12. The following data abort procedure applies during an ongoing data transfer:

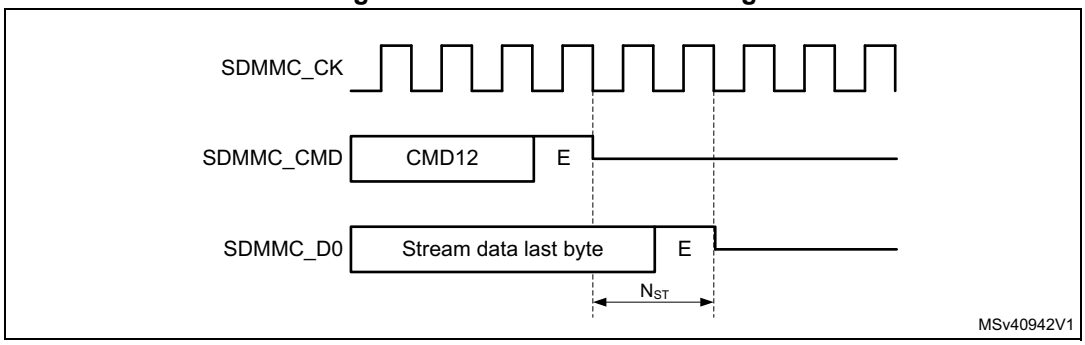
1. Load CMD12 Stop Transmission command in registers and set the CMDSTOP bit.
   – This causes the CPSM Abort signal to be generated when the command is sent to the DPSM.
2. Configure the CPSM to send a command immediately (clear WAITPEND bit).
   – The card, when sending data, stops data transfer 2 cycles after the Stop Transmission command end bit.
   The card when no data is being sent, does not start sending any new data.
   – The host, when sending data, sends one last data bit followed by an end bit after the Stop Transmission command end bit.
   The host when not sending data, does not start sending any new data.
3. When IDMAEN = 0, the FIFO need to be reset with FIFORST.
   – When writing data to the card. On the CMDREND flag, firmware must stop writing data to the FIFO. Subsequently the FIFO must be reset with FIFORST, this flushes the FIFO.
   – When reading data from the card. On the CMDREND flag, firmware must read the remaining data from the FIFO. Subsequently the FIFO must be reset with FIFORST.
4. When IDMAEN = 1, hardware takes care of the FIFO.
   – When writing data to the card. On the CPSM Abort signal, hardware stops the IDMA and subsequently the FIFO is flushed.
   – When reading data from the card. On the CPSM Abort signal, hardware instructs the IDMA to transfer the remaining data from the FIFO to RAM.
5. When the FIFO is empty/reset the DABORT flag is generated.

Stream operation and CMD12

To stop the stream transfer after the last byte to be transfered, the CMD12 end bit timing must be sent aligned with the data stream end of last byte. The following write stream data procedure applies:

1. Initialize the stream data in the DPSM, DTMODE = MCC stream data transfer.
2. Send the WRITE_DATA_STREAM command from the CPSM with CMDTRANS = 1.
3. Preload CMD12 in command registers, with the CMDSTOP bit set.
4. Configure the CPSM to send a command only after a wait pending (WAITPEND = 1) end of last data (according DATALENGTH).
5. Enabling the CPSM to send the STOP_TRANSMISSION command, the stream data end bit and command end bit are aligned.
   – When DATALENGTH > 5 bytes, Command CMD12 is waited in the CPSM to be aligned with the data transfer end bit.
   – When DATALENGHT < 5 bytes, Command CMD12 is started before and the DPSM remains in the Wait_S state to align the data transfer end with the CMD12 end bit.
6. The write stream data can be aborted any time by clearing the WAITPEND bit. This causes the Preloaded CMD12 to be sent immediately and stop the write data stream.

Figure 249. CMD12 stream timing



To stop the read stream transfer after the last byte, the CMD12 end bit timing must occur after the last data stream byte. The following read stream data procedure applies:

1. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   – The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
2. Send CMD12 by the CPSM.
   – CMD12 stops the card sending data.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

Block operation and CMD12

To stop block transfer at the end of the data, the CMD12 end bit must be sent after the last block end bit.

When writing data to the card the CMD12 end bit must be sent after the write data block CRC token end bit. This requires the CMD12 sending to be tied to the data block transmission timing. To stop an Open-ended Multiple block write, the following procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be sent by the DPSM and the CRC token to be received, (DATAEND flag).
   – The DPSM does not send more data than indicated by DATALENGTH.
3. Send CMD12 by the CPSM.
   – CMD12 sets the card to Idle mode.

When reading data from the card the CMD12 end bit must be sent earliest at the same time as the card read data block last data bit. This requires the CMD12 sending to be tied to the data block reception timing. The following stop Open-ended Multiple block read data block procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   – The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
3. Send CMD12 with CMDSTOP bit set by the CPSM.
   – CMD12 stops the Card sending more data and set the card to Idle mode. Any ongoing block transfer is aborted by the Card.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

30.6.3 Sleep (CMD5)

The *e*•MMC card may be switched between a Sleep state and a Standby state by CMD5. In the Sleep state the power consumption of the card is minimized and the Vcc power supply may be switched off.

The CMD5 (SLEEP) is used to initiate the state transition from Standby state to Sleep state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Sleep state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:

1. Enable interrupt on BUSYD0END.
2. Send CMD5 (SLEEP).
3. On BUSYD0END interrupt, card is in Sleep state.
4. Vcc power supply can be switched off.

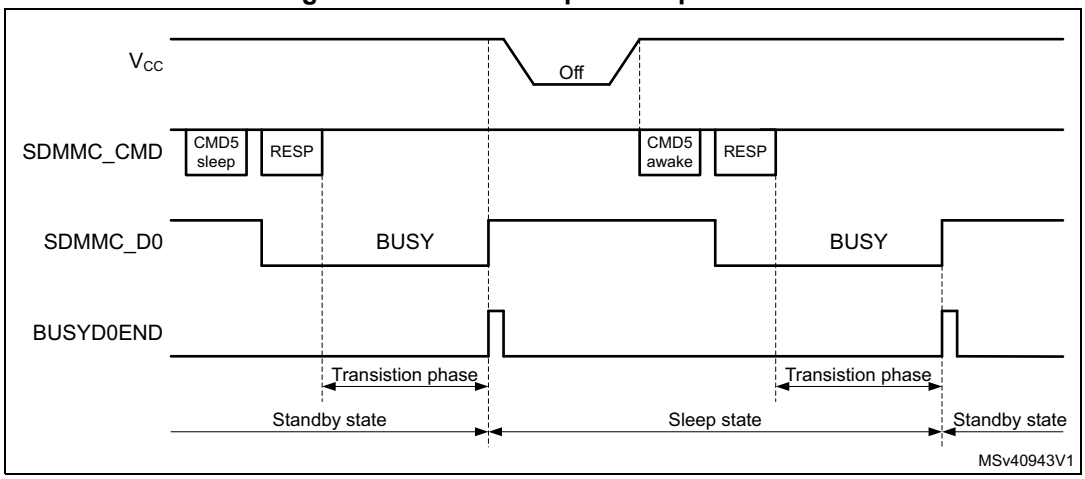
The CMD5 (AWAKE) is used to initiate the state transition from Sleep state to Standby state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Standby state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:

1. Switch on Vcc power supply and wait unit minimum operating level is reached.
2. Enable interrupt on BUSYD0END.
3. Send CMD5 (AWAKE).
4. On BUSYD0END interrupt card is in Standby state.

The Vcc power supply can be switched off only after the Sleep state has been reached. The Vcc supply must be reinstalled before CMD5 (AWAKE) is sent.

Figure 250. CMD5 Sleep Awake procedure



30.6.4 Interrupt mode (Wait-IRQ)

The host and card enter and exit interrupt mode (Wait-IRQ) simultaneously. In interrupt mode there is no data transfer. The only message allowed is an interrupt service request response from the card or the host. For the interrupt mode to work correctly the SDMMC_CK frequency must be set in accordance with the achievable SDMMC_CMD data rate in Open Drain mode, which depend on the capacitive load and pull-up resistor. The CLKDIV must be set >1, and the SETCLKRX must select either the sdmmc_io_in_ck or SDMMC_CLKin source.

The host must ensure that the card is in Standby state before issuing the CMD40 (GO_IRQ_STATE). While waiting for an interrupt response the SDMMC_CK clock signal must be kept active.

A card in interrupt mode (IRQ state):

- is waiting for an internal card interrupt event. Once the event occurs, the card starts to send the interrupt service request response. The response is sent in open-drain mode.
- while waiting for the internal card interrupt event, the card also monitors the SDMMC_CMD line for a start bit. Upon detection of a start bit the card aborts the interrupt mode and switch to Standby state.

The host in interrupt mode (CPSM Wait state waiting for interrupt):

- is waiting for a card interrupt service request response (start bit).
- while waiting for a card interrupt service request response the host may abort the interrupt mode (by clearing the WAITINT register bit), which causes the host to send a interrupt service request response R5 with RCA = 0x0000 in open-drain mode.

When sending the interrupt service request response, the sender bit-wise monitors the SDMMC_CMD bit stream. The sender whose interrupt service request response bit does not correspond to the bit on the SDMMC_CMD line stops sending. In the case of multiple senders only one successfully sends its full interrupt service request response. If the host sends simultaneously, it loses sending after the transmission bit.

To handle the interrupt mode, the following procedure applies:

1. Set the SDMMC_CK frequency in accordance with the achievable SDMMC_CMD data rate in Open-drain mode, CLKDIV must be set >1, and SETCLKRX must select the sdmmc_io_in_ck.
2. Load CMD40 (GO_IRQ_STATE) in the command registers.
3. Enable wait for interrupt by setting WAITINT register bit.
4. Configure the CPSM to send a command immediately.
   – This causes the CMD40 to be sent and the CPSM to be halted in the Wait state, waiting for a interrupt service request response.
5. To exit the wait for interrupt state (CPSM Wait state):
   – Upon the detection of an interrupt service request response start bit the CPSM moves to the Receive state where the response is received. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.
   – To abort the interrupt mode the host clears the WAITINT register bit, which causes the host to send an interrupt service request response by itself. This moves the CPSM to the Receive state. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

Note: On a simultaneous send interrupt service request response start bit collision the host loses the bus access after the transmission bit.

30.6.5 Boot operation

In boot operation mode the host can read boot data from the card by either one of the two boot operation functions:

- Normal boot. (keeping CMD line low)
- Alternative boot (sending CMD0 with argument 0xFFFFFFFA)

The boot data can be read according the following configuration options, depending on card register settings:

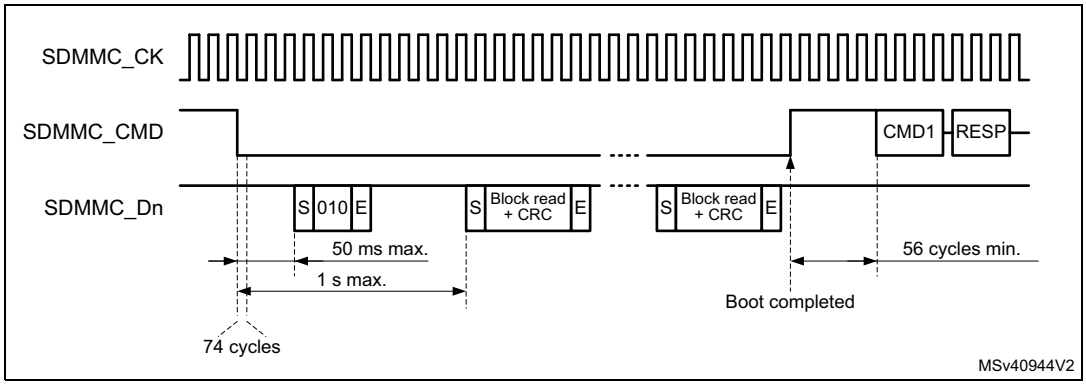
- The partition from which boot data is read (EXT_CSD Byte[179])
- The boot data size (EXT_CSD Byte[226])
- The bus configuration during boot (EXT_CSD Byte[177])
- Receiving boot acknowledgment from the card. (EXT_CSD Byte[179])

If boot acknowledgment is enabled the card send pattern 010 on SDMMC_D0 within 50ms after boot mode has been requested by either CMD line going low or after CMD0 with argument 0xFFFFFFFA. A boot acknowledgment timeout (ACKTIMEOUT) and acknowledgment status (ACKFAIL) is provided.

Normal boot operation

If the SDMMC_CMD line is held low for at least 74 clock cycles after card power-up or reset, before the first command is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD line goes low, the card starts to sent the first boot code data on the SDMMC_Dn line(s). The host must keep the SDMMC_CMD line low until after all boot data has been read. The host can terminate boot mode by pulling the SDMMC_CMD line high.

Figure 251. Normal boot mode operation



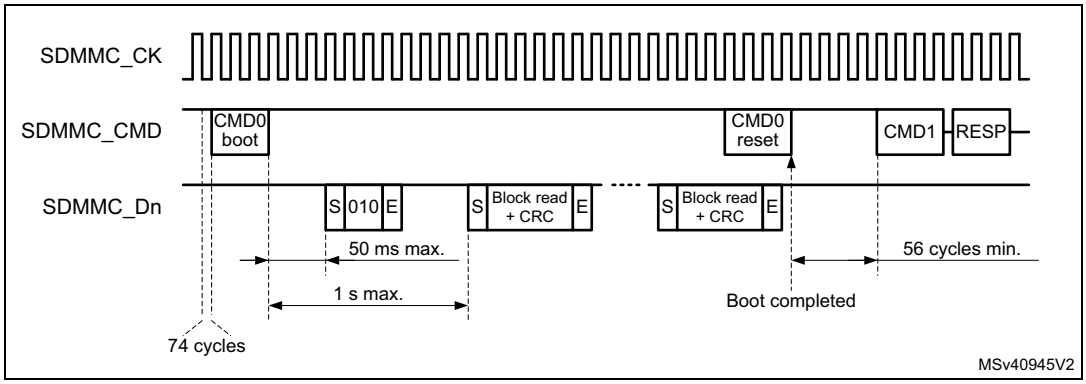
To perform the normal boot procedure the following steps needed:

1. Reset the card.
2. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKFAIL and ACKTIMEOUT interrupt.
3. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data bytes to be received in DATALENGTH.
4. Enable the DTIMEOUT, DATAEND, and CMDSENT interrupts for end of boot command confirmation.
5. Select the normal boot operation mode in BOOTMODE, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN.This causes:
   - the SDMMC_CMD to be driven low. (BOOTMODE = normal boot).
   - the ACK timeout to start.
   - DPSM to be enabled.
6. The incorrect reception of the boot acknowledgment can be detected with ACKFAIL flag or ACKTIMEOUT flag when enabled.
   - when an incorrect boot acknowledgment is received the ACKFAIL flag occurs.
   - when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
7. when all boot data has been received the DATAEND flag occurs.
   - when data CRC fails the DCRCFAIL flag is also generated.
   - when the data timeout occurs the DTIMEOUT flag is also generated.
8. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   - SDMMC has completely received all data and the DPSM is disabled.
9. The boot procedure is terminated by firmware clearing BOOTEN, which causes the SDMMC_CMD line to go high. The CMDSENT flag is generated 56 cycles later to indicate that a new command can be sent.
   - If the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops data reception and disables the DPSM which triggers an DABORT flag when enabled.
10. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command.

Alternative boot operation

After card power-up or reset, if the host send CMD0 with the argument 0xFFFFFFFA after 74 clock cycles before CMD0 is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD0 with argument 0xFFFFFFFA has been sent, the card starts to send the first boot code data on the SDMMC_Dn line(s). The master terminates boot operation by sending CMD0 (Reset).

Figure 252. Alternative boot mode operation



To perform the alternative boot procedure the following steps needed:

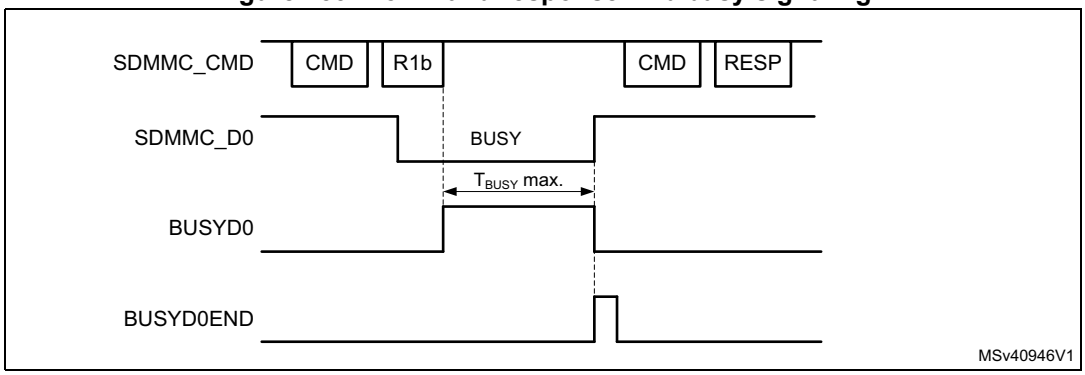
1. Move the SDMMC to power-off state, and reset the card.
2. Move the SDMMC to power-on state. This guarantees the 74 SCDMMC_CK cycles to be clocked before any command.
3. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKTIMEOUT flag.
4. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data to be received in DATALENGTH. Enable the DTIMEOUT and DATAEND flags.
5. Select the alternative boot operation mode in BOOTMODE, load the CMD0 with the 0xFFFFFFFA argument in the command registers. Enable CMDSENT flag for end of boot command confirmation, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This causes:
   - the loaded command and argument to be sent out. (BOOTMODE = alternative boot).
   - the ACK timeout to start.
   - DPSM to be enabled.
6. When the command has been sent the CMDSENT flag is generated, at which time the BOOTEN bit must be cleared.
7. the reception of the boot acknowledgment can be detected with ACKFAIL flag when enabled.
   - when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
8. when all boot data has been received the DATAEND flag occurs.
   - when data CRC fails the DCRCFAIL flag is also generated.
   - when the data timeout occurs the DTIMEOUT flag is also generated.

9. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   – SDMMC has completely received all data and the DPSM is disabled.
10. The BOOTEN bit must be cleared, before terminating the boot procedure by sending CMD0 (Reset) with BOOTMODE = alternative boot. This causes the CMDSENT flag to occur 56 cycles after the Command.
   – if the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops the data transfer and disable the DPSM which triggers an DABORT flag when enabled.
11. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command. When the RESET command has been sent successfully, the BOOTMODE control bit has to be cleared to terminate the boot operation.

30.6.6 Response R1b handling

When sending commands which have a R1b response the busy signaling is reflected in the BUSYD0 register bit and the release of busy with the BUSYD0END flag. The SDMMC_D0 line is sampled at the end of the R1b response and signaled in the BUSYD0 register bit. The BUSYD0 register bit is reset to not busy when the SDMMC_D0 line release busy, at the same time the BUSYD0END flag is generated.

Figure 253. Command response R1b busy signaling



The expected maximum busy time must be set in the DATATIME register before sending the command. When enabled, the DTIMEOUT flag is set when after the R1b response busy stays active longer then the programmed time.

To detect the SDMMC_D0 busy signaling when sending a Command with R1b response the following procedure applies:

- Enable CMDREND flag.
- Send Command through CPSM.
- On the CMDREND flag check the BUSYD0 register bit.
  – If BUSYD0 signals not busy, signal busy release to firmware
  – If BUSYD0 signals busy, wait for BUSYD0END flag
- On BUSYD0END flag signal busy released to firmware.
- On DTIMEOUT flag busy is active longer then programmed time.

30.6.7 Reset and card cycle power

Reset

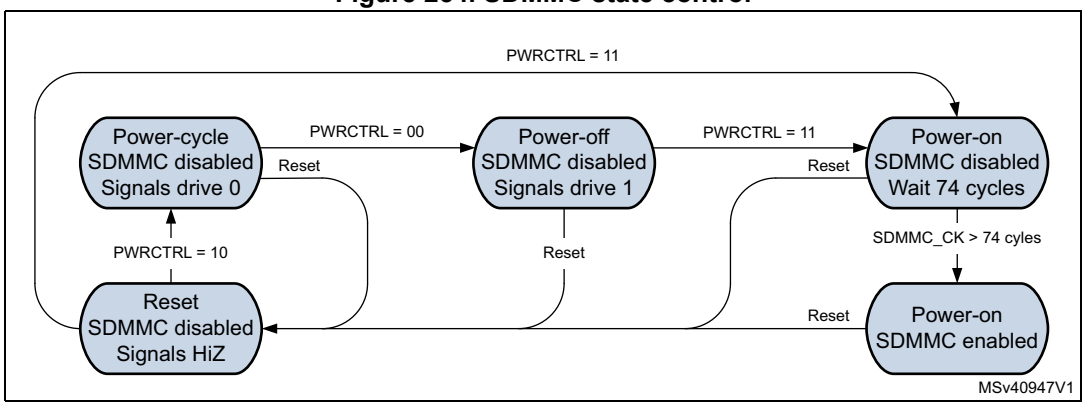
Following reset the SDMMC is in the reset state. In this state the SDMMC is disabled and no command nor data can be transfered. The SDMMC_D[7:0], and SDMMC_CMD are in HiZ and the SDMMC_CK is driven low.

Before moving to the power-on state the SDMMC must be configured.

In the power-on state the SDMMC_CK clock is running. First 74 SDMMC_CK cycles are clocked after which the SDMMC is enabled and command and data can be transfered.

The SDMMC states are controlled by Firmware with the PWRCTL register bits according *Figure 254.*.

Figure 254. SDMMC state control

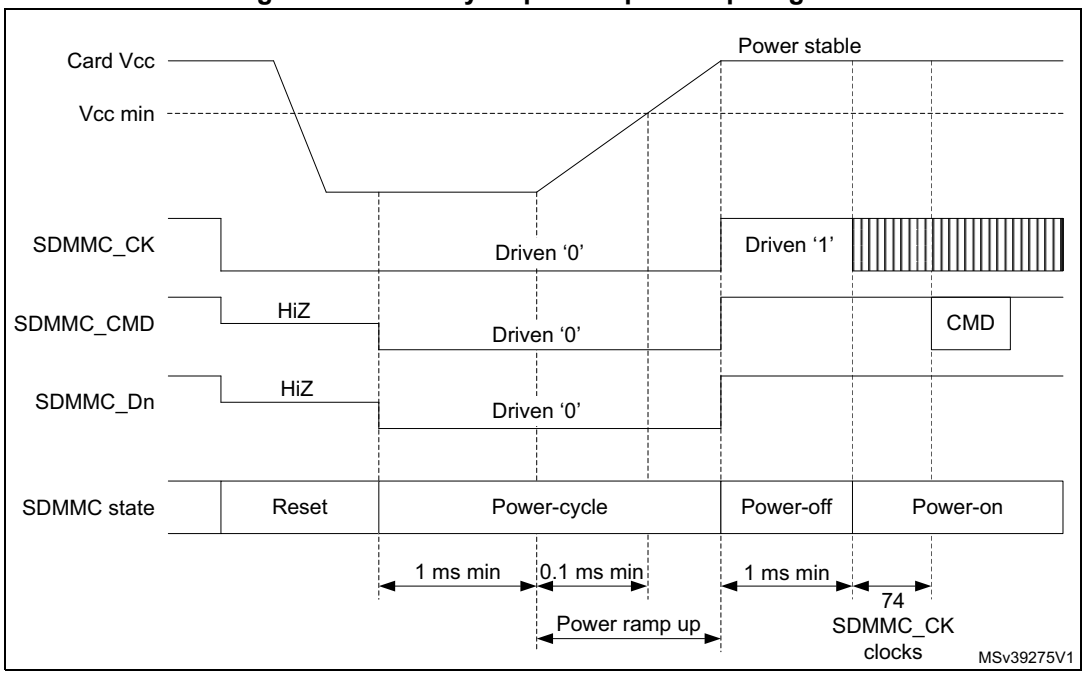


Card cycle power

To perform a card cycle power the following procedure applies:

1. Reset the SDMMC with the RCC.SDMMCxRST register bit. This resets the SDMMC to the reset state and the CPSM and DPSM to the Idle state.
2. Disable the Vcc power to the card.
3. Set the SDMMC in power-cycle state. This makes that the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low, to prevent the card from being supplied through the signal lines.
4. After minimum 1 ms enable the Vcc power to the card.
5. After the power ramp period set the SDMMC to the power-off state for minimum 1 ms. The SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are set to drive 1.
6. After the 1 ms delay set the SDMMC to power-on state in which the SDMMC_CK clock is enabled.
7. After 74 SDMMC_CK cycles the first command can be sent to the card.

Figure 255. Card cycle power / power up diagram



30.7 Hardware flow control

There are two hardware flow control mechanisms:

1. Hardware flow control during data transfer:
   - Only to be used with cycle-aligned data transfers.
2. Block gap hardware flow control:
   - Only used in mode with bus speed SDR50, SDR104, HS200 and DDR50.
   - Must be used with variable delay.

30.7.1 Hardware flow control during data transfer

The hardware flow control during data transfer functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC_CK during data transfer and freeze the SDMMC state machines. The data transfer is stalled when the FIFO is unable to transmit or receive data. The data transfer remains stalled until the transmit FIFO is half full or all data according DATALENGHT has been stored, or until the receive FIFO is half empty. Only state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled or emptied even if flow control is activated.

On an IDMA linked list transfer error, the hardware flow control is disabled. As a consequence, depending on when the IDMA linked list transfer error occurs, an underrun or overrun error may also occur (see *Section : IDMA transfer error management*).

To enable hardware flow control during data transfer, the HWFC_EN register bit must be set to 1. After reset hardware flow control is disabled.

Hardware flow control during data transfer must only be used when the SDMMC_Dn data is cycle-aligned with the SDMMC_CK. Whenever the sdmmc_fb_ck from the DLYB delay block is used, i.e in the case of SDR104 mode with a t_{OP} and Dt_{OP} delay > 1 cycle, hardware flow control during data transfer can not be used and block gap hardware flow control must be used instead.

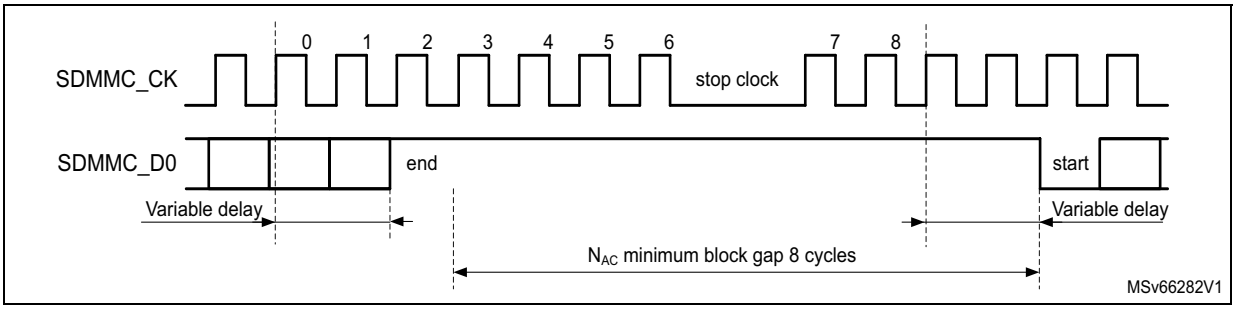
30.7.2 Block gap hardware flow control

The block gap hardware flow control functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors in SDR50, SDR104, HS200 and DDR50 mode (BUSSPEED = 1).

When transmitting, the behavior is to delay the start of a new write block and freeze the SDMMC state machines. The start of a new write block is delayed until the FIFO holds enough data according to the threshold. Only the state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled even if flow control is activated.

When receiving, the behavior is to stop SDMMC_CK during the read block gap and freeze the SDMMC state machines. The start of a new block transfer is stalled, due to stopped clock, until the FIFO has enough free space according to the threshold. Only the state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be emptied even if flow control is activated.

Figure 256. Read block gap hardware flow timing



Warning: When variable delay is used and block gap hardware flow control is enabled, sending commands during multiple block read may disturb the command response reception (CMD12 is not impacted by this).

Table 230. Data block gap hardware flow control behavior

Condition (HWFC_EN = 1 and BUSSPEED = 1)	Description
Data block size ≤ FIFO threshold	New block transfer is only started when the FIFO has enough data (TX mode) / free space (RX mode) up to or more than the THR threshold. *Note: Data flow control is guaranteed. A block transfer is only stared when enough data for at least one block is available / free in the FIFO*
Data block size > FIFO threshold	New block transfer is only started when the FIFO has enough data (TX mode) / free space (RX mode) up to or more than the THR threshold. *Note: Data flow control is not guaranteed. A block transfer is started even when not enough data for one block is available / free in the FIFO. The threshold can be used to trade off transfer latency / throughput versus FIFO underrun / overrun risk.*

On an IDMA linked list transfer error, the hardware flow control is disabled. As a consequence, depending on when the IDMA linked list transfer error occurs, an underrun or overrun error may also occur (see *Section : IDMA transfer error management*).

The block gap hardware flow control is only enabled when HWFC_EN is set to 1, BUSSPEED = 1 and the THR FIFO threshold is different than 0. When BUSSPEED = 0 or FIFO threshold is set to 0, the hardware flow control is used during the data transfer. After reset, the hardware flow control is disabled.

Table 231. Hardware flow control selection

<table>
<tr><th>HWFC_EN</th><th>THR</th><th>BUSSPEED</th><th>Description</th></tr>
<tr><td>0</td><td>X</td><td rowspan="2">X</td><td>Hardware flow control disabled</td></tr>
<tr><td rowspan="3">1</td><td>0</td><td rowspan="2">Hardware flow control during data transfer enabled</td></tr>
<tr><td rowspan="2">not 0</td><td>0</td></tr>
<tr><td>1</td><td>Block gap hardware flow control enabled</td></tr>
</table>

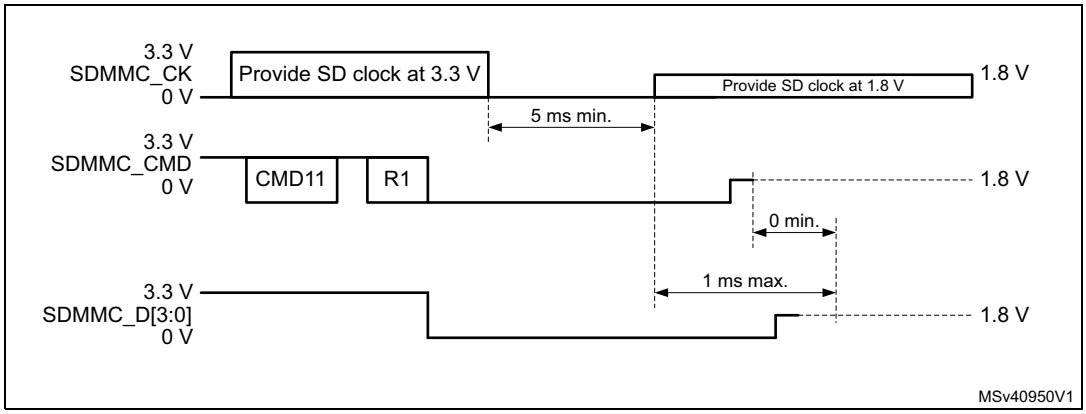
Block gap hardware flow control must be used when the SDMMC_Dn receive data are not cycle-aligned with the SDMMC_CK. This is whenever the sdmmc_fb_ck from the DLYB delay block is used, for example in the case of SDR104 receive mode with a t_{OP} and Dt_{OP} delay > 1 cycle.

30.8 Ultra-high-speed phase I (UHS-I) voltage switch

UHS-I mode (SDR12, SDR25, SDR50, SDR104, and DDR50) requires the support for 1.8 V signaling. After power up the card starts in 3.3V mode. CMD11 invokes the voltage switch

sequence to the 1.8V mode. When the voltage sequence is completed successfully the card enters UHS-I mode with default SDR12 and card input and output timings are changed.

Figure 257. CMD11 signal voltage switch sequence



To perform the signal voltage switch sequence the following steps are needed:

1. Before starting the Voltage Switch procedure, the SDMMC_CK frequency must be set in the range 100 kHz - 400 kHz.
2. The host starts the Voltage Switch procedure by setting the VSWITCHEN bit before sending the CMD11.
3. The card returns an R1 response.
   - if the response CRC is pass, the Voltage Switch procedure continues the host does no longer drive the CMD and SDMMC_D[3:0] signals until completion of the voltage switch sequence. Some cycles after the response the SDMMC_CK is stopped and the CKSTOP flag is set.
   - if the response CRC is fail (CCRCFAIL flag) or no response is received before the timeout (CTIMEOUT flag), the Voltage Switch procedure is stopped.
4. The card drives CMD and SDMMC_D[3:0] to low at the next clock after the R1 response.
5. The host, after having received the R1 response, may monitor the SDMMC_D0 line using the BUSYD0 register bit. The SDMMC_D0 line is sampled two SDMMC_CK clock cycles after the Response. The Firmware may read the BUSYD0 register bit following the CKSTOP flag.
   - When the BUSYD0 is detected low the host firmware switches the Voltage regulator to 1.8V, after which it instructs the SDMMC to start the timing critical section of the Voltage Switch sequence by setting register bit VSWITCH. The hardware continues to stop the SDMMC_CK by holding it low for at least 5 ms.
   - When the BUSYD0 is detected high the host aborts the Voltage Switch sequence and cycle power the card.
6. The card after detecting SDMMC_CK low begins switching signaling voltage to 1.8 V.
7. The host SDMMC hardware after at least 5 ms restarts the SDMMC_CK.
8. The card within 1 ms from detecting SDMMC_CK transition drives CMD and DAT[3:0] high for at least 1 SDMMC_CK cycle and then stop driving CMD and DAT[3:0].
9. The host SDMMC hardware, 1 ms after the SDMMC_CK has been restarted, the SDMMC_D0 is sampled into BUSYD0 and the VSWEND flag is set.

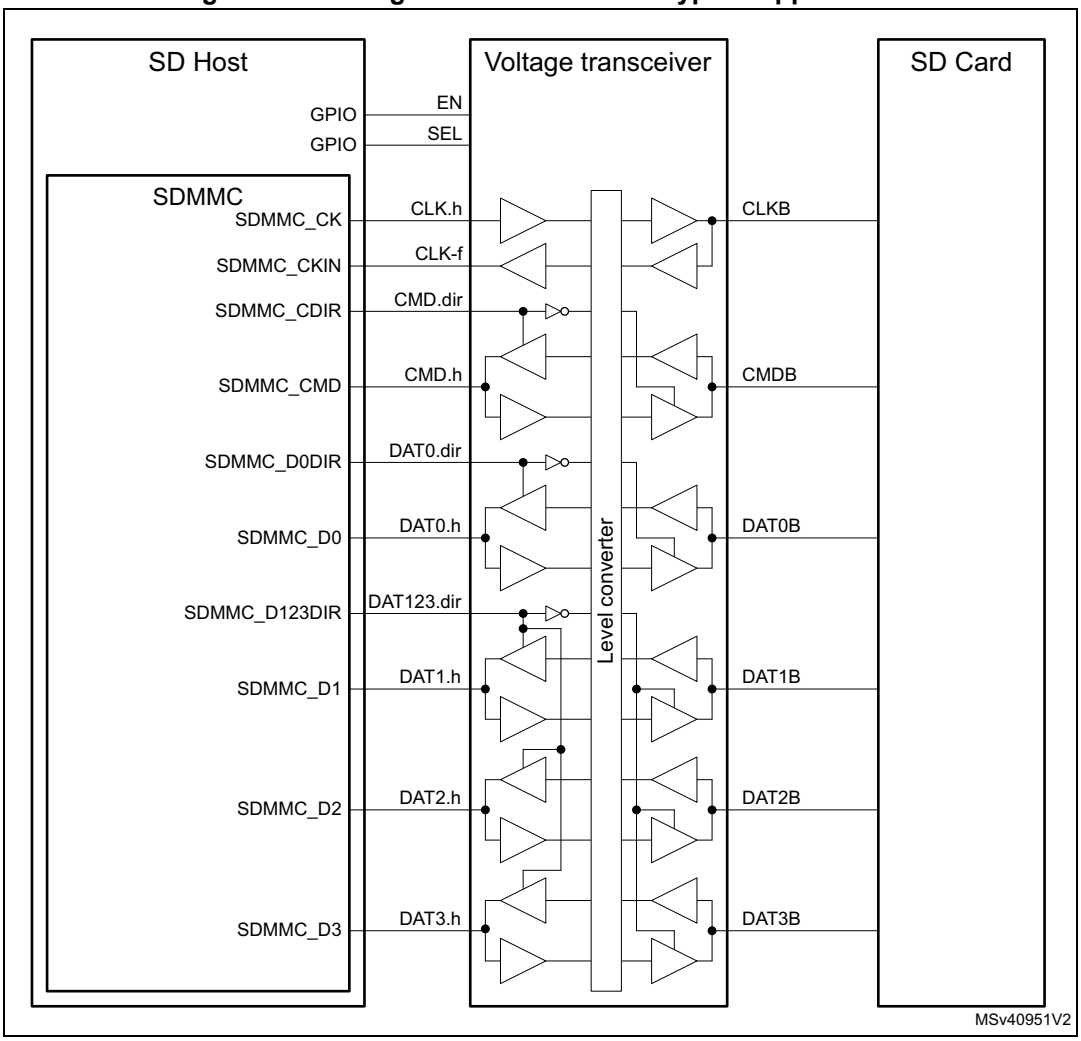
10. The host, on the VSWEND flag, checks SDMMC_D0 line using the BUSYD0 register bit, to confirm completion of voltage switch sequence:
    – When BUSYD0 is detected high, Voltage Switch has been completed successfully.
    – When BUSYD0 is detected low, Voltage Switch has failed, the host cycles the card power.

The minimum 5 ms time to stop the SDMMC_CK is derived from the internal un-gated SDMMC_CK clock, which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The >5 ms time is counted by 2^{12} cycles (10.24 ms @ 400 kHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time for the SDMMC_CK clock to be stopped is longer.

The maximum 1 ms time for the card to drive the SDMMC_Dn and SDMMC_CMD lines high is derived from the internal ungated SDMMC_CK which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The SDMMC checks the lines after >1 ms time which is counted by 2^9 cycles (1.28 ms @ 25 MHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time to check the lines is longer.

The signal voltage level is supported through an external voltage translation transceiver like STMicroelectronics ST6G3244ME.

Figure 258. Voltage switch transceiver typical application



To interface with an external driver (a voltage switch transceiver), next to the standard signals the SDMMC uses the following signals:

- **SDMMC_CKIN** feedback input clock
- **SDMMC_CDIR** I/O direction control for the CMD signal
- **SDMMC_D0DIR** I/O direction control for the SDMMC_D0 signal
- **SDMMC_D123DIR** I/O direction control for the SDMMC_D1, SDMMC_D2 and SDMMC_D3 signals

The voltage transceiver signals **EN** and **SEL** are to be handled through general-purpose I/O.

The polarity of the SDMMC_CDIR, SDMMC_D0DIR and SDMMC_D123DIR signals can be selected through SDMMC_POWER.DIRPOL control bit.

30.9 SDMMC interrupts

Table 232. SDMMC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode
SDMMC	Command response CRC fail	CCRCFAIL	CCRCFAILIE	CCRCFAILC	Yes
SDMMC	Data block CRC fail	DCRCFAIL	DCRCFAILIE	DCRCFAILC	Yes
SDMMC	Command response timeout	CTIMEOUT	CTIMEOUTIE	CTIMEOUTC	Yes
SDMMC	Data timeout	DTIMEOUT	DTIMEOUTIE	DTIMEOUTC	Yes

SDMMC	IDMA transfer error	IDMATE	IDMATEIE	IDMATEC	Yes
SDMMC	IDMA buffer transfer complete	IDMABTC	IDMABTCIE	IDMABTCC	Yes

30.10 SDMMC registers

The device communicates to the system via 32-bit control registers accessible via AHB slave interface.

The peripheral registers have to be accessed by words (32-bit). Byte (8-bit) and half-word (16-bit) accesses trigger an AHB bus error.

30.10.1 SDMMC power control register (SDMMC_POWER)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIR POL	VSWI TCHEN	VSWI TCH	PWRCTRL[1:0]	
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **DIRPOL**: Data and command direction signals polarity selection

This bit can only be written when the SDMMC is in the power-off state (PWRCTRL = 00).

0: Voltage transceiver I/Os driven as output when direction signal is low.

1: Voltage transceiver I/Os driven as output when direction signal is high.

Bit 3 **VSWITCHEN**: Voltage switch procedure enable

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

This bit is used to stop the SDMMC_CK after the voltage switch command response:

0: SDMMC_CK clock kept unchanged after successfully received command response.

1: SDMMC_CK clock stopped after successfully received command response.

Bit 2 **VSWITCH**: Voltage switch sequence start

This bit is used to start the timing critical section of the voltage switch sequence:

0: Voltage switch sequence not started and not active.

1: Voltage switch sequence started or active.

Bits 1:0 **PWRCTRL[1:0]**: SDMMC state control bits

These bits can only be written when the SDMMC is not in the power-on state (PWRCTRL ≠ 11).

These bits are used to define the functional state of the SDMMC signals:

00: After reset, Reset: the SDMMC is disabled and the clock to the Card is stopped, SDMMC_D[7:0], and SDMMC_CMD are HiZ and SDMMC_CK is driven low. When written 00, power-off: the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven high.

01: Reserved (When written 01, PWRCTRL value does not change)

10: Power-cycle, the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.

11: Power-on: the card is clocked, The first 74 SDMMC_CK cycles the SDMMC is still disabled. After the 74 cycles the SDMMC is enabled and the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are controlled according the SDMMC operation.

Any further write is ignored, PWRCTRL value keeps 11.

30.10.2 SDMMC clock control register (SDMMC_CLKCR)

Address offset: 0x004

Reset value: 0x0000 0000

This register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SELCLKRX[1:0]		BUS SPEED	DDR	HWFC_EN	NEG EDGE
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WID BUS[1:0]		Res.	PWR SAV	Res.	Res.	CLKDIV[9:0]									
rw	rw		rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **SELCLKRX[1:0]**: Receive clock selection

These bits can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: sdmmc_io_in_ck selected as receive clock

01: SDMMC_CKIN feedback clock selected as receive clock

10: sdmmc_fb_ck tuned feedback clock selected as receive clock

11: Reserved (select sdmmc_io_in_ck)

Bit 19 **BUSSPEED**: Bus speed for selection of SDMMC operating modes

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

0: DS, HS, SDR12, SDR25, Legacy compatible, High speed SDR, High speed DDR bus speed mode selected

1: SDR50, DDR50, SDR104, HS200 bus speed mode selected

Bit 18 **DDR**: Data rate signaling selection

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

DDR rate must only be selected with 4-bit or 8-bit wide bus mode. (WIDBUS > 00). DDR = 1 has no effect when WIDBUS = 00 (1-bit wide bus).

DDR rate must only be selected with clock division > 1 (CLKDIV > 0).

0: SDR Single data rate signaling

1: DDR double data rate signaling

Bit 17 **HWFC_EN**: Hardware flow control enable

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

0: Hardware flow control is disabled

1: Hardware flow control is enabled

When Hardware flow control is enabled, the meaning of the TXFIFOE and RXFIFOF flags change, see SDMMC status register definition in *Section 30.10.11*.

Bit 16 **NEGEDGE**: SDMMC_CK dephasing selection bit for data and command

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

When clock division = 1 (CLKDIV = 0), this bit has no effect. Data and Command change on SDMMC_CK falling edge.

0: When clock division >1 (CLKDIV > 0) and DDR = 0:

- Command and data changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

When clock division >1 (CLKDIV > 0) and DDR = 1:

- Command changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
- Data changed on the sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

1: When clock division >1 (CLKDIV > 0) and DDR = 0:

- Command and data changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.

When clock division >1 (CLKDIV > 0) and DDR = 1:

- Command changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.
- Data changed on the SDMMC_CK falling edge succeeding a SDMMC_CK edge.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

Bits 15:14 **WIDBUS[1:0]**: Wide bus mode enable bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: Default 1-bit wide bus mode: SDMMC_D0 used (Does not support DDR)

01: 4-bit wide bus mode: SDMMC_D[3:0] used

10: 8-bit wide bus mode: SDMMC_D[7:0] used

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PWRSAV**: Power saving configuration bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

For power saving, the SDMMC_CK clock output can be disabled when the bus is idle by setting PWRSAV:

0: SDMMC_CK clock is always enabled

1: SDMMC_CK is only enabled when the bus is active

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **CLKDIV[9:0]**: Clock divide factor

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

This field defines the divide factor between the input clock (sdmmc_ker_ck) and the output clock (SDMMC_CK): SDMMC_CK frequency = sdmmc_ker_ck / [2 * CLKDIV].

0x000: SDMMC_CK frequency = sdmmc_ker_ck / 1 (Does not support DDR)

0x001: SDMMC_CK frequency = sdmmc_ker_ck / 2

0x002: SDMMC_CK frequency = sdmmc_ker_ck / 4

0x0XX: ..

0x080: SDMMC_CK frequency = sdmmc_ker_ck / 256

0xXXX: ..

0x3FF: SDMMC_CK frequency = sdmmc_ker_ck / 2046

Note: While the SD/SDIO card or e•MMC is in identification mode, the SDMMC_CK frequency must be less than 400 kHz.

The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.

At least seven sdmmc_hclk clock periods are needed between two write accesses to this register. SDMMC_CK can also be stopped during the Read Wait interval for SD I/O cards: in this case the SDMMC_CLKCR register does not control SDMMC_CK.

30.10.3 SDMMC argument register (SDMMC_ARGR)

Address offset: 0x008

Reset value: 0x0000 0000

This register contains a 32-bit command argument, which is sent to a card as part of a command message.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CMDARG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDARG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CMDARG[31:0]**: Command argument

These bits can only be written by firmware when CPSM is disabled (CPSMEN = 0). Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

30.10.4 SDMMC command register (SDMMC_CMDR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMD SUS PEND
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT EN	BOOT MODE	DT HOLD	CPSM EN	WAITP END	WAIT INT	WAITRESP[1:0]		CMD STOP	CMD TRANS	CMDINDEX[5:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **CMDSUSPEND**: The CPSM treats the command as a Suspend or Resume command and signals interrupt period start/end

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
CMDSUSPEND = 1 and CMDTRANS = 0 Suspend command, start interrupt period when response bit BS = 0.
CMDSUSPEND = 1 and CMDTRANS = 1 Resume command with data, end interrupt period when response bit DF = 1.

Bit 15 **BOOTEN**: Enable boot mode procedure

0: Boot mode procedure disabled
1: Boot mode procedure enabled

Bit 14 **BOOTMODE**: Select the boot mode procedure to be used

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0)
0: Normal boot mode procedure selected
1: Alternative boot mode procedure selected

Bit 13 **DTHOLD**: Hold new data block transmission and reception in the DPSM

If this bit is set, the DPSM does not move from the Wait_S state to the Send state or from the Wait_R state to the Receive state.

Bit 12 **CPSMEN**: Command path state machine (CPSM) enable bit

This bit is written 1 by firmware, and cleared by hardware when the CPSM enters the Idle state.
If this bit is set, the CPSM is enabled.
When DTEN = 1, no command is transfered nor boot procedure is started. CPSMEN is cleared to 0.
During Read Wait with SDMMC_CK stopped no command is sent and CPSMEN is kept 0.

Bit 11 **WAITPEND**: CPSM waits for end of data transfer (CmdPend internal signal) from DPSM

This bit when set, the CPSM waits for the end of data transfer trigger before it starts sending a command.
WAITPEND is only taken into account when DTMODE = *e*•MMC stream data transfer, WIDBUS = 1-bit wide bus mode, DPSMACT = 1 and DTDIR = from host to card.

Bit 10 **WAITINT**: CPSM waits for interrupt request

If this bit is set, the CPSM disables command timeout and waits for an card interrupt request (Response).
If this bit is cleared in the CPSM Wait state, it causes the abort of the interrupt mode.

Bits 9:8 **WAITRESP[1:0]**: Wait for response bits

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.
00: No response, expect CMDSENT flag
01: Short response, expect CMDREND or CCRCFAIL flag
10: Short response, expect CMDREND flag (No CRC)
11: Long response, expect CMDREND or CCRCFAIL flag

Bit 7 **CMDSTOP**: The CPSM treats the command as a Stop Transmission command and signals abort to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues the abort signal to the DPSM when the command is sent.

Bit 6 **CMDTRANS**: The CPSM treats the command as a data transfer command, stops the interrupt period, and signals DataEnable to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues an end of interrupt period and issues DataEnable signal to the DPSM when the command is sent.

Bits 5:0 **CMDINDEX[5:0]**: Command index

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

The command index is sent to the card as part of a command message.

Note: 1 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register.

2 MultiMediaCard can send two kinds of response: short responses, 48 bits, or long responses,136 bits. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software distinguishes the type of response according to the send command.

30.10.5 SDMMC command response register (SDMMC_RESPCMDR)

Address offset: 0x010

Reset value: 0x0000 0000

This register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RESPCMD[5:0]					
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RESPCMD[5:0]**: Response command index

Read-only bitfield. Contains the command index of the last command response received.

30.10.6 SDMMC response x register (SDMMC_RESPxR)

Address offset: 0x010 + 0x004 * x, (x = 1 to 4)

Reset value: 0x0000 0000

These registers contain the status of a card, which is part of the received response.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CARDSTATUS[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CARDSTATUS[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CARDSTATUS[31:0]**: Card status according table below
See *Table 233*.

The card status size is 32 or 128 bits, depending on the response type.

Table 233. Response type and SDMMC_RESPxR registers

Register(1)	Short response	Long response
SDMMC_RESP1R	Card status[31:0]	Card status [127:96]
SDMMC_RESP2R	all 0	Card status [95:64]
SDMMC_RESP3R	all 0	Card status [63:32]
SDMMC_RESP4R	all 0	Card status [31:0](2)

1. The most significant bit of the card status is received first.
2. The SDMMC_RESP4R register LSB is always 0.

30.10.7 SDMMC data timer register (SDMMC_DTIMER)

Address offset: 0x024

Reset value: 0x0000 0000

This register contains the data timeout period, in card bus clock periods.

A counter loads the value from this register, and starts decrementing when the data path state machine (DPSM) enters the Wait_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATATIME[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

DATATIME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATATIME[31:0]**: Data and R1b busy timeout period

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

Data and R1b busy timeout period expressed in card bus clock periods.

Note: A data transfer must be written to the data timer register and the data length register before being written to the data control register.

30.10.8 SDMMC data length register (SDMMC_DLENR)

Address offset: 0x028

Reset value: 0x0000 0000

This register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATALENGTH[24:16]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATALENGTH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATALENGTH[24:0]**: Data length value

This register can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Number of data bytes to be transferred.

When DDR = 1 DATALENGTH is truncated to a multiple of 2. (The last odd byte is not transfered)

When DATALENGTH = 0 no data are transfered, when requested by a CPSMEN and CMDTRANS = 1 also no command is transfered. DTEN and CPSMEN are cleared to 0.

Note: For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC_DCTRL). A data transfer must be written to the data timer register and the data length register before being written to the data control register.

For an SDMMC multibyte transfer the value in the data length register must be between 1 and 512.

30.10.9 SDMMC data control register (SDMMC_DCTRL)

Address offset: 0x02C

Reset value: 0x0000 0000

This register controls the data path state machine (DPSM).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FIFO RST	BOOT ACK EN	SDIO EN	RW MOD	RW STOP	RW START	DBLOCKSIZE[3:0]				DTMODE[1:0]		DTDIR	DTEN
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **FIFORST**: FIFO reset, flushes any remaining data

This bit can only be written by firmware when IDMAEN= 0 and DPSM is active (DPSMACT = 1). This bit only takes effect when a transfer error or transfer hold occurs.

0: FIFO not affected.

1: Flush any remaining data and reset the FIFO pointers. This bit is automatically cleared to 0 by hardware when DPSM gets inactive (DPSMACT = 0).

Bit 12 **BOOTACKEN**: Enable the reception of the boot acknowledgment

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Boot acknowledgment disabled, not expected to be received

1: Boot acknowledgment enabled, expected to be received

Bit 11 **SDIOEN**: SD I/O interrupt enable functions

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

If this bit is set, the DPSM enables the SD I/O card specific interrupt operation.

Bit 10 **RWMOD**: Read Wait mode

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Read Wait control using SDMMC_D2

1: Read Wait control stopping SDMMC_CK

Bit 9 **RWSTOP**: Read Wait stop

This bit is written by firmware and auto cleared by hardware when the DPSM moves from the R_W state to the Wait_R or Idle state.

0: No Read Wait stop

1: Enable for Read Wait stop when DPSM is in the R_W state.

Bit 8 **RWSTART**: Read Wait start

If this bit is set, Read Wait operation starts.

Bits 7:4 **DBLOCKSIZE[3:0]**: Data block size

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Define the data block length when the block data transfer mode is selected:

0000: Block length = 2^0 = 1 byte

0001: Block length = 2^1 = 2 bytes

0010: Block length = 2^2 = 4 bytes

0011: Block length = 2^3 = 8 bytes

0100: Block length = 2^4 = 16 bytes

0101: Block length = 2^5 = 32 bytes

0110: Block length = 2^6 = 64 bytes

0111: Block length = 2^7 = 128 bytes

1000: Block length = 2^8 = 256 bytes

1001: Block length = 2^9 = 512 bytes

1010: Block length = 2^{10} = 1024 bytes

1011: Block length = 2^{11} = 2048 bytes

1100: Block length = 2^{12} = 4096 bytes

1101: Block length = 2^{13} = 8192 bytes

1110: Block length = 2^{14} = 16384 bytes

1111: Reserved

When DATALENGTH is not a multiple of DBLOCKSIZE, the transfered data is truncated at a multiple of DBLOCKSIZE. (None of the remaining data are transfered.)

When DDR = 1, DBLOCKSIZE = 0000 must not be used. (No data are transfered)

Bits 3:2 **DTMODE[1:0]**: Data transfer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

00: Block data transfer ending on block count.

01: SDIO multibyte data transfer.

10: *e*•MMC Stream data transfer. (WIDBUS must select 1-bit wide bus mode)

11: Block data transfer ending with STOP_TRANSMISSION command (not to be used with DTEN initiated data transfers).

Bit 1 **DTDIR**: Data transfer direction selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: From host to card.

1: From card to host.

Bit 0 **DTEN**: Data transfer enable bit

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). This bit is cleared by hardware when data transfer completes.

This bit must only be used to transfer data when no associated data transfer command is used (must not be used with SD or *e*•MMC cards).

0: Do not start data transfer without CPSM data transfer command.

1: Start data transfer without CPSM data transfer command.

30.10.10 SDMMC data counter register (SDMMC_DCNTR)

Address offset: 0x030

Reset value: 0x0000 0000

This register loads the value from the data length register (see SDMMC_DLENR) when the DPSM moves from the Idle state to the Wait_R or Wait_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then moves to the Idle state and

when there has been no error, and no transmit data transfer hold, the data status end flag (DATAEND) is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATACOUNT[24:16]

DATACOUNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT[24:0]**: Data count value

When read, the number of remaining data bytes to be transferred is returned. Write has no effect.

Note: This register must be read only after the data transfer is complete, or hold. When reading after an error event the read data count value may be different from the real number of data bytes transfered.

30.10.11 SDMMC status register (SDMMC_STAR)

Address offset: 0x034

Reset value: 0x0000 0000

This register is a read-only register. It contains two types of flag:

- Static flags (bits [28, 21, 11:0]): these bits remain asserted until they are cleared by writing to the SDMMC interrupt Clear register (see SDMMC_ICR)
- Dynamic flags (bits [20:12]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTC**: IDMA buffer transfer complete

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 27 **IDMATE**: IDMA transfer error

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 26 **CKSTOP**: SDMMC_CK stopped in Voltage switch procedure

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 25 **VSWEND**: Voltage switch critical timing section completion
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 24 **ACKTIMEOUT**: Boot acknowledgment timeout
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 23 **ACKFAIL**: Boot acknowledgment received (boot acknowledgment check fail)
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 22 **SDIOIT**: SDIO interrupt received
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 21 **BUSYD0END**: end of SDMMC_D0 Busy following a CMD response detected
This indicates only end of busy following a CMD response. This bit does not signal busy due to data transfer. Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
0: card SDMMC_D0 signal does NOT signal change from busy to not busy.
1: card SDMMC_D0 signal changed from busy to NOT busy.

Bit 20 **BUSYD0**: Inverted value of SDMMC_D0 line (Busy), sampled at the end of a CMD response and a second time 2 SDMMC_CK cycles after the CMD response
This bit is reset to not busy when the SDMMCD0 line changes from busy to not busy. This bit does not signal busy due to data transfer. This is a hardware status flag only, it does not generate an interrupt.
0: card signals not busy on SDMMC_D0.
1: card signals busy on SDMMC_D0.

Bit 19 **RXFIFOE**: Receive FIFO empty
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes full.

Bit 18 **TXFIFOE**: Transmit FIFO empty
This bit is cleared when one FIFO location becomes full.

Bit 17 **RXFIFOF**: Receive FIFO full
This bit is cleared when one FIFO location becomes empty.

Bit 16 **TXFIFOF**: Transmit FIFO full
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes empty.

Bit 15 **RXFIFOHF**: Receive FIFO half full
There are at least half the number of words in the FIFO. This bit is cleared when the FIFO becomes half+1 empty.

Bit 14 **TXFIFOHE**: Transmit FIFO half empty
At least half the number of words can be written into the FIFO. This bit is cleared when the FIFO becomes half+1 full.

Bit 13 **CPSMACT**: Command path state machine active (not in Idle state)
This is a hardware status flag only, does not generate an interrupt.

Bit 12 **DPSMACT**: Data path state machine active (not in Idle state)
This is a hardware status flag only, does not generate an interrupt.

Bit 11 **DABORT**: Data transfer aborted by CMD12
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 10 **DBCKEND**: Data block sent/received
DBCKEND is set when:
- CRC check passed and DPSM moves to the R_W state
or
- IDMAEN = 0 and transmit data transfer hold and DATACOUNT >0 and DPSM moves to Wait_S.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 9 **DHOLD**: Data transfer Hold
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 8 **DATAEND**: Data transfer ended correctly
DATAEND is set if data counter DATACOUNT is zero and no errors occur, and no transmit data transfer hold.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 7 **CMDSENT**: Command sent (no response required)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 6 **CMDREND**: Command response received (CRC check passed, or no CRC)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 5 **RXOVERR**: Received FIFO overrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 4 **TXUNDERR**: Transmit FIFO underrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 3 **DTIMEOUT**: Data timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 2 **CTIMEOUT**: Command response timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
The Command Timeout period has a fixed value of 64 SDMMC_CK clock periods.

Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 0 **CCRCFAIL**: Command response received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Note: FIFO interrupt flags must be masked in SDMMC_MASKR when using IDMA mode.

30.10.12 SDMMC interrupt clear register (SDMMC_ICR)

Address offset: 0x038

Reset value: 0x0000 0000

This register is a write-only register. Writing a bit with 1 clears the corresponding bit in the SDMMC_STAR status register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Set by software to clear the ACKFAIL flag.
0: ACKFAIL not cleared
1: ACKFAIL cleared

Bit 22 **SDIOITC**: SDIOIT flag clear bit
Set by software to clear the SDIOIT flag.
0: SDIOIT not cleared
1: SDIOIT cleared

Bit 21 **BUSYD0ENDC**: BUSYD0END flag clear bit
Set by software to clear the BUSYD0END flag.
0: BUSYD0END not cleared
1: BUSYD0END cleared

Bits 20:12 Reserved, must be kept at reset value.

Bit 11 **DABORTC**: DABORT flag clear bit
Set by software to clear the DABORT flag.
0: DABORT not cleared
1: DABORT cleared

Bit 10 **DBCKENDC**: DBCKEND flag clear bit
Set by software to clear the DBCKEND flag.
0: DBCKEND not cleared
1: DBCKEND cleared

Bit 9 **DHOLDC**: DHOLD flag clear bit
Set by software to clear the DHOLD flag.
0: DHOLD not cleared
1: DHOLD cleared

Bit 8 **DATAENDC**: DATAEND flag clear bit
Set by software to clear the DATAEND flag.
0: DATAEND not cleared
1: DATAEND cleared

Bit 7 **CMDSENTC**: CMDSENT flag clear bit
Set by software to clear the CMDSENT flag.
0: CMDSENT not cleared
1: CMDSENT cleared

Bit 6 **CMDRENDC**: CMDREND flag clear bit
Set by software to clear the CMDREND flag.
0: CMDREND not cleared
1: CMDREND cleared

Bit 5 **RXOVERRC**: RXOVERR flag clear bit
Set by software to clear the RXOVERR flag.
0: RXOVERR not cleared
1: RXOVERR cleared

Bit 4 **TXUNDERRC**: TXUNDERR flag clear bit
Set by software to clear TXUNDERR flag.
0: TXUNDERR not cleared
1: TXUNDERR cleared

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit
Set by software to clear the DTIMEOUT flag.
0: DTIMEOUT not cleared
1: DTIMEOUT cleared

Bit 2 **CTIMEOUTC**: CTIMEOUT flag clear bit
Set by software to clear the CTIMEOUT flag.
0: CTIMEOUT not cleared
1: CTIMEOUT cleared

Bit 1 **DCRCFAILC**: DCRCFAIL flag clear bit
Set by software to clear the DCRCFAIL flag.
0: DCRCFAIL not cleared
1: DCRCFAIL cleared

Bit 0 **CCRCFAILC**: CCRCFAIL flag clear bit
Set by software to clear the CCRCFAIL flag.
0: CCRCFAIL not cleared
1: CCRCFAIL cleared

30.10.13 SDMMC mask register (SDMMC_MASKR)

Address offset: 0x03C

Reset value: 0x0000 0000

This register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTCIE**: IDMA buffer transfer complete interrupt enable
Set and cleared by software to enable/disable the interrupt generated when the IDMA has transferred all data belonging to a memory buffer.
0: IDMA buffer transfer complete interrupt disabled
1: IDMA buffer transfer complete interrupt enabled

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CKSTOPIE**: Voltage switch clock stopped interrupt enable
Set and cleared by software to enable/disable interrupt caused by voltage switch clock stopped.
0: Voltage switch clock stopped interrupt disabled
1: Voltage switch clock stopped interrupt enabled

Bit 25 **VSWENDIE**: Voltage switch critical timing section completion interrupt enable
Set and cleared by software to enable/disable the interrupt generated when voltage switch critical timing section completion.
0: Voltage switch critical timing section completion interrupt disabled
1: Voltage switch critical timing section completion interrupt enabled

Bit 24 **ACKTIMEOUTIE**: Acknowledgment timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment timeout.
0: Acknowledgment timeout interrupt disabled
1: Acknowledgment timeout interrupt enabled

Bit 23 **ACKFAILIE**: Acknowledgment fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment fail.
0: Acknowledgment fail interrupt disabled
1: Acknowledgment fail interrupt enabled

Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.
0: SDIO mode interrupt received interrupt disabled
1: SDIO mode interrupt received interrupt enabled

Bit 21 **BUSYD0ENDIE**: BUSYD0END interrupt enable
Set and cleared by software to enable/disable the interrupt generated when SDMMC_D0 signal changes from busy to NOT busy following a CMD response.
0: BUSYD0END interrupt disabled
1: BUSYD0END interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.
0: Tx FIFO empty interrupt disabled
1: Tx FIFO empty interrupt enabled

Bit 17 **RXFIFOFIE**: Rx FIFO full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.
0: Rx FIFO full interrupt disabled
1: Rx FIFO full interrupt enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.
0: Rx FIFO half full interrupt disabled
1: Rx FIFO half full interrupt enabled

Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.
0: Tx FIFO half empty interrupt disabled
1: Tx FIFO half empty interrupt enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **DABORTIE**: Data transfer aborted interrupt enable
Set and cleared by software to enable/disable interrupt caused by a data transfer being aborted.
0: Data transfer abort interrupt disabled
1: Data transfer abort interrupt enabled

Bit 10 **DBCKENDIE**: Data block end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data block end.
0: Data block end interrupt disabled
1: Data block end interrupt enabled

Bit 9 **DHOLDIE**: Data hold interrupt enable
Set and cleared by software to enable/disable the interrupt generated when sending new data is hold in the DPSM Wait_S state.
0: Data hold interrupt disabled
1: Data hold interrupt enabled

Bit 8 **DATAENDIE**: Data end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data end.
0: Data end interrupt disabled
1: Data end interrupt enabled

Bit 7 **CMDSENTIE**: Command sent interrupt enable
Set and cleared by software to enable/disable interrupt caused by sending command.
0: Command sent interrupt disabled
1: Command sent interrupt enabled

Bit 6 **CMDRENDIE**: Command response received interrupt enable
Set and cleared by software to enable/disable interrupt caused by receiving command response.
0: Command response received interrupt disabled
1: command Response received interrupt enabled

Bit 5 **RXOVERRIE**: Rx FIFO overrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.
0: Rx FIFO overrun error interrupt disabled
1: Rx FIFO overrun error interrupt enabled

Bit 4 **TXUNDERRIE**: Tx FIFO underrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.
0: Tx FIFO underrun error interrupt disabled
1: Tx FIFO underrun error interrupt enabled

Bit 3 **DTIMEOUTIE**: Data timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by data timeout.
0: Data timeout interrupt disabled
1: Data timeout interrupt enabled

Bit 2 **CTIMEOUTIE**: Command timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by command timeout.
0: Command timeout interrupt disabled
1: Command timeout interrupt enabled

Bit 1 **DCRCFAILIE**: Data CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by data CRC failure.
0: Data CRC fail interrupt disabled
1: Data CRC fail interrupt enabled

Bit 0 **CCRCFAILIE**: Command CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by command CRC failure.
0: Command CRC fail interrupt disabled
1: Command CRC fail interrupt enabled

30.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

Address offset: 0x040

Reset value: 0x0000 0000

This register contains the acknowledgment timeout period, in SDMMC_CK bus clock periods.

A counter loads the value from this register, and starts decrementing when the data path state machine (DPSM) enters the Wait_Ack state. If the timer reaches 0 while the DPSM is in this states, the acknowledgment timeout status flag is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACKTIME[24:16]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACKTIME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **ACKTIME[24:0]**: Boot acknowledgment timeout period
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
Boot acknowledgment timeout period expressed in card bus clock periods.

Note: The data transfer must be written to the acknowledgment timer register before being written to the data control register.

30.10.15 SDMMC data FIFO threshold register (SDMMC_FIFOTHRR)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	THR[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **THR[3:0]**: FIFO threshold
This bit can only be written by software when DPSM is inactive (DPSMACT = 0).
Define the data FIFO threshold:
0b0000:threshold = 0 byte (no threshold)
Others: threshold = $2^{(N-1)}$ bytes, threshold must not be programmed bigger than the FIFO size, 256 words.

Note: When THR > DBLOCKSIZE, blocks may not be transferred.

30.10.16 SDMMC DMA control register (SDMMC_IDMACTRLR)

Address offset: 0x050

Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDMAB MODE	IDMA EN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **IDMABMODE**: Buffer mode selection
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: Single buffer mode.
1: Linked list mode.

Bit 0 **IDMAEN**: IDMA enable
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: IDMA disabled
1: IDMA enabled

30.10.17 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER)

Address offset: 0x054

Reset value: 0x0000 0000

This register contains the buffer size when in linked list configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDMA BNDT [10]
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABNDT[9:0]										Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw						

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:6 **IDMABNDT[10:0]**: Number of bytes per buffer

This 11-bit value must be multiplied by 16 to get the size of the buffer in 32-bit words and by 64 to get the size of the buffer in bytes.
Example: IDMABNDT = 0x001: buffer size = 16 words = 64 bytes.
Example: IDMABNDT = 0x400: buffer size = 16384 words = 64 Kbytes.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 5:0 Reserved, must be kept at reset value.

30.10.18 SDMMC IDMA buffer base address register (SDMMC_IDMABASER)

Address offset: 0x058

Reset value: 0x0000 0000

This register contains the memory buffer base address in single buffer configuration and linked list configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDMABASE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABASE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r

Bits 31:0 **IDMABASE[31:0]**: Buffer memory base address bits [31:2], must be word aligned (bit [1:0] are always 0 and read only)

This register can be written by firmware when DPSM is inactive (DPSMACT = 0), and can dynamically be written by firmware when DPSM active (DPSMACT = 1).

30.10.19 SDMMC IDMA linked list address register (SDMMC_IDMALAR)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ULA	ULS	ABR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw													
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMALA[13:0]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **ULA**: Update SDMMC_IDMALAR from linked list when in linked list mode (SDMMC_IDMACTRLR.IDMABMODE select linked list mode)
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMALAR is not to be updated, last linked list item.
1: SDMMC_IDMALAR is to be updated from linked list table.

Bit 30 **ULS**: Update SDMMC_IDMABSIZE from the next linked list when in linked list mode (SDMMC_IDMACTRLR.IDMABMODE select linked list mode and ULA = 1)
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMABSIZER is not to be updated from next linked list table.
1: SDMMC_IDMABSIZER is to be updated from next linked list table.

Bit 29 **ABR**: Acknowledge linked list buffer ready
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
This bit is not taken into account when starting the first linked list buffer from the software programmed register information. ABR is only taken into account on subsequent loaded linked list items.
0: Loaded linked list buffer is not ready (this causes a linked list IDMA transfer error to be generated).
1: Loaded linked list buffer ready acknowledge. Linked list buffer data are transfered by IDMA.

Bits 28:16 Reserved, must be kept at reset value.

Bits 15:2 **IDMALA[13:0]**: Word aligned linked list item address offset
Linked list item offset pointer to the base of the next linked list item structure.
Linked list item base address is IDMABA + IDMALA.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

30.10.20 SDMMC IDMA linked list memory base register (SDMMC_IDMABAR)

Address offset: 0x068

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDMABA[29:14]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABA[13:0]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:2 **IDMABA[29:0]**: Word aligned Linked list memory base address
Linked list memory base pointer.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

30.10.21 SDMMC data FIFO registers x (SDMMC_FIFORx)

Address offset: 0x080 + 0x004 * x, (x =0 to 15)

Reset value: 0x0000 0000

The receive and transmit FIFOs can be only read or written as word (32-bit) wide registers. The FIFOs contain 16 entries on sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO. The FIFO register interface takes care of correct data alignment inside the FIFO, the FIFO register address used by the CPU does matter.

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FIFODATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FIFODATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **FIFODATA[31:0]**: Receive and transmit FIFO data

This register can only be read or written by firmware when the DPSM is active (DPSMACT = 1).

The FIFO data occupies 16 entries of 32-bit words.

31 Delay block (DLYB)

31.1 Introduction

The delay block (DLYB) is used to generate two output clocks that are dephased from 2 input clocks. The phase of each output clock must be programmed by the user application. The output clocks are then used to clock the data transmitted/received by another peripheral such as an SDMMC.

31.2 DLYB main features

The delay block has the following features:

- Frequency range for Lock mode is [50 MHz, 208 MHz]
- 32 phases (delay taps)
- Bypass mode for operation below 50 MHz

31.3 DLYB implementation

Table 235. STM32N6x7xx features

DLYB associated peripheral	DLYBSD1	DLYBSD2
SDMMC1	X	-
SDMMC2	-	X

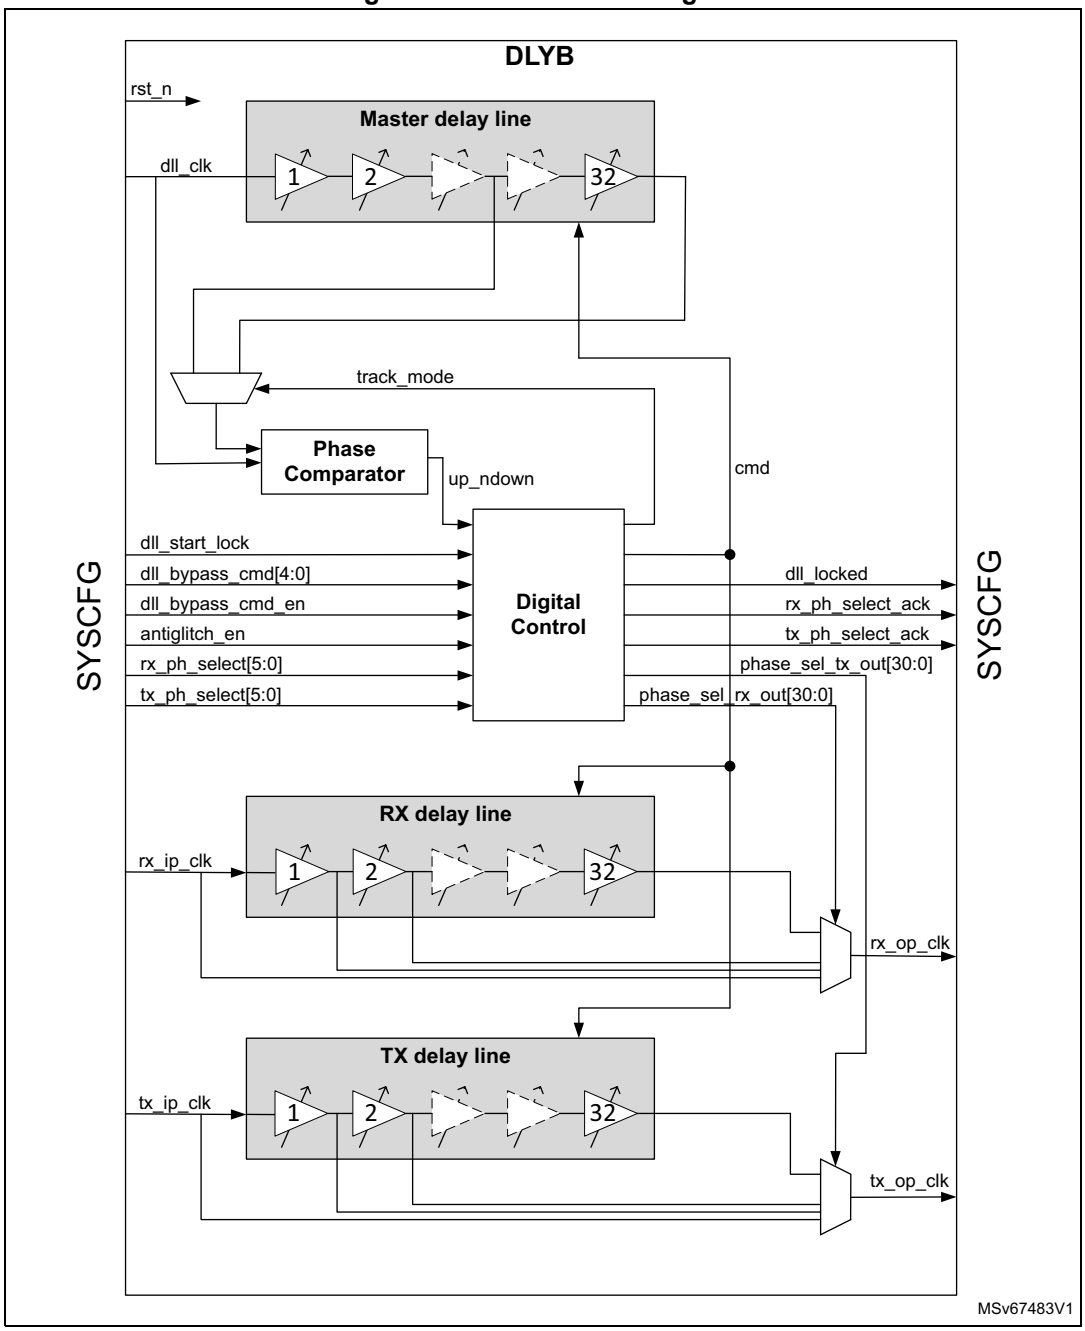
31.4 DLYB functional description

31.4.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- Digital block to generate commands for delay lines and phase selection. This block embeds lock FSM.
- Delay line supporting the unit delays
- Output clock selection multiplexer

Figure 259. DLYB block diagram



31.4.2 DLYB internal signals

Table 236 lists the DLYB functional signals.

Table 236. DLYB functional signals

Signal name	Signal type	Description
dll_clk	Digital input	Free-running input clock used as reference clock for the Master delay line and FSM blocks
tx_ip_clk	Digital input	Input clock of the TX slave delay line
rx_ip_clk	Digital input	Input clock of the RX slave delay line
tx_op_clk	Digital output	Selected output clock of the TX slave delay line
rx_op_clk	Digital output	Selected output clock of the RX slave delay line
rst_n	Digital input	Asynchronous active low reset
dll_start_lock	Digital input	Enable of DLL when configured in Lock mode
dll_locked	Digital output	Lock indicator. When high, it indicates that the FSM has finished the lock sequence. The DLL can be used
tx_ph_select[5:0]	Digital input	Selection of the slave DLL phase shift over 33 for TX path 000000: 0 tap selection 000001: 1 tap selection 011111: 31 taps selection 1xxxxx: 32 taps selection
tx_ph_select_ack	Digital output	When high: phase selected by tx_ph_select is acknowledged When low: output clock tx_op_clk is tied low
rx_ph_select[5:0]	Digital input	Selection of the slave DLL phase shift over 33 for RX path 000000: 0 tap selection 000001: 1 tap selection 011111: 31 taps selection 1xxxxx: 32 taps selection
rx_ph_select_ack	Digital output	When high: phase selected by rx_ph_select is acknowledged When low: output clock rx_op_clk is tied low
antiglitch_en	Digital input	When high: output clocks (tx_op_clk or rx_op_clk) when minimum delay is selected (tx_ph_select = 0 or rx_ph_select=0) are gated to avoid any glitch when phase selection changes When low: output clocks (tx_op_clk or rx_op_clk) when minimum delay is selected (tx_ph_select = 0 or rx_ph_select=0) are not gated (possible glitches if input clocks (tx_ip_clk or rx_ip_clk) are enabled when phase selection changes)
dll_bypass_cmd_en	Digital input	Active high: use dll_bypass_cmd for command generation
dll_bypass_cmd[4:0]	Digital input	permits to force delays for all taps when dll_bypass_cmd_en high: 00000: not functional 00001: pass gate 0 is activated (min delay) 00010: pass gate 1 is activated 11000: pass gate 23 is activated 11001 to 11111: pass gate 23 is activated (max delay)

Table 237 lists the DLYB interconnections. The SDMMCx DLYB registers (DLYBSDx) are highlighted in light gray, RCC registers in dark gray and peripheral ports in blue.

Table 237. DLYB interconnection

Signal name	Source/destination	
	SDMMC1	SDMMC2
dll_clk	ClkDll (sdmmc1_ClkDll)	ClkDll (sdmmc2_ClkDll)
rx_ip_clk	CKio (sdmmc1_io_CKio)	CKio (sdmmc2_io_CKio)
tx_ip_clk	Not used	
rx_op_clk	FB_CLK (sdmmc1_fb_clk)	FB_CLK (sdmmc2_fb_clk)
tx_op_clk	Not used	
rst_n	RCC_MISCRSTR.SDMMC1DLLRST	RCC_MISCRSTR.SDMMC2DLLRST
dll_start_lock	DLYBSD_CFG(1) SDMMC_DLL_EN	DLYBSD_CFG(2) SDMMC_DLL_EN
dll_locked	DLYBSD_STATUS(1) SDMMC_DLL_LOCK	DLYBSD_STATUS(2) SDMMC_DLL_LOCK
tx_ph_select[5:0]	Not used	
tx_ph_select_ack	Not used	
rx_ph_select[5:0]	DLYBSD_CFG(1) SDMMC_RX_TAP_SEL[5:0]	DLYBSD_CFG(2) SDMMC_RX_TAP_SEL[5:0]
rx_ph_select_ack	DLYBSD_STATUS(1) SDMMC_RX_TAP_SEL_ACK	DLYBSD_STATUS(2) SDMMC_RX_TAP_SEL_ACK
antiglitch_en	DLYBSD_CFG(1) SDMMC_DLL_ANTIGLITCH_EN	DLYBSD_CFG(2) SDMMC_DLL_ANTIGLITCH_EN
dll_bypass_cmd_en	DLYBSD_CFG(1) SDMMC_DLL_BYP_EN	DLYBSD_CFG(2) SDMMC_DLL_BYP_EN
dll_bypass_cmd[4:0]	DLYBSD_CFG(1) SDMMC_DLL_BYP_CMD[4:0]	DLYBSD_CFG(2) SDMMC_DLL_BYP_CMD[4:0]

1. Register in DLYB1 instance.
2. Register in DLYB2 instance.

31.4.3 General description

The delay block is structured around one master delay line and two slave delay lines (RX and TX) and there are two operating modes:

- Lock mode (*dll_bypass_cmd_en* = 0)
  - This mode can only be used when the frequency of dll_clk is in the range [50 MHz, 208 MHz]
  - The delay block is enabled by setting *dll_start_lock* to '1'.
  - The delay block locks on the frequency of the *dll_clk* input clock and compensates for voltage and temperature variations. This process determines the command to be applied to each of the 32 delay units (a.k.a. tap) of the master delay line for the total master delay to represent one period of *dll_clk*. This command is copied to each delay unit of the RX and TX delay lines. The command varies with voltage and temperature for the DLL to remain locked. This guarantees that each delay unit of the RX and TX delay lines represents 1/32th of the input clock period.
  - Independent delay values can be selected for the RX and TX delay lines by controlling *rx_ph_select[5:0]* and *tx_ph_select[5:0]* parameters. The granularity of the delay is 1/32th of the input clock period.
- Bypass mode (*dll_bypass_cmd_en* = 1)
  - This mode is required to be able to insert a delay between the *rx_ip_clk* (resp. *tx_ip_clk*) input clock and the *rx_op_clk* (resp. *tx_op_clk*) output clock when the operating frequency is lower than the minimum frequency supported by the delay block in lock mode (frequency < 50 MHz).
  - In this mode, delays in the RX and TX delay lines are used as "pure" delays, i.e. without trying to lock on the frequency of the *dll_clk* input clock. There is therefore no voltage nor temperature compensation in this mode and the RX and TX delay values vary with voltage and temperature. The command applied to each delay unit of the RX and TX delay lines is controlled by *dll_bypass_cmd[4:0]*. Each delay unit includes 24 delay elements. The number of delay elements which are enabled in each delay unit depends on the value of *dll_bypass_cmd[4:0]*.
  - Independent delay values can be selected for the RX and TX delay lines by controlling *rx_ph_select[5:0]* and *tx_ph_select[5:0]* parameters. The total delay inserted by the RX (resp. TX) delay line depends on *rx_ph_select[5:0]* (resp. *tx_ph_select[5:0]*) and *dll_bypass_cmd[4:0]* values.

31.4.4 Lock mode procedure

For frequencies greater or equal to 50MHz, procedure is given below:

1. When *rst_n* is low, DLYB lock FSM is put in Idle mode. Note that *dll_start_lock* must be set to ‘0’ during hard reset.
2. Once the input signal *dll_clk* is stable (after a frequency switch for example) the lock sequence can be started by setting *dll_start_lock* to ‘1’ and maintain this value.
3. During lock sequence DLYB can not be used until *dll_locked* flag is set to ‘1’.
4. Once it is done, delay line for master and slaves are PVT compensated (tracking V and T evolution but not a frequency switch).
5. Then the phase can be programmed using *tx_ph_select[5:0]* and *rx_ph_select[5:0]* input signals. The selected delays are applied to TX output clock and RX output clock once *tx_ph_select_ack* and *rx_ph_select_ack* are set to ‘1’ respectively.
6. If another lock sequence is needed, for a frequency switch for example, *dll_start_lock* signal must go to ‘0’ and sequence can be restarted with step 2.

31.4.5 Bypass mode procedure

For frequencies lower the 50 MHz, procedure is given below:

1. When *rst_n* is low, DLYB lock FSM is put in Idle mode. Note that *dll_start_lock* must be set to ‘0’ during hard reset.
2. Delay block is enabled by setting *dll_bypass_cmd_en* to ‘1’. The command applied to every delay unit is defined by *dll_bypass_cmd[4:0]* input (the value 0 is reserved and must not be used).
3. The phase can be programmed using *tx_ph_select[5:0]* and *rx_ph_select[5:0]* input signals. The selected delays are applied to TX output clock and RX output clock once *tx_ph_select_ack* and *rx_ph_select_ack* are set to ‘1’ respectively. For minimum delay, *tx_ph_select[5:0]* (resp. *rx_ph_select[5:0]*) must be set to 0.

31.5 DLYB SDMMC registers description

There is one DLYB module associated to each SDMMC (see *Section 2.3: Memory organization*). It contains registers to configure the DLL for the RX path. The registers are described below.

31.5.1 Delay block SDMMC DLL configuration (DLYBSD_CFG)

Address offset: 0x0

Reset value: 0x0040 0000

SDMMC DLL configuration register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDMMC_DLL_ANTIGLITCH_EN	SDMMC_DLL_BYP_CMD[4:0]					SDMMC_DLL_BYP_EN
									rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDMMC_RX_TAP_SEL[5:0]						SDMMC_DLL_EN
									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SDMMC_DLL_ANTIGLITCH_EN**: Antiglitch logic enabled when 1

Bits 21:17 **SDMMC_DLL_BYP_CMD[4:0]**: Bypass command

It is applied on RX path and corresponds to the number of delay cells activated (when SDMMC_DLL_BYP_EN is high).

Bit 16 **SDMMC_DLL_BYP_EN**: DLL configuration

0: Lock mode

1: Pure delay

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:1 **SDMMC_RX_TAP_SEL[5:0]**: selection of RX delay

In 1/32th of clock period.

Bit 0 **SDMMC_DLL_EN**: DLL enable

Used to enable the DLL when configured in lock mode.

31.5.2 Delay block SDMMC DLL status (DLYBSD_STATUS)

Address offset: 0x4

Reset value: 0x0000 0002

SDMMC DLL status register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDMMC_RX_TAP_SEL_ACK	SDMMC_DLL_LOCK
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SDMMC_RX_TAP_SEL_ACK**: SDMMC RX delay selection acknowledge
This bit indicates that RX delay line has been configured with the delay selected by SDMMC_RX_TAP_SEL[5:0].

Bit 0 **SDMMC_DLL_LOCK**: SDMMC DLL lock
This bit indicates that DLL is locked to the input frequency.

31.5.3 DLYB register map

Table 238. DLYB register map and reset values

Offset	Register name Reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 162* for the register boundary addresses.

32 Analog-to-digital converters (ADC)

32.1 Introduction

This section describes the implementation of up to 2 ADCs:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master)

Each ADC consists of one 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan, or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned (default configuration) 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

32.2 ADC main features

- High-performance features
  - Up to 2 ADCs which can operate in dual mode
    ADC1 is connected to 18 external channels + 2 internal channels
    ADC2 is connected to 17 external channels + 3 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Management of single-ended and differential inputs (programmable per channels)
  - AHB slave bus interface to allow fast data handling
  - Offset calibration support
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Fixed latency for a trigger to start of sampling
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Data can be routed to MDF for post processing
  - Four dedicated data registers for the injected channels
- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency

  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (autodelayed mode)
- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024
  - Programmable data right and left shifts
- Data preconditioning
  - Gain compensation
  - Offset compensation
- Analog input channels
  - External analog inputs (per ADC): up to 17 GPIO pads
  - 1 channel for the internal reference voltage (V_{REFINT})
  - 1 channel for monitoring the external VBAT power supply pin
  - 1 channel connected to the analog positive reference voltage V_{REF+}
  - 1 channel for monitoring V_{DDCORE} internal voltage
- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timer events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

Figure 260 shows the block diagram of one ADC.

32.3 ADC implementation

Table 239. ADC features

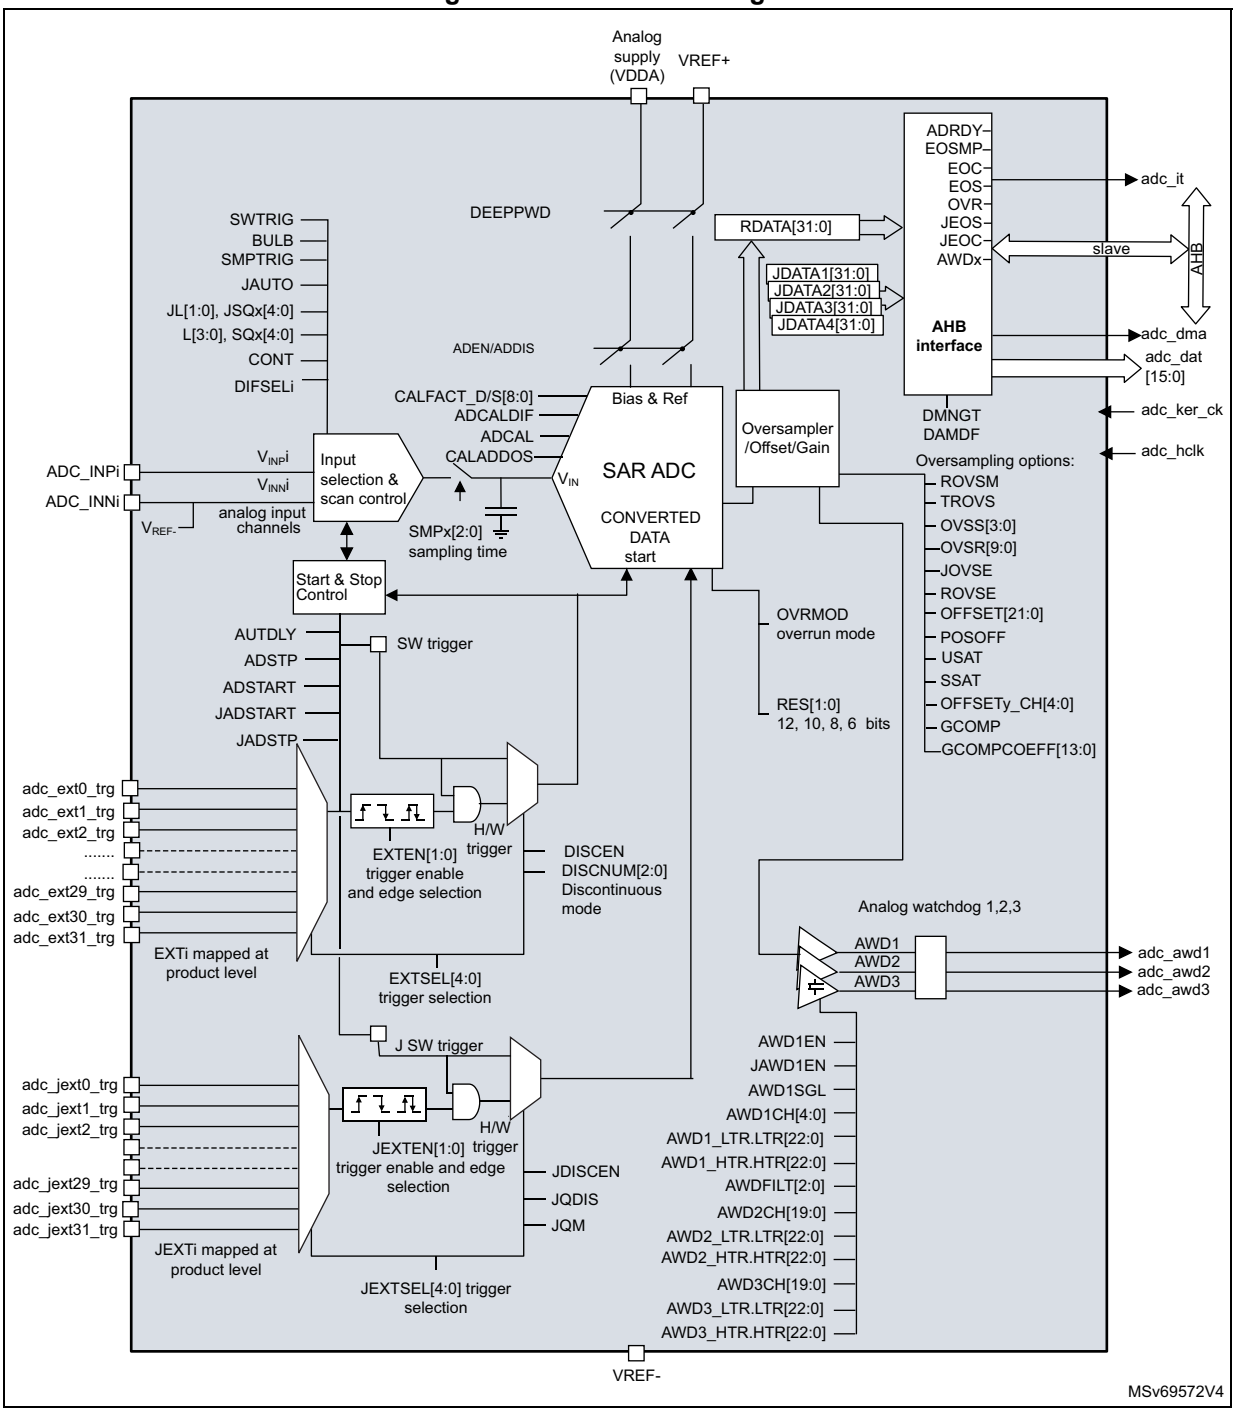
ADC modes/features	ADC1, ADC2
Resolution	12 bits
Maximum sampling speed	5 Msps (12-bit resolution)
Dual mode operation	X
Offset calibration	X
Single-end input	X
Differential input	X
Injected channel conversion	X
Oversampling	up to x1024
Data register	32 bits
DMA support	X
Parallel data output to MDF	X
Offset compensation	X
Gain compensation	X
Number of analog watchdog	3

32.4 ADC functional description

32.4.1 ADC block diagram

Figure 260 shows the ADC block diagram and *Table 240* gives the ADC pin description.

Figure 260. ADC block diagram



32.4.2 ADC pins and internal signals

Table 240. ADC input/output pins

Pin name	Signal type	Description
VDDA	Input, analog supply	Analog power supply
VSSA	Input, analog supply ground	Ground for analog power supply, equal to V_{SS}.
VREF+	Input, analog reference positive	The higher/positive reference voltage for the ADC.
VREF−	Input, analog reference negative	The lower/negative reference voltage for the ADC.
ADCx_INNi/INPi	Negative/positive external analog input signals	20 negative/positive external analog input channels (refer to *Section 32.4.4: ADC connectivity* for details)

Table 241. ADC internal input/output signals

Internal signal name	Signal type	Description
$V_{INP}i$	Positive analog input channels	Positive internal analog input channels connected either to ADCx_INP*i* external channels or to internal channels.
$V_{INN}i$	Negative analog input channels	Negative internal analog input channels connected either to ADCx_INN*i* external channels or to internal channels
adc_ext_trgi	Inputs	ADC external trigger inputs for regular conversions.These inputs are shared between the ADC master and the ADC slave.
adc_jext_trgi	Inputs	ADC external trigger inputs for the injected conversions. These inputs are shared between the ADC master and the ADC slave.
adc_awdy	Output	Internal analog watchdog output signal connected to on-chip timers. (y = Analog watchdog number 1,2,3)
adc_ker_ck	Input	ADC kernel clock
adc_hclk	Input	ADC peripheral clock
adc_it	Output	ADC interrupt
adc_dma	Output	ADC DMA request
adc_dat[15:0]	Output	ADC data outputs

Table 242. ADC1/2 interconnection

Signal name	Source/destination
ADC1 V_{INP}[17]	V_{REFINT} (output voltage from internal reference voltage)
ADC2 V_{INP}[16]	V_{BAT}/4 (VBAT pin input voltage divided by 4)
ADC2 V_{INP}[17]	V_{DDCORE} (internal logic core voltage)
ADC12 V_{INP}[19]	V_{REF+} (higher positive reference voltage)

32.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC kernel clock is independent from the AHB bus clock that is used to access ADC registers.

The adc_ker_ck input clock can be selected between different clock sources (see *Figure 261: ADC clock scheme*). This selection is done in the RCC (refer to section *Reset and clock control (RCC)* for more information):

1. The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous from the AHB clock.
2. The ADC clock can be derived from AHB clock (selected in RCC).

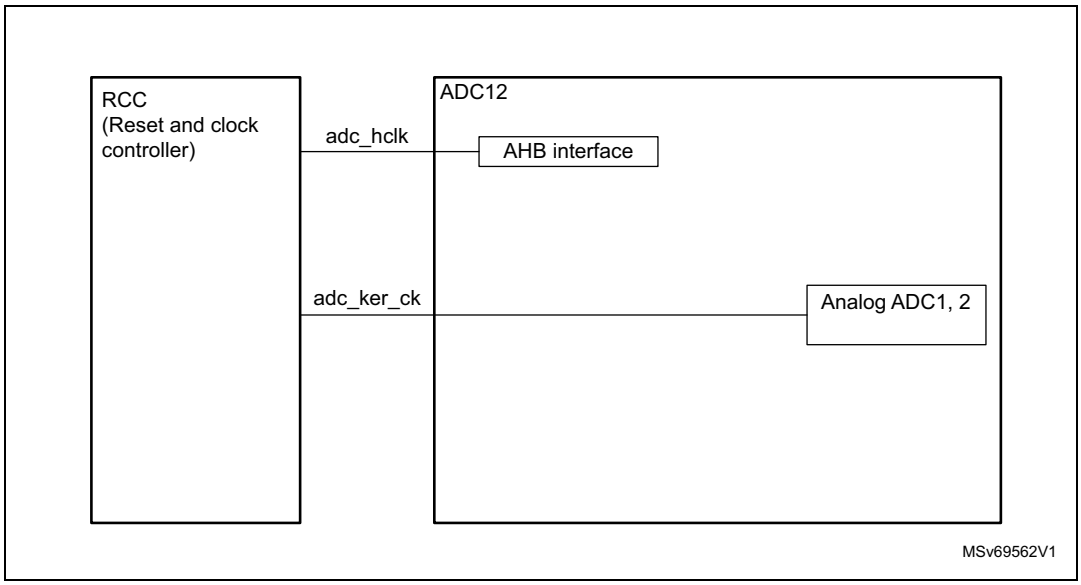
Option **1** has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected.

Option **2** corresponds to a pseudosynchronous clock. This can be useful when the ADC is triggered by a timer and the application requires that the ADC is accurately triggered without any uncertainty (otherwise, an uncertainty of the trigger instant time is added by the resynchronizations between the two clock domains). This accurate trigger is supported only by trgo or trgo2 timer triggers.

For further details on the synchronization between ADC and timers, refer to section *ADC synchronization* in each timer section, and to section *Peripheral clock distribution* in the RCC section.

The clock is configured through the RCC and must be compliant with the operating frequency specified in the device datasheet.

Figure 261. ADC clock scheme



Clock ratio constraint between ADC clock and AHB clock

There are no constraints to respect for the ratio between the ADC clock and the AHB clock. However, the ratio must be carefully chosen to avoid any overrun especially if the clock AHB is much slower than the ADC clock.

32.4.4 ADC connectivity

ADC inputs are connected to external channels as well as internal sources as described below.

Figure 262. ADC1 connectivity

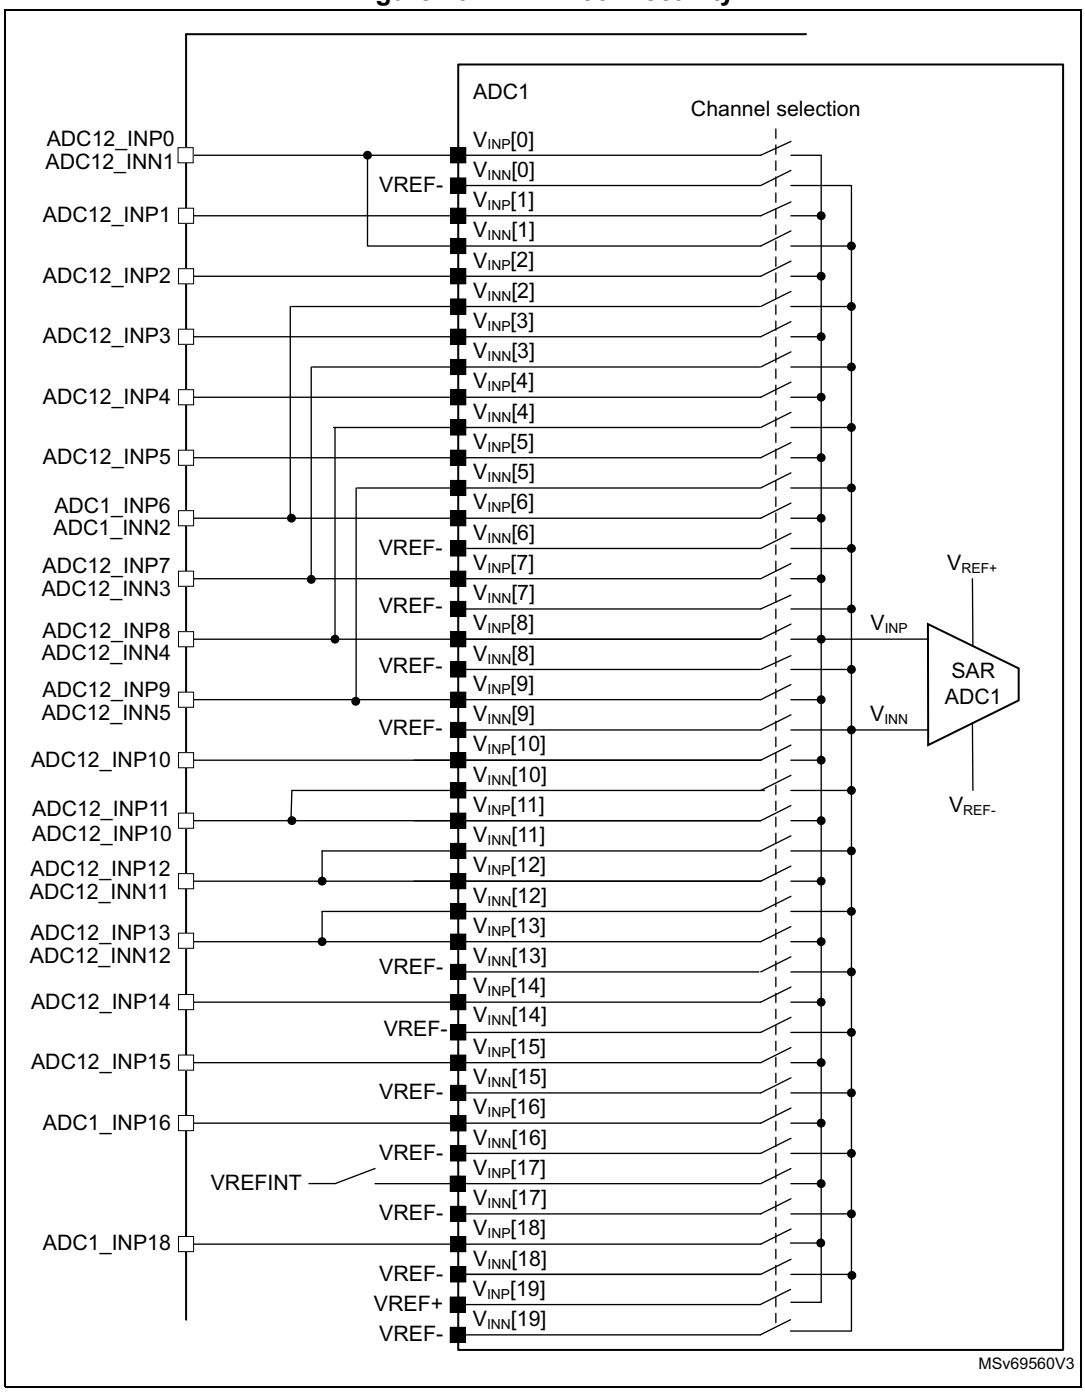


Figure 263. ADC2 connectivity

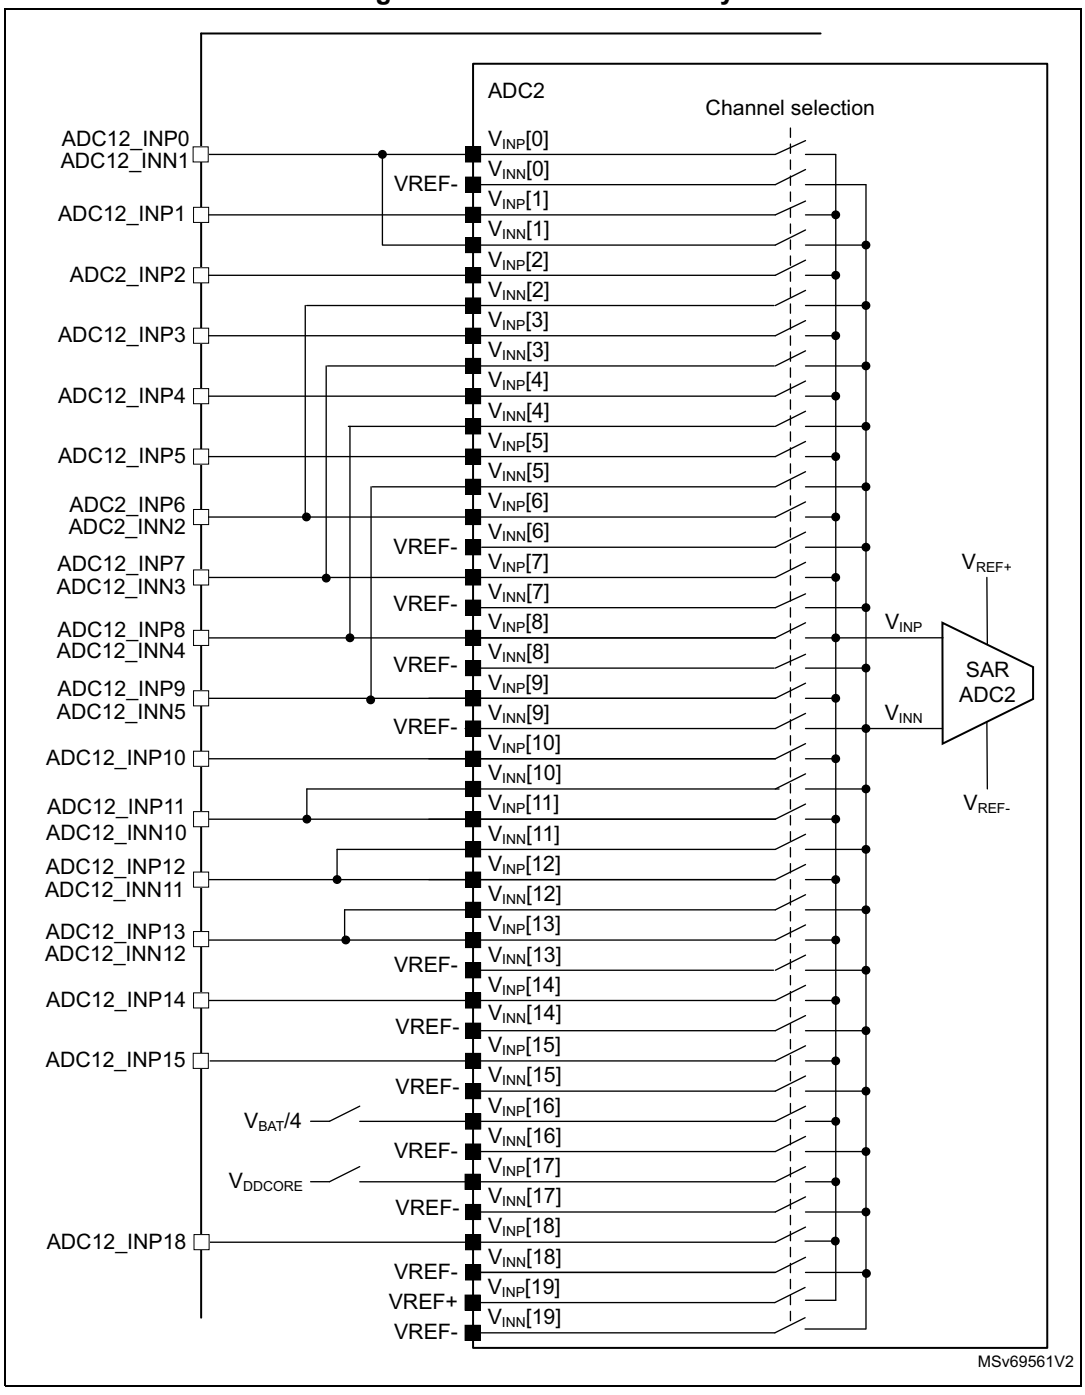


32.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

32.4.6 ADC Deep-power-down mode (DEEPPWD)

By default, the ADC is in deep-power-down mode where its supply voltage is internally switched off to reduce the leakage currents (the reset state of DEEPPWD bit is 1 in the ADC_CR register).

To start ADC operations, it is first required to exit Deep-power-down mode by clearing the DEEPPWD bit.

When ADC operations are complete, the ADC can be disabled by clearing the ADEN bit of the ADC_CR register.

Power can be saved by entering ADC Deep-power-down mode again (by setting DEEPPWD of ADC_CR register). This is particularly interesting before entering Stop mode.

32.4.7 Single-ended and differential input channels

ADC channels can be configured to be either single-ended inputs or differential inputs by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be programmed when no ADC conversion is ongoing. Note that the DIFSEL[i] bits corresponding to single-ended channels must be programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel "*i*" is the difference between the external voltage $V_{INP[i]}$ and V_{REF-}.

In differential input mode, the analog voltage to be converted for channel "*i*" is the difference between the external voltage $V_{INP[i]}$ (positive input) and $V_{INN[i]}$ (negative input).

In differential mode, the output data are unsigned data. When $V_{INP[i]}$ equals V_{REF-}, $V_{INN[i]}$ equals V_{REF+} and the output data is 0x000 (12-bit resolution mode). When $V_{INP[i]}$ equals V_{REF+}, $V_{INN[i]}$ equals V_{REF-} and the output data is 0xFFF.

$$\text{Converted value} = \frac{\text{ADC_Full_Scale}}{2} \times \left[1 + \frac{V_{INP} - V_{INN}}{V_{REF+}}\right]$$

When the ADC is configured in differential mode, the input signals are supposed to be differential (the common-mode voltage must be fixed at $V_{REF+}/2$ voltage).

Internal channels are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to *Section 32.4.4: ADC connectivity*.

Caution: When configuring channel "*i*" in differential input mode, its negative input voltage $V_{INN[i]}$ is connected to another channel. As a consequence, this channel is no longer usable in single-

ended or differential mode, and must never be configured to be converted. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADCs unusable. The only exception is interleaved mode for ADC master and the slave.

32.4.8 Calibration (ADCAL, CALADDOS, ADC_CALFACT)

A software calibration is required before launching the application. During the calibration sequence, the ADC calculates a 9-bit calibration factor, which is then internally applied to the ADC. Each ADC must follow the calibration procedure to calibrate the zero offset.

The calibration removes the offset error that may vary from chip to chip due to process or bandgap variation. It is a prerequisite to any ADC operation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Clear ADCALDIF before launching a calibration that is applied for single-ended input conversions.
- Set ADCALDIF before launching a calibration that is applied for differential input conversions.

The calibration needs to be run by combinations of hardware and software. When the calibration procedure is complete, the calibration factor must be written to the CALFACT_S[8:0] bits for the single-ended calibration factor and CALFACT_D[8:0] for the differential calibration factor.

The calibration factor can be written only if the ADC is enabled and no conversion is ongoing (ADEN = 1, ADSTART = 0 and JADSTART = 0). It is recommended to calibrate again the ADC if V_{REF+} voltage changes of more than 10% (see *Section 32.4.33: Monitoring the internal voltage reference*).

Software procedure to calibrate the ADC

1. Ensure DEEPPWD = 0, ADEN = 1 and wait until the ADRDY bit is set.
2. Set ADCAL and ensure CALADDOS = 0.
3. Select the calibration input mode by clearing ADCALDIF (single-ended input).
4. Set the ADSTART bit in the ADC_CR register.
5. Wait until the ADSTART bit is cleared or the EOC flag is set.
6. Read the ADC_DR register, then copy the converted data to the memory.
7. Repeat from step 4 several times (for example eight times).
8. Average the data stored in memory by dividing the accumulated data by the number of the conversions
9. If the averaged data is zero, set CALADDOS. Repeat all steps from step 4.
10. Store the averaged data to CALFACT_S[8:0].
11. Select the calibration input mode by setting ADCALDIF (differential input).
12. Keep the same CALADDOS setting as the one obtained during the single-end calibration.
13. Repeat steps 4 to 8.
14. Subtract 0x7FF from the averaged data. If the result is positive, store it in the CALFACT_D[8:0] bitfield. If it is negative, set CALADDOS, then repeat steps from 4 to 8.
15. Subtract again 0x7FF from the new averaged data. The resulting value is positive. Store it in CALFACT_D[8:0].
16. CALADDOS is now set, so clear ADCALDIF, and repeat steps 4 to 8.
17. Store the averaged data in CALFACT_S[8:0].
18. Clear ADCAL bit.

Software procedure to reinject a calibration factor into the ADC

1. Ensure ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion ongoing).
2. Set ADCAL.
3. Program CALADDOS, CALFACT_S and CALFACT_D with the new calibration factors.
4. Clear ADCAL.

Note: Depending on the calibration result, the ADC full-scale output may not reach 0xFFF (12-bit mode) for single-ended mode and [0x000,0xFFF] (12-bit mode) for differential mode.

Converting single-ended and differential analog inputs with a single ADC

If the ADC has to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1.

32.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure described in *Section 32.4.6: ADC Deep-power-down mode (DEEPPWD)*).

Once DEEPPWD is cleared, the ADC can be enabled. It requires a t_{STAB} stabilization time before starting converting accurately (see *Figure 264*).

Two control bits enable or disable the ADC:

- Set ADEN to enable the ADC. The ADRDY flag is set once the ADC is ready for operation.
- Set ADDIS to disable the ADC. ADEN and ADDIS are automatically deasserted by hardware as soon as the analog ADC is effectively disabled.

Regular conversions can then start either by setting ADSTART (refer to *Section 32.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*) or when an external trigger event occurs if triggers are enabled.

Injected conversions start by setting JADSTART or when an external injected trigger event occurs, if injected triggers are enabled.

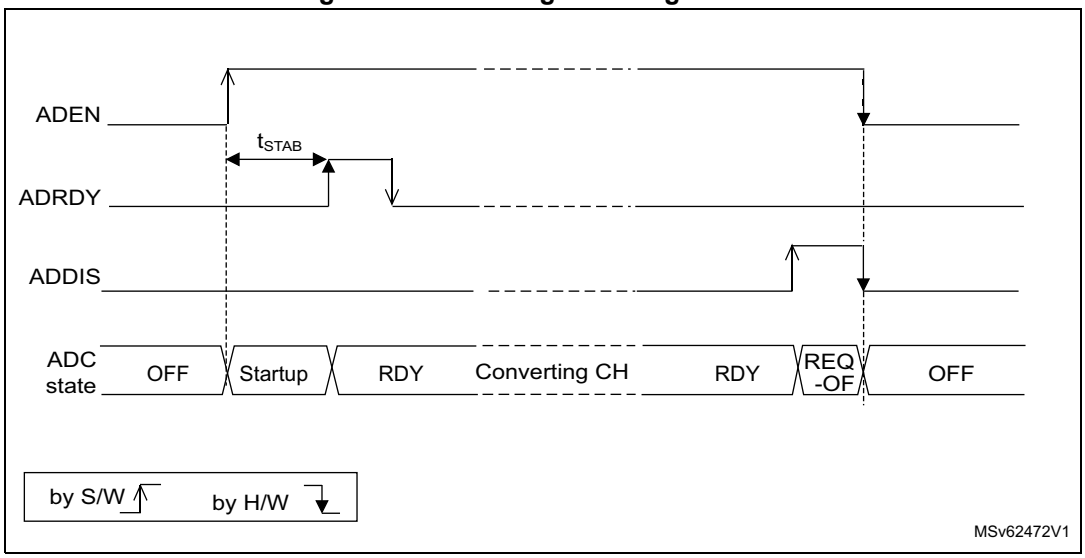
Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by programming it to 1.
2. Set ADEN.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done by using the associated interrupt (ADRDYIE must be set).
4. Clear the ADRDY bit in the ADC_ISR register by programming it to 1 (optional).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop all regular and injected ongoing conversions by setting ADSTP and JADSTP. Then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait for ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 264. Enabling/disabling the ADC



32.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC section) and configure the ADEN bit in the ADC_CR register, only if the ADC is disabled (ADEN must be cleared).

The software can then write the ADSTART, JADSTART and ADDIS control bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

The following constraints apply to all the other control bits of the ADC_CFGRx, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if no regular conversions are ongoing (ADSTART must be cleared).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if no injected conversions are ongoing (JADSTART must be cleared).
- ADC_TRy registers can be modified when an analog-to-digital conversion is ongoing (refer to *Section 32.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)* for details).
- To modify the all above control bits when the software trigger function is used, an ADSTP or JADSTP must be issued to make sure all activities are stopped, even if ADSTART and JADSTART are cleared.

The software is allowed to write the ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and if there is no pending request to disable the ADC. In addition, the software can write the ADC_JSQR register only if JADSTART is cleared and no injected conversion is ongoing. Refer to *Section 32.6.14: ADC injected sequence register (ADC_JSQR)* for additional details.

Note: There is no hardware protection to prevent forbidden write accesses to ADC control bits. In such cases, the ADC state may become unknown. To recover from this situation, the ADC must be disabled (ADEN = 0 as well as all the bits of the ADC_CR register).

32.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 20 multiplexed channels per ADC, out of which:

- Up to 17 analog inputs coming from GPIO pads (ADCx_INN/INP[i]). Depending on the device, not all of them are available on GPIO pads.
- The ADC is connected to up to 4 internal analog inputs:
  - internal reference voltage (V_{REFINT})
  - V_{BAT} monitoring channel ($V_{BAT}/4$)
  - V_{REF+} positive reference voltage
  - V_{DDCORE} voltage

  To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VREFEN, VBATEN in the ADCC_CCR registers, or by enabling the corresponding bit in the *ADC option register (ADC_OR)*.

Refer to *ADC interconnection* tables in *Section 32.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to ADC pins.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_INN/INP3, ADCx_INN/INP8, ADCx_INN/INP2, ADCx_INN/INP2, ADCx_INN/INP0, ADCx_INN/INP2, and ADCx_INN/INP2.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to four conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while a regular conversion is ongoing. ADC regular conversions must consequently be stopped by setting ADSTP (refer to *Section 32.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)*).

In addition, the ADC_JSQR register must not be modified while an injected conversion is ongoing. ADC injected conversions must consequently be stopped by setting JADSTP, except when JQDIS is cleared.

32.4.12 Channel preselection register (ADC_PCSEL)

The PCSEL bit of the ADC_PCSEL register controls the analog switch integrated in the I/O.

For each channel selected through SQRx or JSQRx bits, the corresponding PCSEL bit must be configured in advance in the ADC_PCSEL register. The ADC input multiplexer selects the ADC input according to SQRx and JSQRx configuration with very high speed. The analog switch integrated in the I/O cannot react as fast as the ADC multiplexer. To avoid the delay due to the analog switch control on the I/O, it is necessary to preselect the input channels that are selected through the SQRx and JSQRx. The selection is based on the V_{INP} of each ADC input. For example, if the ADC converts ADCx_INN/INP1, PCSEL1 bit must also be set in ADC_PCSEL register. If ADCx_INN/INP1 is configured as a differential channel, both PCSEL1 and PCSEL0 must be set, which corresponds to ADC1_INN1.

Note: Configuring the PCSEL bit is not necessary for the internal channels (such as V_{REFINT}).

32.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be sufficient for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time, which is programmable through the SMP[2:0] bits of the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 1.5 ADC clock cycles
- SMP = 001: 2.5 ADC clock cycles
- SMP = 010: 6.5 ADC clock cycles
- SMP = 011: 11.5 ADC clock cycles
- SMP = 100: 23.5 ADC clock cycles
- SMP = 101: 46.5 ADC clock cycles
- SMP = 110: 246.5 ADC clock cycles
- SMP = 111: 1499.5 ADC clock cycles

The total conversion time is calculated as follows:

$$T_{CONV} = \text{Sampling time} + 13.5 \text{ ADC clock cycles}$$

Example

With $F_{adc_ker_ck}$ = 30 MHz and a sampling time of 1.5 ADC clock cycles:

$$T_{CONV} = (1.5 + 13.5) \times \text{ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns}$$

The ADC notifies the end of the sampling phase by asserting the EOSMP flag (only for regular conversion).

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum and a maximum sampling times as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode

The bulb sampling mode enables to obtain longer sampling time.

When the BULB bit is set in the ADC_CFGR2 register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.

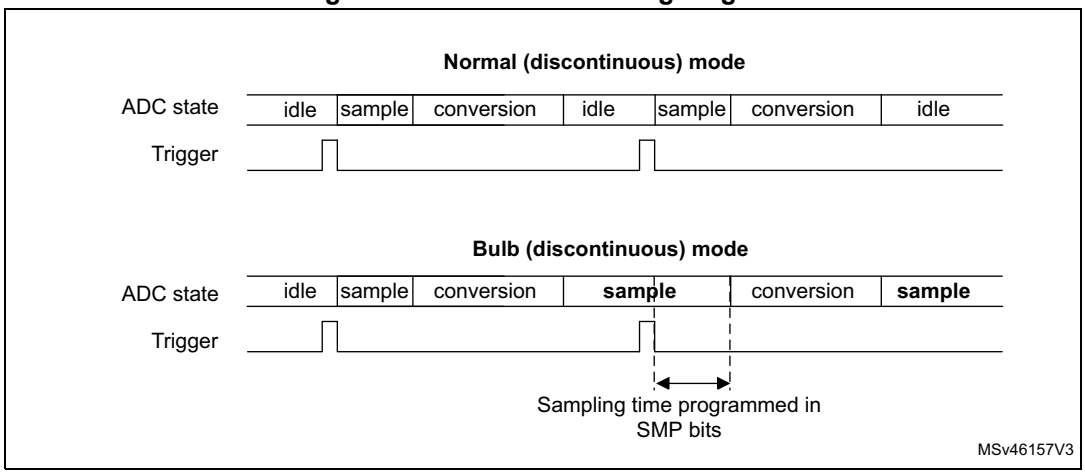
The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The bulb mode is neither compatible with the continuous conversion mode nor with the injected channel conversion.

The BULB bit can be modified only when the ADEN bit of the ADC_CR register is cleared.

When the BULB bit is set, it is not allowed to set the SMPTRIG bit in ADC_CFGR2.

Figure 265. Bulb mode timing diagram



Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed through SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected (EXTEN[1:0] = 01), each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

Due to the synchronization mechanism, the minimum allowed pulse width is seven adc_ker_ck periods.

When a software trigger is selected (EXTEN[1:0] = 00), the software trigger is not the ADSTART bit of ADC_CR but the SWTRIG bit. The SWTRIG bit has to be set to start the sampling period, and it has to be cleared to end the sampling period and start the conversion. In this mode, the minimum sampling time is limited to seven ADC clock cycles.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is only compatible with the discontinuous mode. DISCNUM must be cleared for regular conversion mode. It is not supported for injected conversion mode and autoinjection mode.

When the SMPTRIG bit is set, setting the BULB bit is not allowed and injected conversions are not supported.

The sampling time control trigger mode is not compatible with the following dual modes: DUAL[4:0] = 0b00010, 0b00011, 0b00101, 0b00110, 0b00111, and 0b01001.

32.4.14 Single conversion mode

To enable the single conversion mode for regular channels, clear both CONT and DISCEN bits in ADC_CFGR1 register. To enable it on injected channel, clear JDISCEN bit.

In single conversion mode, the ADC performs once all the regular conversions of the programmed channels. This mode is started by one of the following events:

- ADSTART bit set in the ADC_CR register (for a regular channel)
- JADSTART bit set in the ADC_CR register (for an injected channel)
- An external hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit 8-level FIFO accessible through the ADC_DR register,
- The EOC (end of regular conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers,
- The JEOC (end of injected conversion) flag is set, and
- An interrupt is generated if the JEOCIE bit is set.

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set, and
- An interrupt is generated if the JEOSIE bit is set.

The ADC then stops until a new external regular or injected trigger occurs or until the ADSTART or JADSTART bit is set again.

The single conversion mode is compatible with bulb and sampling time control trigger modes.

Note: To convert a single channel, program a sequence with a length of 1.

32.4.15 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts all the conversions of the sequence. This mode is started by setting the CONT bit of the ADC_CFGR1 register, either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the eight 32-bit word FIFO accessible through the ADC_DR register.
- The EOC (end of conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled, this means that it is forbidden to set both DISCEN and CONT bits.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit) (refer to Section : Autoinjection mode).

32.4.16 Starting conversions (ADSTART, JADSTART)

ADC regular conversions can be started by setting ADSTART.

When ADSTART is set, the conversion starts:

- Immediately if EXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected regular hardware trigger, if EXTEN[1:0] is not equal to 00.

The application software starts ADC injected conversions by setting JADSTART.

When JADSTART is set, the conversion starts:

- Immediately if JEXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected injected hardware trigger, if JEXTEN[1:0] is not equal to 00.

Note: In autoinjection mode (JAUTO = 1), use the ADSTART bit to start regular conversions followed by autoinjected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether an ADC operation is ongoing. The ADC can be reconfigured while ADSTART and JADSTART are both cleared, indicating that the ADC is idle.

ADSTART is deasserted by hardware:

- In single mode with software regular trigger (CONT = 0, EXTEN = 0x0): at any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT and EXTEN don’t care), after execution of the ADSTP procedure asserted by the software

Note: In continuous mode (CONT = 1), ADSTART is not deasserted by hardware when EOS is asserted because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTEN ≠ 0x00), ADSTART is not deasserted by hardware when EOS is asserted to help the software that does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is deasserted by hardware:

- In single mode with software injected trigger (JEXTEN = 0x0): at the end of each injected conversion sequence (JEOS assertion) or at the end of each subgroup processing if JDISCEN = 1
- In all cases (JEXTEN=x), after execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, the ADSTART bit must not be set if the EOC flag is still high.

In bulb mode (BULB = 1), the previous end-of-conversion automatically starts the sampling, then setting ADSTART starts the conversion including the programmed sampling time.

In sampling time control trigger mode (SMPTRIG = 1), SWTRIG bit must be set to start the conversion.

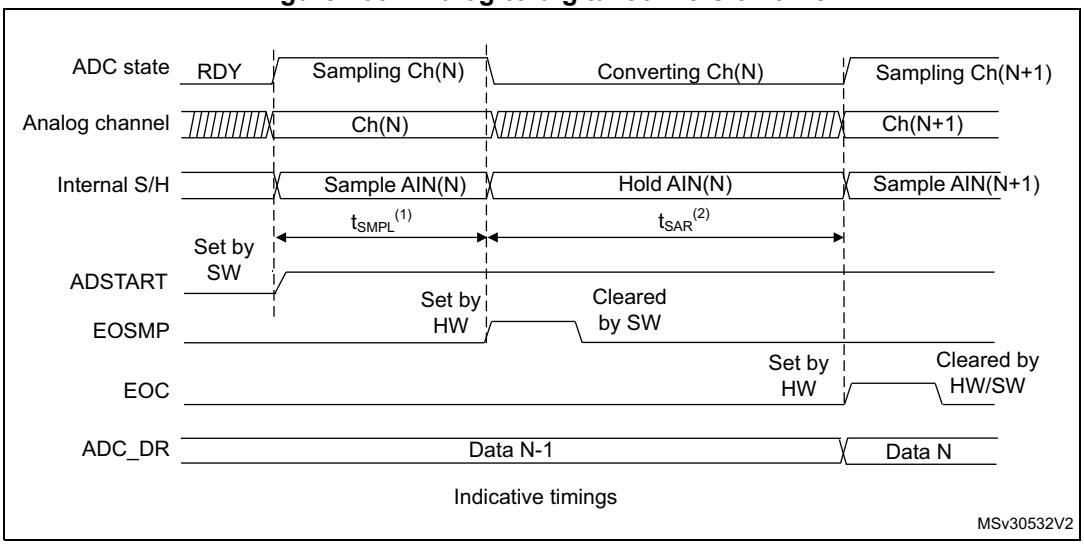
32.4.17 Timing

The elapsed time between the start of a conversion and the end of a conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$T_{CONV} = T_{SMPL} + T_{SAR} = [1.5\ _{|min} + 13.5\ _{|12bit}] \times T_{ADC_CLK}$

$T_{CONV} = T_{SMPL} + T_{SAR} = 50\ ns\ _{|min} + 450\ ns\ _{|12bit} = 500\ ns$ (for $F_{adc_ker_ck} = 30\ MHz$)

Figure 266. Analog-to-digital conversion time



1. t_{SMPL} depends on SMP[2:0].
2. t_{SAR} depends on RES[2:0].
3. The bulb and the sampling time control trigger modes are not described in the above figure.

32.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop ongoing regular conversions by setting ADSTP and ongoing injected conversions by setting JADSTP.

Stopping conversions resets the ongoing ADC operation. The ADC can then be reconfigured (for example by changing the channel selection or the trigger). It is then ready for a new operation.

Injected conversions can be stopped while regular conversions are still ongoing and vice versa. This allows, for instance, the reconfiguration of the injected conversion sequence and triggers while regular conversions are still ongoing (and vice versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with the partial result discarded (the ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (the ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC restarts a new sequence).

Once this procedure is complete, ADSTP/ADSTART bits (for regular conversion), or JADSTP/JADSTART bits (for injected conversion) are deasserted by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In autoinjection mode (JAUTO = 1), setting the ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 267. Stopping ongoing regular conversions

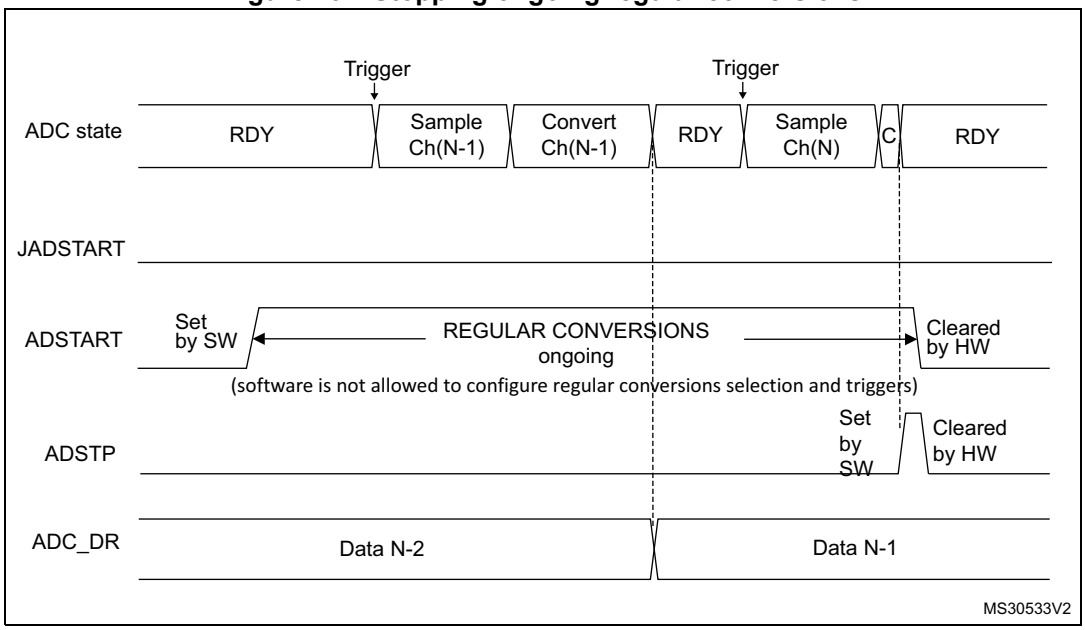


Figure 268. Stopping ongoing regular and injected conversions

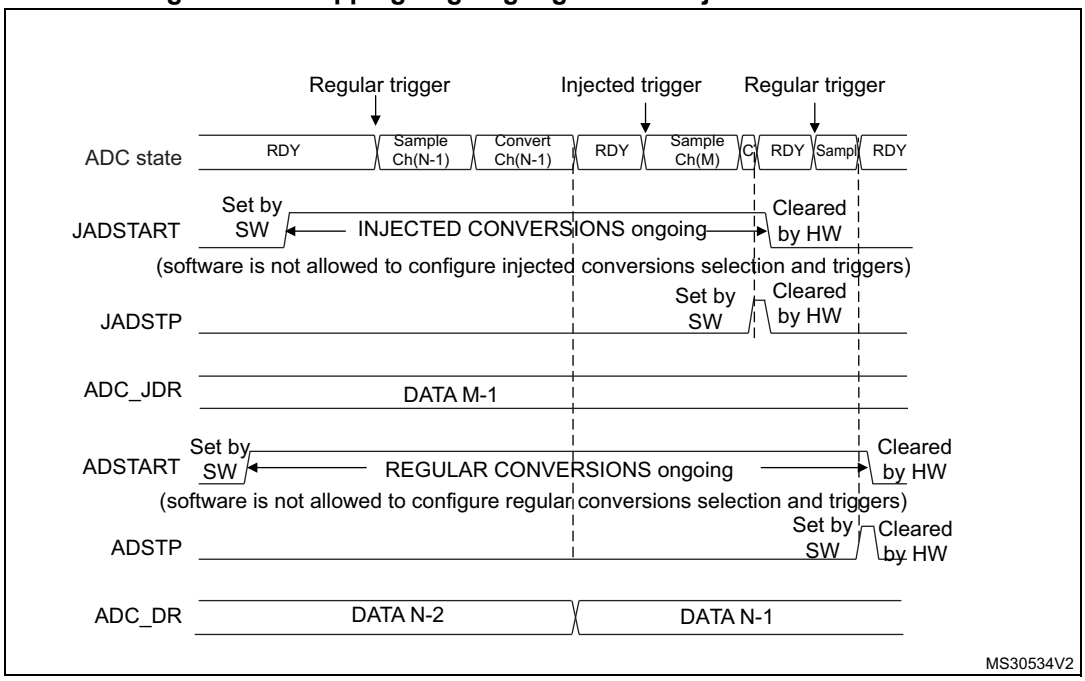


32.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (for example timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

The regular trigger selection is effective once the software has set ADSTART while the injected trigger selection is effective once the software has set JADSTART bit.

All hardware triggers that occur while a conversion is ongoing are ignored:

- If ADSTART = 0, regular hardware triggers are ignored.
- If JADSTART = 0, injected hardware triggers are ignored.

Table 243 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 243. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware trigger detection disabled, software trigger detection enabled
01	Hardware trigger with detection on the rising edge (sampling time controlled in hardware trigger mode)
10	Hardware trigger with detection on the falling edge
11	Hardware trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

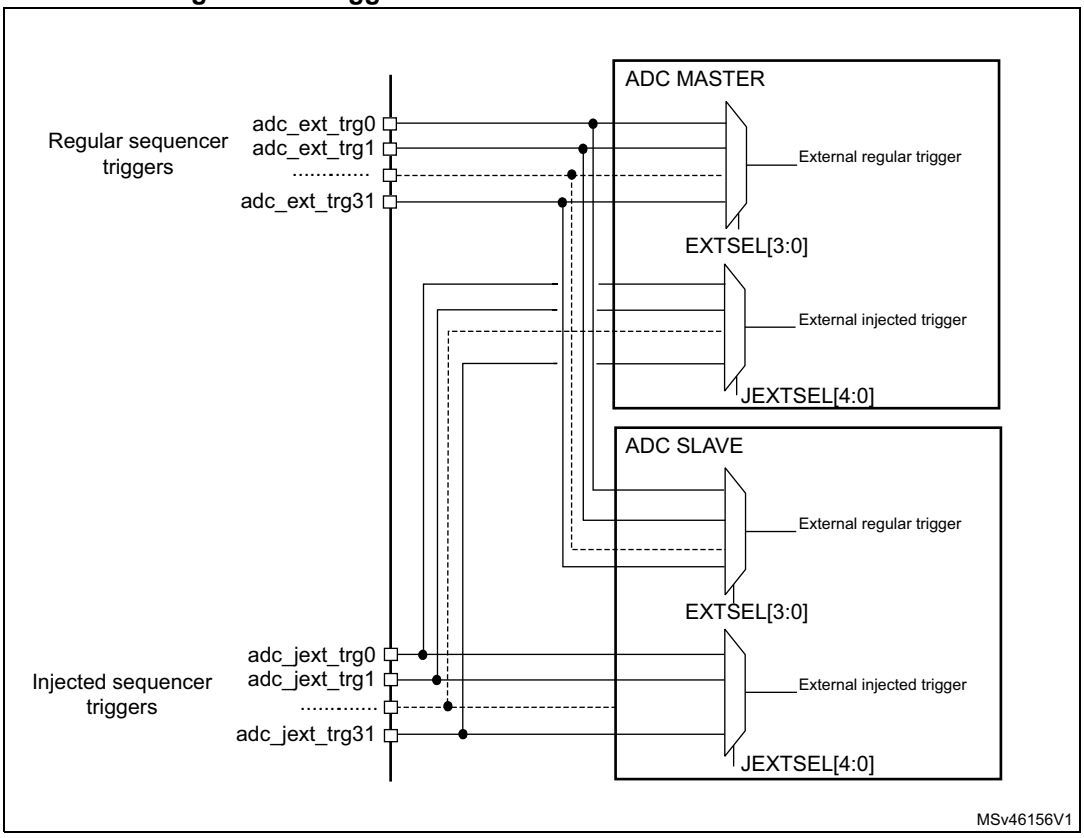
Table 244. Configuring the trigger polarity for injected external triggers

JEXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

The EXTSEL and JEXTSEL control bits select which, out of 32 possible events, can trigger the conversion of the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Figure 269. Triggers shared between ADC master and slave



Refer to *ADC interconnection* tables in *Section 32.4.2: ADC pins and internal signals* for the list of the external triggers that can be used for regular conversion.

32.4.20 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR1 register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once if JDISCEN = 0).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 270* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 1.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Autoinjection mode

If the JAUTO bit in the ADC_CFGR1 register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

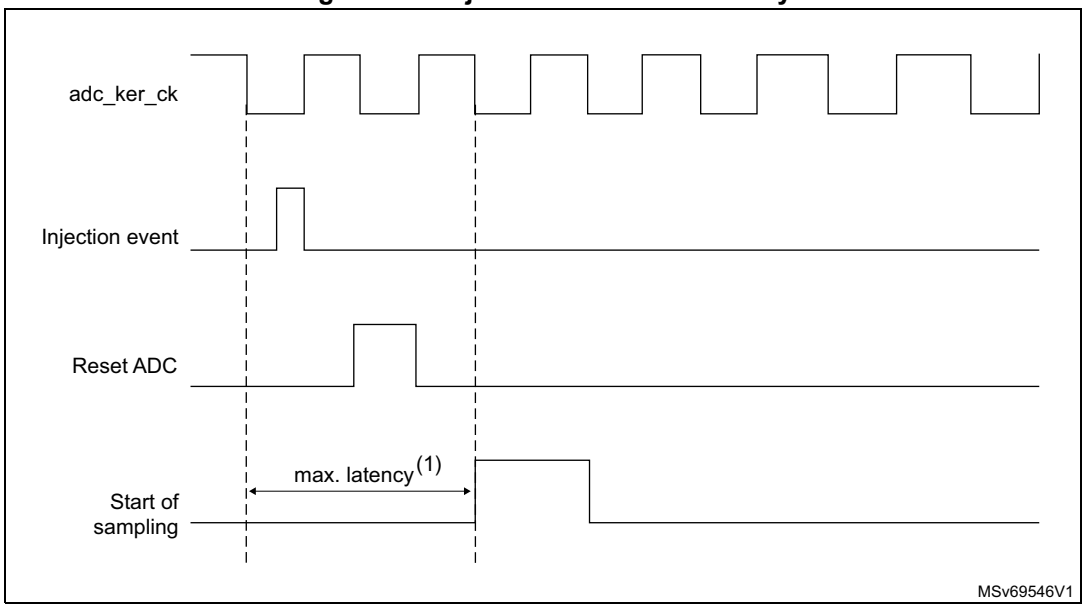
In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the autoinjected and discontinuous modes simultaneously.

Figure 270. Injected conversion latency



1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

32.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR1 register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - First trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).
  - Second trigger: channels converted are 6, 7, 8 (an EOC event is generated at the end of each conversion).
  - Third trigger: channels converted are 9, 10, 11 (an EOC event is generated at the end of each conversion) and an EOS event is generated after the conversion of channel 11.
  - Fourth trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).

  - ...
- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - First trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: The channel numbers referred to in the above example might not be available on all devices.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the fourth trigger reconverts the channels 1, 2 and 3 in the first subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR1 register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - First trigger: channel 1 converted (a JEOC event is generated)
  - Second trigger: channel 2 converted (a JEOC event is generated)
  - Third trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all devices.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the fourth trigger reconverts the first injected channel 1.

It is not possible to use both autoinjection mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

32.4.22 Programmable resolution (RES) - fast conversion mode

Faster conversions can be performed by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] control bits. *Figure 275*, *Figure 276*, *Figure 277* and *Figure 278* show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to *Table 245*.

Table 245. T_{SAR} timings depending on resolution

RES (bits)	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at $F_{adc_ker_ck}$ = 30 MHz	T_{CONV} (ADC clock cycles) (with Sampling time= 1.5 ADC clock cycles)	T_{CONV} (ns) at $F_{adc_ker_ck}$ = 30 MHz
12	13.5 ADC clock cycles	450 ns	15 ADC clock cycles	500.0 ns
10	11.5 ADC clock cycles	383.33 ns	13 ADC clock cycles	433.33 ns
8	8.5 ADC clock cycles	203.33 ns	10 ADC clock cycles	333.33 ns
6	6.5 ADC clock cycles	216.67 ns	8 ADC clock cycles	266.66 ns

32.4.23 End of conversion and end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application at the end of each regular conversion (EOC) event and injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set. The software can clear the EOC flag either by programming it to 1 or by reading ADC_DR. If ADC_DR FIFO is not emptied, the EOC flag is set again and an interrupt can be generated again.

The ADC sets the JEOC flag as soon as new injected conversion data is available in one of the ADC_JDRy registers. An interrupt can be generated if the JEOCIE bit is set. The software can clear the JEOC flag either by programming it to 1 or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of the sampling phase by setting the EOSMP flag (for regular conversions only). The EOSMP flag is cleared by software by programming it to 1. An interrupt can be generated if the EOSMPIE bit is set.

32.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application at the end of each regular sequence (EOS) and injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the conversion of the last data of the regular sequence is complete. An interrupt can be generated if the EOSIE bit is set. The EOS flag is cleared by the software by programming it to 1.

The ADC sets the JEOS flag as soon as the conversion of the last data of the injected sequence is complete. An interrupt can be generated if the JEOSIE bit is set. The JEOS flag is cleared by the software by programming it to 1.

32.4.26 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)

Data and alignment

At the end of each regular channel conversion (when an EOC event occurs), the result of the converted data is stored in the 32-bit wide ADC_DR data register with FIFO. Since the data register has eight levels of FIFO, the EOC flag is raised again as far as the FIFO is not emptied.

At the end of each injected channel conversion (when a JEOC event occurs), the result of the converted data is stored in the 32-bit wide corresponding ADC_JDRy data register.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFGR2 register select the alignment of the data stored after the conversion. By default, data are right-aligned. Refer to *Figure 275*, *Figure 276*, *Figure 277* and *Figure 278* for examples of data alignment.

Note: The data can be aligned in normal and oversampling mode. The OVSS[3:0] bitfield is only effective in oversampling mode.

Offset

An unsigned offset value y (y = 1, 2, 3, 4) can be applied to a channel by programming a value different from 0 in the OFFSET[21:0] bitfield of the ADC_OFRy register. The channel to which the offset is applied is programmed to the OFFSETy_CH[4:0] bits of ADC_OFCFGRy register. The offset can be positive or negative depending on the value of POSOFF bit. When POSOFF is cleared, the converted value is subtracted by the user-defined offset written in OFFSET[21:0] bits. The result can be a negative value. The read data is consequently signed and the SEXT bit represents the extended sign value.

The offset value must be lower than the maximum conversion value (for example the maximum offset value is 0xFFF in 12-bit mode).

The offset can be used to convert unsigned data to signed data (for example the offset value is equal to 0x800 in 12-bit mode).

The offset correction is also supported in oversampling mode. In this mode, the offset is subtracted when all the oversampling operations are complete.

Note: It is not allowed to select the same channel for different OFFSETy_CH[4:0] values except when OFFSET[21:0] is 0.

Table 250 describes how the computation is performed for all the possible ADC resolutions and offset settings.

Table 246. Offset computation versus data resolution

Resolution (RES[1:0] bits)	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
00: 12-bit	DATA[11:0]	OFFSET[11:0]	Signed or unsigned 24-bit data, right aligned to [11:0]	-
01: 10-bit	DATA[11:2],00	OFFSET[11:2]	Signed or unsigned 24-bit data, right aligned to [9:0]	The user must configure OFFSET[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	OFFSET[11:4]	Signed or unsigned 24 bit data right aligned to [7:0]	The user must configure OFFSET[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	OFFSET[11:6]	Signed or unsigned 24 bit data right aligned to [5:0]	The user must configure OFFSET[5:0] to 0b000000.

Figure 275, *Figure 276*, *Figure 277* and *Figure 278* show alignments for signed and unsigned data.

Figure 275. Right alignment (offset disabled, unsigned value)

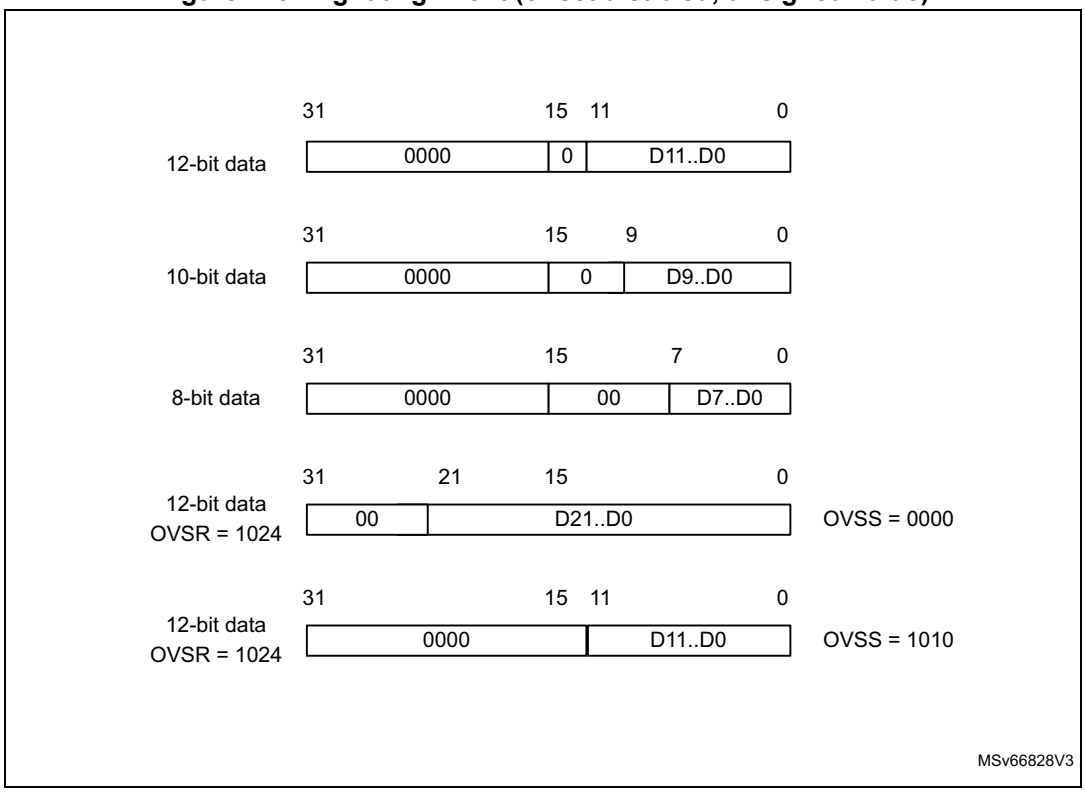

Figure 276. Right alignment (offset enabled, signed value)

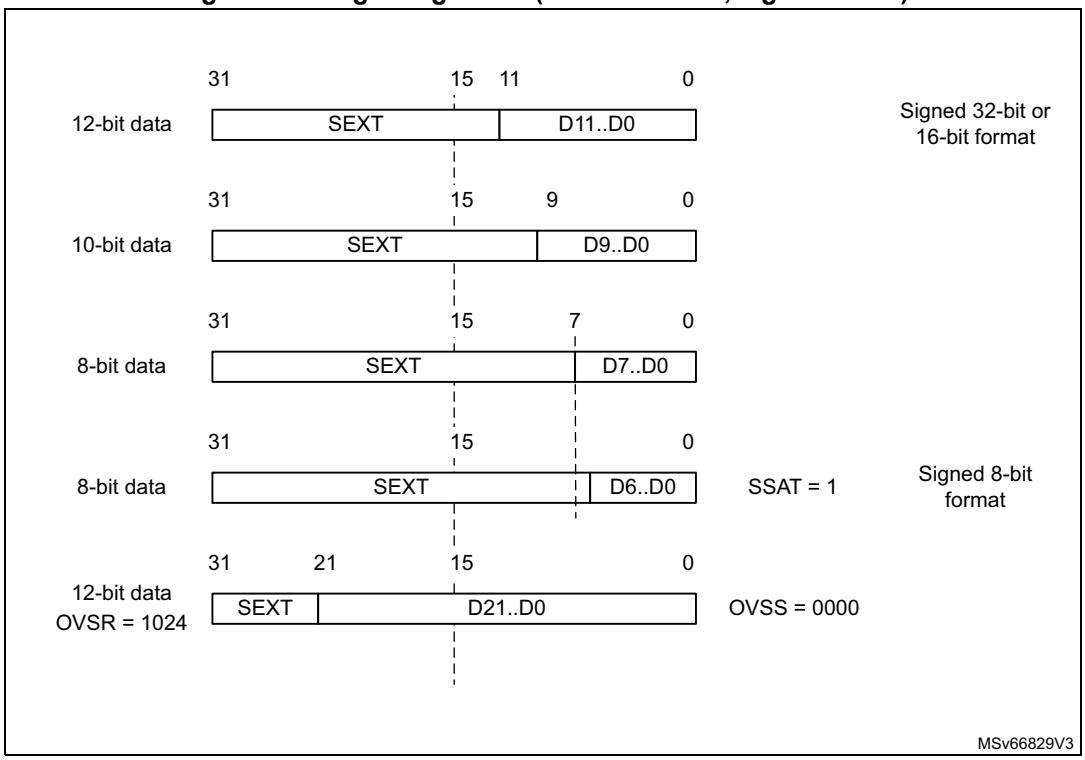

Figure 277. Left alignment (offset disabled, unsigned value)

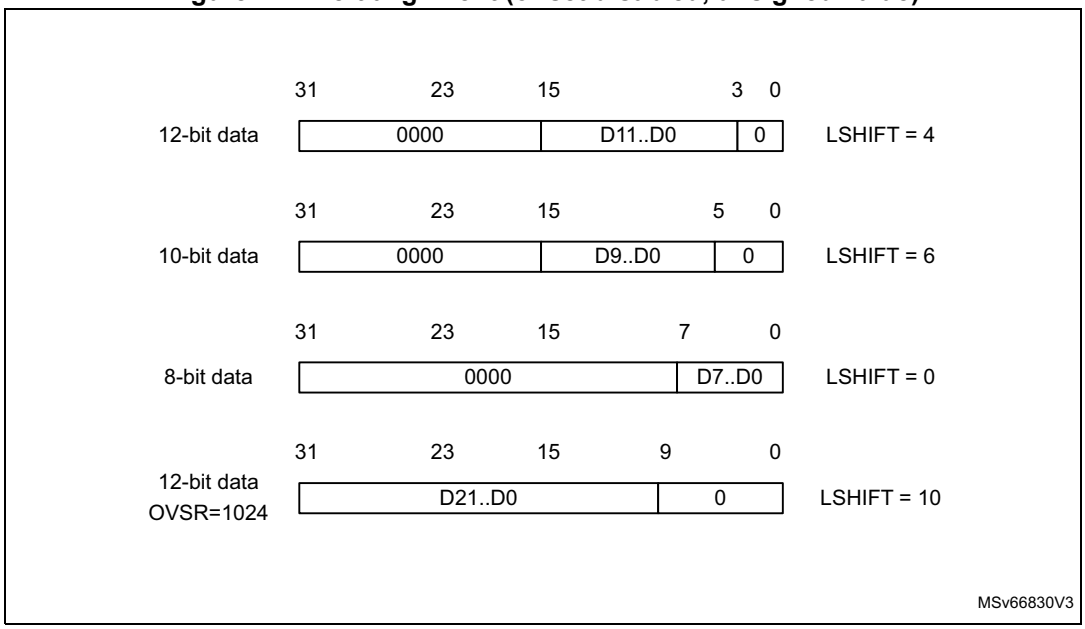

Figure 278. Left alignment (offset enabled, signed value)

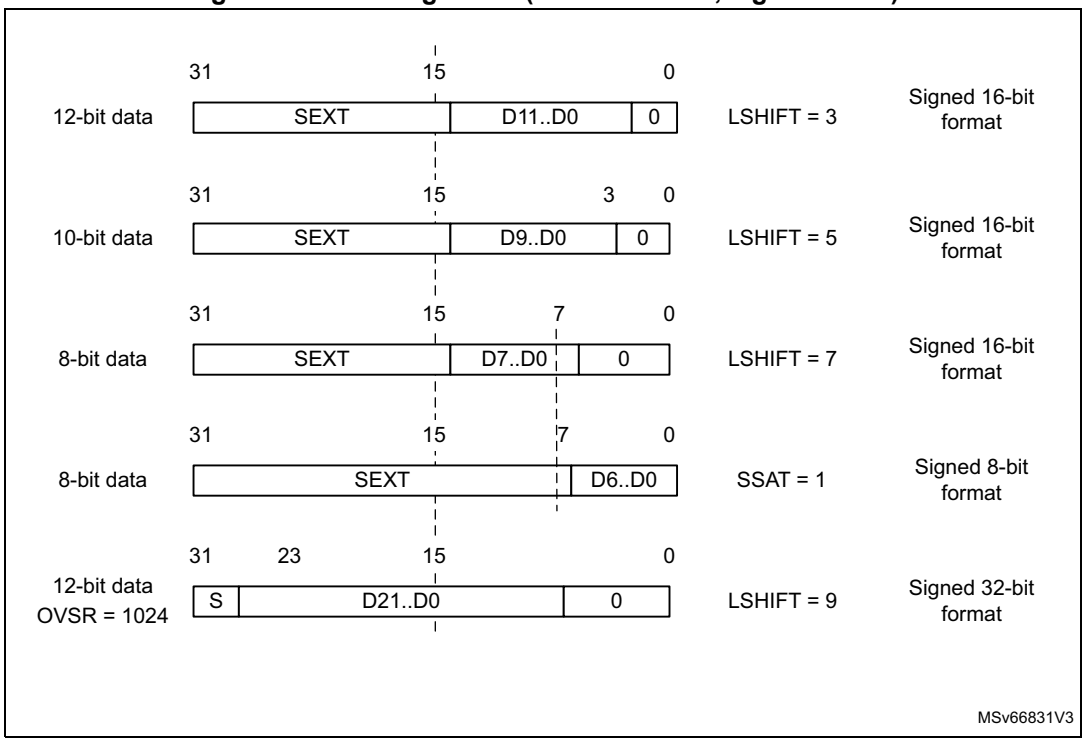

Management of signed and unsigned saturation format (SSAT, USAT)

The offset correction might result in the data width to be wider than the original data.

To limit the original data width, the data saturation can be enabled through the SSAT and USAT bits of the ADC_OFCFGRy register.

Unsigned 12-bit data can be extended to 13-bit signed data by using an offset value different from 0x800.

The original data width can be preserved by setting SSAT bit to limit the data width to 12 bits.

Unsigned data can be saturated to the original data width by setting the USAT bit.

Table 247 shows the sign-extended data format corresponding to different resolutions.

Table 247.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	0	Sign-extended 13-bit significant data: SEXT[31:13] DATA[12:0]	0x0000 07FF - 0xFFFF F800
1	0	Sign-extended 12-bit significant data: SEXT[31:12] DATA[11:0]	0x7FF - 0x800

Table 247.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	1	Unsigned saturation 12-bit signification data: DATA[11:0]	0xFFF - 0x000
1	1	Reserved	-

Table 248 provides numerical examples for four different offset values.

Table 248. Numerical examples for 32-bit or 16-bit format

Raw conversion result	Offset value	Result SSAT = 0 USAT = 0	Result SSAT = 0 USAT = 1	Result SSAT = 1 USAT = 0
0xFFF	0x800	0x0000 07FF	0x07FF	0x07FF
0x800		0x0000 0000	0x0000	0x0000
0x000		0xFFFF F800	0x0000	0xF800
0xFFF	0x820	0x0000 07DF	0x07DF	0x07DF
0x800		0xFFFF FFE0	0x0000	0xFFE0
0x000		0xFFFF F7E0	0x0000	0xF7E0
0xFFF	0x7E0	0x0000 081F	0x081F	0x07FF
0x800		0x0000 0020	0x0020	0x0020
0x000		0xFFFF F820	0x0000	0xF820
0xFFF	0x020	0x0000 0FDF	0x0FDF	0x0FDF
0x800		0x0000 07E0	0x07E0	0x07E0
0x000		0xFFFF FFE0	0x0000	0xFFE0

Caution: SSAT must not be used in conjunction with USAT. No hardware check is performed to ensure that this condition is respected.

Gain compensation

When the GCOMP bit is set in the ADC_GCOMP register, the gain compensation is activated on all the converted data. After each conversion, data is calculated using the following formula.

$$DATA = DATA(\text{adc result}) \times (GCOMPCOEFF) / 4096$$

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in RDATAx or JDATAx bitfields, the LSB−1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used in oversampling mode, the gain calculation is performed after the accumulation and

right-shift operations to minimize the power consumption (the gain calculation is done only once and not at each conversion).

The internal multiplier width is 32 bits and the input data width for the gain compensation must be less than 18 bits. When using oversampling with injected and regular conversion mode, the ROVSM bit of the ADC_CFGR2 register must be set to resume the pending conversion with the correct value.

When the gain compensation is activated, the ADC conversion latency is increased by one clock cycle. In continuous and scan conversion modes, the ADC conversion rate does not change.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) issues a notification that the regular converted data has not been read (by the CPU or the DMA) before the ADC_DR FIFO (eight stages) is overflowed, or adc_hclk clock is too slow to manage the data.

The OVR flag is set when a new conversion completes while ADC_DR register FIFO was full. An interrupt is generated if the OVRIE bit is set.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP. The OVR flag is cleared by software by programming it to 1.

Data can be configured to be preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0

  The overrun event preserves the data register from being overwritten: the old data are maintained up to ADC_DR FIFO depth (eight data) and the new conversion is discarded and lost. If OVR remains at 1, further conversions occur but the result data is also discarded.
- OVRMOD = 1

  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversion is performed normally and the ADC_DR register always contains the latest converted data. In this mode, DMA burst mode nor MDF output mode cannot be supported.

Figure 279. Example of overrun (OVRMOD = 0)

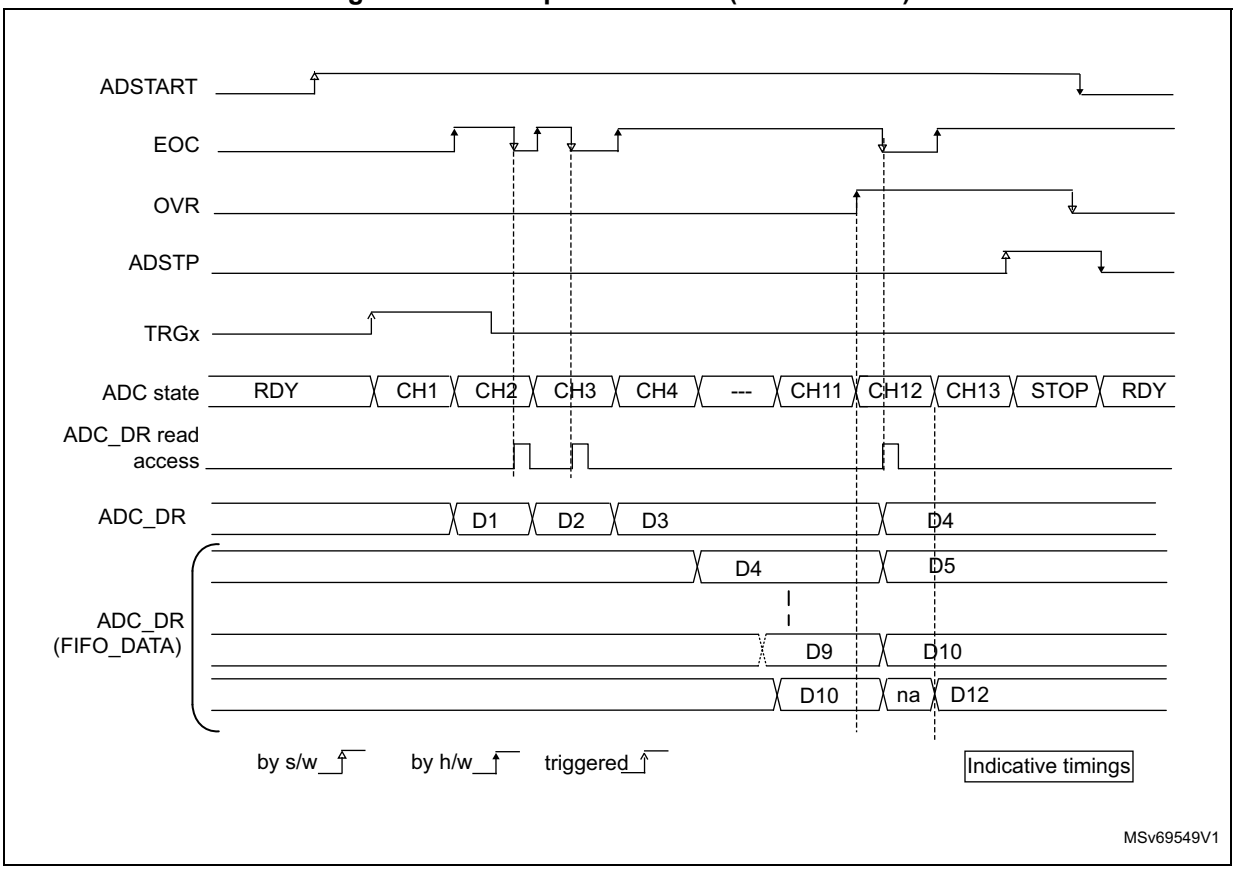

Figure 280. Example of overrun (OVRMOD = 1)

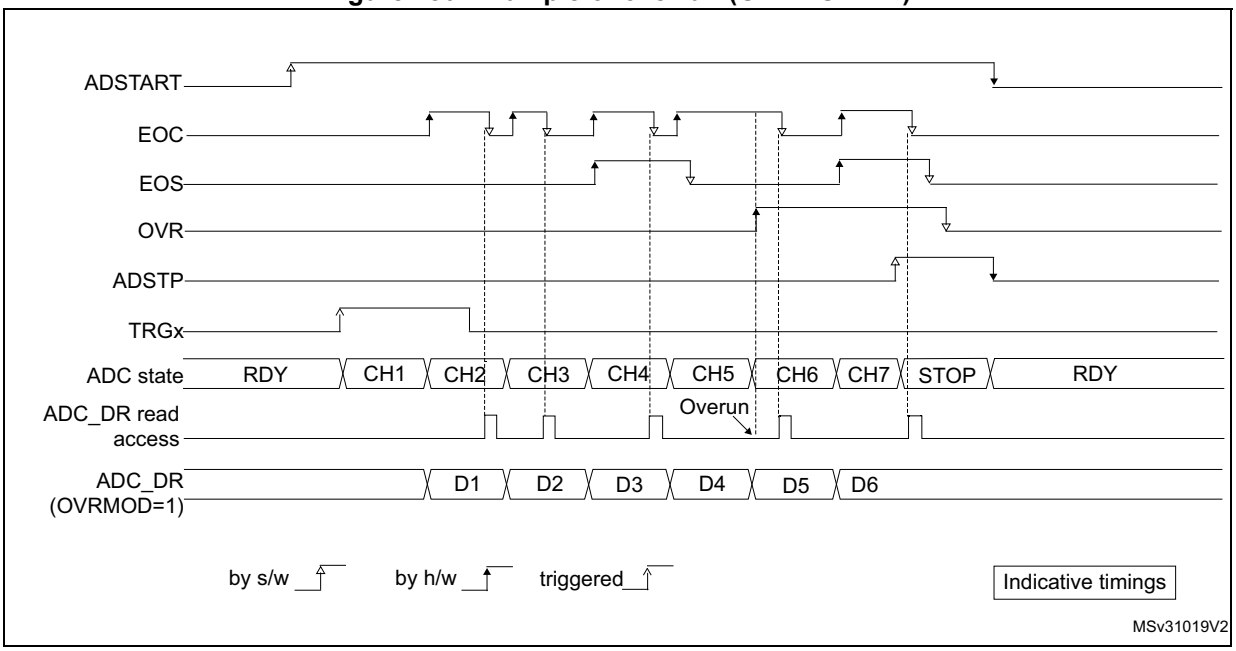

Note: Even if overrun may occur for injected channels, there is no overrun detection on these channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as errors.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and the OVR flag must be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

When the DMA mode is enabled (DMNGT[1:0] = 01 or 11 in the ADC_CFGR1 register in single ADC mode or DAMDF different from 00 in dual ADC mode), a DMA request is generated after each channel conversion. This allows the transfer of the converted data from the ADC_DR register to the destination location configured in the DMA.

Despite this, if an overrun occurs (OVR = 1) because the DMA cannot serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA, which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of the OVRMOD bit, the data are either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD)*). If OVRMOD = 0 (data preserved), DMA transfer requests are blocked.

Two different DMA modes are proposed depending on the application usage. They can be configured through the DMNGT[1:0] bitfield of the ADC_CFGR1 register in single ADC mode and the DAMDF bit of the ADCC12_CCR register in dual ADC mode, respectively:

- DMA one-shot mode (DMNGT[1:0] = 01)

  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT[1:0] = 11)

  This mode is suitable when programming the DMA in circular mode.

DMA one-shot mode (DMNGT[1:0] = 01)

In one-shot mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (that is when DMA_LACK interrupt occurs, see *Direct-memory controller* section) even if a new conversion has been started.

When DMA transfers are complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen,
- All ongoing conversions are aborted with the partial result discarded,
- No new DMA request is issued to the DMA controller in order to avoid generating an overrun error if there are still conversions that are started,
- The scan sequence is stopped and reset, and
- The DMA is stopped.

DMA circular mode (DMNGT[1:0] = 11)

In circular mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows the configuration of the DMA in circular mode to handle a continuous analog input data stream.

DMA with FIFO

The output data register features an eight-stage FIFO. Two different DMA requests are generated in parallel. When a data is available, an “SREQ single request” is generated. When four data are available, a “BREQ burst request” is generated. The DMA can be programmed either in single-transfer mode or in burst mode (four beats). The appropriate request line is selected by the DMA according to the mode selected. Refer to *Section Direct memory access controller* for further information.

Due to the existence of FIFO, DMA requests are generated until the FIFO is emptied. To stop DMA requests even when the FIFO is not emptied, set the ADSTP bit.

32.4.27 Managing conversions using the MDF

The ADC conversion results can be transferred directly to the MDF.

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers the 16 least significant bits of the regular data register to the MDF through adcx_dat[15:0] bus, which in turn resets the EOC flag once the transfer is effective.

The data format must be in 16-bit signed format:

ADC_DR[31:16] = Don’t care

ADC_DR[15] = Sign

ADC_DR[14:0] = Data

Any value above the 16-bit signed format is truncated.

To obtain a 16-bit signed format, the OFFSET function needs to be activated.

In this mode, OVRMOD = 1 is not supported.

32.4.28 Dynamic low-power features

Autodelayed conversion mode (AUTDLY)

The ADC implements an autodelayed conversion mode controlled by the AUTDLY configuration bit. Autodelayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

Regular conversion mode

When AUTDLY is set, a new conversion can start if the following conditions are met:

- All the previous data of the same group have been treated, and
- The ADC_DR register has been read or the EOC bit has been cleared (see *Figure 281*).

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data.

The delay is inserted after each regular conversion.

Injected conversion mode

When AUTDLY is set, a new conversion can start only if the JEOS bit has been cleared (see *Figure 282*). Since there are four ADC_JDRy registers, the autodelay is performed at the end on the injected conversion sequence.

There is no delay inserted between each conversion of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored. This is not the case for software triggers for which the ADSTART and JADSTART bits can still be set during the autodelay to restart the conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see *Figure 282*).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see *Figure 284*).

The behavior is slightly different in autoinjection mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 285*).

Caution: In autoinjection mode, there is no delay between the last regular conversion and the first injected conversion. The user must clear the last EOC flag before clearing the JEOS flag, otherwise the next sequence might start before EOC flag is cleared.

In autodelay mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In autodelay mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

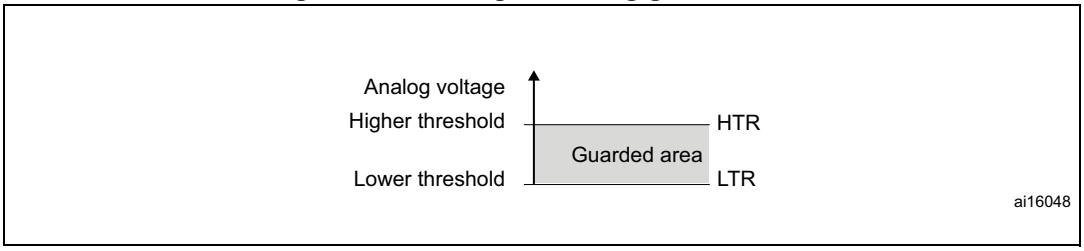
32.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 286. Analog watchdog guarded area



AWDy flag and interrupt

An interrupt can be enabled for each of the three analog watchdogs by setting AWDyIE in the ADC_IER register (y = 1, 2, 3).

AWDy (y = 1, 2, 3) flag is cleared by software by writing 1 to it, or by setting ADDIS.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Analog watchdog filter for watchdog 1

When an ADC is configured with only one input channel (selecting several channels in scan mode is not allowed), a valid ADC conversion data range can be configured through the ADC_AWD1LTR and ADC_AWD1HTR registers. When the conversion results have consecutively passed the threshold for more than the watchdog filter value (AWDFILT[2:0] + 1), AWD1_OUT is generated as well as the AWD1 flag. Before this value is reached, AWD1 output is not activated.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

Table 249 shows how the ADC_CFGR1 registers must be configured to enable the analog watchdog on one or more channels.

Table 249. Analog watchdog channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog flag is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed through HTR[22:0] bits of the ADC_AWD1HTR register and LTR[22:0] bits of the ADC_AWD1LTR register for the analog watchdog 1.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024, offset and gain compensation)

When converting data with a resolution of less than 12 bits (defined by RES[1:0] bits), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data.

Table 250 describes how the comparison is performed for all the possible resolutions and for analog watchdog 1.

Table 250. Analog watchdog 1, 2, 3 comparison

Resolution (RES[1:0] bits)	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned(1)	Thresholds	
00: 12-bit	DATA[11:0]	LTR[22:0] and HTR[22:0]	-
01: 10-bit	DATA[11:2],00	LTR[22:0] and HTR[22:0]	The user must configure LTR[1:0] to 0b00 and HTR[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	LTR[22:0] and HTR[22:0]	The user must configure LTR[3:0] to 0b0000 and HTR[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	LTR[22:0] and HTR[22:0]	The user must configure LTR[5:0] to 0b000000 and HTR[5:0] to 0b000000.

1. Refer to *Section : Gain compensation* for additional details on analog watchdog comparison.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCH[19:0] (of ADC_AWD2CR and ADC_AWD3CR).

The corresponding watchdog is enabled when any bit of AWDCH[19:0] (of ADC_AWD2CR and ADC_AWD3CR) is set.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024 and offset compensation in signed format with gain compensation) and is programmed through the ADC_AWD2HTR, ADC_AWD2LTR, ADC_AWD3HTR and ADC_AWD3LTR registers.

When converting data with a resolution of less than 12 bits (defined by RES[1:0]) bits), the LSBs of the programmed threshold must be kept cleared, the internal comparison being performed on the full 12-bits converted data (left aligned).

ADCx_AWDy_OUT signal output generation

Each analog watchdog is associated with an internal hardware signal ADC_AWDy_OUT (*y* being the watchdog number), which is directly connected to the ETR input (external trigger) of some of the on-chip timers. Refer to the on-chip timers sections to understand how to select the ADC_AWDy_OUT signal as ETR.

ADC_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDy_OUT is reset after the end of the next guarded conversion that is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS). Note that stopping regular or injected conversions (by setting ADSTP or JADSTP) has no influence on the generation of ADCx_AWDy_OUT.

Note: The AWDy flag is set by hardware and reset by software: the AWDy flag has no influence on the generation of ADC_AWDy_OUT (ex: ADC_AWDy_OUT can toggle while the AWDy flag remains at 1 if the software did not clear the flag).

The AWDy flag is cleared by programming it to 1 or by set ADDIS bit. ADSTP and JADSTP bits do not reset the AWDy flag.

Figure 287. ADC_AWDy_OUT signal generation (on all regular channels)

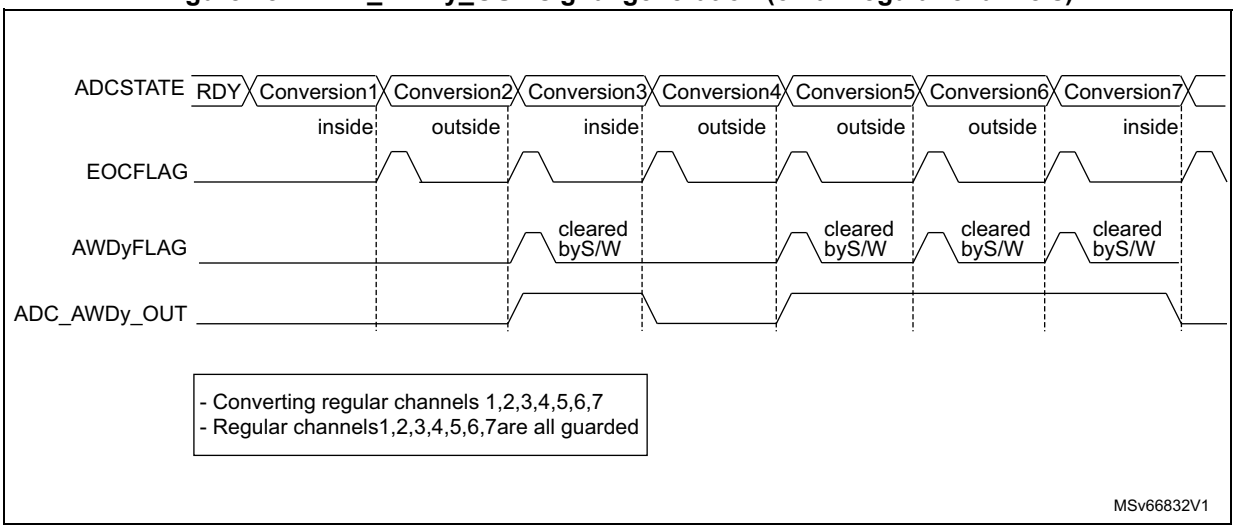


Figure 288. ADC_AWDy_OUT signal generation (AWDy flag not cleared by software)

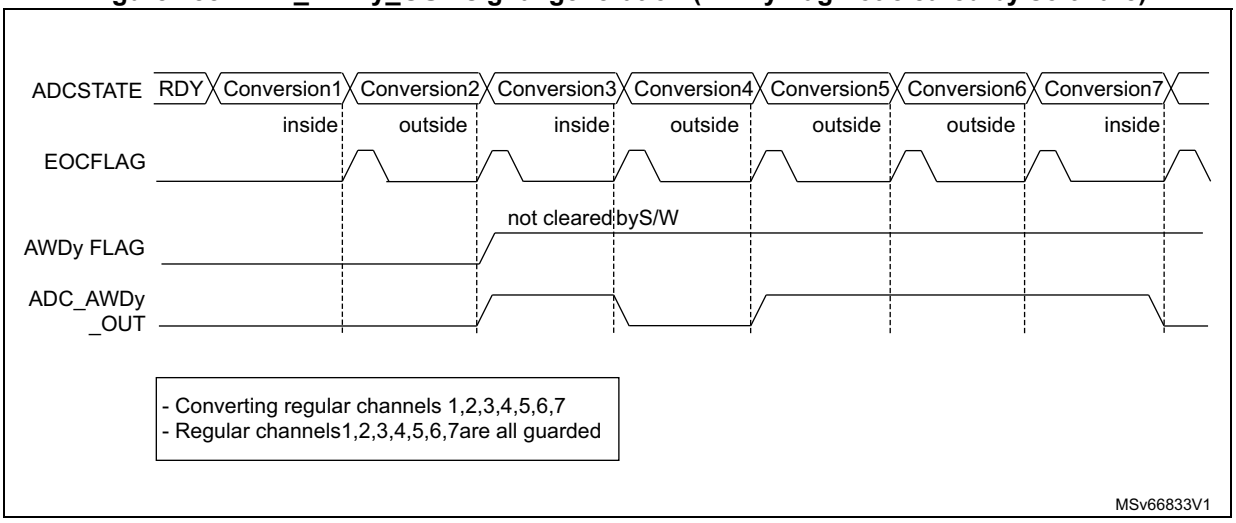

Figure 289. ADC_AWDy_OUT signal generation (on a single regular channel)

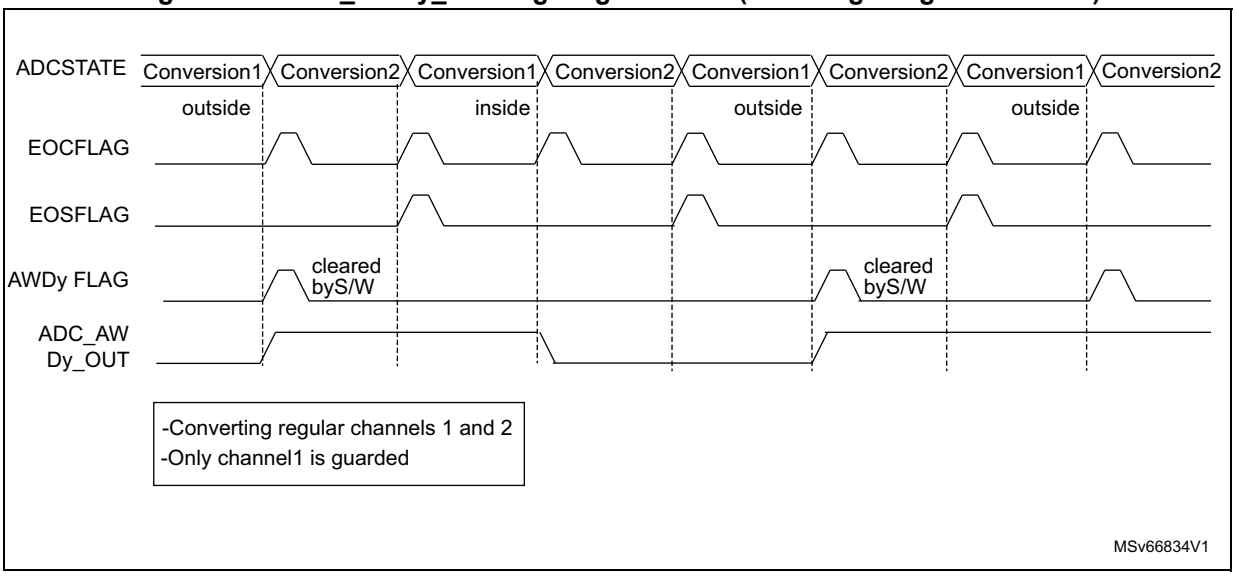

Figure 290. ADC_AWDy_OUT signal generation (on all injected channels)

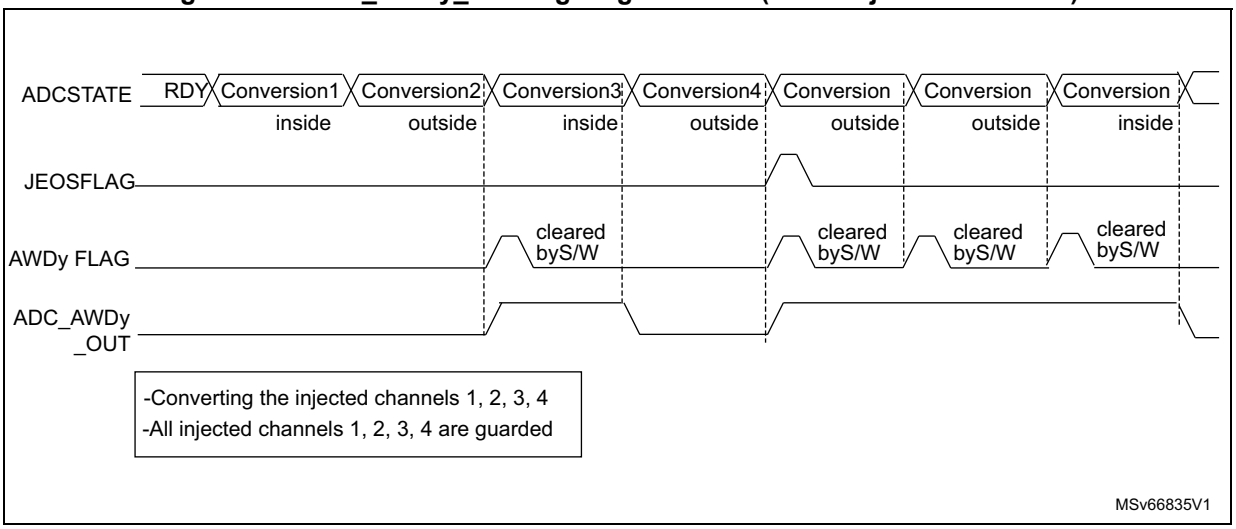

Analog watchdog threshold control

LTR[22:0] and HTR[22:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTR[22:0] and HTR[22:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new modified threshold, no interrupt and AWDy_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion that started after the threshold update. If AWDy_OUT is already asserted, programming the new thresholds does not deassert the AWDy_OUT signal. However, the watchdog threshold must not be changed twice during the four adc_ker_ck periods.

Analog watchdog with gain and offset compensation

When the gain and offset compensation are enabled, the analog watchdog compares the data after the compensation.

32.4.30 Oversampler

The oversampling unit performs data preprocessing to offload the device. It is able to handle multiple conversions and average them into a single data with increased data width, up to 22-bit.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

It enables the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement and basic filtering.

The oversampling ratio N is defined through the OVSR[9:0] bits of the ADC_CFGR2 register. They can range from 2x to 1024x. The division coefficient *M* consists of a right bit shift up to 10 bits. It is defined through the OVSS[3:0] bits of the ADC_CFGR2 register.

The summation unit can yield a result up to 22 bits, which can be left or right shifted. When the right shift is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred to the ADC_DR data register.

Figure 291 gives a numerical example of the processing, from a raw 22-bit accumulated data to the final 12-bit result.

Figure 291. 12-bit result oversampling with 10-bit right shift and rounding

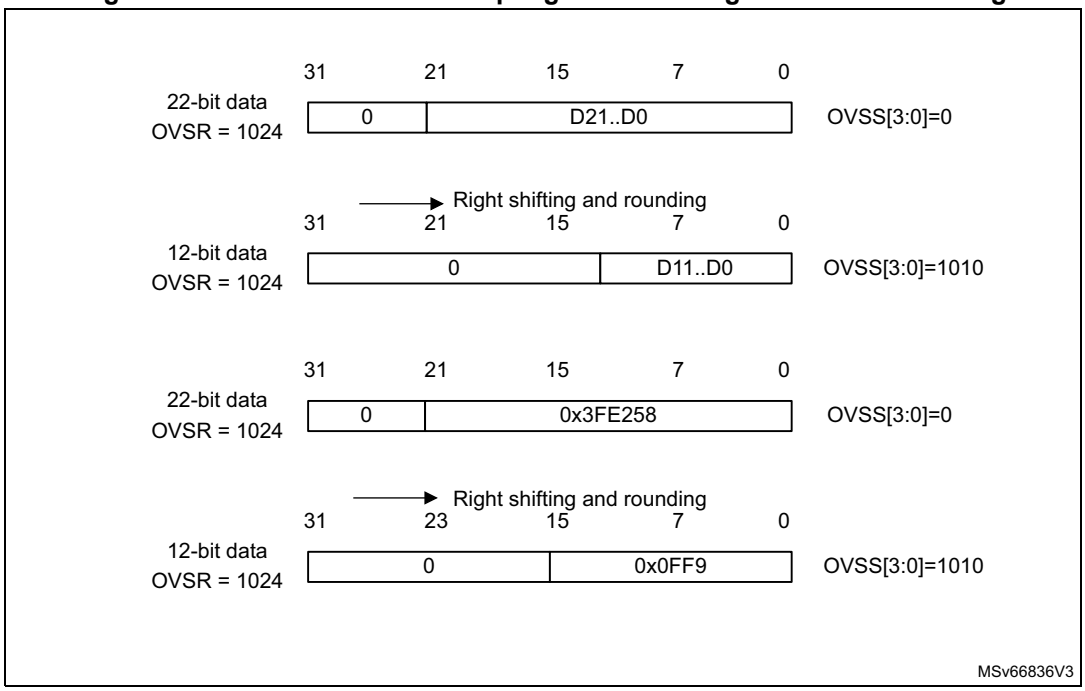

Table 279 gives data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 251. Maximum output results versus N and M

Over sampling ratio	Max Raw data	No-shift OVSS = 0000	1-bit shift OVSS = 0001	2-bit shift OVSS = 0010	3-bit shift OVSS = 0011	4-bit shift OVSS = 0100	5-bit shift OVSS = 0101	6-bit shift OVSS = 0110	7-bit shift OVSS =0111	8-bit shift OVSS = 1000

The conversion timing rate does not change in oversampling mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversion, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase.
- The end of conversion (EOC) occurs once every N conversion, when the oversampled result is available.
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after a total of N x sequence length conversions).

Unlike the conversion rate, the conversion latency changes in oversampling mode: each single conversion introduces an additional accumulation. As a result, an additional clock cycle is required when all the conversions are complete, after the accumulation and right-shift. The EOC flag is set two additional clock cycles after the conversion is complete.

ADC operating modes supported in oversampling mode (single ADC mode)

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous conversion modes
- ADC conversions started either by software or triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits of the ADC_CFGR1 register) are accumulated, truncated, rounded, and shifted in the same way as 12-bit conversions are.

Analog watchdog

The analog watchdog functionality is maintained, with the following differences:

- The RES[1:0] bits are ignored and the comparison is always done using the full 23-bit values HTR[22:0] and LTR[22:0].
- The comparison is performed on the oversampled accumulated value before shifting.

Triggered mode

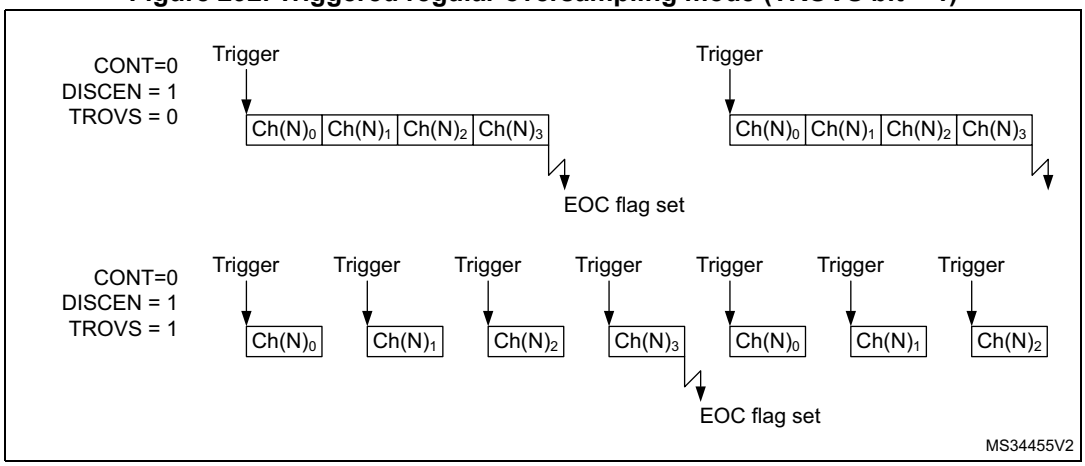
The oversampling can also be used for basic filtering purpose. Although it not a very powerful filter (slow roll-off and limited stop band attenuation), it can act as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched-mode power supply). For this purpose, a specific discontinuous mode can be enabled through the TROVS bit in ADC_CFGR2, to be able to achieve an oversampling frequency defined by the user and independent from the conversion time itself. The TROVS bit is supported with hardware trigger mode.

Figure 292 shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

If the TROVS bit is set, neither JAUTO nor AUTODLY is supported.

Figure 292. Triggered regular oversampling mode (TROVS bit = 1)



Injected and regular sequencer management in oversampling mode

In oversampling mode, injected and regular sequencers can have different behaviors. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only

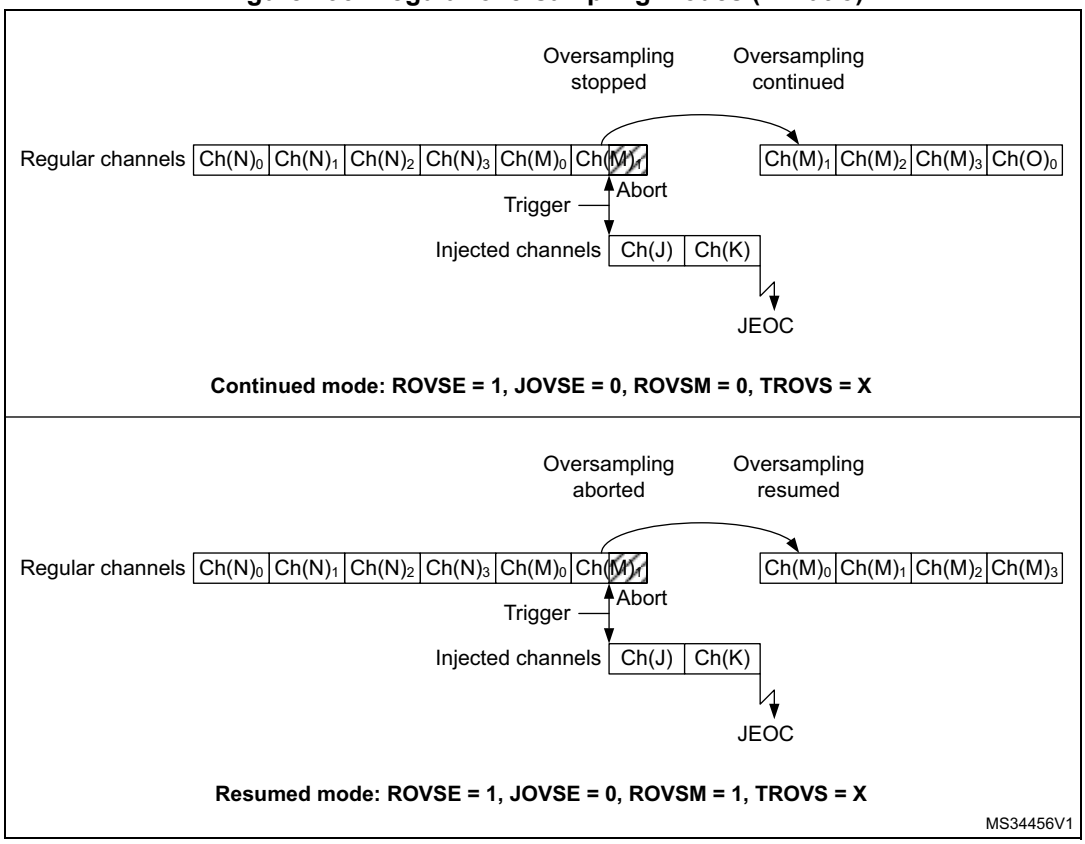
The regular oversampling mode ROVSM bit defines how the regular oversampling sequence is resumed if it is interrupted by an injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is

complete whatever the injection frequency (providing at least one regular conversion can be complete between triggers);

- In resumed mode, the accumulation restarts from 0 (previous conversion results are ignored). This mode guarantees that all the data used for oversampling were converted back-to-back within a single time slot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequence is blocked.
- *Figure 293* gives examples for a 4x oversampling ratio.

Figure 293. Regular oversampling modes (4x ratio)



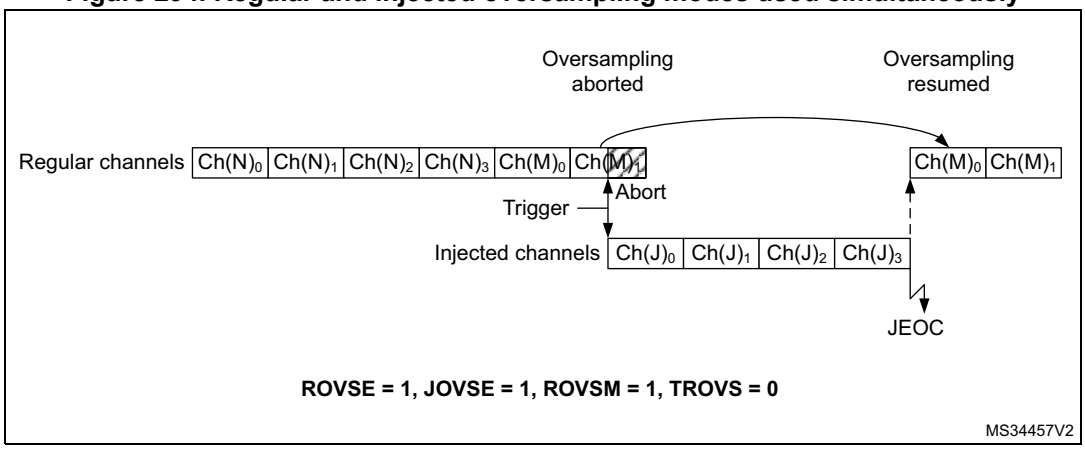
Oversampling injected channels only

The injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling must be resumed (ROVSM bit = 1), as shown in *Figure 294*.

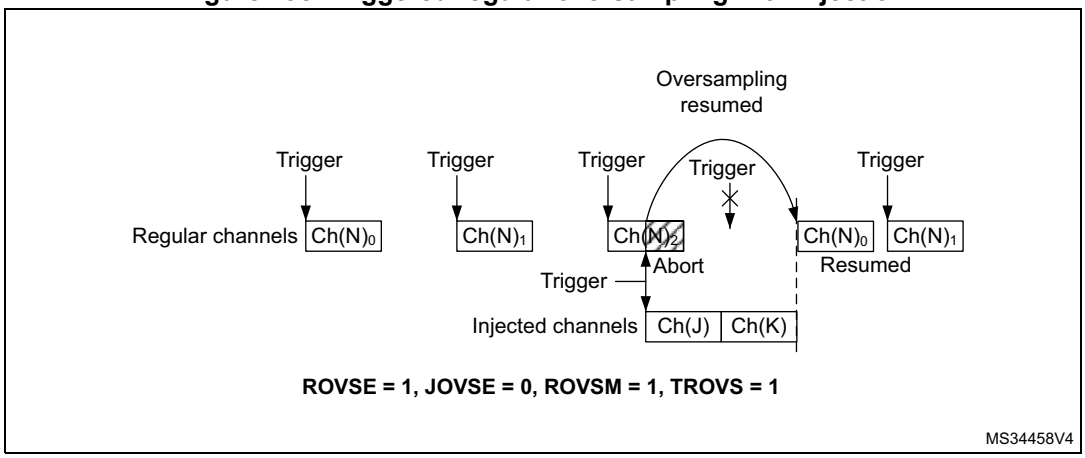
Figure 294. Regular and injected oversampling modes used simultaneously



Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled and the ROVSM bit set (Resumed mode is forced). The JOVSE bit must be reset. The behavior is shown in *Figure 295*.

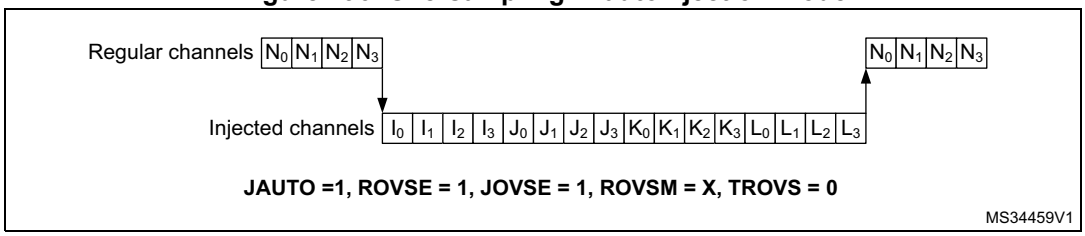
Figure 295. Triggered regular oversampling with injection



Autoinjection mode

It is possible to oversample autoinjected sequences and store all conversion results in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1. Other combinations are not supported. The ROVSM bit is ignored in autoinjection mode. *Figure 296* shows how the conversions are sequenced.

Figure 296. Oversampling in autoinjection mode



In addition, the triggered mode can be enabled using the TROVS bit. In this case, the ADC must be configured as follows: JAUTO = 1, DISCEN = 0, JDISCEN = 0, DISCNUM = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Combined modes summary

Table 252 summarizes all combinations, including the modes that are not supported.

Table 252. Oversampler operating mode summary

Regular oversampling ROVSE	Injected oversampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode
1	0	1	1	Triggered regular resumed mode
1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

32.4.31 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see *Figure 297*).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADC master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCC_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

In dual ADC mode (when DUAL[4:0] bits in the ADCC_CCR register are not equal to zero), the CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JAUTO bits of the ADC_CFGR1 register are shared between the master and slave ADC: the slave ADC bits are ignored and always apply to the corresponding bits of the master ADC.

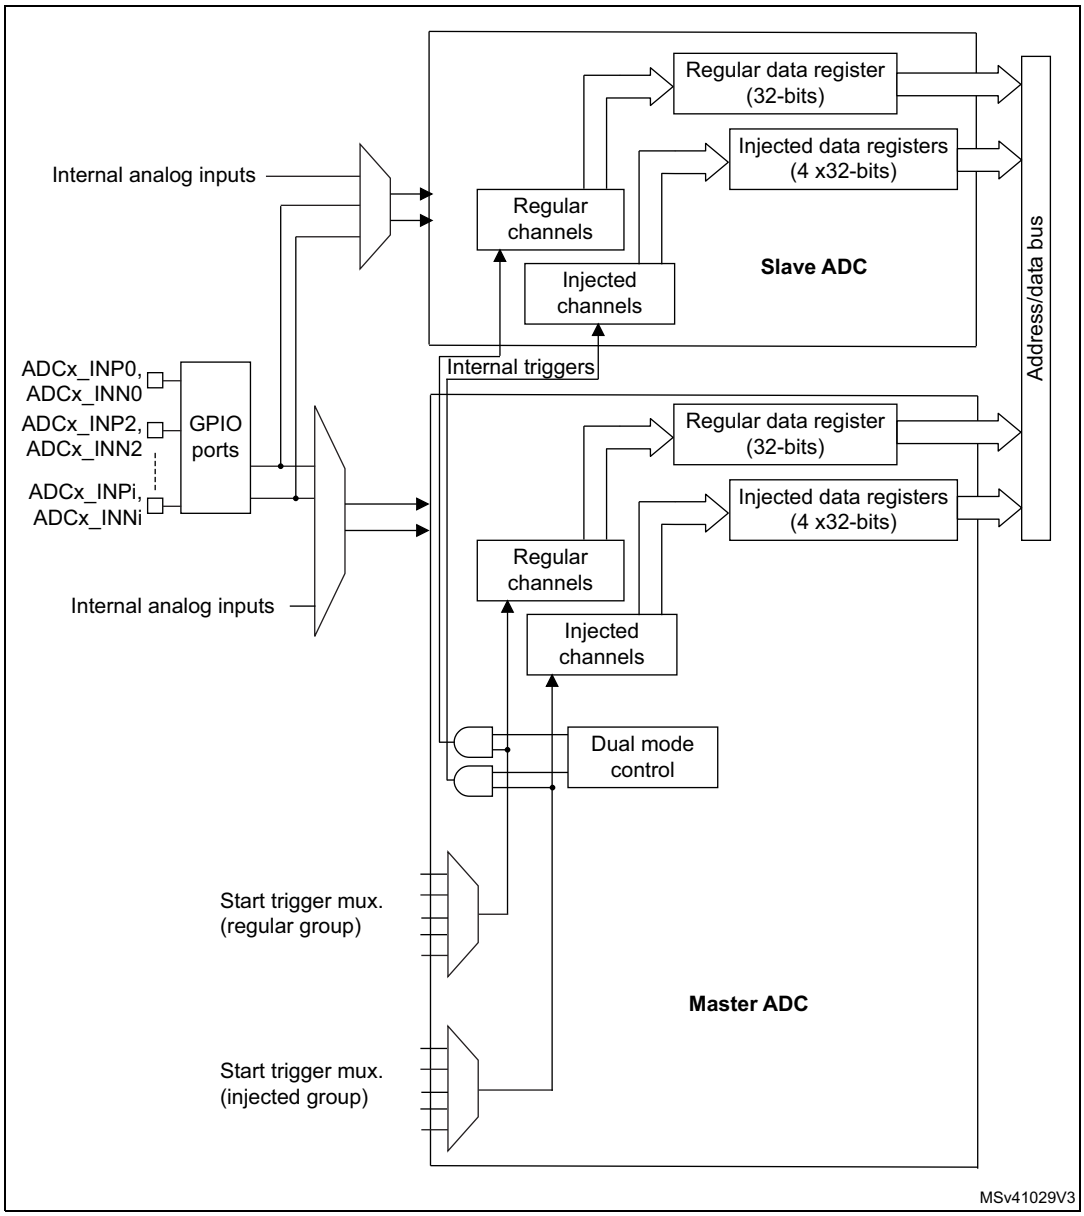
To start a conversion in dual mode, the user must program the EXTEN[1:0], EXTSEL, JEXTEN[1:0] and JEXTSEL bits of the master ADC only to configure a software or hardware trigger and a regular or injected trigger (the EXTEN[1:0] and JEXTEN[1:0] bits of the slave ADC are don't care).

In regular simultaneous or interleaved modes, once the user sets the ADSTART or ADSTP bit of the master ADC, the corresponding bit of the slave ADC is automatically set. However, ADSTART or ADSTP bit of the slave ADC is not necessarily cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes, once the user sets the JADSTART or JADSTP bit of the master ADC, the corresponding bit of the slave ADC is automatically set. However, JADSTART or JADSTP bit of the slave ADC is not necessarily cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCC_CDR). The flags can also be read in parallel by reading the dual-mode status register (ADCC_CSR).

Figure 297. Dual ADC block diagram



1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADCC_CDR) contains both the master and slave ADC regular converted data.

Injected simultaneous mode

The injected simultaneous mode is selected by programming DUAL[4:0] bits to 0b00101.

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

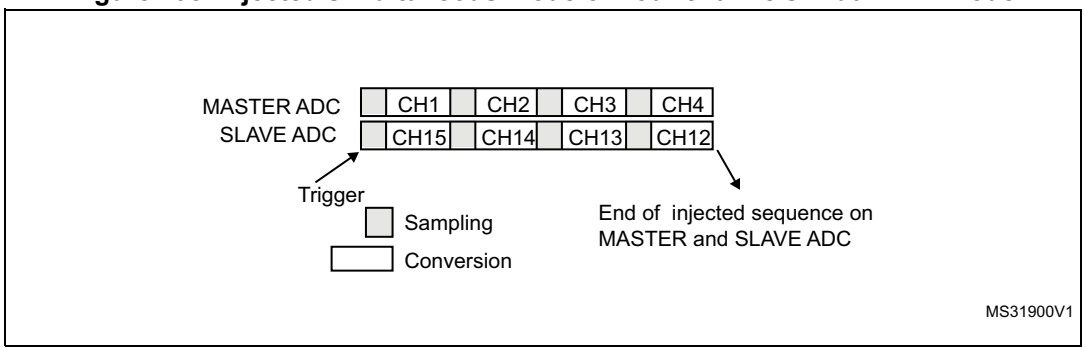
In simultaneous mode, the user software must convert sequences with the same length.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

The software is notified by interrupts when it can read the data:

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master-injected sequence is equal to the duration of the slave injected one (as shown in *Figure 298*), the software can enable only one of the two JEOS interrupts (for example the master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 298. Injected simultaneous mode on four channels: Dual ADC mode



If JDISCEN is set, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with the AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored.
  There is the same behavior for regular sequences occurring on the slave ADC.

Regular simultaneous mode with independent injected conversions

The regular simultaneous mode is selected by programming DUAL[4:0] bits to 0b00110.

This mode applies to a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR1 register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on the master or on the slave) aborts the current simultaneous conversions both for master and slave. They are restarted once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, the user software must convert sequences with the same length.

The software is notified by interrupts when it can read the data:

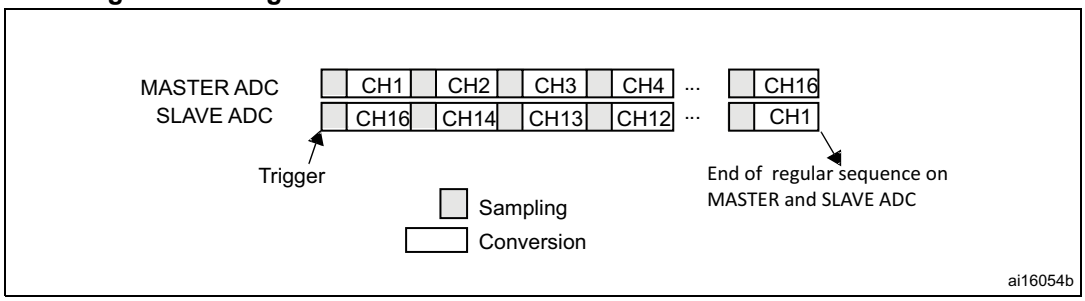
- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (as shown in *Figure 299*), the software can enable only one of the two EOC interrupts (for example the master EOC) and read both converted data from the common data register (ADCC_CDR).

The regular data can also be read using the DMA. Several methods are possible:

- Use two DMA channels (one for the master and one for the slave). In this case DAMDF[1:0] bits must be kept cleared:
- Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
- Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configure the dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  a) Set DAMDF[1:0] = 0b10 or 0b11 (depending on resolution).
  b) A single DMA channel is used (the one corresponding to the master). Configure the DMA master ADC channel to read the common ADC register (ADCC_CDR).
  c) A single DMA request is generated each time both master and slave EOC events occur. At that time, the slave ADC converted data are available in the upper half-word of the ADCC_CDR 32-bit register and the master ADC converted data available in the lower half-word of the ADCC_CDR register.
  d) Both EOC flags are cleared when the DMA reads the ADCC_CDR register.

Note: When DAMDF[1:0] = 0b10 or 0b11, the user must program the same number of conversions in the master and in the slave sequence. Otherwise, the remaining conversions do not generate a DMA request.

Figure 299. Regular simultaneous mode on 16 channels: dual ADC mode



If the DISCEN bit is set, each "*n*" simultaneous conversion of the regular sequence require a regular trigger event to occur ("n" is defined by DISCNUM).

This mode can be combined with the AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence starts only if the common data register (ADCC_CDR) (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCC_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

The DMA can be used to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master sequence is equal to the number of conversions in the slave sequence.
- For each simultaneous conversion of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert, the sampling time and the resolution of each channel.

Note: This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

Interleaved mode with independent injected conversions

This mode is selected by programming DUAL[4:0] bits to 0b00111.

It can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately,
- The slave ADC starts after a delay of several ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay between two conversions in interleaved mode is configured in the DELAY bits in the ADCC_CCR register (see *Table DELAY bits versus ADC resolution*). This delay starts counting one half cycle after the end of the sampling phase of the master

conversion. This way, an ADC cannot start a conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However, the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Note: In case of 16-bit data format, only the EOC interrupt of the slave can be enabled and the common data register (ADCC_CDR) can be read. For 32-bit data format, enable both the slave and master EOC interrupts and the ADCC_CDR2 register. However, in this case, the user must make sure that the durations of the conversions are compatible to ensure that, inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the DAMDF mode.

Regular data can also be transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the DAMDF mode, as described below:

1. Configure DAMDF[1:0] = 0b10 or 0b11 (depending on resolution).
2. A single DMA channel is used (the one of the masters). Configure the DMA master ADC channel to read the common ADC register (ADCC_CDR).
3. A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of the ADCC_CDR register.
4. Both EOC flags are cleared when the DMA reads the ADCC_CDR register.

Table 253. DELAY bits versus ADC resolution(1)

DELAY bits	12-bit resolution	10-bit resolution	8-bit resolution	6-bit resolution
0000	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$
0001	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$
0010	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$
0011	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$
0100	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$
0101	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$
0110	7 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$

1000	9 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$
1001	10 * $T_{adc_ker_ck}$	10 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$

Table 253. DELAY bits versus ADC resolution(1) (continued)

DELAY bits	12-bit resolution	10-bit resolution	8-bit resolution	6-bit resolution
1010	11 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$
1011	12 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$
1100	13 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$
others	13 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$

1. Preliminary information, subject to change.

Figure 300. Interleaved mode on 1 channel in continuous conversion mode: Dual ADC mode

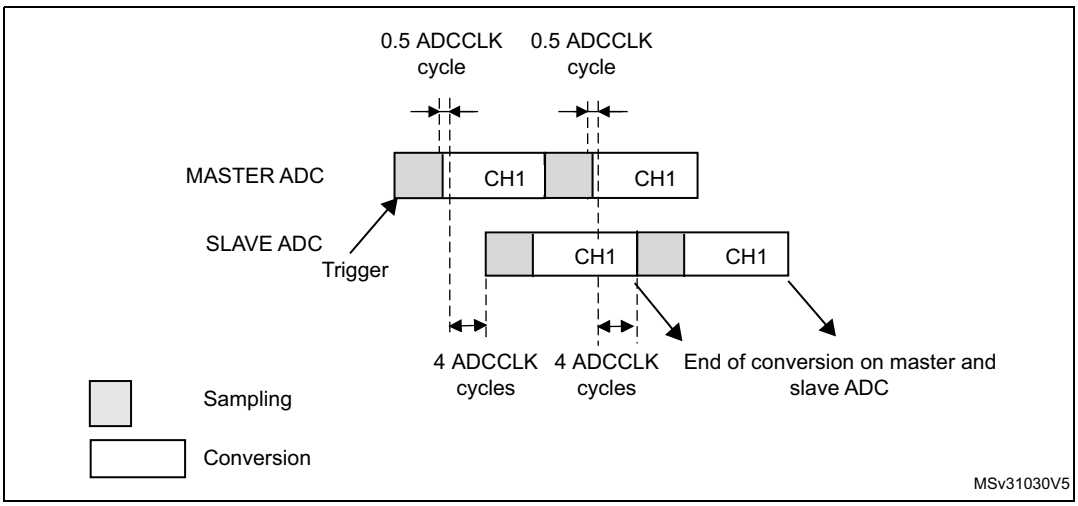

Figure 301. Interleaved mode on 1 channel in single conversion mode: Dual ADC mode

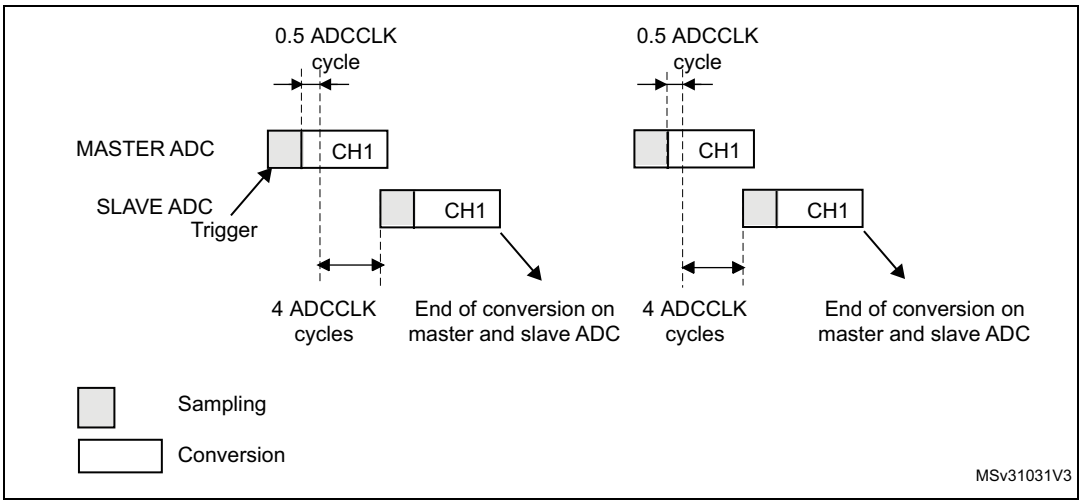


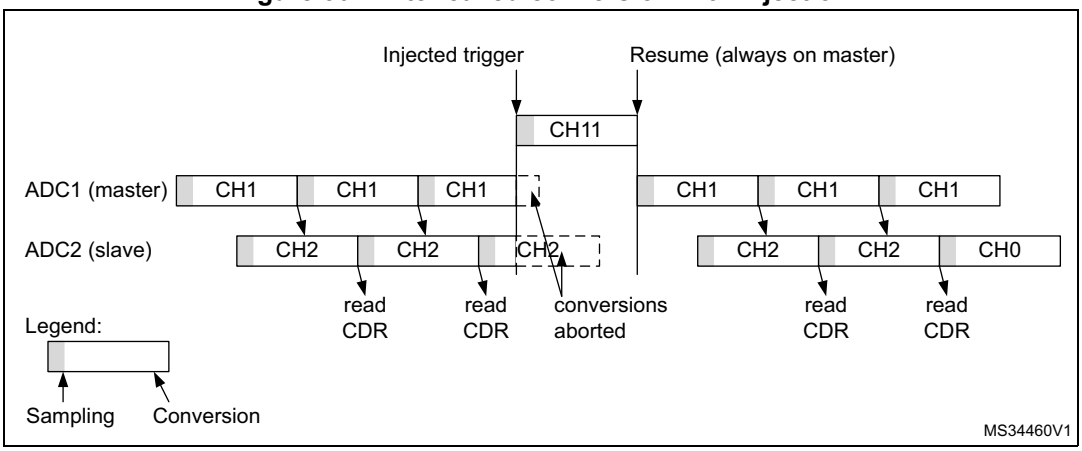
If the DISCEN bit is set, each "*n*" simultaneous conversion ("*n*" is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In interleaved mode, injected conversions are supported. When injection is done (either on master or slave), both master and the slave regular conversions are aborted and the sequence is restarted from the master (see *Figure 302*).

Note: In interleaved mode, the ADCx_AWDy_OUT signal for the master ADC is synchronized with the EOC of the master ADC, but the interrupt flag is synchronized with the EOC/JEOC flag of the slave ADC.

In addition, the ROVSM = 0 setting is not supported in oversampling mode.

Figure 302. Interleaved conversion with injection



Alternate trigger mode

The alternate trigger mode is selected by programming DUAL[4:0] bits to 0b01001.

This mode can only be started on an injected group. The source of the external trigger comes from the multiplexer injected group of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN[1:0] must not be 0x0.

Injected discontinuous mode disabled (JDISCEN=0 for both ADC)

1. When the first trigger occurs, all injected master ADC channels in the group are converted.
2. When the second trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on...

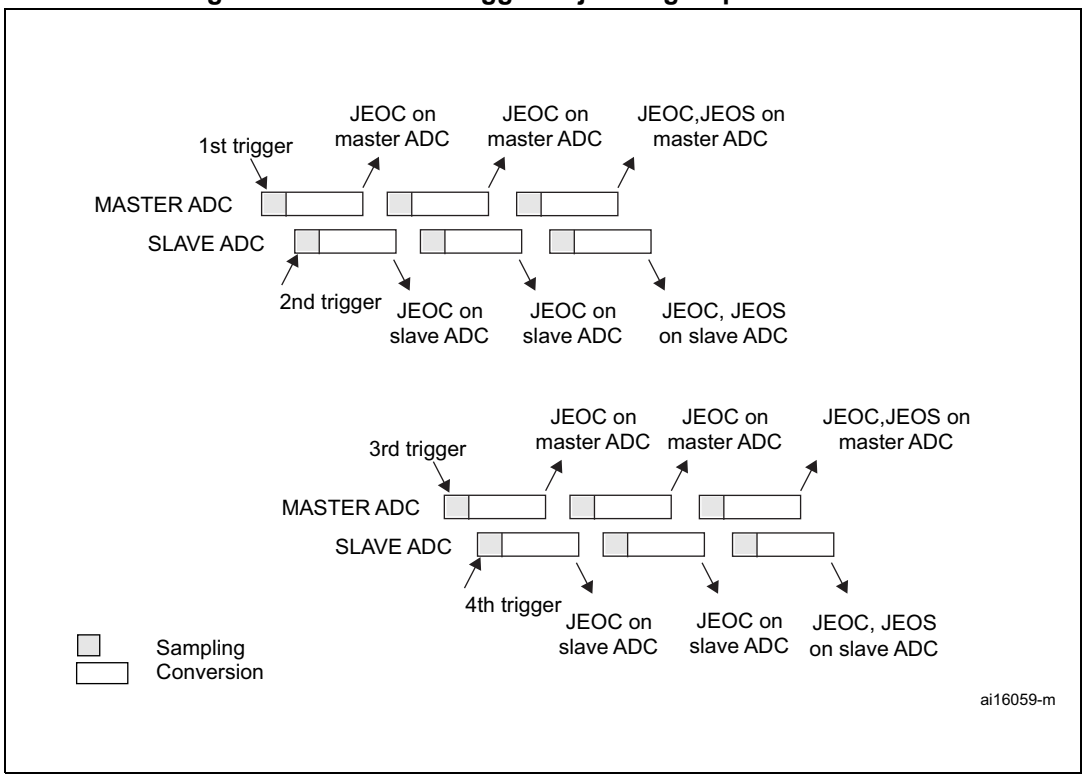
A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

Figure 303. Alternate trigger: injected group of each ADC



Note: Regular conversions can be enabled on one or all ADCs. In this case, the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between two trigger events must be greater than or equal to one ADC clock period. The minimum time interval between two trigger events that start conversions on the same ADC is the same as in the single ADC mode.

Injected discontinuous mode enabled (JDISCEN = 1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:

1. When the first trigger occurs, the first injected channel of the master ADC is converted.
2. When the second trigger occurs, the first injected channel of the slave ADC is converted.
3. And so on...

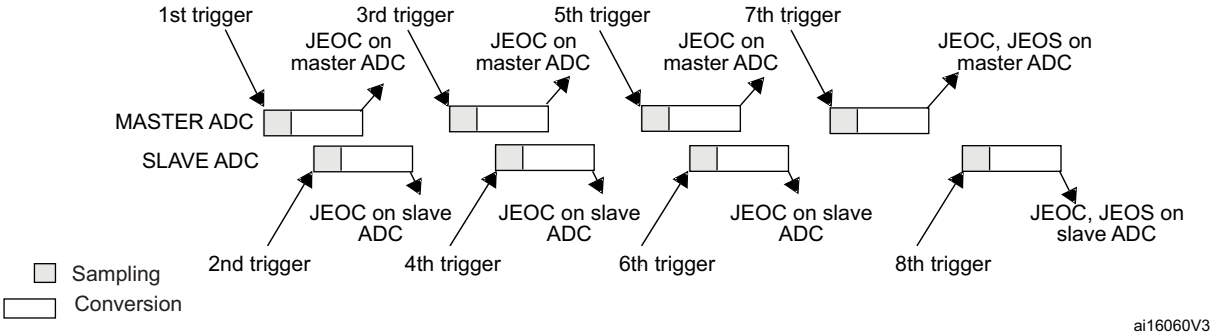
A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted, then the alternate trigger process restarts.

Figure 304. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode



Combined regular/injected simultaneous mode

This mode is selected by programming DUAL[4:0] bits to 0b00001.

The simultaneous conversion of a regular group can be interrupted to start the simultaneous conversion of an injected group.

Note: In combined regular/injected simultaneous mode, the user software must convert sequences with the same length or ensure that the interval between triggers is longer than the sum of the conversion times of the two sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous and alternate trigger mode

This mode is selected by programming DUAL[4:0] bits to 0b00010.

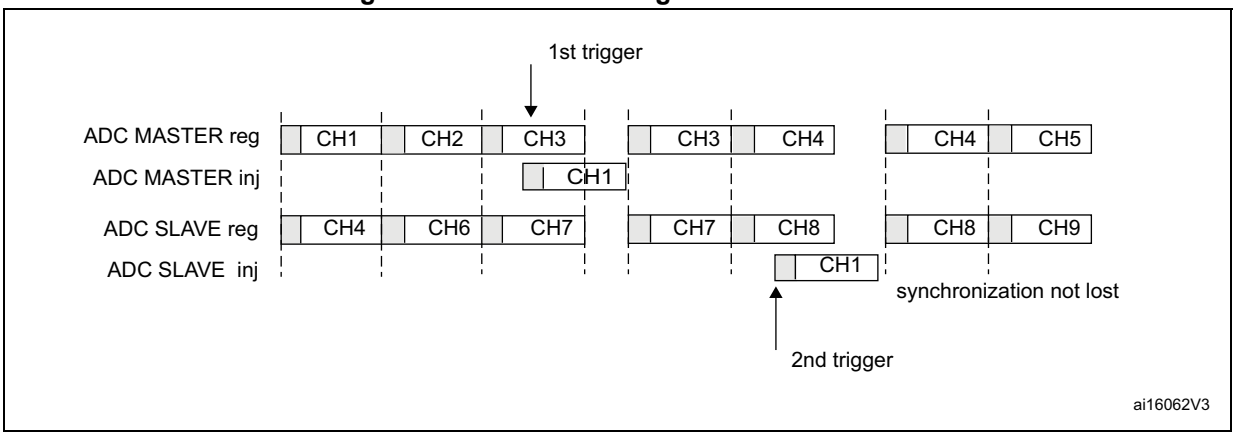
The simultaneous conversion of a regular group can be interrupted to start the alternate trigger conversion of an injected group. *Figure 305* shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion immediately starts after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

Note: In combined regular simultaneous + alternate trigger mode, the user software must convert sequences with the same length or ensure that the interval between triggers is longer than the sum of the conversion times of the two sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

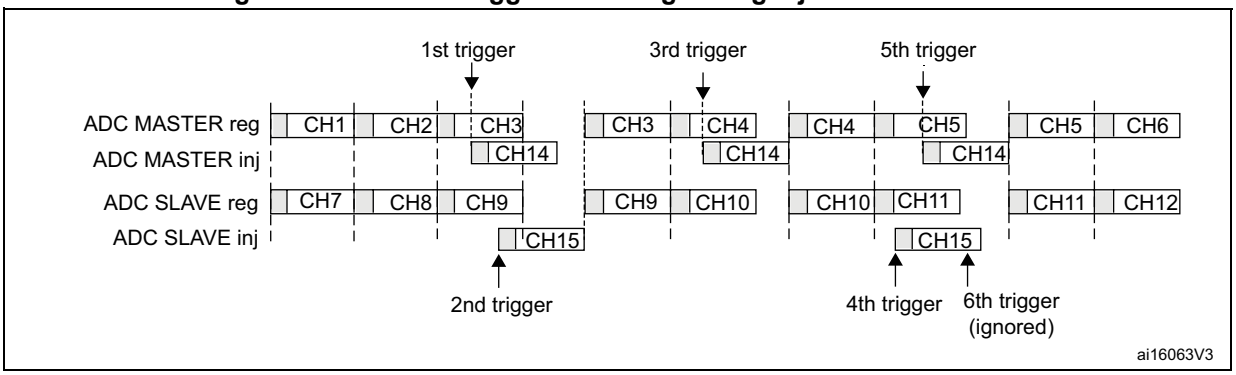
The software trigger is not supported for injected conversions.

Figure 305. Alternate + regular simultaneous



If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. *Figure 306* shows the behavior in this case (note that the sixth trigger is ignored because the associated alternate conversion is not complete).

Figure 306. Case of trigger occurring during injected conversion



Combined injected simultaneous and interleaved mode

This mode is selected by programming DUAL[4:0] bits to 0b00011.

An interleaved conversion can be interrupted with a simultaneous injected event.

In this case, the interleaved conversion is immediately interrupted and the simultaneous injected conversion starts. At the end of the injected sequence, the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master's one. *Figure 307*, *Figure 308* and *Figure 309* show examples of this behavior.

Note: In this mode, the ROVSM =0 setting is not supported in oversampling mode.

Caution: In this mode, it is mandatory to use the common data register to read the regular data with a single read access. Otherwise, master-slave data coherency is not guaranteed.

Figure 307. Interleaved single channel CH0 with injected sequence CH11, CH12

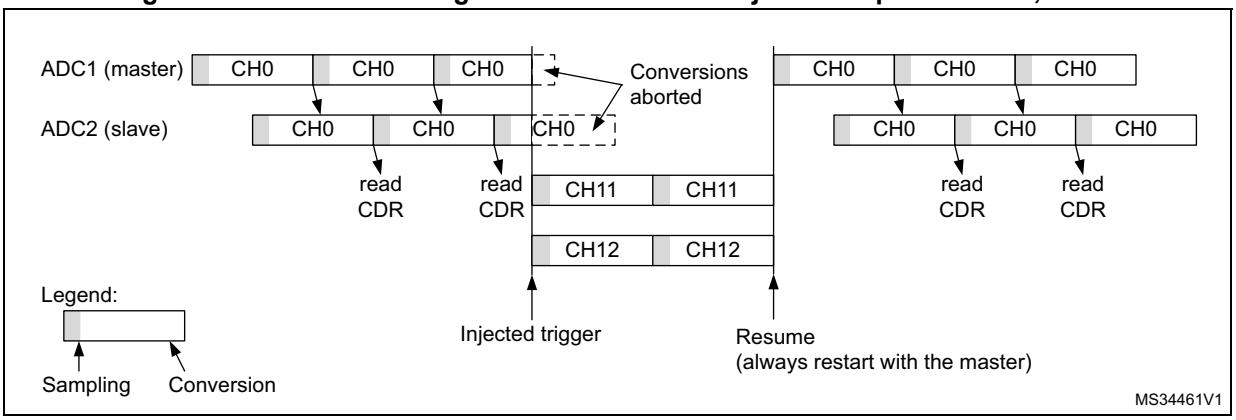


Figure 308. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 1: Master interrupted first

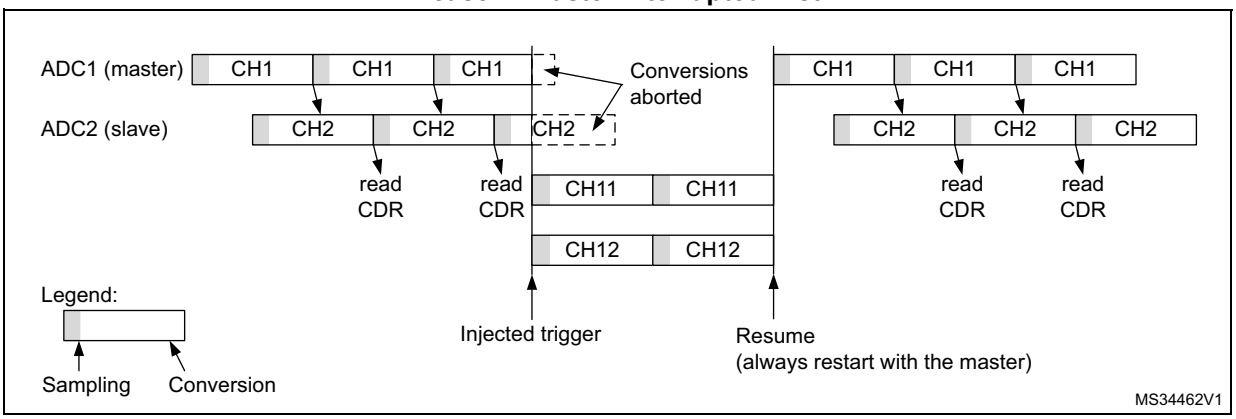

Figure 309. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 2: Slave interrupted first

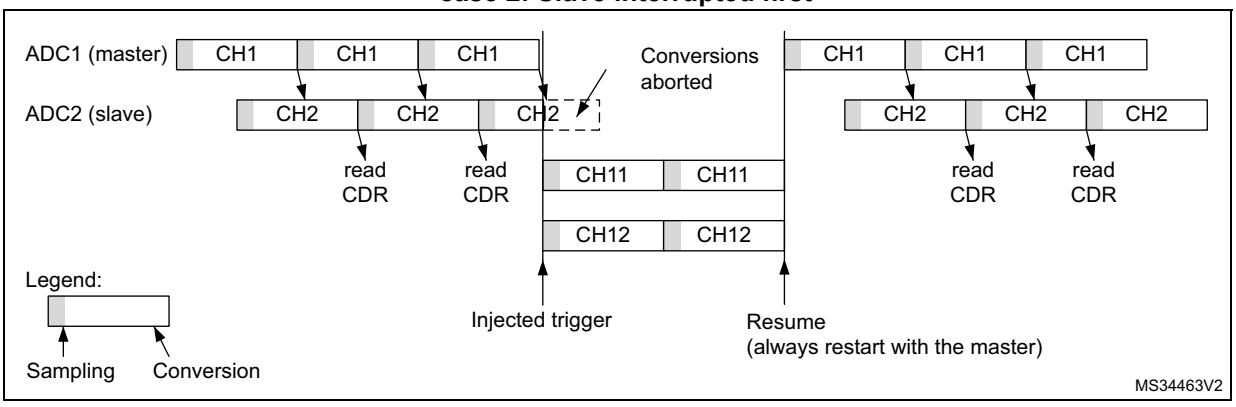
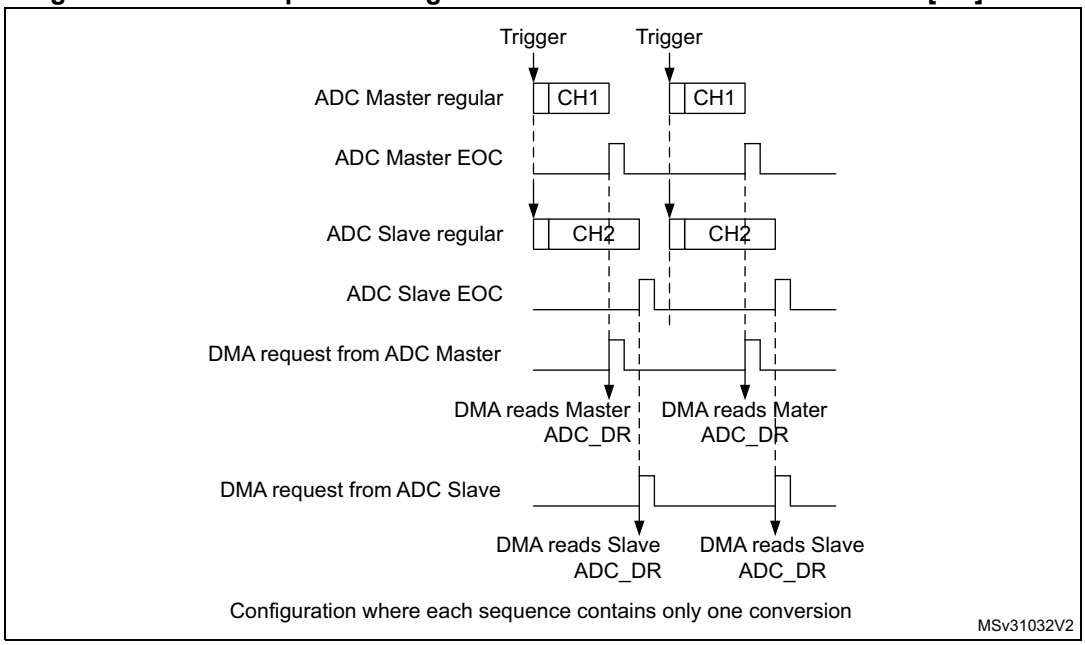


DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to *Figure 310: DMA Requests in regular simultaneous mode when DAMDF[1:0]=0b00*).

Figure 310. DMA Requests in regular simultaneous mode when DAMDF[1:0]=0b00



In interleaved mode, it is also possible to save one DMA channel and transfer both data using a single DMA channel. To do this, the DAMDF[1:0] bits must be configured in the ADCC_CCR register:

- **DAMDF[1:0] = 0b10, 32-bit format:**

  A single DMA request is generated alternatively after either the master or slave EOC events have occurred. At that time, the data are alternatively available in the 32-bit register ADCC_CDR2 32-bit register.

  This mode is used in interleaved mode and in regular simultaneous mode when the data width is above 16 bits (conversion data width can exceed 16 bits when functions such as oversampling, compensation and left-bit shift, are used).

  Example:

  Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:

  First DMA request: ADCC_CDR2[31:0] = MST_ADC_DR[31:0]

  Second DMA request: ADCC_CDR2[31:0] = SLV_ADC_DR[31:0]

- **DAMDF[1:0] = 0b10, 16-bit format**:

  A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCC_CDR contains the two half-words representing two ADC-converted data. The slave ADC data takes the upper half-word and the master ADC data takes the lower half-word.

  This mode is used in interleaved mode and in regular simultaneous mode when the data width is less than 16 bits. Any value above 16-bit in the master or the slave-converted data is truncated to the least 16 significant bits.

Example:

Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:

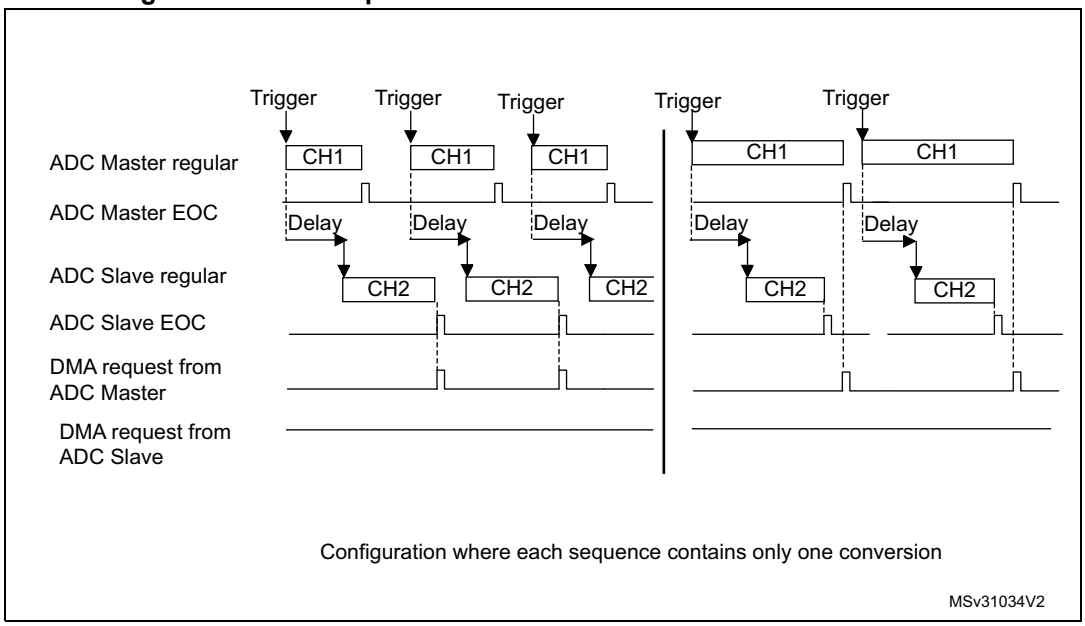
First DMA request:

ADCC_CDR[31:0] = (SLV_ADC_DR[15:0] << 16) | MST_ADC_DR[15:0]

Second DMA request:

ADCC_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

Figure 311. DMA requests in interleaved mode when DAMDF = 0b10



Note: When using dual ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion data is available.

- **DAMDF[1:0] = 0b11**:

  This mode is similar to the DAMDF[1:0] = 0b10 configuration. The only difference is that on each DMA request (two data are available), two bytes representing two ADC converted data are transferred as a half-word.

  This mode is used in interleaved and regular simultaneous mode when the resolution is 6 bits or 8 bits and data are not signed

  Example:

  Interleaved dual mode: a DMA request is generated each time two data items are available:

  First DMA request:

  ADCC_CDR[15:0] = (SLV_ADC_DR[7:0] << 8)| MST_ADC_DR[7:0]

  Second DMA request:

  ADCC_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

Note: DMA burst mode is not supported in ADC dual mode.

Overrun detection

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). The EOC bit corresponding to one ADC might remains set because the data register of this ADC contains valid data.

DMA one-shot mode/ DMA circular mode when multi-ADC mode is selected

When DAMDF mode is selected (0b10 or 0b11), DMNGT[1:0] bits of the ADCC_CCR register must also be configured to select between DMA one-shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA*

Stopping the conversions in dual ADC modes

In dual ADC mode, the user software must set the ADSTP/JADSTP control bits in the master ADC to stop the conversions of both ADC. The other ADSTP control bit on the slave ADC has no effect in dual ADC mode. Except in DMA one-shot mode, the ADSTP control bit for the master ADC does not affect the slave ADC DMA request signal. In this case, the ADSTP bit must be set on the slave ADC.

Once both ADCs are effectively stopped, the ADSTART/JADSTART bits on the master and slave ADCs are both deasserted by hardware.

Interleaved mode with oversampling

When oversampling is enabled, the ROVSM bit must be set.

Regular sampling in continued mode is supported.

Analog watchdog in dual mode

The analog watchdog is supported in dual mode.

Disabling the ADC in dual mode

During a dual-mode operation, the master ADC shares the ADC clock with the slave ADC. To disable the ADC correctly through the ADDIS bit of ADC_CR, set the ADSTP (or JADSP) bit on the master ADC and, if DUAL[4:0] equals 0b00101, 0b00110, 0b00111, or 0b01001, set ADSTP (or JADSP) on the slave ADC as well. Once ADSTP (or JADSTP) becomes 0 both for the master and slave ADCs, set the ADDIS bit on the slave ADC, then set the ADDIS bit on the master ADC.

MDF mode in dual ADC interleaved mode

In dual ADC interleaved modes (DUAL[4:0] = 0b00011 or DUAL[4:0] = 0b00111), the ADC conversion results can be transferred directly to the MDF.

This mode is enabled by setting DMNGT[1:0] bits to 0b10 in the master ADC ADC_CFGR1 register.

The ADC transfers alternatively the 16 least significant bits of the regular data register from the master and the slave converter to a single channel of the MDF. Each transfer resets the EOC flag of each channel once the transfer is complete.

The data format must be 16-bit signed:

ADC_DR[15:12] = Sign extended

ADC_DR[11] = Sign

ADC_DR[10:0] = Data

To obtain 16-bit signed format, the software must configure OFFSET[11:0] bits to 0x800 with OFFSETy_CH[4:0] selecting the target channel set.

Only right aligned data can be set as MDF input format (see *Figure 276: Right alignment (offset enabled, signed value)*).

MDF mode in dual ADC simultaneous mode

It is not mandatory to use the MDF in dual ADC simultaneous mode since conversion data are handled by each individual channel. Single mode with same trigger source results in simultaneous conversion with MDF interface.

Dual ADC modes supported in oversampling mode

It is possible to have oversampling enabled when working in dual ADC configuration for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

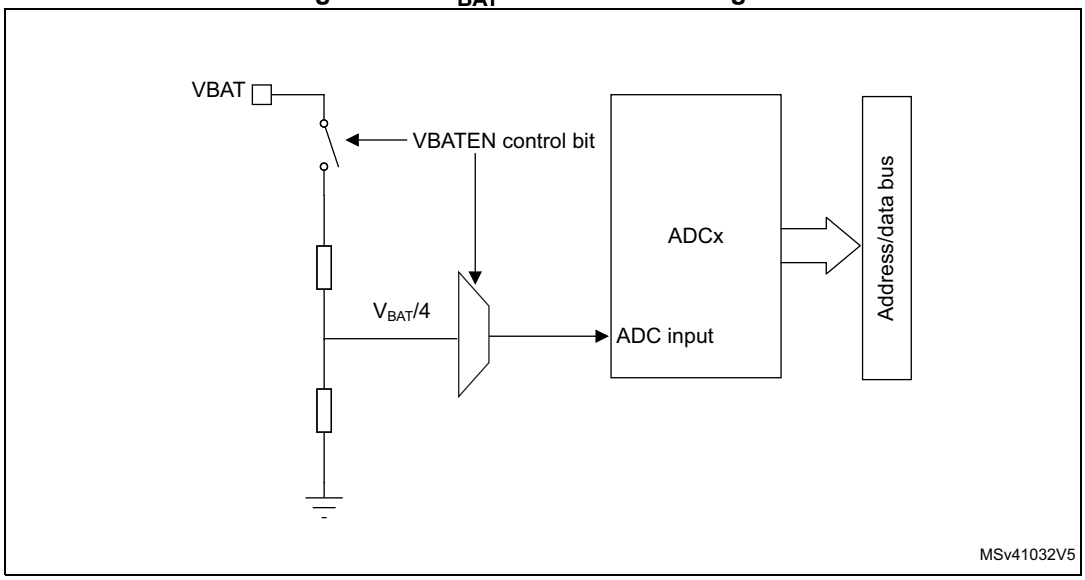
32.4.32 V_{BAT} supply monitoring

The VBATEN bit in the ADCC_CCR register is used to switch to the battery voltage. As the V_{BAT} voltage can be higher than V_{DDA}, to ensure the correct operation of the ADC, the V_{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect $V_{BAT}/4$ to the ADC input channels (see *Table: ADC interconnection* in *Section 32.4.2: ADC pins and internal signals* for more details). As a consequence, the converted digital value is one fourth of the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the $V_{BAT}/4$ voltage.

Figure 312 shows the block diagram of the V_{BAT} sensing feature.

Figure 312. V_{BAT} channel block diagram



1. The VBATEN bit must be set to enable the conversion of internal channel for $V_{BAT}/4$.

32.4.33 Monitoring the internal voltage reference

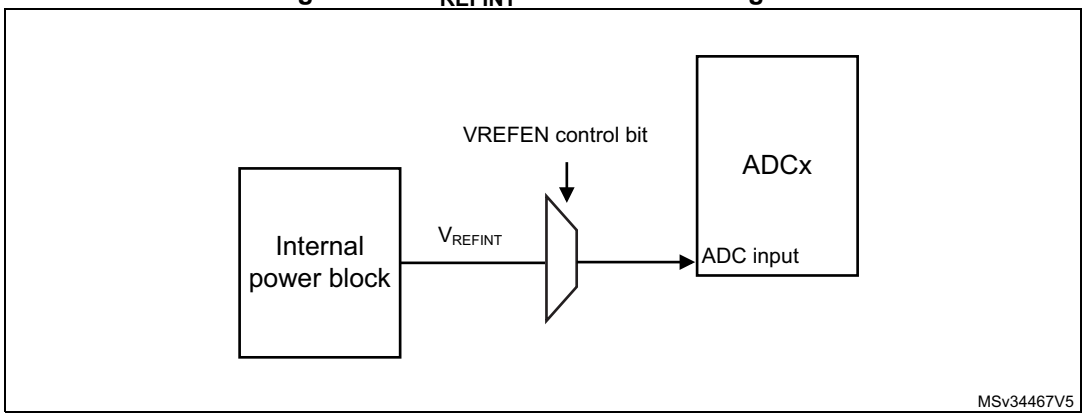
It is possible to monitor the internal voltage reference (V_{REFINT}) to have a reference point for evaluating the ADC V_{REF+} voltage level.

Refer to the *ADC interconnection* table in *Section 32.4.2: ADC pins and internal signals* for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

Figure 313 shows the block diagram of the V_{REFINT} sensing feature.

Figure 313. V_{REFINT} channel block diagram



1. The VREFEN bit of the ADCC_CCR register must be set to enable the conversion of internal channels (V_{REFINT}).

Calculating the actual V_{REF+} voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When V_{DDA} is connected to V_{REF+}, it is possible to compute the actual V_{DDA} voltage using the embedded internal reference voltage (V_{REFINT}). V_{REFINT} and its calibration data acquired by the ADC during the manufacturing process at V_{REF+} can be used to evaluate the actual V_{DDA} voltage level.

The following formula gives the actual V_{REF+} voltage supplying the device:

$$V_{REF+} = V_{REF+_Charac} \times VREFINT_CAL / VREFINT_DATA$$

Where:

- V_{REF+_Charac} is the value of V_{REF+} voltage characterized at V_{REFINT} during the manufacturing process. It is specified in the device datasheet.
- VREFINT_CAL is the VREFINT calibration value.
- VREFINT_DATA is the actual VREFINT output value converted by ADC.

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between V_{REF+} and the voltage applied on the converted channel.

For some applications, the V_{REF+} value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from V_{REF+}:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

By replacing V_{REF+} by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{V_{REF+_Charac} \times VREFINT_CAL \times ADC_DATA}{VREFINT_DATA \times FULL_SCALE}$$

For applications where V_{REF+} is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

Where:

– VREFINT_CAL is the VREFINT calibration value.
– ADC_DATA is the value measured by the ADC on channel x (right-aligned).
– VREFINT_DATA is the actual VREFINT output value converted by the ADC.
– FULL_SCALE is the maximum digital value of the ADC output. For example with 12-bit resolution, we obtain $2^{12} – 1 = 4095$, or $2^8 – 1 = 255$ with 8-bit resolution.

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

32.4.34 Monitoring the supply voltage

The ADCs are connected to the internal supply voltage. To use the ADC to measure this voltage, enable the connection through ADC option register.

32.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (ADRDY flag)
- On the end of any conversion for regular groups (EOC flag)
- On the end of a sequence of conversion for regular groups (EOS flag)
- On the end of any conversion for injected groups (JEOC flag)
- On the end of a sequence of conversion for injected groups (JEOS flag)
- When an analog watchdog detection occurs (AWD1, AWD2 and AWD3 flags)
- When the end of the sampling phase occurs (EOSMP flag)
- When the data overrun occurs (OVR flag)

Separate interrupt enable bits are available for flexibility.

Note: Interrupts are generated by the AHB clock domain. Since the ADC clock is adc_ker_ck, interrupt flags are delayed due to the synchronization between adc_ker_ck and AHB clock domains.

Table 254. ADC interrupts

Interrupt vector	Interrupt event	Event flag	Enable Control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby mode
ADC	ADC ready	ADRDY	ADRDYIE	Set by hardware and cleared by software	Yes	No
	End of conversion of a regular group	EOC	EOCIE			
	End of conversion sequence of a regular group	EOS	EOSIE			
	End of conversion of an injected group	JEOC	JEOCIE			
	End of conversion sequence of an injected group	JEOS	JEOSIE			
	Analog watchdog 1 flag is set	AWD1	AWD1IE			
	Analog watchdog 2 flag is set	AWD2	AWD2IE			
	Analog watchdog 3 flag is set	AWD3	AWD3IE			
	End of sampling phase	EOSMP	EOSMPIE			
	Overrun	OVR	OVRIE			

32.6 ADC registers (for each ADC)

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

32.6.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
						rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD3LTR and ADC_AWD3HTR registers. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD2LTR and ADC_AWD2HTR registers. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD1LTR and ADC_AWD1HTR registers. It is cleared by software. writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6 **JEOS:** Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

Bit 5 **JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it, or by reading the corresponding ADC_JDRy register

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel (a new conversion has completed while the EOC flag was already set) or when adc_hclk clock is too slow to manage the data.

It is cleared by software writing 1 to it.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.

0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular Conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Note: When the OVR flag is raised, the EOSMP flag is not generated correctly.

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

32.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	AWD3IE	AWD2IE	AWD1IE	JEOSIE	JEOCIE	OVRIE	EOSIE	EOCIE	EOSMPIE	ADRDYIE
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 5 **JEOCIE**: End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3 **EOSIE**: End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2 **EOCIE**: End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

32.6.3 ADC control register (ADC_CR)

Address offset: 0x008

Reset value: 0x2000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAL	ADCALDIF	DEEPPWD	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs	rw	rw													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	JADSTP	ADSTP	JADSTART	ADSTART	ADDIS	ADEN
										rs	rs	rs	rs	rs	rs

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to enter ADC calibration mode.

0: Normal mode

1: Calibration mode

Note: The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1, ADCAL = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled, Calibration mode enabled and no conversion ongoing).

Bit 30 **ADCALDIF**: Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or differential input mode for the calibration.

0: Single-ended input calibration mode when ADCAL = 1

1: Differential input calibration mode when ADCAL = 1

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

0: ADC not in Deep-power down

1: ADC in Deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0 and ADEN =0).

Bits 28:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be reconfigured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

When a software trigger is used, JADSTART bit is cleared by hardware, but JADSTP bit must be programmed to reconfigure the ADC.

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP command).

It is cleared by hardware when the conversion is effectively discarded. and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

When a software trigger is used, ADSTART bit is cleared by hardware. However it is necessary to write ADSTP bit to reconfigure the ADC.

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop ongoing regular conversions. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use ADSTP).

Note: In dual ADC regular simultaneous mode and interleaved mode, the ADSTP bit of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

This bit is cleared by hardware:

– In single conversion mode when software trigger is selected (JEXTSEL=0x0 and JDISEN = 1): at the assertion of the end of injected conversion sequence (JEOS) flag.

– In all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN = 1,ADDIS = 0 and JAUTO = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared).

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

This bit is cleared by hardware:

– in single conversion mode when software trigger is selected (EXTSEL = 0x0 and DISEN = 1): at the assertion of the end of regular conversion sequence (EOS) flag.

– in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and place it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: The software is allowed to set ADDIS only when ADEN = 1, ADDIS = 0 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all the bits of ADC_CR registers are cleared (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

32.6.4 ADC configuration register (ADC_CFGR1)

Address offset: 0x00C

Reset value: 0x8000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	AWD1CH[4:0]					JAUTO	JAWD1EN	AWD1EN	AWD1SGL	Res.	JDISCEN	DISCNUM[2:0]			DISCEN
	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	AUTDLY	CONT	OVRMOD	EXTEN[1:0]		EXTSEL[4:0]					Res.	RES[1:0]		DMNGT[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel 0 monitored by AWD1

00001: ADC analog input channel 1 monitored by AWD1

.....

10011: ADC analog input channel 19 monitored by AWD1

Others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.

Note: The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers. The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO:** Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

0: Automatic injected group conversion disabled

1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADEN = 0, ADSTART = 0, and JADSTART = 0.

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the JAUTO bit of the master ADC.

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on injected channels

1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on regular channels

1: Analog watchdog 1 enabled on regular channels

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels

0: Analog watchdog 1 enabled on all channels

1: Analog watchdog 1 enabled on a single channel

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 21 Reserved, must be kept at reset value.

Bit 20 **JDISCEN:** Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: When dual mode is enabled (DUAL bits of ADCC_CCR register are not equal to zero), the JDISCEN bit of the slave ADC is no more writable and its content is equal to the JDISCEN bit of the master ADC.

Bits 19:17 **DISCNUM[2:0]:** Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCNUM[2:0] bits of the slave ADC are no more writable and their content is equal to the DISCNUM[2:0] bits of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled

1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCEN bits of the slave ADC is no more writable and its content is equal to the DISCEN bit of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the autodelayed conversion mode.

0: Autodelayed conversion mode off

1: Autodelayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCEN bits of the slave ADC is no more writable and its content is equal to the DISCEN bit of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCEN bits of the slave ADC is no more writable and its content is equal to the DISCEN bit of the master ADC.

Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: adc_ext_trg0
00001: adc_ext_trg1
00010: adc_ext_trg2
00011: adc_ext_trg3
00100: adc_ext_trg4
00101: adc_ext_trg5
00110: adc_ext_trg6
00111: adc_ext_trg7
...
11111: adc_ext_trg31

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit
01: 10-bit
10: 8-bit
11: 6-bit

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 1:0 **DMNGT[1:0]**: Data management configuration

These bits are set and cleared by software to select how the ADC interface output data are managed.

00: Regular conversion data stored in DR only
01: DMA one-shot mode selected
10: MDF mode selected
11: DMA circular mode selected

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

32.6.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
		LSHIFT[3:0]		Res.	Res.	OVSR[9:0]									
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMPTRIG	SWTRIG	BULB	Res.	Res.	ROVSM	TROVS	OVSS[3:0]				Res.	Res.	Res.	JOVSE	ROVSE
rw	rw	rw			rw	rw	rw	rw	rw	rw				rw	rw

Bits 31:28 **LSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

0000: No left shift
0001: 1-bit left shift
0010: 2-bit left shift
0011: 3-bit left shift
0100: 4-bit left shift
0101: 5-bit left shift
0110: 6-bit left shift
0111: 7-bit left shift
1000: 8-bit left shift
1001: 9-bit left shift
1010: 10-bit left shift
1011: 11-bit left shift
1100: 12-bit left shift
1101: 13-bit left shift
1110: 14-bit left shift
1111: 15-bit left shift

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **OVSR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

0: 1x (no oversampling)
1: 2x
2: 3x
...
1023: 1024x

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 15 **SMPTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.

0: Sampling time control trigger mode disabled
1: Sampling time control trigger mode enabled

If EXTEN[1:0] bits are set to 01, the sampling time starts on the trigger rising edge, and the conversion starts on the trigger falling edge.

The SMPTRIG bit must not be set when the SMPTRIG bit is set.

When EXTEN[1:0] bits are set to 00, set SWTRIG to start the sampling and clear the BULB bit to start the conversion.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with sampling time control trigger mode.

Bit 14 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to trigger the conversion in sampling time control trigger mode.

0: Software trigger starts the conversion for sampling time control trigger mode
1: Software trigger starts the sampling for *sampling time control trigger mode*

Note: The software is allowed to write this bit only when ADSTART = 0, JADSTART = 0 (which ensures that no conversion is ongoing), SMPTRIG = 1, and EXTEN[0:1] = 00.

Bit 13 **BULB**: Bulb sampling mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Bulb sampling mode disabled

1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.

BULB bit must not be set when the SWTRIG bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

Note: The software is allowed to write this bit only when ADEN = 0. When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with bulb mode.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). It is recommended to clear both JOVSE and GCOMP when ROVSM = 0.

Bit 9 **TROVS**: Triggered regular oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No shift

0001: 1-bit shift

0010: 2-bit shift

0011: 3-bit shift

0100: 4-bit shift

0101: 5-bit shift

0110: 6-bit shift

0111: 7-bit shift

1000: 8-bit shift

1001: 9-bit shift

1010: 10-bit shift

Other: reserved, must not be used

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected oversampling enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected oversampling disabled

1: Injected oversampling enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ROVSE**: Regular oversampling enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular oversampling disabled

1: Regular oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing)

32.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP9[2:0]			SMP8[2:0]			SMP7[2:0]			SMP6[2:0]			SMP5[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP5[0]	SMP4[2:0]			SMP3[2:0]			SMP2[2:0]			SMP1[2:0]			SMP0[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles

001: 2.5 ADC clock cycles

010: 6.5 ADC clock cycles

011: 11.5 ADC clock cycles

100: 23.5 ADC clock cycles

101: 46.5 ADC clock cycles

110: 246.5 ADC clock cycles

111: 1499.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

32.6.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP19[2:0]			SMP18[2:0]			SMP17[2:0]			SMP16[2:0]			SMP15[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 19 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles
001: 2.5 ADC clock cycles
010: 6.5 ADC clock cycles
011: 11.5 ADC clock cycles
100: 23.5 ADC clock cycles
101: 46.5 ADC clock cycles
110: 246.5 ADC clock cycles
111: 1499.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

32.6.8 ADC channel preselection register (ADC_PCSEL)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCSEL[19:16]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **PCSEL[19:0]**: Channel i ($V_{INP[i]}$) preselection

These bits are written by software to preselect the input channel I/O to be converted.

0: Input channel i ($V_{INP[i]}$) is not preselected for conversion, the result of the ADC conversion for this channel is wrong

1: Input channel i ($V_{INP[i]}$) is preselected for conversion

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

32.6.9 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ4[4:0]					Res.	SQ3[4:0]					Res.	SQ2[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ2[3:0]				Res.	SQ1[4:0]					Res.	Res.	L[3:0]			
rw	rw	rw	rw		rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** 4th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]:** 3rd conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]:** 2nd conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 1st in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]:** Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion

0001: 2 conversions

...

1111: 16 conversions

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

32.6.10 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ9[4:0]					Res.	SQ8[4:0]					Res.	SQ7[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ7[3:0]				Res.	SQ6[4:0]					Res.	SQ5[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 9th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 8th in the regular conversion sequence

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 7th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 6th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 5th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

32.6.11 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ14[4:0]					Res.	SQ13[4:0]					Res.	SQ12[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ12[3:0]				Res.	SQ11[4:0]					Res.	SQ10[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]:** 14th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 14th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]:** 13th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 13th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]:** 12th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 12th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]:** 11th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 11th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]:** 10th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 10th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

32.6.12 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]:** 16th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 16th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]:** 15th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 15th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

32.6.13 ADC regular data register (ADC_DR)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA[31:0]**: Regular data converted

These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in *Section 32.4.26: Data management*.

32.6.14 ADC injected sequence register (ADC_JSQR)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JSQ4[4:0]					Res.	JSQ3[4:0]					Res.	JSQ2[4:1]			
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JSQ2[0]	Res.	JSQ1[4:0]					JEXTEN[1:0]		JEXTSEL[4:0]					JL[1:0]	
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **JSQ4[4:0]:** 4th conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]:** 3rd conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]:** 2nd conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]:** 1st conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

00010: adc_jext_trg2

00011: adc_jext_trg3

00100: adc_jext_trg4

00101: adc_jext_trg5

00110: adc_jext_trg6

00111: adc_jext_trg7

...

11111: adc_jext_trg31

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JL[1:0]:** Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

32.6.15 ADC offset y configuration register (ADC_OFCFGRy)

Address offset: 0x050 + 0x004 * (y -1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OFFSET_CH[4:0]					SSAT	USAT	POS OFF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:27 **OFFSET_CH[4:0]:** Channel selection for the data offset y

These bits are written by software to define the channel to which the offset programmed in bits OFFSET[21:0] applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the data offset y.

Bit 26 **SSAT**: Signed saturation enable

This bit is set and cleared by software to enable the signed saturation feature.(see *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*).

0: Offset is subtracted maintaining the data integrity and extending converted data size (13-bit signed format)

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **USAT**: Unsigned saturation enable

This bit is set and cleared by software to enable the unsigned saturation feature.

0: Offset is subtracted maintaining the data integrity

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **POSOFF**: Positive offset enable

This bit is set and cleared by software to enable the positive offset

0: Negative offset

1: Positive offset

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:0 Reserved, must be kept at reset value.

32.6.16 ADC offset y register (ADC_OFRy)

Address offset: 0x060 + 0x004 * (y -1), (y= 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OFFSET[21:16]					
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **OFFSET[21:0]:** Data offset y for the channel programmed in OFFSETy_CH[4:0] bits

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the OFFSETy_CH[4:0] bits. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

32.6.17 ADC gain compensation register (ADC_GCOMP)

Address offset: 0x070

Reset value: 0x0000 1000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GCOMP	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	GCOMPCOEFF[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **GCOMP:** Gain compensation mode

This bit is set and cleared by software to enable the Gain compensation mode.

0: Regular ADC operation mode

1: Gain compensation enabled and applied on all channels.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing)

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:0 **GCOMPCOEFF[13:0]:** Gain compensation coefficient

These bits are set and cleared by software to program the gain compensation coefficient.

00 1000 0000 0000: gain factor of 0.5

...

01 0000 0000 0000: gain factor of 1

10 0000 0000 0000: gain factor of 2

11 0000 0000 0000: gain factor of 3

...

The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.9999756

Note: This gain compensation is only applied when GCOMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing).

32.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x080 + 0x004 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JDATA[31:16]

JDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **JDATA[31:0]:** Injected data

These bits are read-only. They contain the conversion result from injected channel y. The data are left- or right-aligned as described in *Section 32.4.26: Data management*.

32.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR)

Address offset: 0x0A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

AWDCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWDCH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD2

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD2

When AWDCH[19:0] = 000..0, the analog Watchdog 2 is disabled

Note: The channels selected by AWDCH must be also selected in the SQRi or JSQRi registers.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

32.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0x0A4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

AWDCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWDCH[19:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD3

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD3

When AWDCH[19:0] = 000..0, the analog Watchdog 3 is disabled

Note: The channels selected by AWDCH must be also selected in the SQRi or JSQRi registers.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

32.6.21 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR)

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LTR[22:16]						
									rw	rw	rw	rw	rw	rw	rw

LTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **LTR[22:0]**: Analog watchdog 1 lower threshold

These bits are set and cleared by software to define the lower threshold for analog watchdog 1.

Refer to *Section 32.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)*.

32.6.22 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR)

Address offset: 0x0AC

Reset value: 0x003F FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
AWDFILT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	HTR[22:16]

HTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **AWDFILT[2:0]**: Analog watchdog filtering parameter

These bits are set and cleared by software.

000: No filtering, one detection generates an AWD1 flag or an interrupt

001: two consecutive detections generate an AWD1 flag or an interrupt

...

111: Eight consecutive detections generate an AWD1 flag or an interrupt

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 28:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 1 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 1. Refer to *Analog windows watchdog* section.

32.6.23 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR)

Address offset: 0x0B0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 2 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 2. Refer to *Analog windows watchdog* section.

32.6.25 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR)

Address offset: 0x0B8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 3 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 3. Refer to *Analog windows watchdog* section.

32.6.27 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0x0C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIFSEL[19:16]			
												rw	rw	rw	rw

DIFSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **DIFSEL[19:0]:** Differential mode for channels 19 to 0.

These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or differential mode.

DIFSEL[i] = 0: ADC analog input channel is configured in single-ended mode

DIFSEL[i] = 1: ADC analog input channel i is configured in differential mode

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

32.6.28 ADC calibration factors (ADC_CALFACT)

Address offset: 0x0C4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CAL ADDOS	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT_D[8:0]								
rw							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT_S[8:0]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **CALADDOS**: Calibration additional offset

This bit is set by software to add a positive offset at the input stage of ADC for calibration purpose.

0: Calibration additional positive offset disabled

1: Calibration additional positive offset enabled

Note: The software is allowed to write these bits only when ADEN = 1, ADCAL = 1, ADSTART = 0, and JADSTART = 0 (ADC is enabled, calibration mode is selected, and no conversion is ongoing).

Bits 30:25 Reserved, must be kept at reset value.

Bits 24:16 **CALFACT_D[8:0]**: Calibration factors in differential mode

These bits are written by hardware or by software.

Once a differential input calibration is complete, they are updated by hardware with the calibration factors.

The software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored in the analog ADC, it is applied once a new differential conversion is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADCAL = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled, no calibration is ongoing and no conversion is ongoing).

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 **CALFACT_S[8:0]**: Calibration factors In single-ended mode

These bits are written by hardware or by software.

Once a single-ended input calibration is complete, they are updated by hardware with the calibration factors.

The software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored in the analog ADC, it is applied once a new single-ended conversion is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADCAL = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled, no calibration is ongoing and no conversion is ongoing).

This bit can only be cleared by a power-on reset.

32.6.29 ADC option register (ADC_OR)

Address offset: 0x0D0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OP2	OP1	OP0
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **OP2:** Option bit 2

This bit is set and cleared by software to enable/disable the V_{DDCORE} channel.

0: V_{DDCORE} channel disabled

1: V_{DDCORE} channel enabled

Note: This bit is only available in ADC2 and ADC3.

Bit 1 **OP1:** Option bit 1

This bit is set and cleared by software to choose the ADC bandgap source

0: ADC internal bandgap disabled

1: ADC internal bandgap enabled

Note: The software is allowed to write this bit only when ADC is disabled.

Bit 0 **OP0:** Option bit 0

This bit is set and cleared by software to enable the internal reference buffer.

0: ADC internal reference voltage buffer disabled

1: ADC internal reference voltage buffer enabled

Note: The software is allowed to write this bit only when ADC is disabled.

32.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs.

32.7.1 ADC common status register (ADCC_CSR)

Address offset: 0x000

Reset value: 0x0000 0000

This register provides an image of the flags of the different ADCs. Nevertheless it is read-only and does not allow to clear the different flags. Instead each flag must be cleared by writing 0 to it in the corresponding ADC_ISR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **AWD3_SLV:** Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 24 **AWD2_SLV:** Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 23 **AWD1_SLV:** Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 22 **JEOS_SLV:** End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 21 **JEOC_SLV:** End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 20 **OVR_SLV:** Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 19 **EOS_SLV:** End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 18 **EOC_SLV:** End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 17 **EOSMP_SLV:** End of sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

Bit 16 **ADRDY_SLV:** Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3_MST:** Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST:** Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST:** Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST:** End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST:** End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST:** Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST:** End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST:** End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST:** End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST:** Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

32.7.2 ADC common control register (ADCC_CCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBATEN	Res.	VREFEN	Res.	Res.	Res.	Res.	Res.	Res.
							rw		rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAMDF[1:0]		Res.	Res.	DELAY[3:0]				Res.	Res.	Res.	DUAL[4:0]				
rw	rw			rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable
This bit is set and cleared by software to enable/disable the V_{BAT} channel.
0: V_{BAT} channel disabled
1: V_{BAT} channel enabled
Note: V_{BAT} is not available on all ADC instances. Refer to Section 32.4.4: ADC connectivity for details.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **VREFEN**: V_{REFINT} enable
This bit is set and cleared by software to enable/disable the V_{REFINT} channel.
0: V_{REFINT} channel disabled
1: V_{REFINT} channel enabled
Note: V_{REFINT} is not available on all ADC instances. Refer to Section 32.4.4: ADC connectivity for details.
Note: The software is allowed to write this bit only when ADEN = 0.

Bits 21:16 Reserved, must be kept at reset value.

Bits 15:14 **DAMDF[1:0]:** Dual ADC mode data format
This bitfield are set and cleared by software. It specifies the data format in the common data register ADCC_CDR and ADCC_CDR2.
00: Dual ADC mode without data packing (ADCC_CDR and ADCC_CDR2 registers not used).
01: Reserved
10: Data formatting mode for any data width (ADCC_CDR data register is used when the data width is less than 16 bits, otherwise ADCC_CDR2 register is used)
11: Data formatting mode for data width lower that 8 bits (ADCC_CDR data register is used)
Note: The software is allowed to write these bits only when ADEN = 0 (which ensures that no regular conversion is ongoing).

Bit 13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY[3:0]:** Delay between two sampling phases
These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to *Table 253* for the value of ADC resolution versus DELAY bits values.
Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]:** Dual ADC mode selection
These bits are written by software to select the operating mode.
All the ADCs independent:
00000: Independent mode
The following settings apply to dual mode, master and slave ADCs working together
00001: Combined regular simultaneous + Injected simultaneous mode
00010: Combined regular simultaneous + Alternate trigger mode
00011: Combined interleaved mode + Injected simultaneous mode
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only
Others: Reserved
All other combinations are reserved and must not be programmed
Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

32.7.3 ADC common regular data register for dual mode (ADCC_CDR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA_SLV[15:0]

RDATA_MST[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **RDATA_SLV[15:0]:** Regular data of the slave ADC

In dual mode, these bits contain the regular data of the slave ADC. Refer to *Section 32.4.31: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.

In dual mode, these bits contain the regular data of the master ADC. Refer to *Section 32.4.31: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*)

In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

32.7.4 ADC common regular data register for dual mode (ADCC_CDR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RDATA_ALT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA_ALT[31:0]**: Regular data of the master/slave alternated ADCs.

In dual mode, these bits contain the regular 32-bit data of the master and the slave ADC. Refer to *Section 32.4.31: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*)

32.8 ADC register map

ADC1 and ADC2 are master and slave ADC, respectively.

Table 255. ADC register map and reset values for each ADC

Refer to *Section 2.3* for the register boundary addresses.

33 Digital temperature sensor (DTS)

33.1 Introduction

The DTS is a high-precision low-power junction temperature sensor (TS). It is composed of a configurable controller plus two embedded temperature sensors, TS0 and TS1. The controller features a generic interface that enables the DTS to be accessed in read and write modes, through the APB bus.

33.2 DTS main features

The temperature sensor main features are the following:

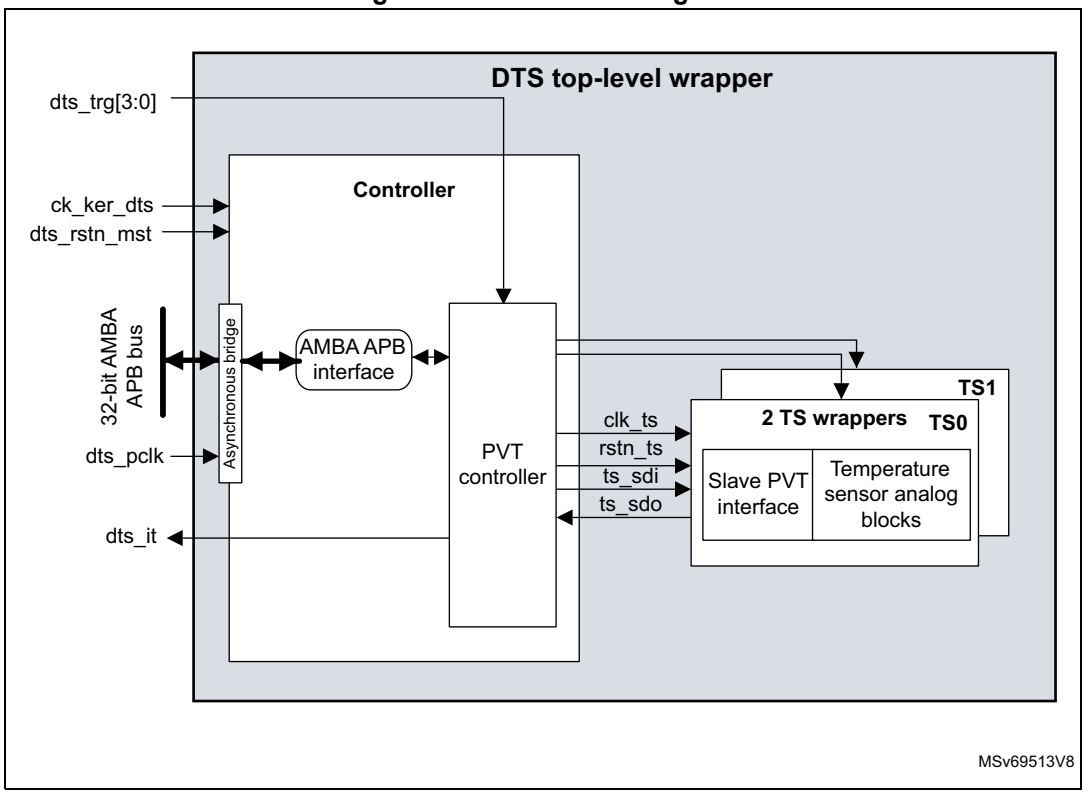
- For each sensor:
  - Two programmable (rise or fall) hardware alarms incorporating hysteresis
  - Status registers recording the minimum and maximum data values received
- A power-up timer with IRQ to support manual operation

33.3 DTS functional description

33.3.1 DTS block diagram

Figure 314 shows the DTS block diagram.

Figure 314. DTS block diagram



The DTS incorporates an APB interface configured to control two temperature sensors, TS0 and TS1, through a process, voltage and temperature (PVT) controller.

33.3.2 DTS pins and internal signals

Table 257. DTS internal input/output signals

Internal signal name	Signal type	Description
dts_pclk	Input	APB bus clock
ck_ker_dts	Input	DTS main clock
dts_rstn_mst	Input	Master reset (asynchronous, active low)
AMBA APB bus	Input/output	APB Interface
dts_it	Output	IRQ interrupt from the DTS peripheral
dts_trg[3:0]	Inputs	Trigger interface
Temperature sensor (TS) interface		
clk_ts	Input	Temperature sensor SDA clock

Table 257. DTS internal input/output signals (continued)

Internal signal name	Signal type	Description
rstn_ts	Input	Temperature sensor SDA reset (asynchronous, active low)
ts_sdi	Input	Temperature sensor SDA slave data Input
ts_sdo	Output	Temperature sensor SDA slave data output

Table 258. DTS interconnection

Internal signal name	Source/Destination
dts_trg[0]	lptim4_out
dts_trg[1]	lptim2_ch1
dts_trg[2]	lptim3_ch1
dts_trg[3]	exti13

33.3.3 DTS reset and clocks

DTS clocks

The DTS is clocked by ck_ker_dts.

The PVT controller incorporates a clock synthesizer in the TS block. The synthesizers generate the clock and timing strobes for the slave serial data adapters (SDA) and the clock for the embedded TS blocks (clk_ts).

The synthesizer CLK_SYNTH_HI[7:0]/CLK_SYNTH_LO[7:0] counters allow the integer division of the ck_ker_dts clock to generate the TS clock (clk_ts) at frequency ratios from 1/2 to 1/512 (see *DTS TSC clock synthesizer register (DTS_TSCCLKSYNTHR)*). Separate counters are used to generate timing control strobes that are aligned with the clk_ts clock. These timing strobes are used by the master serial adapters to control the sample point of the serial data inputs and the hold time of the serial data outputs.

The system clock ck_ker_dts frequency is determined by the RCC. CLK_SYNTH_HI[7:0] and CLK_SYNTH_LO[7:0] must be programmed so that the ratio CLK_SYNTH_HI[7:0]/CLK_SYNTH_LO[7:0] enables to obtain a clk_ts serial clock that falls within the TS operating frequency range (from 4 to 8 MHz).

The TS frequency is defined by:

$$\text{clk_ts frequency} = 1 / ((\text{CLK_SYNTH_HI[7:0]} + 1) + (\text{CLK_SYNTH_HI[7:0]} + 1)) \times \text{ck_ker_dts frequency}$$

For example:

For ck_ker_dts = 64.0 MHz and a TS operating frequency ranging between 4 and 8 MHz, setting the ck_ker_dts to clk_ts divider factor to 8:1 (CLK_SYNTH_HI[7:0] and CLK_SYNTH_LO[7:0] both programmed to 0x03), returns an TS operating frequency of 64.0 MHz / 8 = 8 MHz, which falls within the acceptable operating frequency range of 4 to 8 MHz. This enables to obtain an overall divider factor of 8 and a ck_ker_dts serial clock duty cycle of 50/50.

For ck_ker_dts = 8 MHz, the configuration must be:

CLK_SYNTH_LO[7:0] = 0x0

CLK_SYNTH_HI[7:0] = 0x0

CLK_SYNTH_HOLD[3:0]= 0x1

clk_ts = 4 MHz

clk_ts duty cycle = 50 %

The CLK_SYNTH_HOLD[3:0] value must be programmed to accommodate the worst-case serial data path propagation delays without exceeding the synthesized clock period, this means that:

$$\text{CLK_SYNTH_HOLD[3:0]} \leq \text{CLK_SYNTH_HI[7:0]} + \text{CLK_SYNTH_LO[7:0]} + 1$$

DTS reset

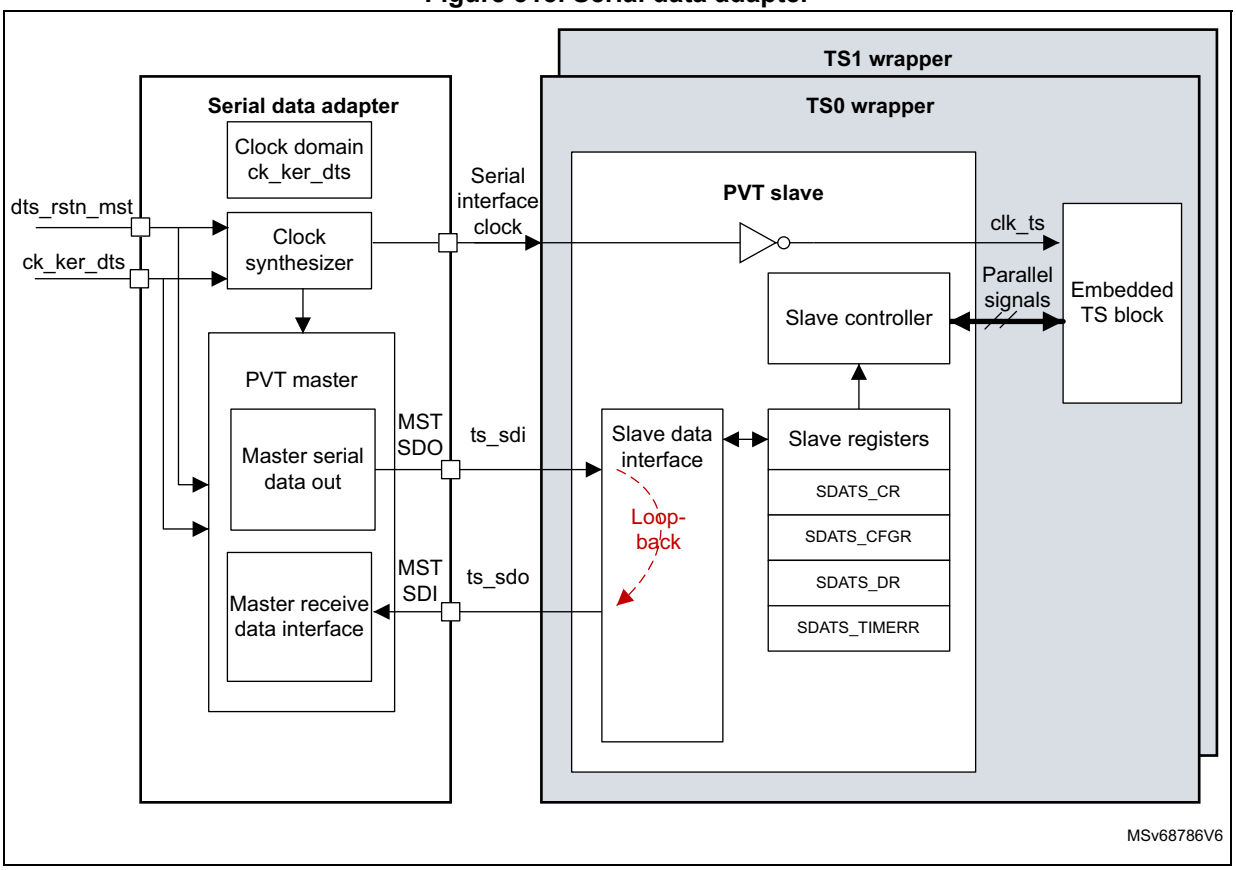
The DTS is reset using the asynchronous active-low dts_rstn_mst input.

When the master dts_rstn_mst is asserted, the entire DTS is reset, all APB internal registers and the PVT controller. It also powers down and resets the embedded TS blocks.

When de-asserted, the APB interface responds to requests after a three clock-cycle delay.

33.3.4 DTS serial data adapter (SDA)

Figure 315. Serial data adapter



The serial data adapter (SDA) allows the TS blocks to be configured and controlled via serial data interfaces (SDIF). The purpose of the SDA is to minimize the number of signals that need to be routed from the PVT controller to each TS block.

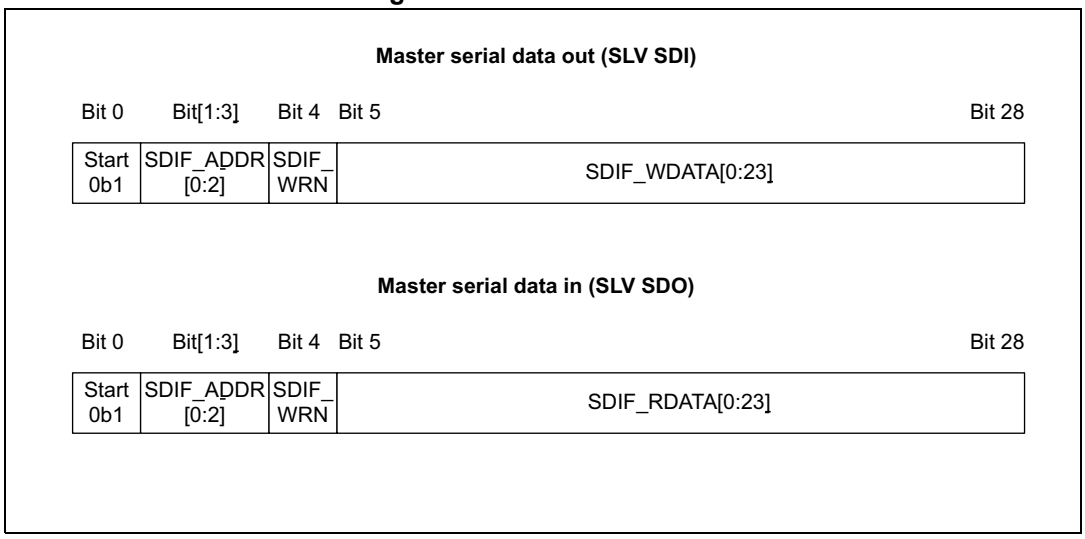
A master usually transmits data to all its active PVT slave devices. However, it is possible to inhibit the programming of one or more slaves to allow different configuration options to be applied. To achieve power saving, it is also possible to disable completely a TS block by disabling its clock and forcing reset.

The serial data interface also provides loop-back functionality (shown in red in *Figure 315*) to support system integration testing without having to power up the embedded TS block.

SDA data format

The serial data streams consist of an active-high start bit, 3-bit register address (SDIF_ADDR[2:0]), register write/not read enable (SDIF_WRN), and 24-bit data field (SDIF_WDATA[23:0]). The input and output serial data stream formats are shown in *Figure 316*. It must be noted that the serial data streams are little endian, meaning that the individual data fields are shifted LSB first.

Figure 316. SDA data format



SDA read

When reading data from the SDA slave registers (SDIF_WRN = 0), the SLV SDI bit stream is shifted to SLV SDO (delayed by one clk_ts cycle) and the register read data value is output on SDIF_RDATA[23:0]. The read data value is then made available in the PVT controller DTS_TSnSDIFRDATAR register (where *n* corresponds to the TS instance number).

SDA write

When writing data to the SDA slave registers (SDIF_WRN = 1), the SLV SDI bit stream is automatically shifted to SLV SDO and SDIF_RDATA[23:0] = SDIF_WDATA[23:0]. The write data loop-back value is then made available in the corresponding PVT controller DTS_TSnSDIFRDATAR register.

A special loop-back mode is available by writing to the (read-only) SDATS_DR register when SDIF_WRN = 1 and SDIF_ADDR[2:0] = 0x3. In this mode, the loop-back data value is also written to the PVT controller TS data registers (DTS_TSnSDIFRDATAR). When writing loop-back data to the TS data registers, the SDA TS_DATA[23:0] field **must** be set to 0x0.

The DTS_TSnSDIFRDATAR loop-back functionality can be used to verify the integrity of the serial data transfer between the PVT controller and remote PVT slave devices.

The special DTS_TSnSDIFRDATAR loop-back functionality is provided to test the PVT controller operation without having to power up the embedded TS block, for example when a fault or alarm occurs.

The loop-back functionality is disabled whenever the PVT slave is configured to automatic data recovery when the TS_AUTO bit of PVT SDATS_CR register is asserted.

SDA automatic data recovery

The automatic data recovery is enabled through TS_AUTO bit of SDATS_CR register.

In automatic data recovery mode, the SDIF_LOCK flag is set in the DTS_TSCSDIF_SR register, the SDA interface becomes write-only and all SDA read requests are ignored. In this mode, the SLV automatically streams TS_DATA[23:0] to the PVT controller each time new data samples become available, while setting SDIF_ADDR[2:0] to 0x3 and SDIF_WRN to 1. The automatically recovered data are made available in the PVT controller DTS_TSnSDIFRDATAR and DTS_TSnSDIFRDATAR registers.

SDA SDIF programming

The SDA slave is accessed via the TS SDIF control register DTS_TSCSDIF_CFGR, by setting the SDIF_WDATA[23:0], the SDIF_ADDR[2:0] and the SDIF_WRN, and asserting the SDIF_PROG bit. This SDA read or write request is normally set up using a single PVT register write access.

Once a programming request has been issued, the SDIF_BUSY flag in the DTS_TSCSDIF_SR register is set, and any additional read or write programming requests is ignored until the current access completes.

SDA controller operation

The SDA slave controller features two operating modes: manual (default) and automatic. In both modes, the embedded TS block is configured through the SDATS_CFGR register.

In manual operating mode, when the TS_AUTO bit of SDATS_CR register is de-asserted, the embedded TS block is controlled directly through the SDATS_CR register fields TS_PD, TS_RSTN, TS_RUN_ONCE, TS_RUN_CONT and TS_CLOAD. In manual mode, the user is responsible for ensuring that the PD, RSTN, CLOAD and RUN signals are applied in the correct order and at appropriate times. Sample data from the TS block are captured in the SDA slave SDATS_DR register at the end of the conversion. The user must either poll the SDATS_DR register or leave sufficient time for the conversion to complete before reading the SDATS_DR register in order to recover the sample data from the slave SDA.

In automatic mode, when the TS_AUTO bit is asserted in SDATS_CR register, the embedded TS block is controlled by the slave SDA. When either TS_RUN_ONCE or TS_RUN_CONT bit of the TS_SDATS_CR register is asserted, the slave SDA sequences the PD, RSTN, CLOAD, and RUN signals that drive the TS block to perform one or more conversions. In this mode sample data from the TS block are captured in the SDA slave SDATS_DR register at the end of the conversion before being automatically streamed to the PVT controller.

In trigger mode, when a trigger is asserted at DTS top level, this value is compared to the value programmed in bits 18 to 16 (TRIG[2:0]) of the SDATS_CFGR register. If it is equal, the TS_RUN_ONCE bit is automatically asserted. Sample data from each TS block are captured in the SDA slave SDATS_DR register at the end of the conversion.

SDA slave registers

The serial data adapter registers are accessible through the SDIF interface of the PVT controller.

Table 259. SDA slave registers

SDIF_ADDR[2:0]	Reset value	Register	Description
0x0	0x000001	SDATS_CR	TS control register (see *Table 260*)
0x1	0x000000	SDATS_CFGR	TS configuration register (see *Table 261*)
0x3	0x000000	SDATS_DR	TS data / SDA loop-back register (see *Table 262*)
0x4	-	Reserved	-
0x5	0x000000	SDATS_TIMERR	TS power-up Timer register (see *Table 260*)

Table 260. SDA TS control register (SDATS_CR)

Bitfield range	Bitfield description	Access type
Bits 23:10	Reserved, must be kept at reset value.	-
Bit 9	**TS_STOP:** TS force stop This self-clearing bit immediately returns the slave TS controller to the default TS control state and terminates any serial data activity. This is not a clean shut-down and it may invalidate any data operations currently in progress. 0: TS not stopped 1: TS stopped	rs
Bit 8	**TS_AUTO:** TS automatic mode This bit is used in conjunction with TS_RUN_CONT and TS_RUN_ONCE to automatically power up the embedded TS and run conversions. Asserting TS_RUN_CONT triggers continuous conversions, while asserting TS_RUN_ONCE triggers a single conversion. If TS_AUTO is de-asserted while conversions are running, the controller waits for any active conversions to complete and then returns to the default TS control state. 0: Automatic mode disabled 1: Automatic mode enabled	rw
Bits 7:5	Reserved, must be kept at reset value.	-
Bit 4	**TS_CLOAD:** TS configuration load This self-clearing bit provides the embedded TS cload input in the default TS control state (TS automatic mode disabled). 0: TS configuration not loaded 1: TS configuration loaded	rs
Bit 3	**TS_RUN_CONT:** TS run continuous The TS_RUN_CONT control bit is ORed with TS_RUN_ONCE in order to provide the embedded TS run input in the default TS control state (TS automatic mode disabled). This bit is active high.	rw

Table 260. SDA TS control register (SDATS_CR) (continued)

Bitfield range	Bitfield description	Access type
Bit 2	**TS_RUN_ONCE:** TS run once Provided TS_RUN_CONT is not asserted, this self-clearing bit asserts the embedded TS run input for one clock cycle when it is in the default TS control state (TS automatic mode disabled). This bit is active on the rising edge.	rs
Bit 1	**TS_RSTN:** TS reset This bit provides the embedded TS rstn input in the default TS control state (TS automatic mode must be disabled). 0: TS reset 1: TS not reset	rw
Bit 0	**TS_PD:** TS power-down This bit provides the embedded TS pd input when in the default TS control state (TS automatic mode disabled). 0: No TS power-down 1: TS power-down	rw

Table 261. SDA TS configuration register (SDATS_CFGR)

Bitfield range	Bitfield description	Access type
Bits 23:20	Reserved, must be kept at reset value.	-
Bit 19	**CLKDIS:** TS clock gating disable bit 0: Clock enabled 1: Clock disabled	rw
Bits 18:16	**TRIG[2:0]:** Trigger selection bits 000: no trigger source selected 001: dts_trg[0] selected 010: dts_trg[1] selected 011: dts_trg[2] selected 100: dts_trg[3] selected Others: Reserved, must not be used Refer to *Section 33.3.7: Temperature sensor configuration* for details.	rw
Bits 15:8	**TS1_CFG[7:0]:** TS1 configuration TS1_CFG[7:5]: TS1 resolution 000:12 bits 001:10 bits 010: 8 bits Other: reserved, must not be used TS1_CFGR[4]: TS1 output mode 0: parallel interface 1: serial interface (default) TS1_CFGR[3:0]: TS1 communication enable bit 0000: no communication 0001: communication enabled. Others: Reserved, must not be used.	rw

Table 261. SDA TS configuration register (SDATS_CFGR)

Bitfield range	Bitfield description	Access type
Bits 7:0	**TS0_CFG[7:0]:** TS0 configuration TS0_CFG[7:5]: TS0 resolution 000:12 bits 001:10 bits 010: 8 bits Other: reserved, must not be used TS0_CFGR[4]: TS0 output mode 0: parallel interface 1: serial interface (default) TS0_CFGR[3:0]: TS0 communication enable bit 0000: no communication 0001: communication enabled. Others: Reserved, must not be used.	rw

Table 262. SDA TS data register (SDATS_DR)

Bitfield range	Bitfield description	Access type
Bits 23:19	Reserved, must be kept at reset value.	-
Bit 18	**TS_DONE:** TS sample done flag This bit provides a way to identify when a new data sample has been recovered while manually polling the SDATS_DR register. In manually polling, the TS_DONE flag is cleared when the SDATS_DR register is read. The sample done flag is asserted when new sample data becomes available. It is automatically cleared in TS automatic mode as the SDATS_DR value is transmitted to the PVT controller. 0: No new data sample 1: New data sample	r
Bit 17	**TS_FAULT:** TS sample fault When asserted, this bit indicates that the embedded TS has signaled a fault. The TS_FAULT flag is updated when new data are received. 0: No TS sample fault 1: TS sample fault	r
Bit 16	**TS_TYPE:** TS sample type The TS_TYPE flag is updated when new data is received. 0: Indicates valid data 1 Indicates either analog access, signature select or fault debug mode	r
Bits 15:0	**TS_DATA[15:0]:** TS sample data	r

Table 263. SDA TS timer register (SDATS_TIMERR)

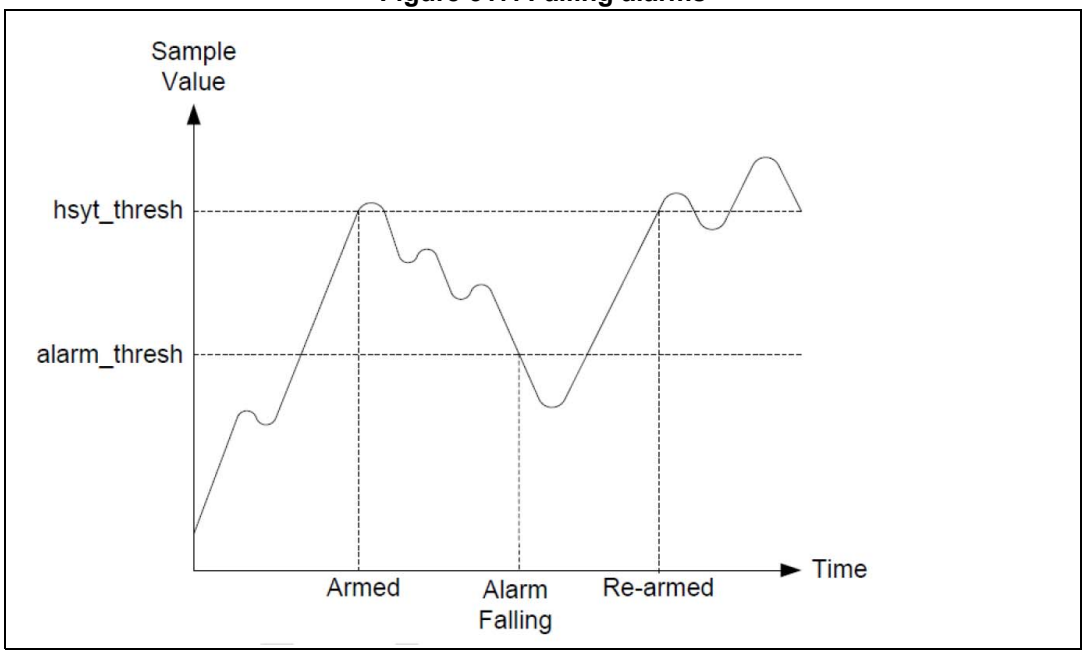
Bitfield range	Bitfield description	Access type
Bits 23:16	Reserved, must be kept at reset value.	-
Bits 15:0	**TS_PU_DLY[15:0]:** TS power-up delay The value is expressed in units of clk_ts cycles. Typical power-up delays are 256 cycles.	rw

33.3.5 Alarms

The DTS provides two alarms, alarm A and alarm B, for each TS block. The alarms feature programmable hysteresis and can be configured to detect either rising or falling sample values. They are disabled by setting the hysteresis threshold to a value that is equal to the alarm threshold (default condition). Once enabled, the alarms generate an interrupt if the value of the recovered data sample equals or exceeds the rising or falling alarm threshold. Once an alarm has been triggered, the hysteresis threshold provides a recovery window during which the alarm cannot trigger again.

Falling alarms

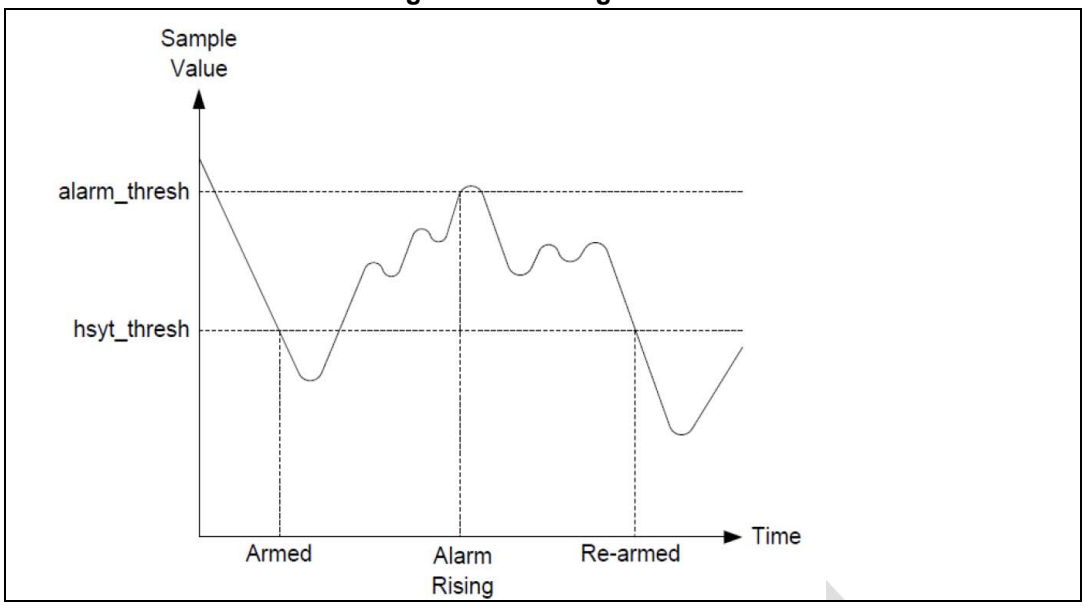
Figure 317. Falling alarms



Setting the hysteresis threshold greater than the alarm threshold creates a falling alarm. When configured as a falling alarm, the alarm is armed when the recovered sample value is greater than or equal to the hysteresis threshold. Once armed, a falling alarm triggers when the recovered sample value is less than or equal to the alarm threshold. An alarm is automatically disarmed once triggered and does not rearm until the recovered sample value is again greater than or equal to the hysteresis threshold. The alarm is also disarmed if an invalid sample value is received, that is if unexpected fault or type flags are detected.

Rising alarms

Figure 318. Rising alarms



Setting the hysteresis threshold less than the alarm threshold creates a rising alarm. When configured as a rising alarm, the alarm is armed when:

1. The associated clock synthesizer is first enabled (initial conversion).
2. The recovered sample value is less than or equal to the hysteresis threshold.
3. An invalid sample value is received, that is when an unexpected fault or type flags are detected.

Once armed, a rising alarm triggers when the recovered sample value is greater than or equal to the alarm threshold. The alarm is automatically disarmed once triggered and does not rearm until the recovered sample value is again less than or equal to the hysteresis threshold.

33.3.6 Main APB programming routines

This section gives several examples of routines to configure the PVT controller, program the SDA registers, and perform single or continuous temperature conversions.

Configure the PVT controller

1. STEP 1: Configure the PVT controller Interrupts:
   a) Write DTS_PVT_IER register:

      The timer is only intended to be used when using the TS block in bypass mode, so this interrupt must remain disabled .

   b) Write DTS_TSn_IER register:

      In the unlikely event of the TS block signaling a fault, the recovered data values are considered invalid and any active alarm is disarmed until the fault is removed. The fault IRQ is generated the first time a TS that an TS block signals a fault. If the fault is not cleared by the user, then no further interrupts are raised. It is recommended to enable always this interrupt.

2. STEP 2: Configure the PVT controller alarms:
   a) Write DTS_TSnALARMA_CFGR register:

      Alarms are enabled when the ALARM_THRESH is not equal to the HYST_THRESH.

      When enabling alarms, make sure that the corresponding IRQ is also enabled.
   b) Write DTS_TSnALARMB_CFGR register:

      Alarms are enabled when the ALARM_THRESH is not equal to the HYST_THRESH.

      When enabling alarms, make sure the corresponding IRQ is also enabled.
3. STEP 3: PVT sample control:
   a) Write DTS_TSCSMPL_CR register:

      When SMPL_DISCARD is set, TS data samples are temporarily discarded, but the sample counter continues to increment.

      When SMPL_CTR_HOLD is asserted, the sample counter is prevented from rolling over when the maximum sample count is reached.

      When SMPL_CTR_DISABLE is asserted, the sample counter is disabled.
4. STEP 4: PVT sample control:
   a) Write DTS_TSnHILORESETR for each TS instance.

Configure the SDA registers

1. STEP 1: Program the SDA registers:
   a) Read DTS_TSCSDIF_SR register:

      The SDIF_LOCK flag must be low, indicating that SDIF automatic mode has not been enabled.

      Before proceeding further, make sure that the serial data interface is inactive by checking that the SDIF_BUSY flag is low.
   b) Write DTS_TSCSDIF_CR register to fetch the remote slave SDA register value:

      SDIF_PROG = 0x1

      SDIF_WRN = 0x1

      SDIF_ADDR[2:0]: this bitfield selects the desired SDA register.

      SDIF_WDATA[23:0]: this bitfield provides the SDA write data value.

      Program the SDA register bits in the following order:

      SDATS_TIMERR register

      SDATS_CFGR register

      SDATS_CR register (see notes below).

Note: Setting the TS_AUTO bit and either TS_RUN_ONCE or TS_RUN_CONT bit in the SDATS_CR register initiates a conversion and sets the SDIF_LOCK flag. Once the SDIF_LOCK flag is set, the SDA registers become write-only.

The SDIF_WDATA[23:0] value is also reflected in the DTS_TSnSDIFRDATAR *registers.*

2. STEP 2: Read the SDA register values:
   a) Read DTS_TSCSDIF_SR register:
      The SDIF_LOCK flag must be low, indicating SDIF automatic mode has not been enabled.
      Before proceeding further, make sure the serial data interface is inactive by checking that the SDIF_BUSY flag is low.
   b) Write DTS_TSCSDIF_CR register to fetch the remote slave SDA register value:
      SDIF_PROG = 0x1
      SDIF_WRN = 0x0
      SDIF_ADDR[2:0]: this bitfield selects the desired SDA register.
      SDIF_WDATA[23:0]: this bitfield is not used and can be set to any value.

Note: Once the SDIF_LOCK flag is set, the SDA registers become write-only and any read requests is ignored.

The read data value (SDIF_RDATA[23:0]) is also reflected in the DTS_TSnSDIFRDATAR *register.*

   c) Read the SDA register value from the DTS_TSnSDIFRDATAR register*s*.

Run once

1. STEP 1:
   a) Read DTS_TSCSDIF_SR register:
      The SDIF_LOCK flag is low indicating that the SDIF automatic sample mode is not enabled.
      Verify that the serial data interface is not in use by checking that the SDIF_BUSY flag is low.
   b) Write DTS_TSCSDIF_CR register:
      SDIF_PROG = 0x1
      SDIF_WRN = 0x1
      SDIF_ADDR[2:0] = 0x0 to select the SDATS_CR register
      SDIF_WDATA[23:0] = 0x000104 to assert TS_AUTO and the self-clearing TS_RUN_ONCE bits
2. STEP 2: Wait for a sample done IRQ
   a) Read the DTS_TSnSDIFDONER register:
      Verify that one or more SDATS_DR registers have been updated by checking that the SDIF_SMPL_DONE flags are set to 0x1.
   b) Read the DTS_TSCSMPLCNTR register:
      The sample counter value contained in DTS_TSCSMPLCNTR increments whenever TS data (TS_DATA[23:0]) are updated.
   c) Read the DTS_TSnSDIFRDATAR register:
      Read the TS sample data, type and fault values.
      If the fault bit is set, the sample data value is unreliable, and must be discarded.
      The SDIF_SMPL_DONE flag in the DTS_TSnSDIFDONER register is automatically cleared when the SDATS_DR register is read.

Continuous run

1. STEP 1
   a) Read DTS_TSCSDIF_SR register:
      The SDIF_LOCK flag is low to indicate that the SDIF automatic sample mode is not enabled.
      Verify that the serial data interface is not in use by checking that the SDIF_BUSY flag is low.
   b) Write DTS_TSCSDIF_CR register:
      SDIF_PROG = 0x1
      SDIF_WRN = 0x1
      SDIF_ADDR[2:0] = 0x0
      SDIF_WDATA[23:0] = 0x000108 (value to assert TS_AUTO and the run continuous TS_RUN_CONT bits)
2. STEP 2: Wait for a sample done IRQ
   a) Read the DTS_TSnSDIFDONER register:
      Verify that the SDATS_DR registers have been updated by checking that the sample done SDIF_SMPL_DONE flags are set to 0x1.
   b) Read DTS_TSCSMPLCNTR register:
      The sample counter increments whenever the DTS_TSnSDIFRDATAR value is updated.
   c) Read DTS_TSnSDIFRDATAR register:
      Read the TS sample data, type and fault values.
      If the fault bit is set, the sample data value is unreliable, and must be discarded.
      The SDIF_SMPL_DONE flag in the DTS_TSnSDIFDONER register is automatically cleared when the SDATS_DR register is read.

33.3.7 Temperature sensor configuration

The temperature sensor can be configured through the internal register *SDA TS configuration register (SDATS_CFGR)*.

Selecting the conversion mode

The sensor operates only in a single mode to read the temperature value. This mode is selected by setting SDATS_CFGR[3:0] bits to 0b0001.

The temperature value is obtained using the formula provided in *Calculating the temperature*. It does not require any calibration.

Configuring the output options

The conversion time can be configures through SDATS_CFGR[7:5] bits. It can be shortened to reduce the counter output value with the drawback of degrading the temperature measurement accuracy (see *Table 264*).

The output data are available in the TS_DATA[15:0] bitfield of the SDATS_DR register.

Data can be output in parallel or serial mode depending on the setting of SDATS_CFGR[4] bit:

- 0: parallel output

  All the data bits are sent simultaneously through TS_DATA[11:0].
- 1: serial output (default mode)

  The data are sent serially on bit 11 of the TS_DATA bitfield.

  Serial data are always 12-bit wide whatever the output options. Using a lower resolution (such as 10 bits) results in similar output values with trailing zeroes.

Table 264. Output resolution configuration

Resolution	SDATS_CFGR[7:5] bits	Accuracy degradation	Comments
12 bits	0b000	-	Temperature value available on TS_DATA[11:0]
10 bits	0b001	±0.4 °C	Temperature value available on TS_DATA[11:2]
8 bits	0b010	±1.5 °C	Temperature value available on TS_DATA[11:4]
Others not allowed	0b011	-	Not allowed
	0b1XX	-	Not allowed

Calculating the temperature

The digital output is converted to an uncalibrated temperature value by using the following formula:

$$\text{Temp (°C)} = G + H \times \text{Eqbs} + J \times F_{clk_ts}$$

Where:

Temp = Temperature in degrees Celsius

Eqbs = Nbs/Cal5 – 0.5, Nbs being the digital output, TS_DATA[11:0], latched after conversion

F_{clk_ts} = Temperature sensor SDA clock frequency (in MHz)

For G, H, J and Cal5 values, please refer to device datasheet"

Configuring the triggers

Triggers can be configured through bits 18 to 16 (TRIG[2:0]) of the SDATS_CFGR register:

TRIG[2:0] = 0b001: dts_trg[0] is selected.

TRIG[2:0] = 0b010: dts_trg[1] is selected.

TRIG[2:0] = 0b011: dts_trg[2] is selected.

TRIG[2:0] = 0b100: dts_trg[3] is selected.

Disabling the clock

The TS clock can be disabled by setting the CLKDIS of the SDATS_CFGR, when the TS is not used and it does not operate in automatic mode.

33.4 DTS interrupts

The DTS provides a single active high (level) hardware interrupt output from the controller. This is the logical OR of all the embedded TS interrupt sources and the common delay timer.

The enabling, masking, and status of the interrupts are readily available through the IRQ control registers. The interrupts from each TS instance are coalesced into a single interrupt, the status of which can be observed through the DTS_TSn_ISR register. The index number of a set bit indicates the source TS number with an interrupt condition.

Each TS block can generate an interrupt based on the following sources:

- The irq_smpl indicates that sample data have been updated for the corresponding TS instance.
- The irq_alarma indicates that the recovered sample value has exceeded the programmed alarm A threshold for the corresponding TS instance.
- The irq_alarmb indicates that the recovered sample value has exceeded the programmed alarm B threshold for the corresponding TS instance.
- The irq_fault indicates that the corresponding TS instance has signaled a fault.

When an interrupt event occurs, the rising edge is detected and the corresponding flag is set in the interrupt source register, DTS_TSn_ISR. The IRQ status bits are individually gated (logical AND) with their corresponding interrupt enabled in the DTS_TSn_IER register to generate interrupt request bits. These IRQ bits are then ORed together and registered by ck_ker_dts to generate the interrupt outputs for IRQ control registers.

Once set the interrupt source bits are sticky, they must be cleared by writing a 1 to the corresponding bit of the DTS_TSn_ICR register. This also clears the associated IRQ if it has been enabled.

Interrupt events are triggered when the following flags are asserted or the force bits in the DTS_TSnIRQTESTR register are set. The forcing allows interrupts to be manually generated for software test purposes.

- irq_smpl: asserted whenever a new TS data sample is recovered.
- irq_alarma: asserted whenever the alarm A thresholds have been reached.
- irq_alarmb: asserted whenever the alarm B thresholds have been reached.
- irq_fault: asserted whenever the TS block asserts its fault output.

Generally, the embedded temperature sensors run continuously relying on their alarms to signal out-of-bounds conditions. The user would usually disable the sample done flags for these TS types unless they wish to log every data sample.

Table 265. DTS interrupts

Interrupt event	Event flag	Enable control bit	Interrupt clear method
irq_smpl	IRQ_STATUS_DONE	IRQ_EN_DONE	IRQ_CLEAR_DONE
irq_alarma	IRQ_STATUS_ALARMA	IRQ_EN_ALARMA	IRQ_CLEAR_ALARMA

Table 265. DTS interrupts

Interrupt event	Event flag	Enable control bit	Interrupt clear method
irq_alarmb	IRQ_STATUS_ALARMB	IRQ_EN_ALARMB	IRQ_CLEAR_ALARMB
irq_fault	IRQ_STATUS_FAULT	IRQ_EN_FAULT	IRQ_CLEAR_FAULT

33.5 DTS registers

The APB interface supports 32-bit word aligned addresses (byte access is not supported).

The memory map contains a mixture of read-only, read-write, and write-only register fields. The write-only bits are self-clearing bits that are generally used to create strobes. Reserved register fields and any undefined register addresses are read-only and return zero when read.

Table 266 shows the DTS memory map overview.

Table 266. DTS register memory map

Address boundary	Register bank	Register block size	Address locations	Description
0x0000 - 0x003F	PVT common registers	0x40	16	PVT common registers
0x0040 - 0x007F	PVT interrupt registers	0x40	16	PVT interrupt registers
0x0080 - 0x00BF	TS common registers	0x40	16	TS common registers
0x00C0 - 0x00FF	TS 0 individual registers	0x40	16	TS0 dedicated registers (such as IRQ, alarms and samples)
0x0100 - 0x013F	TS 1 individual registers	0x40	16	TS1 dedicated registers (such as IRQ, alarms and samples)

33.5.1 DTS PVT common registers

The PVT common registers are used to configure the timer and read back the lock status.

DTS PVT register lock register (DTS_PVTREG_LOCKR)

The DTS can be locked by software using the DTS_PVTREG_LOCKR register. Any write to the register locks all DTS registers except for the PVT common registers.

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **LOCK[31:0]:** PVT software lock register
Any write to this register locks all DTS registers except for the PVT common registers. Once locked, the DTS registers are read-only. The software lock can be removed by writing 0x1ACC E551.

DTS PVT lock status register (DTS_PVTLOCK_SR)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HW_LOCK_STATUS	SW_LOCK_STATUS
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **HW_LOCK_STATUS:** Hardware lock input status
This bit indicates the status of the hardware lock input to the PVT controller.

Bit 0 **SW_LOCK_STATUS:** Software lock input status
This bit indicates the current state of the lock register.

DTS PVT timer control register (DTS_PVTTMR_CR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_RUN
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TMR_DELAY[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **TMR_RUN:** Timer count enable bit
This bit enables the timer count function.

Bits 15:0 **TMR_DELAY[15:0]:** Timer delay
This bitfield can be used to configure the timer delay.

DTS PVT timer status register (DTS_PVTTMR_SR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_DONE	TMR_BUSY
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TMR_DONE:** Counter delay expiration flag
This bit is set when the counter delay has expired.

Bit 0 **TMR_BUSY:** Counter busy flag
This bit is set while the counter is active.

33.5.2 PVT IRQ registers

The PVT IRQ registers are present in all build configurations of the PVT controller.

DTS PVT IRQ enable register (DTS_PVT_IER)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS_IRQ_ENABLE	TMR_IRQ_ENABLE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TS_IRQ_ENABLE:** TS IRQ source enable bit
Set this bit to enable the TS IRQ to the processor.

Bit 0 **TMR_IRQ_ENABLE:** Timer IRQ source enable bit
Set this bit to enable the timer IRQ to the processor.

DTS PVT IRQ timer mask register (DTS_PVTIRQTRMASKR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_IRQ_MASK
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TMR_IRQ_MASK:** Timer IRQ source mask bit
Set this bit to mask the timer IRQ to the processor.

DTS PVT IRQ TS mask register (DTS_TS_MR)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_IRQ_MASK	TS0_IRQ_MASK
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TS1_IRQ_MASK:** TS1 IRQ source mask bit
Set this bit to mask TS1 IRQ to the processor.

Bit 0 **TS0_IRQ_MASK:** TS0 IRQ source mask bit
Set this bit to mask TS0 IRQ to the processor.

DTS PVT IRQ timer status register (DTS_PVTTR_SR)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_IRQ_STATUS
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TMR_IRQ_STATUS:** Timer IRQ status bit after masking
This bit reflects the timer IRQ status after the mask has been applied.

DTS PVT IRQ TS status register (DTS_TS_ISR)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_IRQ_STATUS	TS0_IRQ_STATUS
														r	r

Bits 2 Reserved, must be kept at reset value.

Bit 1 **TS1_IRQ_STATUS:** TS1 IRQ status bit after masking
This bit reflects the timer IRQ status after the mask has been applied.
Note: The bit is set when the corresponding TS block has issued an IRQ interrupt to the processor.

Bit 0 **TS0_IRQ_STATUS:** TS0 IRQ status bit after masking
This bit reflects the timer IRQ status after the mask has been applied.
Note: The bit is set when the corresponding TS block has issued an IRQ interrupt to the processor.

DTS PVT IRQ timer raw status register (DTS_PVTTMRRAW_ISR)

Address offset: 0x070

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_IRQ_RAW_STATUS
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TMR_IRQ_RAW_STATUS:** TMR IRQ status bit before masking
This bit reflects the timer IRQ status before the mask is applied.

DTS PVT IRQ TS raw status register (DTS_TSRAW_ISR)

Address offset: 0x074

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_IRQ_RAW_STATUS	TS0_IRQ_RAW_STATUS
														r	r

Bits 2 Reserved, must be kept at reset value.

Bit 1 **TS1_IRQ_RAW_STATUS:** TS1 IRQ status bit before masking
This bit reflects the timer IRQ status before the mask is applied.

Bit 0 **TS0_IRQ_RAW_STATUS:** TS0 IRQ status bit before masking
This bit reflects the timer IRQ status before the mask is applied.

33.5.3 TS common registers

DTS TSC clock synthesizer register (DTS_TSCCLKSYNTHR)

Address offset: 0x080

Reset value: 0x0001 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLK_SYTH_EN	Res.	Res.	Res.	Res.	CLK_SYNTH_HOLD[3:0]			
							rw					rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLK_SYNTH_HI[7:0]								CLK_SYNTH_LO[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **CLK_SYTH_EN:** Synthesized clk_ts enable bit
0: Disabled
1: Enabled

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CLK_SYNTH_HOLD[3:0]:** SDA master-to-SDA slave output hold delay/SDA slave-to-SDA master input setup delay
The delay is counted from the rising edge of clk_ts. It is expressed in units of ck_ker_dts cycles. The default value is 0b0001.

Bits 15:8 **CLK_SYNTH_HI[7:0]:** Synthesized clk_ts high period
This is a zero-Indexed value expressed in units of ck_ker_dts cycles.

Bits 7:0 **CLK_SYNTH_LO[7:0]:** Synthesized clk_ts low period
This is a zero-Indexed value expressed in units of ck_ker_dts cycles.

DTS TSC SDIF interface disable register (DTS_TSCSDIFDISABLER)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_SDIF_DISABLE	TS0_SDIF_DISABLE
														rw	rw

Bits 2 Reserved, must be kept at reset value.

Bit 1 **TS1_SDIF_DISABLE:** TS1 serial data interface (SDIF) disable bit

When this bit is asserted, it completely disables TS1 instance by forcing TS1 clock and reset low.

0: Enabled

1: Disabled

Bit 0 **TS0_SDIF_DISABLE:** TS0 serial data interface (SDIF) disable bit

When this bit is asserted, it completely disables the selected TS0 instance by forcing TS0 clock and reset low.

0: Enabled

1: Disabled

Note: Any disable action must be applied before SDIF programming begins.

DTS TSC SDIF status register (DTS_TSCSDIF_SR)

Address offset: 0x088

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDIF_LOCK	SDIF_BUSY
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SDIF_LOCK:** SDIF locked flag

This bit is set when the slave automatic mode is requested, to indicate that the serial data interface (SDIF) is now a write-only interface (see *Section : SDA controller operation*).

In slave automatic mode, the data register (SDATS_DR) is automatically updated within the PVT controller whenever new TS data become available

0: Unlocked

1: Locked

Bit 0 **SDIF_BUSY:** SDIF busy flag

When asserted, this bit indicates either that the serial data interface (SDIF) is busy and any SDIF programming requests are ignored, or the clock synthesizer/disable SDIF state is being updated.

0: SDIF not busy/no clock synthesizer/disable SDIF state update ongoing

1: SDIF busy/clock synthesizer/disable SDIF state update ongoing

DTS TSC SDIF register (DTS_TSCSDIF_CR)

Address offset: 0x08C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SDIF_PROG	Res.	Res.	Res.	SDIF_WRN	SDIF_ADDR[2:0]			SDIF_WDATA[23:16]							
w				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDIF_WDATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SDIF_PROG:** Serial interface program request

This self-clearing bit is ignored if the SDIF_BUSY or the SDIF_LOCK flag is set, and the request is a read request (SDIF_WRN = 0).

0: No SDIF program request

1: SDIF program requested

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 **SDIF_WRN:** Serial interface write/no read control bit

0: SDIF read

1: SDIF write

Bits 26:24 **SDIF_ADDR[2:0]:** Serial interface register address

This bitfield contains the address of the target SDIF register, SDIF_ADDR[2:0].

Bits 23:0 **SDIF_WDATA[23:0]:** Serial interface write data

This bitfield contains the write data SDIF_DATA[23:0].

DTS TSC SDIF halt register (DTS_TSCSDIFHALTR)

Address offset: 0x090

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDIF_STOP
															w

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **SDIF_STOP:** Serial data interface (SDIF) stop
This self-clearing bit immediately stops all SDIF programming activity in the unlikely event of it becoming locked. It must not be required during normal operation.
0: Not stopped
1: Stopped

DTS TSC SDIF control register (DTS_TSCSDIF_CFGR)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDIF_INHIBIT[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **SDIF_INHIBIT[1:0]:** Serial data interface (SDIF) programming inhibit
When asserted, this bit inhibits the serial programming of the selected TS instance(s). The inhibition must be applied before SDIF programming begins.
00: No Inhibition
01: TS0 inhibited/TS1 serial programming activated (SPA)
10: TS1 inhibited/TS0 serial programming activated (SPA)
11: TS1 and TS0 inhibited

DTS TSC sample control register (DTS_TSCSMPL_CR)

Address offset: 0x0A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SMPL_DISCARD	SMPL_CTR_HOLD	SMPL_CTR_DISABLE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **SMPL_DISCARD:** Sample discard bit

This feature can be used to temporarily discard received data samples. When this bit is set, data recovery is disabled but the external TS may continue running.

0: Data samples not discarded

1: Data samples discarded

Bit 1 **SMPL_CTR_HOLD:** Sample counter hold bit

When this bit is asserted, the sample counter is prevented from rolling over when the maximum sample count is reached.

0: Counter not on hold

1: Counter on hold

Bit 0 **SMPL_CTR_DISABLE:** Sample counter disable bit

0: Sample counter enabled

1: Sample counter disabled

DTS TSC sample clear register (DTS_TSCSDIFSMPLCLRR)

Address offset: 0x0A4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SMPL_CNTER_CLEAR
															w

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **SMPL_CNTER_CLEAR:** Sample counter clear bit

The sample counter value is set to zero when this self-clearing bit is programmed to 1.

0: Counter value not cleared

1: Counter value cleared

DTS TSC sample count register (DTS_TSCSMPLCNTR)

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMPL_COUNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SMPL_COUNT[15:0]:** Sample counter

The 16-bit counter increments each time a new data sample is available. The counter is cleared by writing 1 to DTS_TSCSDIFSMPLCLRR. The sample counter overflow operation is determined by SMPL_CTR_HOLD.

33.5.4 TS individual registers

DTS TSn IRQ enable register (DTS_TSn_IER)

Address offset: 0x0C0 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IRQ_EN_ALARMB	IRQ_EN_ALARMA	Res.	IRQ_EN_DONE	IRQ_EN_FAULT
											rw	rw		rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **IRQ_EN_ALARMB:** Alarm B IRQ enable bit

Bit 3 **IRQ_EN_ALARMA:** Alarm A IRQ enable bit

Bit 2 Reserved, must be kept at reset value.

Bit 1 **IRQ_EN_DONE:** Sample done IRQ enable bit

Bit 0 **IRQ_EN_FAULT:** Fault IRQ enable bit

DTS TSn IRQ status register (DTS_TSn_ISR)

Address offset: 0x0C4 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											r	r		r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **IRQ_STATUS_ALARMB:** Alarm B IRQ status bit

Bit 3 **IRQ_STATUS_ALARMA:** Alarm A IRQ status bit

Bit 2 Reserved, must be kept at reset value.

Bit 1 **IRQ_STATUS_DONE:** Sample done IRQ status bit

Bit 0 **IRQ_STATUS_FAULT:** Fault IRQ status bit

DTS TSn IRQ clear register (DTS_TSn_ICR)

Address offset: 0x0C8 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											w	w		w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **IRQ_CLEAR_ALARMB:** Alarm B IRQ clear bit

Bit 3 **IRQ_CLEAR_ALARMA:** Alarm A IRQ clear bit

Bit 2 Reserved, must be kept at reset value.

Bit 1 **IRQ_CLEAR_DONE:** Sample done IRQ clear bit

Bit 0 **IRQ_CLEAR_FAULT:** Fault IRQ clear bit

DTS TSn IRQ test register (DTS_TSnIRQTESTR)

Address offset: 0x0CC + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw		rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **IRQ_TEST_ALARMB:** Alarm B IRQ test bit

Bit 3 **IRQ_TEST_ALARMA:** Alarm A IRQ test bit

Bit 2 Reserved, must be kept at reset value.

Bit 1 **IRQ_TEST_DONE:** Sample done IRQ test bit

Bit 0 **IRQ_TEST_FAULT:** Fault IRQ test bit

DTS TSn SDIF RDATA register (DTS_TSnSDIFRDATAR)

Address offset: 0x0D0 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDIF_RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **SDIF_RDATA[23:0]:** SDIF read data

DTS TSn SDIF done register (DTS_TSnSDIFDONER)

Address offset: 0x0D4 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDIF_SMPL_DONE
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **SDIF_SMPL_DONE:** Sample done flag

The sample done flag is asserted when a new data sample is available. The sample done flag is automatically cleared when the associated data register is read.

0: No new data sample available

1: New data sample available

DTS TSn SDIF data register (DTS_TSnSDIFDATAR)

Address offset: 0x0D8 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SAMPLE_DATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SAMPLE_FAULT:** Sample fault

This bit is set to indicate that the TS block has signaled a fault. The sample data must be discarded.

Bit 16 **SAMPLE_TYPE:** TS sample type

0: Indicates valid data

1: Indicates either analog access, signature select or fault debug mode

The TS_TYPE flag is updated when new data are received.

Bits 15:0 **SAMPLE_DATA[15:0]:** Sample data.

Reading this register clears the state of the SDIF_SMPL_DONE flag in DTS_TSnSDIFDONER register.

DTS TSn alarm A configuration register (DTS_TSnALARMA_CFGR)

Address offset: 0x0E0 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SMPL_HI_CLR	SMPL_LO_SET
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SMPL_HI_CLR:** Sample high clear 0

All the bits of the stored sample high value are initialized to 0 when written.

Bit 0 **SMPL_LO_SET:** Sample Low Set

All the bits of the stored sample low value are initialized to 1 when written.

34 Voltage reference buffer (VREFBUF)

34.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for the on-chip ADCs, and also as voltage reference for external components through the VREF+ pin.

34.2 VREFBUF implementation

The table below describes the VREFBUF voltages typical values:

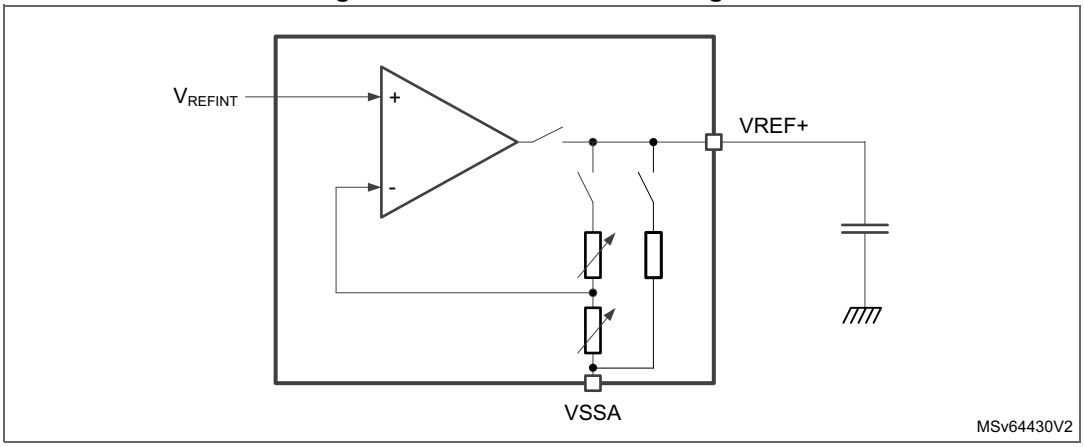
Table 271. VREFBUF typical values

Symbol	Value
VREFBUF0	1.21 V
VREFBUF1	1.5 V

Note: Refer to the product datasheet for more details.

34.3 VREFBUF functional description

Figure 319. VREFBUF block diagram



The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference V_{REFINT}. The VREFBUF supports two voltages[a], which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: VREFBUF0 voltage selected
- VRS = 001: VREFBUF1 voltage selected

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

Table 272. VREF buffer modes

ENVR	HIZ	VREF buffer configuration
0	0	VREFBUF buffer off mode: – V_{REF+} pin pulled-down to V_{SSA}
0	1	External voltage reference mode (default value): – VREFBUF buffer off – V_{REF+} pin input mode
1	0	Internal voltage reference mode: – VREFBUF buffer on – V_{REF+} pin connected to VREFBUF buffer output
1	1	Hold mode: – VREF is enable without output buffer, VREF+ pin voltage is hold with the external capacitor – VRR detection disabled and VRR bit keeps last state

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

34.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

a. The minimum V_{DDA} voltage depends on VRS setting, refer to the product datasheet.

34.5 VREFBUF power sequence

While VREFBUF is activated, V_{DDA} supply changing from 1.8 V to 0 V can cause large current flowing from the V_{REF+} output capacitor to the V_{DDA} power domain through on-chip parasitic resistance. To avoid this current, the following procedure is required:

- While V_{DDA} is available, configure VREFBUF in buffer off mode.
- Wait for V_{REF+} to discharge (through internal pull-down) to less than 100 mV (typically 1 ms, depending on the capacitor value).
- Switch off V_{DDA} supply to 0 V.

34.6 VREFBUF registers

34.6.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VRS[2:0]			VRR	Res.	HIZ	ENVR
									rw	rw	rw	r		rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

VRS = 000: VREFBUF0 voltage selected.

VRS = 001: VREFBUF1 voltage selected.

Others: Reserved

Note: Refer to the product datasheet for each VREFBUFx voltage setting value.
The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).

Bit 3 **VRR:** Voltage reference buffer ready

0: the voltage reference buffer output is not ready.

1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ:** High impedance mode

This bit controls the analog switch to connect or not the V_{REF+} pin.

0: V_{REF+} pin is internally connected to the voltage reference buffer output.

1: V_{REF+} pin is high impedance.

Refer to *Table 272: VREF buffer modes* for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR:** Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.

0: Internal voltage reference mode disable (external voltage reference mode).

1: Internal voltage reference mode (reference buffer enable or hold mode) enable.

34.6.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRIM[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **TRIM[5:0]**: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

Reset:

TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the OTP memory during the production test.

VRS change:

TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the OTP memory during the production test.

Write in TRIM[5:0]:

User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

34.6.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Table 273. VREFBUF register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Reset value																											x	x	x	x	x	x

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

35 Multi-function digital filter (MDF)

35.1 MDF introduction

The multi-function digital filter (MDF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- motor control
- metering

The MDF features 6 digital serial interfaces (SITFx) and digital filters (DFLTx) with flexible digital processing options to offer up to 24-bit final resolution.

The DFLTx of the MDF also include the filters of the audio digital filter (ADF).

The MDF can receive, via its serial interfaces, streams coming from various digital sensors.

The MDF supports the following standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

A flexible bitstream matrix (BSMX) allows the connection of any incoming bitstream to any filter.

The MDF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition it is possible to insert a high-pass filter or a DC offset correction block.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, decimation ratio, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible trigger interface can be used to control the conversion start. This timing control can trigger simultaneous conversions or insert a programmable delay between conversions.

The MDF features an out-off limit detectors (OLD) function. There is one OLD for each digital filter chain. Independent programmable thresholds are available for each OLD, making it very suitable for over-current detection.

A short circuit detector (SCD) is also available for every selected bitstream. The SCD is able to detect a short-circuit condition with a very short latency. Independent programmable thresholds are offered in order to define the short circuit condition.

The digital processing is performed using only the kernel clock. The MDF requests the bus interface clock (AHB clock) only when data must be transfered or when a specific event requests the attention of the system processor.

35.2 MDF main features

- AHB interface
- 6 serial digital inputs:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- Flexible matrix (BSMX) for connection between filters and digital inputs
- 2 inputs to connect the internal ADCs
- 6 flexible digital filter paths, including:
  - A configurable CIC filter:
    - Can be split into 2 CIC filters: high-resolution filter and out-off limit detector
    - Can be configured in $Sinc^4$ filter
    - Can be configured in $Sinc^5$ filter
    - Adjustable decimation ratio
  - A reshape filter to improve the out-off band rejection and in-band ripple
  - A high-pass filter to cancel the DC offset
  - An offset error cancellation
  - Gain control
  - Saturation blocks
  - An out-off limit detector
- Short-circuit detector
- Clock absence detector
- 16- or 24-bit signed output data resolution
- Continuous or single conversion
- Possibility to delay independently each bitstream
- Various trigger possibilities
- Break generation on out-of limit or short-circuit detector events
- Autonomous functionality in Stop mode(s)
- DMA can be used to read the conversion data
- Interrupts services

35.3 MDF implementation

The devices embed one MDF instance and one ADF instance, both being digital filters with common features.

Table 274. MDF features (1)

Modes or features	MDF1
Number of filters (DFLT) and serial interfaces (SITF)	6
MDF_CKI[x] connected to pads	X

Table 274. MDF features (1) (continued)

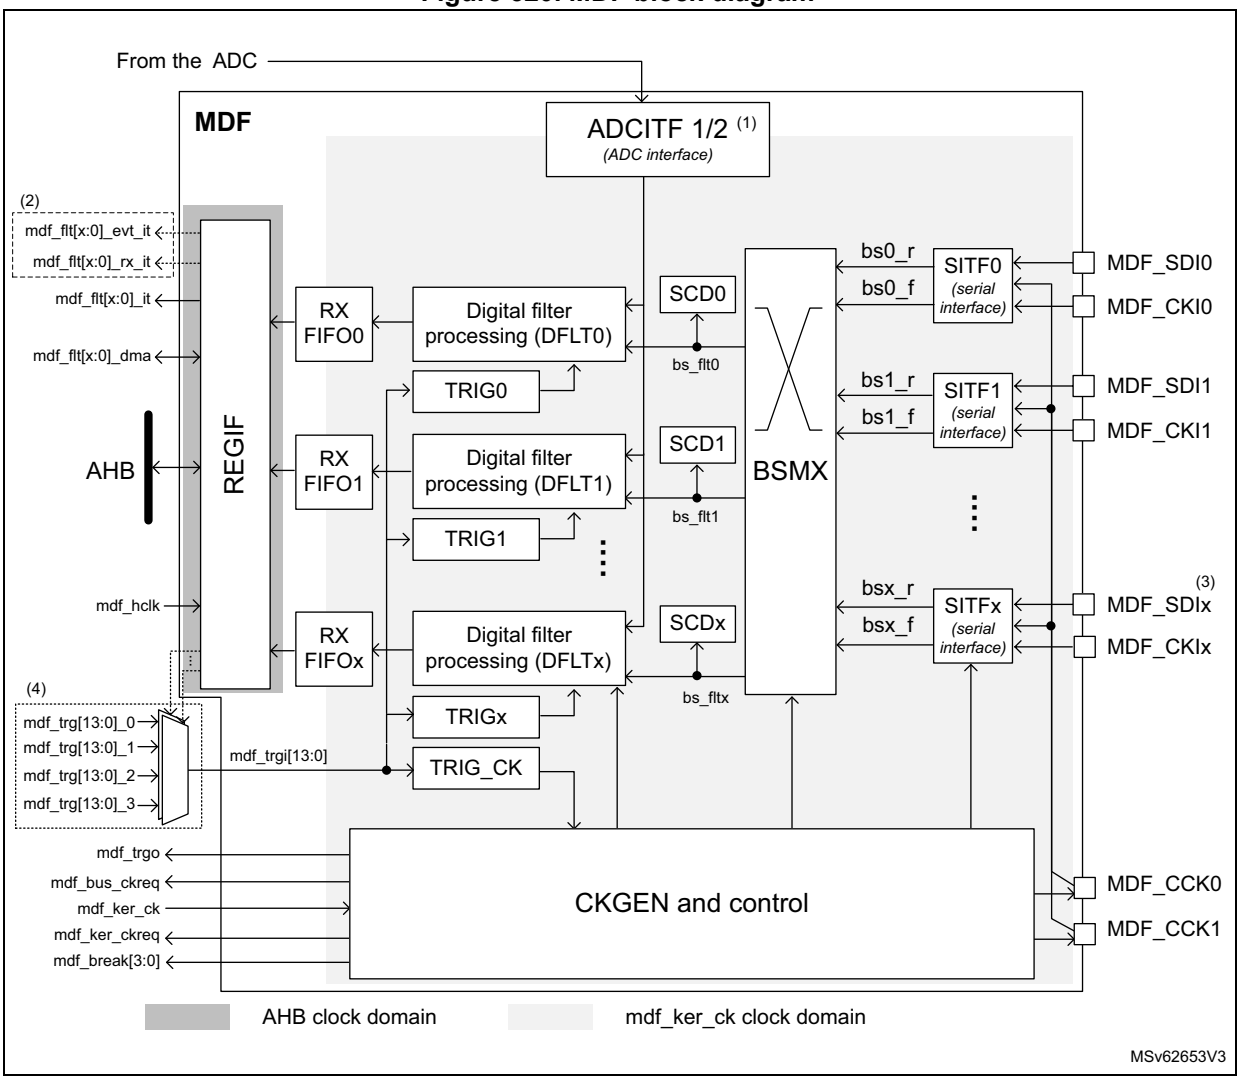
Modes or features	MDF1
Sound Activity Detection (SAD)	-
RXFIFO depth (number of 24-bit words)	4
Number of trigger inputs	14
ADC connected to ADCITF1	ADC1
ADC connected to ADCITF2	ADC2
Motor dedicated features (SCD, OLD, OEC, INT, snapshot, break)	X
Main path with CIC4, CIC5	X
Main path with CIC1,2, 3 or FastSinc	X
RSFLT, HPF, SAT, SCALE, DLY, Discard functions	X
Global Interrupts MDF_FLT[0:0] (mdf_it[0:0])	X
Receive interrupts MDF_RX[0:0] (mdf_rx_it[0:0])	-
Event interrupts MDF_EVT[0:0] (mdf_evt_it[0:0])	-
Autonomous in Stop mode	X(2)
Only DMA of filter 0 connected	-
All DMA channels connected	X

1. 'X' = supported, '-' = not supported.
2. Only in Stop SVOS high mode.

35.4 MDF functional description

35.4.1 MDF block diagram

Figure 320. MDF block diagram



1. Refer to *Section 35.3: MDF implementation* to check if the ADCITF is available, and which ADCs are connected.
2. Not always implemented, refer to the vector table of the product for details.
3. Refer to *Section 35.3: MDF implementation* to check the number of filter instances available.
4. The number of trigger inputs depends on the product. Refer to *Section 35.3: MDF implementation* for details.

35.4.2 MDF pins and internal signals

Table 275. MDF external pins

Name	Signal type	Comment
MDF_CKIy (y = 0 to 5)(1)	Input	Dedicated clock signals from external sensors
MDF_SDIy (y = 0 to 5)(1)	Input	Data signal from external sensors
MDF_CCKy (y = 0, 1)	Input/output	Clock outputs for external sensor, or common clock input from external sensors

1. The number of inputs available depends on the number of filters. Refer to *Section 35.3* for details.

Table 276. MDF internal signals

Name	Signal type	Comment
mdf_trgi[13:0]	Input	Trigger inputs in order to control the acquisition (see *Table 277: MDF trigger connections* for details)
mdf_trgo	Output	Trigger output for synchronizing several MDFs
mdf_break[3:0]	Output	Break signals event generation from over-current detector or short-circuit detector (see the next table for details)
mdf_flt[5:0]_dma(1)	Input/output	DMA request/acknowledge signals for each filter processing chain
mdf_flt[5:0]_it(1)	Output	Global interrupt signals, for each MDF filter
mdf_flt[5:0]_rx_it(1)(2)	Output	Receive interrupt signals, for each MDF filter.
mdf_flt[5:0]_evt_it(1)(2)	Output	Event interrupt signals, for each MDF filter.
mdf_bus_ckreq	Output	Bus interface clock request output
mdf_ker_ckreq	Output	Kernel clock request output
mdf_ker_ck	Input	Kernel clock input
mdf_hclk	Input	AHB bus interface clock input
mdf_adcitf1_dat[15:0]	Input	ADCITF1 data input
mdf_adcitf2_dat[15:0]	Input	ADCITF2 data input

1. The number of signals available depends on the number of filters. Refer to *Section 35.3* for details.
2. Not always connected. See the interrupt vector table for details.

The table below shows the way the trigger inputs of the MDF are connected.

Table 277. MDF trigger connections

Trigger name	Trigger source
mdf_trgi0	EXTI15
mdf_trgi1	EXTI11
mdf_trgi2	tim1_trgo
mdf_trgi3	tim1_trgo2
mdf_trgi4	tim3_trgo

Table 277. MDF trigger connections (continued)

Trigger name	Trigger source
mdf_trgi5	tim4_trgo

mdf_trgi11	lptim1_ch1
mdf_trgi12	adf_sad_det signal (from ADF)
mdf_trgi13	adf_trgo signal (from ADF)
mdf_trgo	-

The table below shows the way the break outputs of the MDF are connected.

Table 278. MDF break connections

Trigger name	Trigger source
mdf_break0	tim1_brk_cmp[8]
mdf_break1	tim1_brk2_cmp[8]
mdf_break2	tim8_brk_cmp[8]
mdf_break3	tim8_brk2_cmp[8]

35.4.3 Serial input interfaces (SITF)

The SITFx input interfaces allow the connection of the external sensors to the digital filters, via the bitstream matrix (BSMX). The SITFx serial interface can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The amount of SITFx instances is equal to the amount of filters.

The data from each serial interface can be routed to any filter in order to perform:

- the PDM to PCM conversion
- the out-off limit detection
- the short detection

The serial interfaces are enabled by setting the corresponding SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external ΣΔ modulator.

Note: Before enabling the serial interface, the user must insure that the mdf_proc_ck is already enabled (see Section 35.4.5 for details).

The SITFx are controlled via the *MDF serial interface control register x (MDF_SITFxCR)*.

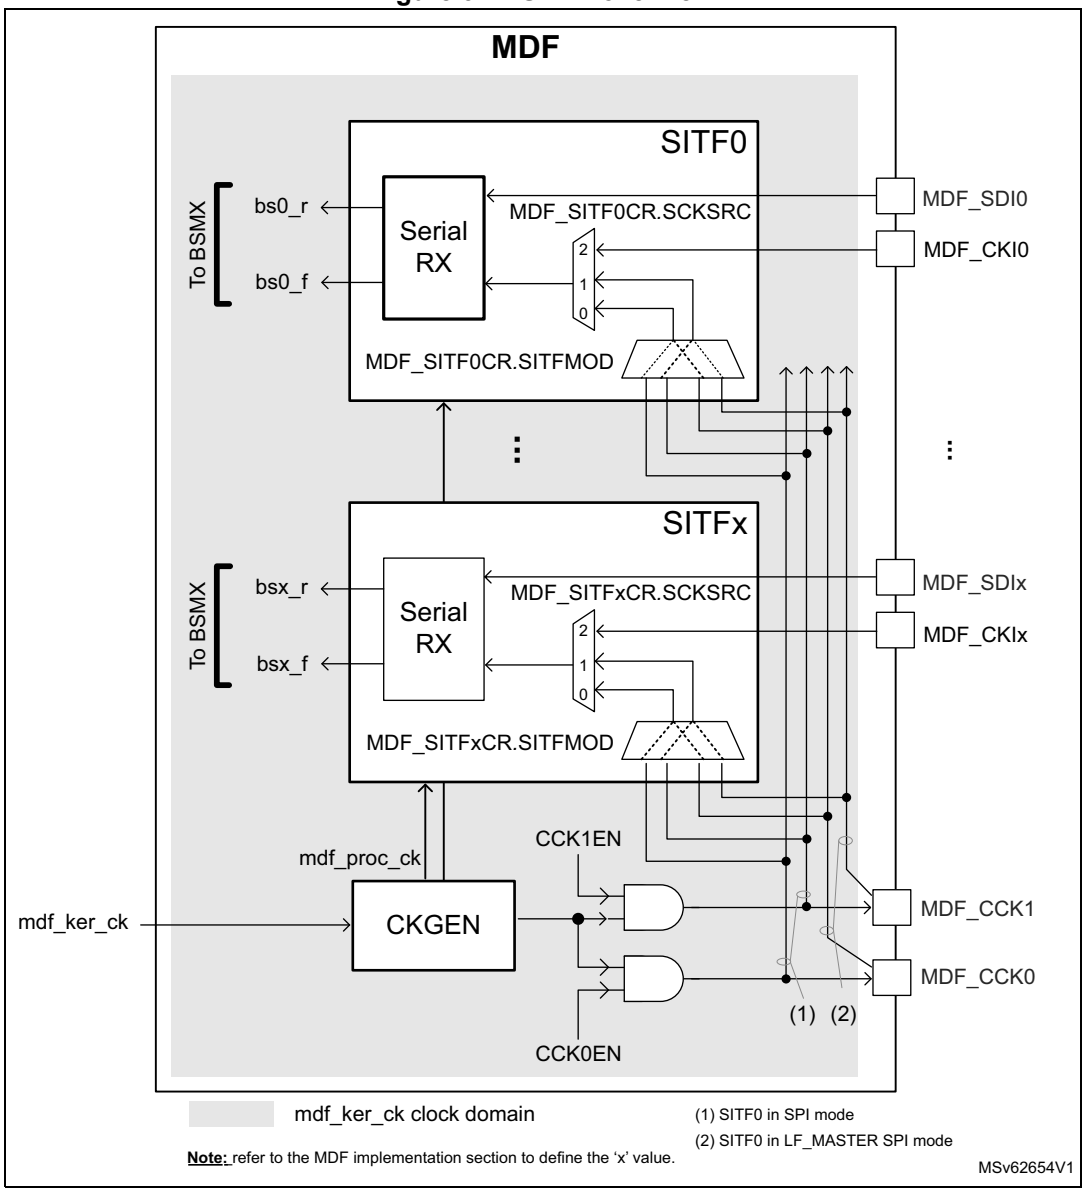
As shown in *Figure 321*, for each SITF, there is a large choice of clocking possibilities:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on MDF_CCK0 or MDF_CCK1 or MDF_CKIx pin (see 2 in *Figure 321*).
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source must be the clock directly provided by the CCKDIV to the MDF_CCK0 or MDF_CCK1 pin (see 1 in *Figure 321*). In this case MDF_CKIx must not be selected.

See *Table 279* for additional information.

Note: Using the common clock (MDF_CCK0 or MDF CCK1) can be helpful to share the same clock between several SITFx.

Figure 321. SITFx overview



LF_MASTER and normal SPI modes

The LF_MASTER SPI mode is a special mode allowing the usage of a mdf_proc_ck clock frequency, only two times higher than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

In LF_MASTER SPI mode, the MDF must provide the bitstream clock to the external sensors via MDF_CCK0 and MDF_CCK1 pins, and receives the bitstream data via the serial data input MDF_SDIx.

For each SITFx, the application must select the same clock than the one provided to the external sensor (MDF_CCK0 or MDF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

Warning: The MDF_CKIx pin cannot be used in LF_MASTER SPI mode.

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the mdf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select MDF_CCK0, MDF_CCK1 or MDF_CKIx clock for the capture of the data received via the MDF_SDIx pin.

The MDF can generate a clock to the sensors via MDF_CCK0 or MDF_CCK1 if needed.

For all SPI modes, all SITFs can share the same clock input (MDF_CCK0 or MDF_CCK1), in order to optimize the amount of requested I/Os.

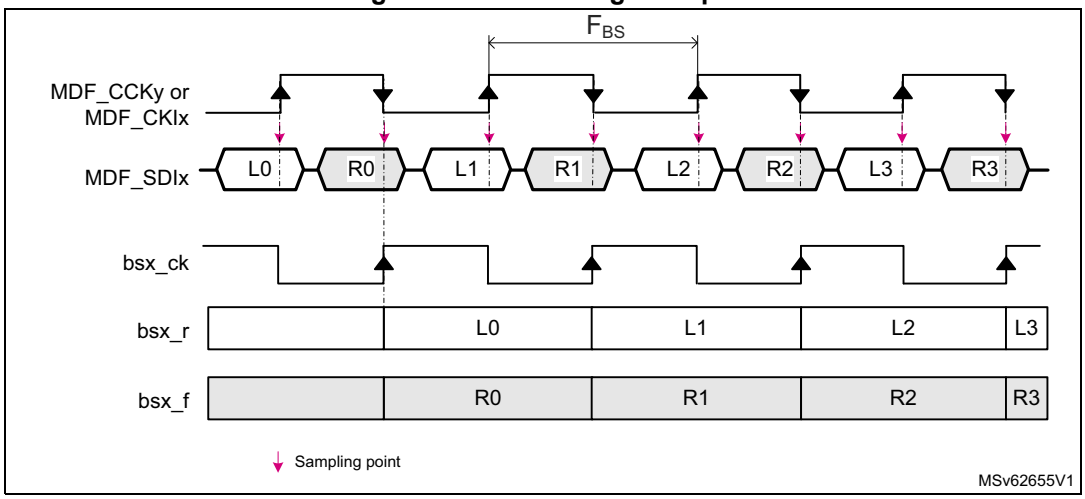
For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITFx always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bsx_f)
- bitstream received using the bitstream clock rising edge (bsx_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.

Figure 322. SPI timing example



To properly synchronize/receive the data stream, the frequency of the mdf_proc_ck clock must be adjusted according to the constraints listed in *Table 280*.

Clock absence detection

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] bitfield of the corresponding SITFx. If the MDF does not detect clock transitions for a duration of STH[4:0] x $T_{mdf_proc_ck}$, then the CKABF flag is set.

An interrupt can be generated if CKABIE is set to 1. The STH[4:0] bitfield is in the *MDF serial interface control register x (MDF_SITFxCR)*.

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.

   If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF i= 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

Note: The clock absence detection feature is not available in the LF_MASTER SPI mode.

Manchester mode

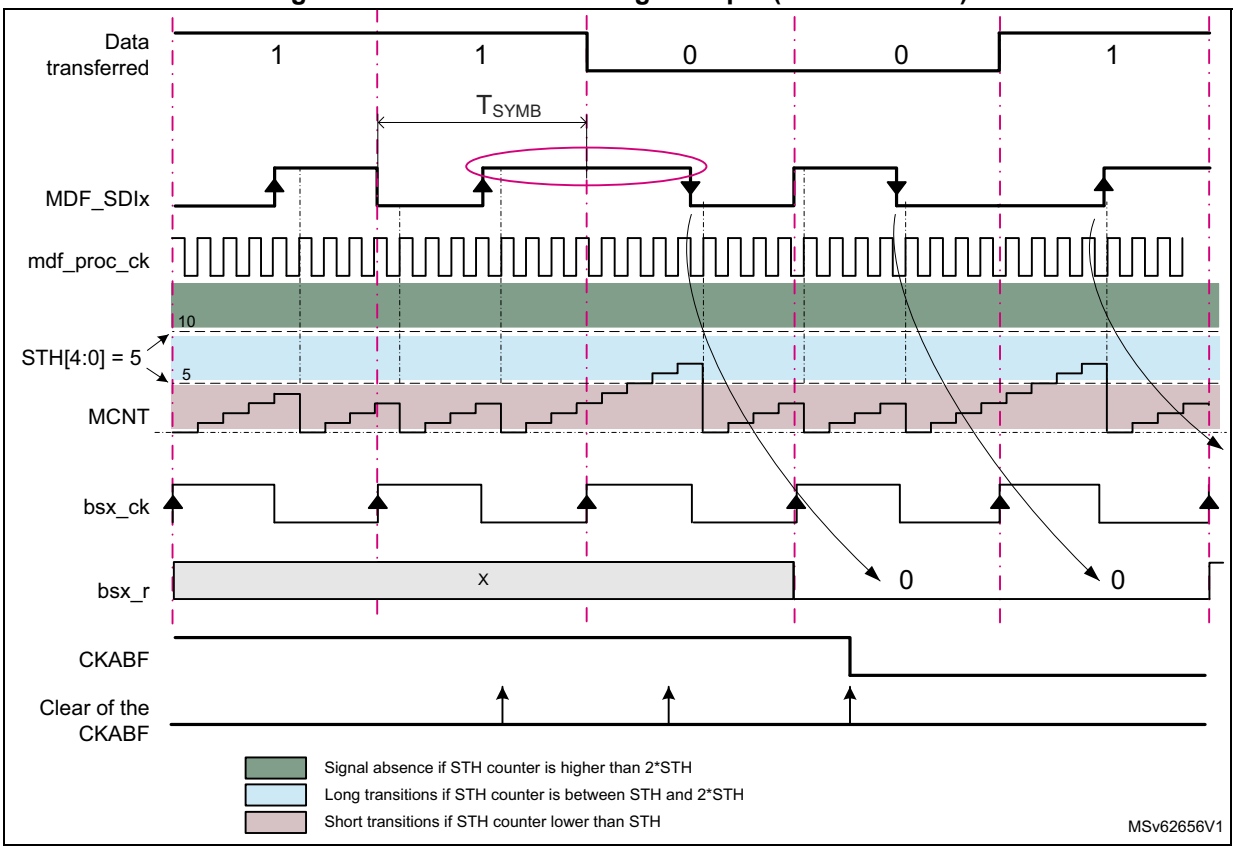
In Manchester coded format, the MDF receives data stream from the external sensor via the MDF_SDIx pin only.

The MDF_CKIx pins are not needed in this mode.

Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bsx_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0

Figure 323. Manchester timing example (SITFMOD = 11)



To decode the incoming Manchester stream, the user must program the STH[4:0] bitfield in the *MDF serial interface control register x (MDF_SITFxCR)*. The STH[4:0] bitfield is used by the SITFx to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the MDF_SDIx input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. *Figure 323* shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate (T_{SYMB}) must respect the following formula:

$$(STH + 1) \times T_{mdf_proc_ck} < T_{SYMB} < (2 \times STH \times T_{mdf_proc_ck})$$

It is recommended to compute STH as follows:

$$STH[4:0] = round\left(\frac{(2 \times OVR) - 1}{3}\right)$$

where OVR represents the ratio between the mdf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the mdf_proc_ck clock must be adjusted according to the constraints listed in *Table 280*.

The clock absence flag CKABF is set to 1 when no transition is detected during more than 2 x STH[4:0] x $T_{mdf_proc_ck}$, or when the SITFx is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.

When the serial interface is enabled, the MDF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the *Figure 323*) is detected.

The end of the synchronization phase can be checked by following the software sequence:

1. Clear the CKABF flag in the *MDF DFLTx interrupt status register x (MDF_DFLTxISR)* by writing CKABF bit to 1. If the serial interface is not yet synchronized, the hardware immediately sets the CKABF flag to 1.
2. Read the CKABF flag.
   – If CKABF = 1, go back to step 1.
   – If CKABF = 0, the Manchester interface is synchronized and provides valid data.

Programming example

In the following example, the MDF kernel clock frequency ($F_{mdf_ker_ck}$) is 100 MHz and the received Manchester stream is at about 6 MHz (F_{SYMB}).

1. Provide a valid mdf_proc_ck to the SITFx.

   The mdf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).

   PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, $F_{mdf_proc_ck}$ = 50 MHz (8.33 times higher than the Manchester symbol frequency).
2. Compute STH.

   OVR is given by: OVR = $F_{mdf_proc_ck}$ / F_{SYMB} = 50 MHz / 6 MHz = 8.33.

   Then STH[4:0] = $\text{round}\left(\frac{(2 \times 8.33) - 1}{3}\right) = 5$

   The minimum allowed frequency for the Manchester stream is then:

   1 / (2 × STH × $T_{mdf_proc_ck}$) = 1 / (10 x 20 ns) = 5 MHz

   The maximum allowed frequency for the Manchester stream is then:

   1 / ((STH+1) × $T_{mdf_proc_ck}$) = 1 / (6 x 20 ns) = 8.33 MHz

35.4.4 ADC slave interface (ADCITF)

The ADCs are not always connected to the MDF. Refer to *Section 35.3* to check the situation for this product.

The MDF allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] bitfield in the *MDF digital filter configuration register x (MDF_DFLTxCICR)* allows the application to select either data from the ADCs.

Warning: The MDF does not support receiving interleaved data from one of the ADCITF input.

35.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the MDF:

- AHB clock (mdf_hclk) used for the register interface
- kernel clock (mdf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the MDF_CCK0 and MDF_CCK1 pins. All those clocks are generated from the mdf_ker_ck.

The processing clock (mdf_proc_ck) is used to run all the signals processing and to re-sample the incoming serial or parallel stream.

Note: The reshape filter (RSFLT) needs up to 24 cycles of mdf_proc_ck clock to process a sample.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the MDF_CCK0 and MDF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).

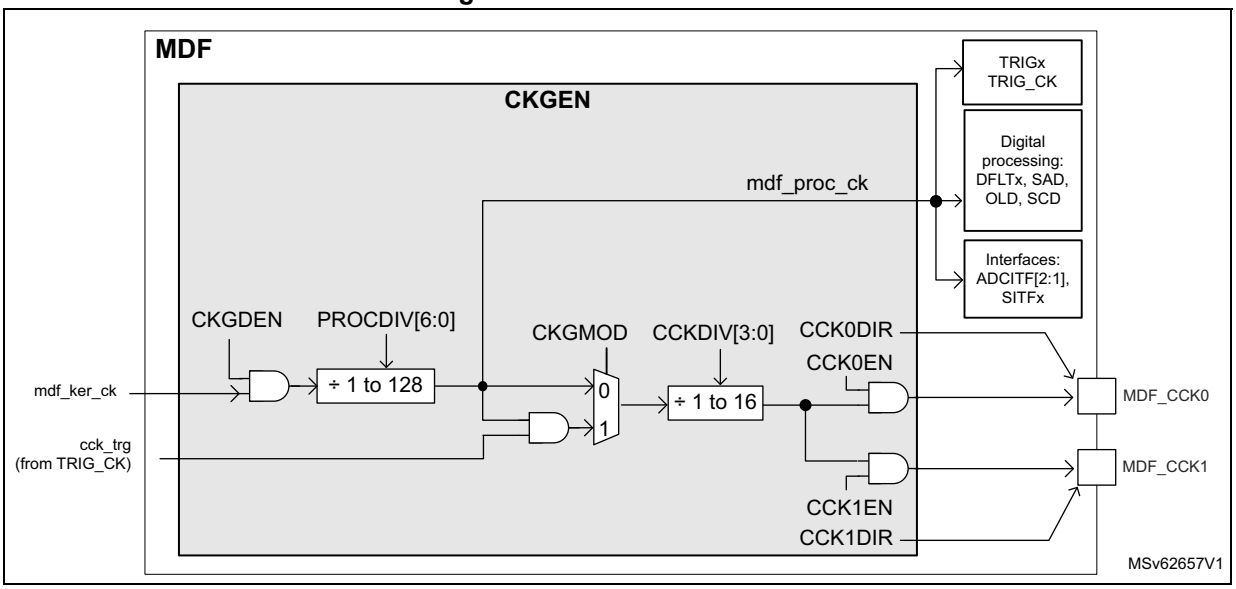
The mdf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All bits and fields controlling the CKGEN are in MDF_CKGCR.

Figure 324. CKGEN overview



The trigger logic for CKGEN is handled by the TRG_CK block. As shown in *Figure 333*, the CCKDIV divider can be triggered on the rising or falling edge of one of the 16 trigger sources. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the MDF_CCKy (y = 0,1) clock of several MDF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the MDF_CCK0 or MDF_CCK1 pin CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

Table 279. Control of the common clock generation(1)

CCKyEN	CCKyDIR	Description
0	0	The MDF_CCKy pin is in input. An external clock can be connected to the MDF_CCKy pin and used by the SITFx in order to decode the serial stream
0	1	The MDF_CCKy pin is in output. No clock is generated, thus the MDF_CCKy pin is driven low.
1	1	The MDF_CCKy pin is in output. A clock is generated on the MDF_CCKy pin. The SITFx can use this pin as clock source in order to decode the serial stream

1. The configuration with CCKyEN = 1 and CCKyDIR = 0 must be avoided (no interest).

When CCKyDIR = 1, as soon as the CCKyEN bit is set to 1, a clock is generated to the corresponding output without any spurs.

Note: The mdf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITFx or DFLTx).

CKGEN activation sequence example

1. Set CKGDEN to 0.
2. Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of mdf_hclk and two periods of mdf_proc_ck.
3. Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0] and TRGSENS.
4. Set CKGDEN to 1.
5. Set CCKxDIR to 1 (optional).
6. Set CCKxEN to 1 (optional).

When needed, at any moment, the CCK0EN or CCK1EN value can be changed without disabling the clock generator.

Clock frequency constraints

The table below shows the frequency constraints to receive and process properly the samples.

Table 280. Clock constraints with respect to the incoming stream(1)

SITFx mode	MDF clock constraints	
	With RSFLT disabled	With RSFLT enabled
LF_MASTER SPI	F_{MDF_CCKy} max frequency limited to 5 MHz	
	$F_{mdf_proc_ck} > 2 * F_{MDF_CCKy}$ and $F_{mdf_hclk} \geq F_{mdf_proc_ck}$	$F_{mdf_proc_ck} > 24 * F_{MDF_CCKy} / (MCICD+1)$ and $F_{mdf_proc_ck} > 2 * F_{MDF_CCKy}$ and $F_{mdf_hclk} \geq F_{mdf_proc_ck}$
MASTER SPI SLAVE SPI	F_{MDF_CKx} max frequency limited to 25 MHz	
	$F_{mdf_proc_ck} > 4 * F_{MDF_CKKy}$ and F_{mdf_hclk} higher or equal to $F_{mdf_proc_ck}$	$F_{mdf_proc_ck} > 24 * F_{MDF_CKKy} / (MCICD+1)$ and $F_{mdf_proc_ck}$ higher than 4 x F_{MDF_CKKy} and F_{mdf_hclk} higher or equal to $F_{mdf_proc_ck}$
Manchester	F_{SYMB} max frequency limited to 20 MHz	
	$F_{mdf_proc_ck}$ higher than 6 * F_{SYMB} and $F_{mdf_hclk} \geq F_{mdf_proc_ck}$	$F_{mdf_proc_ck}$ higher than 24 * $F_{MDF_CKKy} / (MCICD+1)$ and $F_{mdf_proc_ck} > 6 * F_{SYMB}$ and $F_{mdf_hclk} \geq F_{mdf_proc_ck}$

1. F_{MDF_CKKy} represents the frequency of the clock received via MDF_CKIx and MDF_CCKy, or generated via MDF_CCKy.F_{SYMB} represents the frequency of the received symbol rate for Manchester mode.

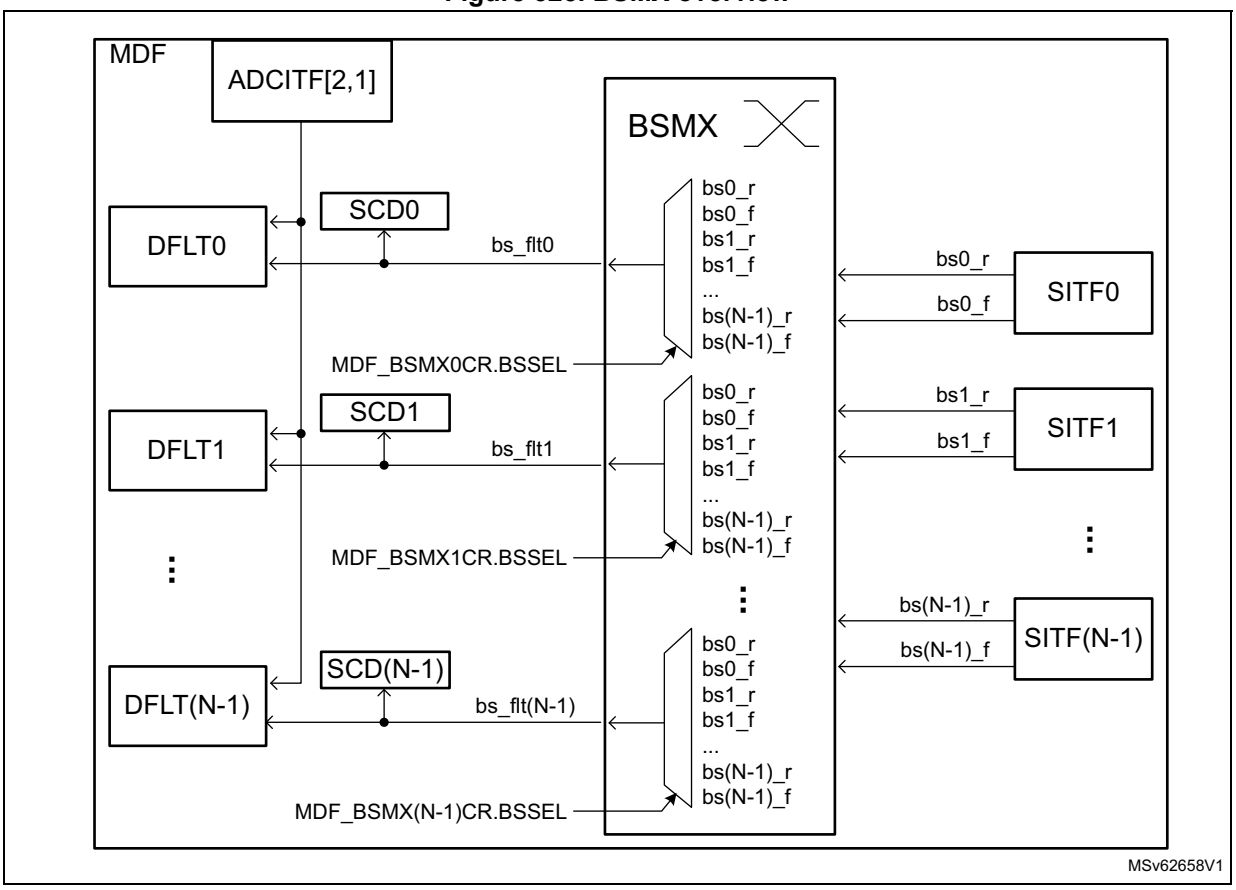
35.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from all serial interfaces (SITFx) and provides the selected input to the digital filters (DFLTx) and to the short-circuit detectors (SCDx). For each filter path, any of the bitstream input can be selected.

As shown in the *Figure 321*, each SITFx block provides two bitstreams (bsx_r and bsx_f) to the BSMX.

The application to select the wanted stream via the *MDF bitstream matrix control register x (MDF_BSMXxCR)*. This selection is intended to be static.

Figure 325. BSMX overview



BSMX programming sequence example

The BSSEL[4:0] bitfield cannot be changed if the corresponding SCDx, OLDx or DFLTx is enabled. The following steps are needed to change the value of BSMX, for filter path x:

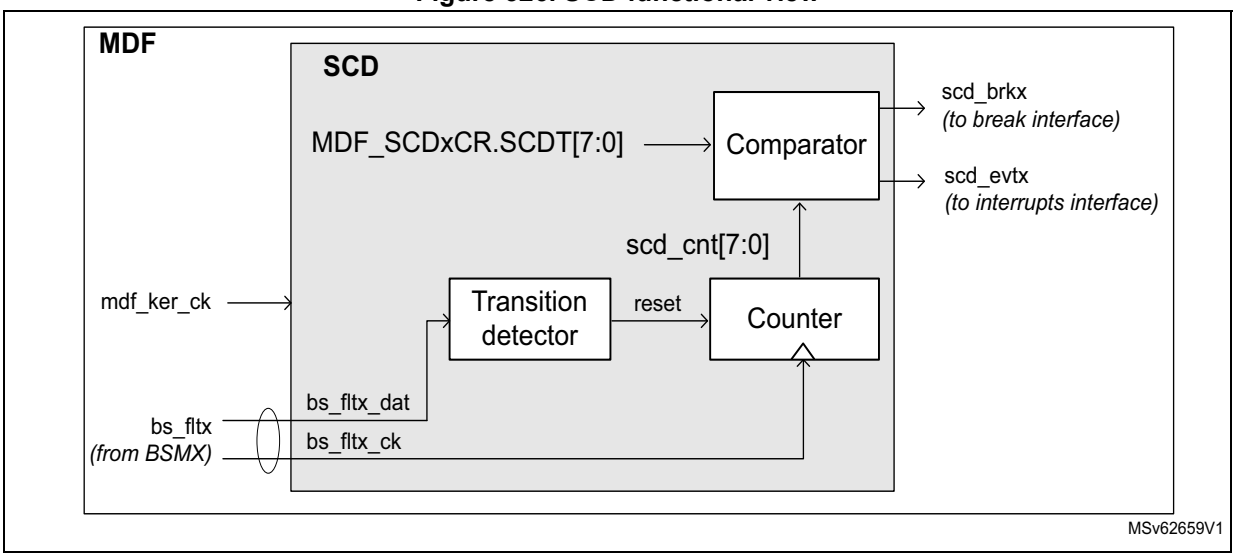
1. Set SCDEN of SCDx to 0.
2. Set DFLTEN of DFLTx to 0.
3. Set OLDEN of OLDx to 0.
4. Wait for BSMXACTIVE = 0.
5. Program BSSEL[4:0] of filter path x.
6. Set SCDEN of SCDx to 1 (optional).
7. Set DFLTEN of DFLTx to 1 (optional).
8. Set OLDEN of OLDx block to 1 (optional).

35.4.7 Short-circuit detectors (SCD)

The SCDx detects, with a very fast response time, if an analog signal reached saturated values (out-of-full scale ranges) and remained on this value for a given time.

This behavior can detect short-circuit or open-circuit errors (such as over current or over voltage). An interrupt event or/and a break signal can be generated.

Figure 326. SCD functional view

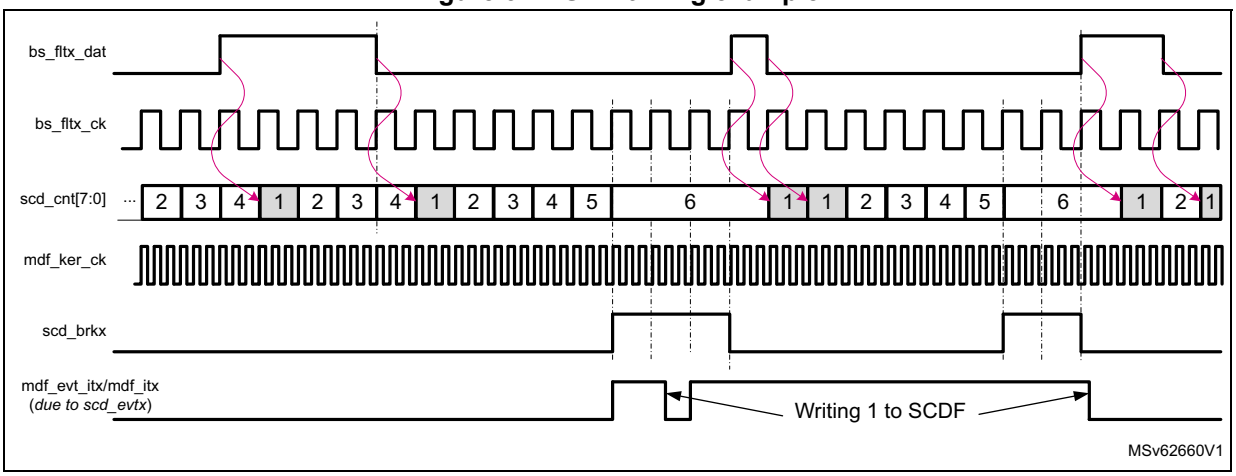


The SCDx is counting consecutive zeros or consecutive ones received from the serial interface (SITFx). A counter is restarted if there is a change in the data stream received. If this counter reaches a short-circuit threshold value (SCDT[7:0] in the *MDF short circuit detector control register x (MDF_SCDxCR)*), then a short-circuit event is invoked. Each BSMX output has its own short-circuit detector. Any BSMX output can be continuously monitored by setting the corresponding SCDEN bit to 1 in MDF_SCDxCR. Each SCD has its own threshold settings (SCDT) and its own status bit (SCDF).

The figure below shows an example where SCDT[7:0] is set to six. The break signal remains high as long as the short circuit condition is present.

No overrun event is generated when the interrupt event is pending while a new short-circuit condition is detected.

Figure 327. SCD timing example



The SCDx event generated by the SCDx block can be assigned to break output signals mdf_break[3:0]. The break signal assignment to a given short-circuit detector event is done by BKSCD[3:0] in MDF_SCDxCR. The break outputs are shared with the over-current function.

Note: SCDs cannot be used to monitor the ADC data interface (ADCITF).

SCD activation sequence example

1. Enable and configure CKGEN to generate the mdf_proc_ck.
2. Set SCDEN to 0.
3. Wait for SCDACTIVE = 0. If SCDEN was previously enabled, this phase can take two periods of mdf_hclk, and two periods of mdf_proc_ck.
4. Program BKSCD[3:0] and SCDT[7:0].
5. Set SCDEN to 1.

Note: BKSCD[3:0] and SCDT[7:0] must not be changed when SCDACTIVE = 1.

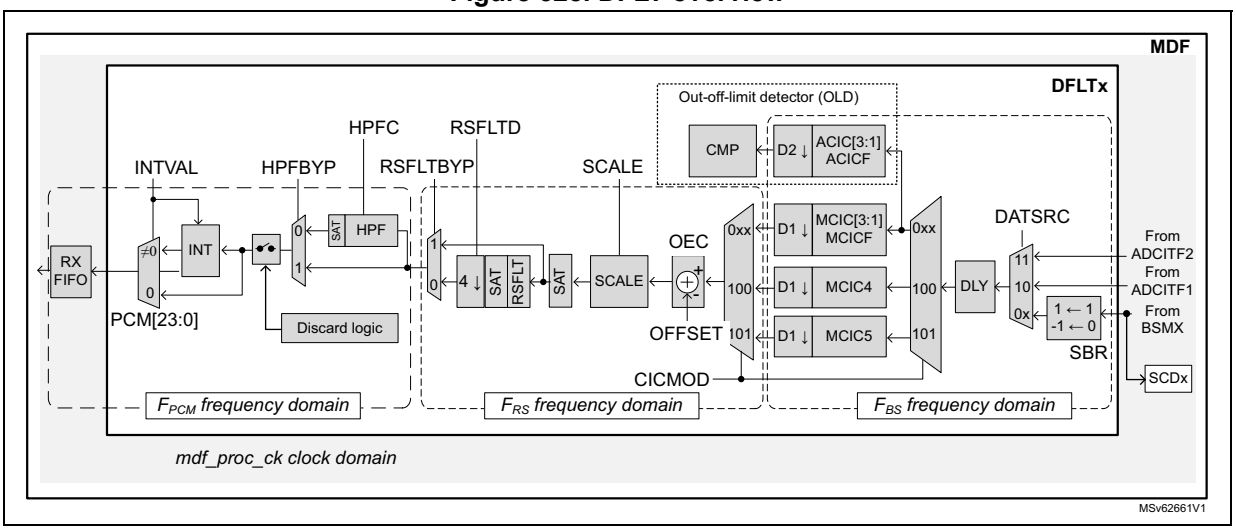
35.4.8 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- source selector
- clock skipper delay (DLY)
- CIC decimation filter that can be configured:
  - in single $Sinc^4$ or $Sinc^5$ order CIC (MCIC)
  - in two CIC filters:
    - a main filter (MCIC), high resolution
    - an auxiliary filter (ACIC), low-latency, for the out-off-limit detector (OLD)
    - both MCIC and ACIC can be configured as $Sinc^1$, $Sinc^2$, $Sinc^3$ or FastSinc
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- integrator (INT)
- receive RXFIFO

Figure 328 shows the filter-path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

Figure 328. DFLT overview



Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.

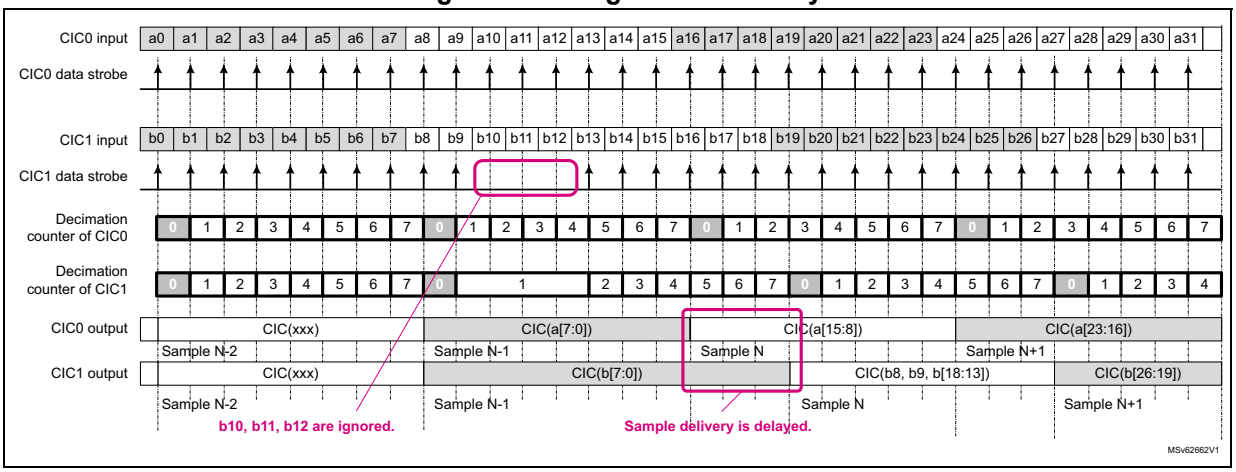
This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate, must be applied to the incoming stream.This feature is helpful when the MDF is synchronized with other ADF or MDF blocks for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is performed by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

Figure 329 shows an example of how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another ADF or MDF instance.

Figure 329. Programmable delay



The CIC of filter 1 (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is build from input samples a[23:16] while the sample N+1 of CIC1 is build from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

Note: When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

Warning: It is not recommended to apply a delay bigger than the programmed decimation ratio (CIC + RSFLT decimation), especially if the MDF is programmed in interleaved acquisition mode. There is a strong risk of data misalignment inside the FIFOs.

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the corresponding DFLTx is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the corresponding digital filter is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

   When the MDF skipped the amount of wanted data strobes, then SKPBF goes back to 0.
3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

The effect of the delay performed with this mechanism is cumulative as long as the MDF is enabled. In a given filter, if the application performs a D1 delay, followed by a D2 delay, then all other active filters are delayed by D1 + D2.

Data coming from ADCs can also benefit of this feature.

In interleaved acquisition mode, it is up to the application to insure that the delay applied on the different microphones is in line with the depth of the RXFIFO buffers. If the relative delay between each activated filter is less than the decimation ratio, then it costs one FIFO location.

If the interleaved acquisition mode is not used, then the delay value has no impact on the RXFIFO buffering.

Note: If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

Cascaded-integrator-comb (CIC) filter

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a $Sinc^N$ function, this is why they are often called Sinc filters.

The $Sinc^N$ digital filter embedded into the MDF is configurable according to the application targeted.

- For audio applications, such as speech capture from digital microphones, the application can select a high-resolution low-pass decimation filter by setting CICMOD to 100 or 101.
- If the targeted application is motor control or any other sensor capture, then the application can configure the CIC in order to offer a main filter path for acquisition (MCIC) and an auxiliary filter for fast-event generation (ACIC). This auxiliary filter can be used for example, to detect over-current conditions. This mode is selected by setting CICMOD[2:0] = 0xx.

When CICMOD[2:0] = 0xx, the following CIC filters are available:

- main filter (MCIC)
- auxiliary CIC filter (ACIC)

Both of them are configurable in FastSinc, $Sinc^1$ to $Sinc^3$.

When CICMOD[2:0] = 100, the CIC is configured into a single $Sinc^4$ and when CICMOD[2:0] = 101, the CIC is configured into a single $Sinc^5$ filter.

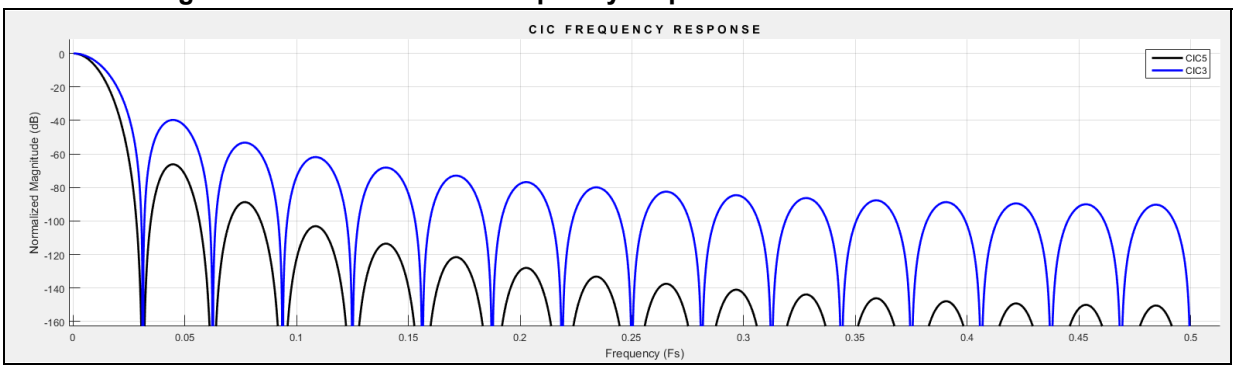
The filters have the following transfer function (impulse response in z domain):

- $Sinc^N$ filter type: $$H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^N$$
- FastSinc filter type: $$H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^2 \cdot (1 + z^{-(2 \cdot D)})$$

where N can be 1, 2, 3, 4 or 5, and D is the decimation ratio.

D is equal to MCICD+1 or ACICD+1.

Figure 330. CIC3 and CIC5 frequency response with decimation ratio = 32



CIC output data size

The size of samples delivered by the CIC (DS_{CIC}) depends on the following parameters:

- CIC order (N)
- CIC decimation ratio (D)
- data size of the input stream (DSIN)

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (DS_{CIC}) according to the parameters above.

$$DS_{CIC} = \left(\frac{N \times Ln(D)}{Ln(2)}\right) + DS_{IN}$$

and the CIC gain is given by this formula:

$$G_{CIC} = (D)^{N}$$

The decimation ratio can be adjusted from 2 to 512 for the main CIC filter and from 1 to 32 for the auxiliary CIC filter.

The table below gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

Note: DS_{IN} = 1 bit for a serial bitstream but can be up to 16 bits when coming from the ADCITF.

Table 281. Data size according to CIC order and CIC decimation values

Decimation	Data size (bits) when DS_{IN} = 1 bit (data from SITFx)						Data size (bits) when DS_{IN} = 12 bits (data from ADCITF)					
	Sinc^1	Sinc^2	FastSinc	Sinc^3	Sinc^4	Sinc^5	Sinc^1	Sinc^2	FastSinc	Sinc^3	Sinc^4	Sinc^5
4	3	5	6	7	9	11	14	16	17	18	20	22
8	4	7	8	10	13	16	15	18	19	21	24	-
12	5	9	9	12	16	19	16	20	21	23	-	-
16	5	9	10	13	17	21	16	20	21	24	-	-
24	6	11	12	15	20	24	17	22	23	-	-	-
32	6	11	12	16	21	26	17	22	23	-	-	-

Table 281. Data size according to CIC order and CIC decimation values

Decimation	Data size (bits) when DS_{IN} = 1 bit (data from SITFx)						Data size (bits) when DS_{IN} = 12 bits (data from ADCITF)					
	Sinc^1	Sinc^2	FastSinc	Sinc^3	Sinc^4	Sinc^5	Sinc^1	Sinc^2	FastSinc	Sinc^3	Sinc^4	Sinc^5
64	7	13	14	19	25	-	18	24	25	-	-	-
128	8	15	16	22	-	-	19	26	-	-	-	-
256	9	17	18	25	-	-	20	-	-	-	-	-
512	10	19	20	-	-	-	21	-	-	-	-	-

The LSB part of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-off-band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

The table below shows the maximum allowed decimation ratio for the CIC filter, depending on the input data size. Bigger decimation ratio causes a wrap-around of the signal at CIC output, for strong input signals.

Note: The MDF cannot detect or prevent a CIC wrap-around.

Table 282. Maximum decimation ratio versus order and input data size

Filter order	Max. decimation ratio when DS_{IN} = 1 bit (SITFx)	Max. decimation ratio when DS_{IN} = 12 bits (ADCITF)	Max. decimation ratio when DS_{IN} = 16 bits (ADCITF)
Sinc^1	512	512	512
Sinc^2	512	128	32
FastSinc	512	90	22
Sinc^3	322	25	10
Sinc^4	76	11	5
Sinc^5	32	6	4

Scaling (SCALE) and saturation (SAT)

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (- 48.2 dB) and can be increased by up to 12 bits (+ 72.2 dB).

The gain is adjusted by the SCALE[5:0] bitfield in the *MDF digital filter configuration register x (MDF_DFLTxCICR)*.

SCALE[5:0] can be changed even if the corresponding DLFTx is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of mdf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

The table below shows the possible gain values.

Table 283. Possible gain values

SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)
0x20	- 48.2	0x2B	- 14.5	0x06	+ 18.1	0x11	+ 51.7
0x21	- 44.6	0x2C	- 12.0	0x07	+ 21.6	0x12	+ 54.2
0x22	- 42.1	0x2D	- 8.5	0x08	+ 24.1	0x13	+ 57.7
0x23	- 38.6	0x2E	- 6.0	0x09	+ 27.6	0x14	+ 60.2
0x24	- 36.1	0x2F	- 2.5	0x0A	+ 30.1	0x15	+ 63.7
0x25	- 32.6	0x00	0.0	0x0B	+ 33.6	0x16	+ 66.2
0x26	- 30.1	0x01	+ 3.5	0x0C	+ 36.1	0x17	+ 69.7
0x27	- 26.6	0x02	+ 6.0	0x0D	+ 39.6	0x18	+ 72.2
0x28	- 24.1	0x03	+ 9.5	0x0E	+ 42.1	-	-
0x29	- 20.6	0x04	+ 12.0	0x0F	+ 45.7	-	-
0x2A	- 18.1	0x05	+ 15.6	0x10	+ 48.2	-	-

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The MDF performs saturation operations at the following levels:

- after the SCALE block (performed by the SAT block). The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the *MDF DFLTx interrupt enable register x (MDF_DFLTxIER)* and *MDF DFLTx interrupt status register x (MDF_DFLTxISR)*.

Gain adjustment policy

To get the best MDF performances, it is important to properly adjust the gain value via SCALE[5:0].

A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full scale, for the maximum input signal.

A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

$$\frac{LN(SIN_{pp} \cdot D^N)}{LN(2)} < 26$$

where N represents the CIC order, D the decimation ratio and SIN_{pp} the maximum peak-to-peak amplitude of the input signal.

SIN_{pp}can take:

– a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF

– a maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048) for samples coming from a 12-bit ADC

Example: a $Sinc^4$ can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

$$\frac{LN(0.7 \cdot 96^4)}{LN(2)} \sim 25.82 \text{ bits} < 26 \text{ bits}$$

2. Adjust the SCALE value.

To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

The SCALE value in dB is selected using this formula:

$$SCALE_{dB} < 20 \cdot \log 10\left(\frac{2^{NB}}{SIN_{pp} \cdot D^N}\right)$$

where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. $SCALE_{dB}$ represents the gain value selected by SCALE[5:0].

Example: for a $Sinc^4$ with a decimation ratio of 96 and a SIN_{pp} of 0.7:

– If the RSFLT is bypassed:

$$20 \cdot \log 10\left(\frac{2^{24}}{0.7 \cdot 96^4}\right) \sim 11 \text{ dB}$$

$SCALE_{dB}$ value must be lower than - 11 dB. The closest lower value is - 12dB (SCALE[5:0] = 0x2C).

– If the RSFLT is enabled:

$$20 \cdot \log 10\left(\frac{2^{22}}{0.7 \cdot 96^4}\right) \sim 23 \text{ dB}$$

$SCALE_{dB}$ value must be lower than - 23 dB, the closest lower value is - 24.1 dB (SCALE[5:0] = 0x28).

If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

The table below proposes gain values for different filter configurations, when the data comes from the SITFx, according to the CIC order, and the CIC decimation ratio. This table is not exhaustive, and considers a full-scale input signal (see *Section 35.7.5* for details).

Table 284. Recommended maximum gain values versus CIC decimation ratios

CIC decimation ratio	Gain settings (dB) for configuration SITF + CICx + RSFLT (+ HPF)					Gain settings (dB) for configuration SITF + CICx (+ HPF)				
	CIC5	CIC4	CIC3	CIC2	CIC1	CIC5	CIC4	CIC3	CIC2	CIC1
8	33.6	51.7	69.7	72.2	72.2	45.7	63.7	72.2	72.2	72.2
12	18.1	39.6	60.2			30.1	51.7			
16	3.5	27.6	51.7			15.6	39.6	63.7		
20	- 6.0	21.6	48.2			6.0	33.6	60.2		
24	- 12.0	15.6	42.1	69.7		0	27.6	54.2		
28	- 20.6	9.5	36.1	66.2		- 8.5	21.6	48.2		
32	-26.6	3.5	33.6	63.7		- 14.5	15.6	45.7		
48	-	- 8.5	24.1	57.7		-	3.5	31.6	69.7	
64	-	- 20.6	15.6	51.7		-	-8.5	27.6	63.7	
128	-	-	- 2.5	39.6		-	-	9.5	51.7	
256	-	-	- 20.6	27.6		-	-	-8.5	39.6	

Reshaping filter (RSFLT)

In addition to the CIC, the MDF offers a reshaping IIR filter mainly dedicated to the audio application but also usable in other applications.

When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLTD bit in the *MDF reshape filter configuration register x (MDF_DFLTxRSFR)*.

The RSFLT can be bypassed by setting RSFBYP to 1 in MDF_DFLTxRSFR.

The table below shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency (F_C) depends on the sample rates at its input (F_{RS}), and is given by the following formula:

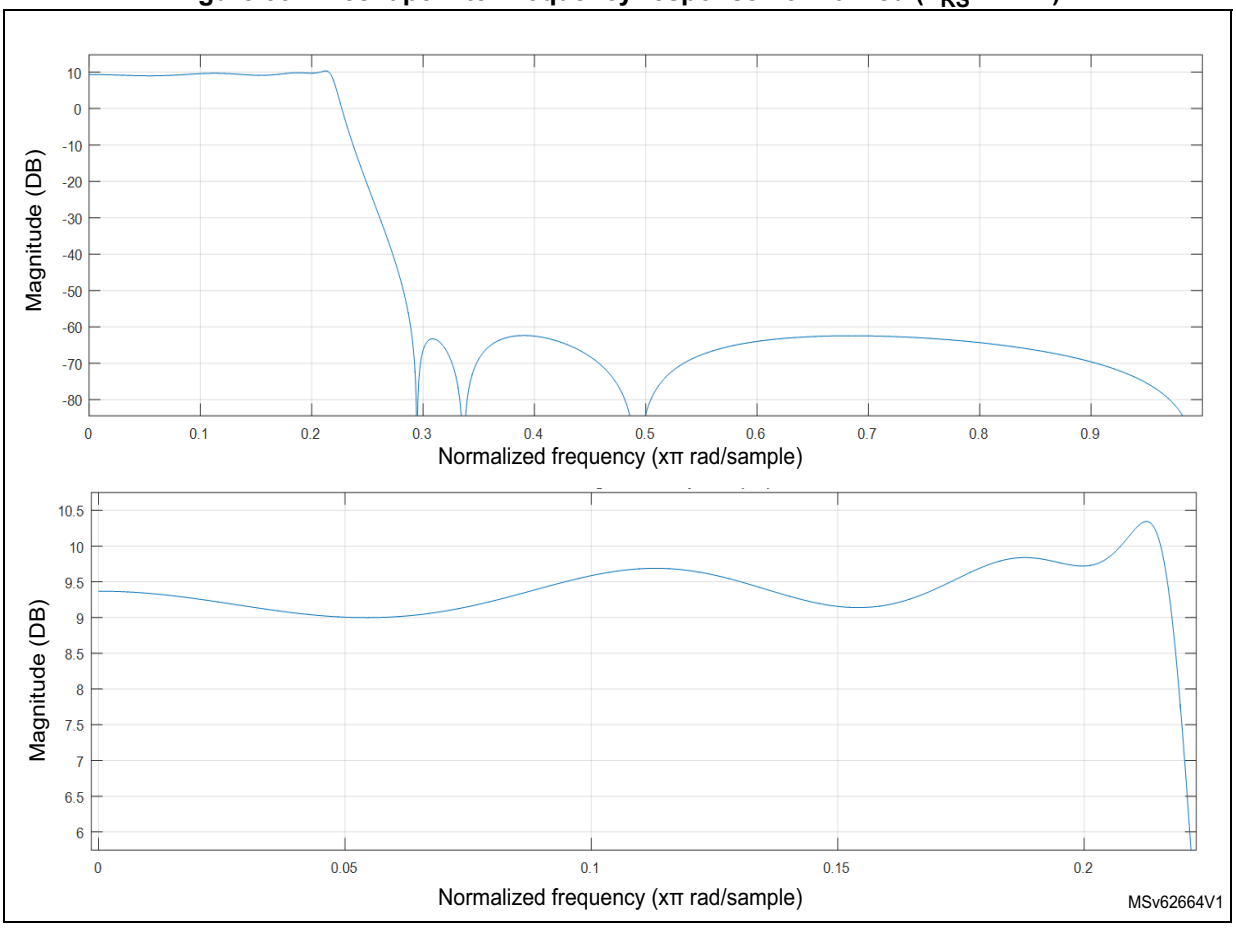
$$F_C = 0.111 \times F_{RS}$$

Table 285. Most common microphone settings

Sample rate (kHz) at RSFLT (F_{RS})	Pass band (kHz)	D2	PCM sampling rate (kHz)
32	3.55	4	8
64	7.1	4	16
128	14.2	4	32
192	21.3	4	48

The figure below shows the frequency response of the reshape filter.

Figure 331. Reshape filter frequency response normalized (F_{RS} / 2 = 1)



The RSFLT gain is about 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of mdf_proc_ck clock to process one sample at F_{RS}. When the RSFLT is enabled, the application must insure that the mdf_proc_ck is at least 24 times faster F_{RS}.

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new sample while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provide x a faster mdf_proc_ck clock to the RSFLT.

High-pass filter (HPF)

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the *MDF reshape filter configuration register x (MDF_DFLTxRSFR)*.

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source and it must be removed from the final data.

The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the *MDF reshape filter configuration register x (MDF_DFLTxRSFR)*, among the following values:

- 0.000625 x F_{PCM}
- 0.00125 x F_{PCM}
- 0.00250 x F_{PCM}
- 0.00950 x F_{PCM}

Table 286. HPF 3 dB cut-off frequencies examples

HPFC	3 dB cut-off frequency for common F_{PCM} frequencies (Hz)		
	F_{PCM} = 8 kHz	F_{PCM} = 16 kHz	F_{PCM} = 48 kHz
0	5	10	30
1	10	20	60
2	20	40	120
3	76	152	456

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

Offset error compensation (OEC)

Each digital filter has its own OEC. The offset correction is performed by subtracting to the signal provided by the CIC, the OFFSET[25:0] in the *MDF offset error compensation control register x (MDF_OECxCR)*.

Due to the internal resynchronization, there is a delay of some cycles of mdf_proc_ck clock between the moment where the application writes the new offset, and the moment where the new offset value is effectively applied to the samples. If the application attempts to write a new offset value while the previous one is not yet applied, this new offset value is ignored. Reading back OFFSET[25:0] informs the application on the current offset value.

Integrator (INT)

The INT performs additional decimation and a resolution increase of data coming from the digital filter. The INT simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The INT is enabled by setting INTVAL[6:0] to a value different from 0.

The amount of integrated values can be defined by INTVAL[6:0] in the range of 2 to 128.

In order to control the data width at the integrator output, the resulting data can be divided by 1, 4, 32 or 128. This feature is controlled by INTDIV[1:0].

35.4.9 Out-of-limit detector (OLD)

The OLD triggers an event when a signal reaches or crosses given maximum and minimum threshold values. The generated event can drive an interrupt or break signals (mdf_break[3:0]) when conditions are met.

The OLD can be used only if the CIC filter is configured in motor and sensing mode (CICMOD[2:0] = 0xx).

The OLD takes the input signal selected by the main filter, process it using a $Sinc^N$ or FastSinc filter (ACIC), and compares the resulting signal to programmed thresholds.

The OLD is enabled via the OLDEN bit in MDF_OLD0CR. Once enabled, the input data are continuously monitored. There is no need to have the DFLTx enabled for using the OLD function.

The MDF offers a high- and low-threshold register that are compared with given data values.

The application can generate an event if the signal is inside or outside the boundary defined by those two thresholds. This behavior is controlled via THINB in the MDF_OLD0CR.

If the application only wants to generate an event when the input signal is higher than OLDTHH, then THINB and OLDTHL must both be cleared to 0.

If the application only wants to generate an event when the input signal is lower than OLDTHH, then THINB must be set to 1 and OLDTHL must be cleared to 0.

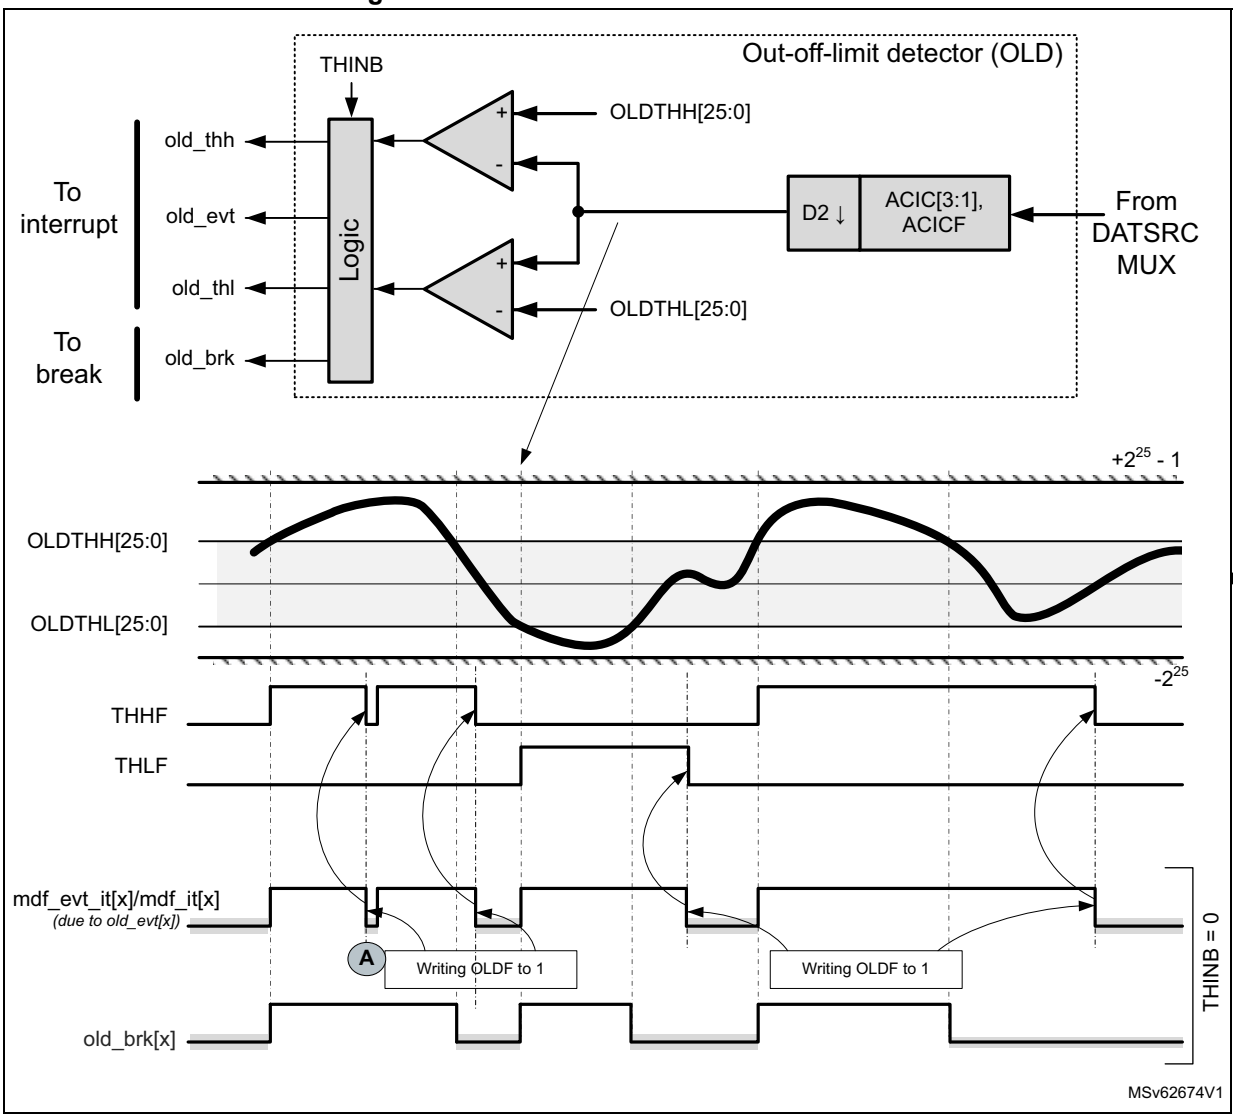
Note: It is not recommended to set a OLDTHL to a value bigger than OLDTHH.

The response time of the OLD depends on several parameters, the most important are listed hereafter:

- sampling rate frequency used by the external sensor
- ACIC decimation ratio
- ACIC order

The OLD can be used for over-current detection but also as current limiter if the PWM signal is generated by a timer receiving a old_brk signal. Generally, to get a fast response time for over-current detection, it is recommended to use the ACIC with lowest order as possible and the minimum decimation ratio. FastSinc is also a good choice for over-current detection. The application must perform a trade-off between the filter resolution and the response time.

Figure 332. Out-of-limit detector thresholds



Status flags are available in order to inform the application that an OLD event is detected. Latched events are cleared by writing 1 into the OLDF bit.

As shown in *Figure 332*, when THINB = 0, the interrupt signal remains active as long as the signal is outside the gray area. At position A, the application clears the interrupt, but the interrupt is re-asserted because the signal is still outside the gray area. When the application clears OLDF, THHF and THLF are cleared as well.

An OLD event can be assigned to one or several break output signals (mdf_break[3:0]). The break signal assignment to a given OLD event is done by BKOLD[3:0] in the *MDF out-of limit detector control register x (MDF_OLDxCR)*.

Note: The generation of break signals is independent from the interrupts generation.

OLD activation sequence example

1. Enable and configure CKGEN.
2. Set OLDEN to 0.

3. Wait for OLDACTIVE = 0. If OLDEN was previously enabled, this phase can take two periods of mdf_hclk and two periods of mdf_proc_ck.
4. Program BKOLD[3:0], ACICN[1:0], ACICD[4:0], THINB,OLDTHL[25:0] and OLDTHH[25:0].
5. Set OLDEN to 1.

35.4.10 Digital filter acquisition modes

The MDF offers the following modes to perform a data capture:

- asynchronous continuous acquisition mode
- asynchronous single-shot acquisition mode
- synchronous continuous acquisition mode
- synchronous single-shot acquisition mode
- window continuous acquisition mode
- synchronous snapshot acquisition mode

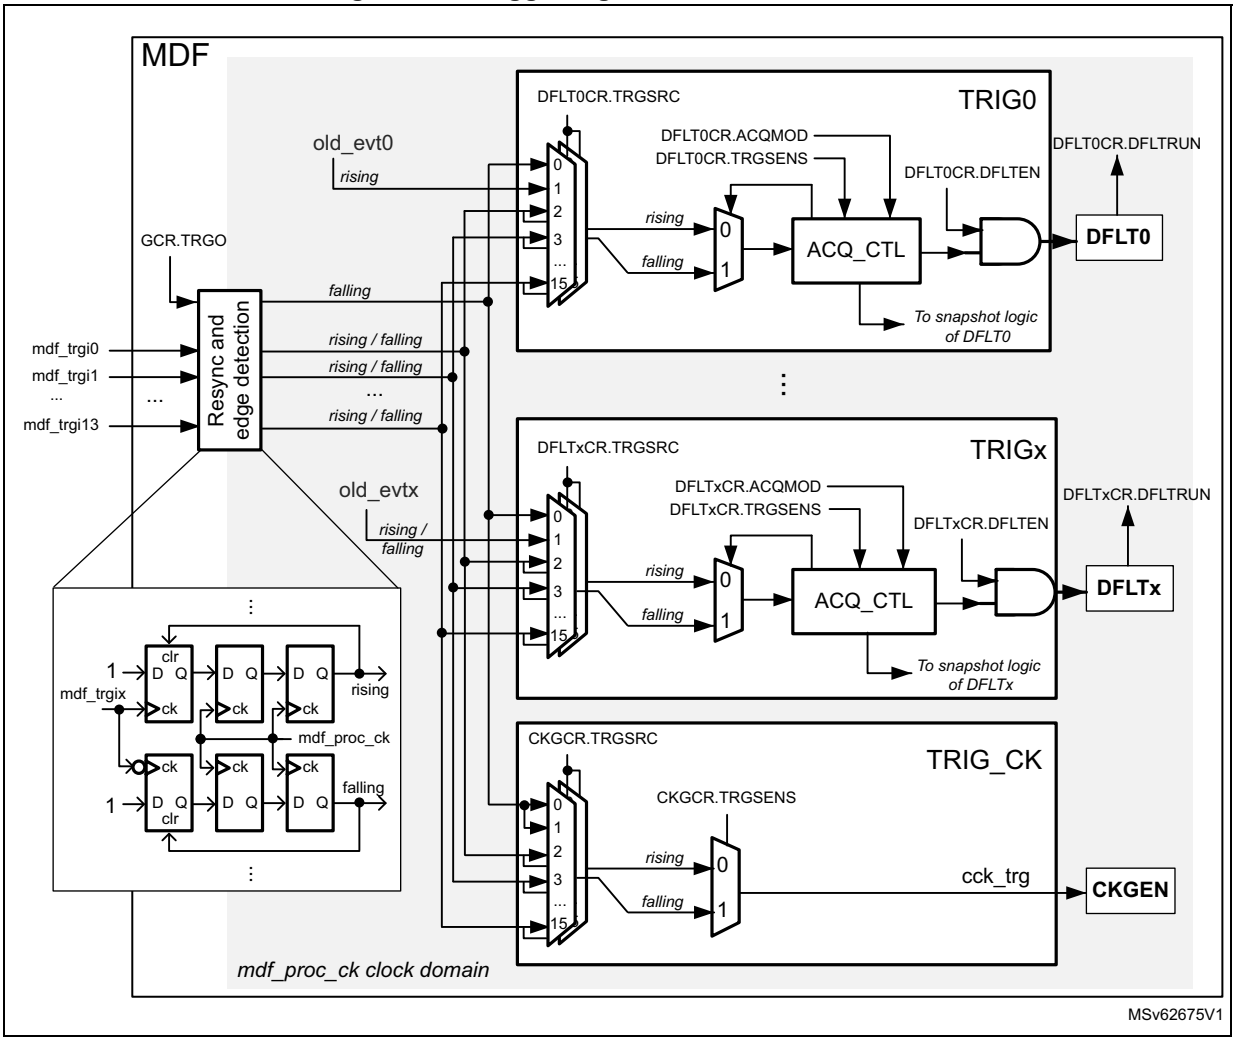
For each filter, one of these modes can be selected independently.

Note: To perform a data capture, the filters, the interfaces providing the data (SITFx or ADCITF) and the CKGEN must be enabled. If needed, MDF_CCK0 or MDF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This resets the filters and flushes the RXFIFO of the corresponding filter path. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filters are reset.

The figure below shows a simplified view of the trigger logic available for each filter and for the clock generator.

Figure 333. Trigger logic for DFLT and CKGEN



A block common to all TRIG blocks performs the rising and falling edges detection and the resynchronization of the input triggers to the mdf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the mdf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select one of the following trigger sources:

- mdf_trgi[13:0] signals (refer to *Table 277* for the trigger connections)
- TRGO bit in MDF_GCR
- OLD event of each filter path

The edge sensitivity can also be selected, except for TRGO and OLD events.

Asynchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition on one or several filters by simply writing their DFLTEN bits to 1.

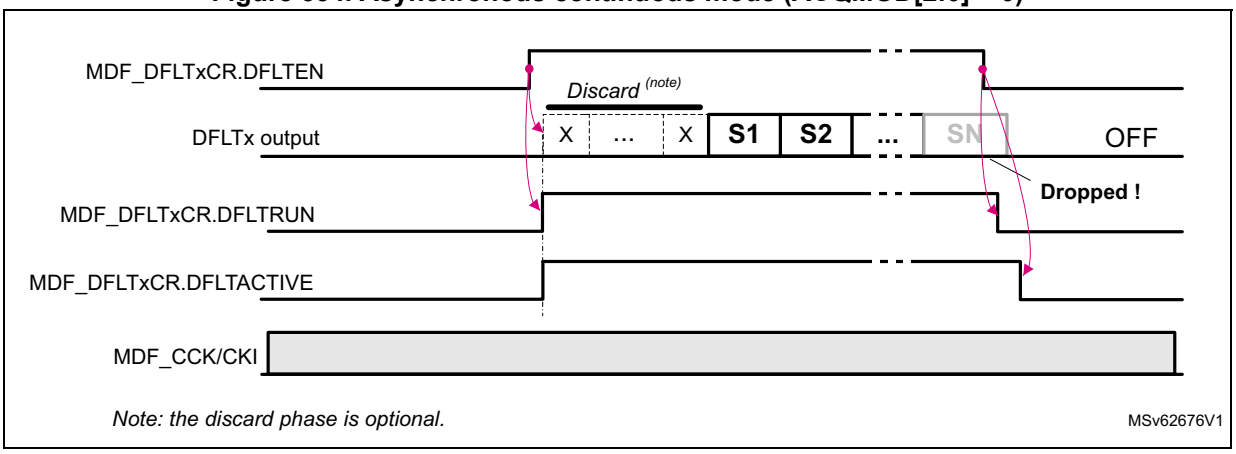
The Asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN) so that the mdf_proc_ck frequency is compatible with the targeted application (see examples in *Table 290*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1 for the filters to enable, the acquisition sequence starts immediately.

The figure below shows a simplified example of the samples generated by the DFLTx.

Figure 334. Asynchronous continuous mode (ACQMOD[2:0] = 0)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Asynchronous single-shot acquisition mode

This mode allows the application to start the acquisition of one sample on one or several filters by simply writing their DFLTEN bits to 1.

The Asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are cleared to 0):

1. Configure and enable the clock generator (CKGEN), so that the mdf_proc_ck frequency is compatible with the targeted application (see examples in *Table 286*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit of the requested data interfaces.

5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1 for the filters to enable, each selected filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, for each filter, the application must:

1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.

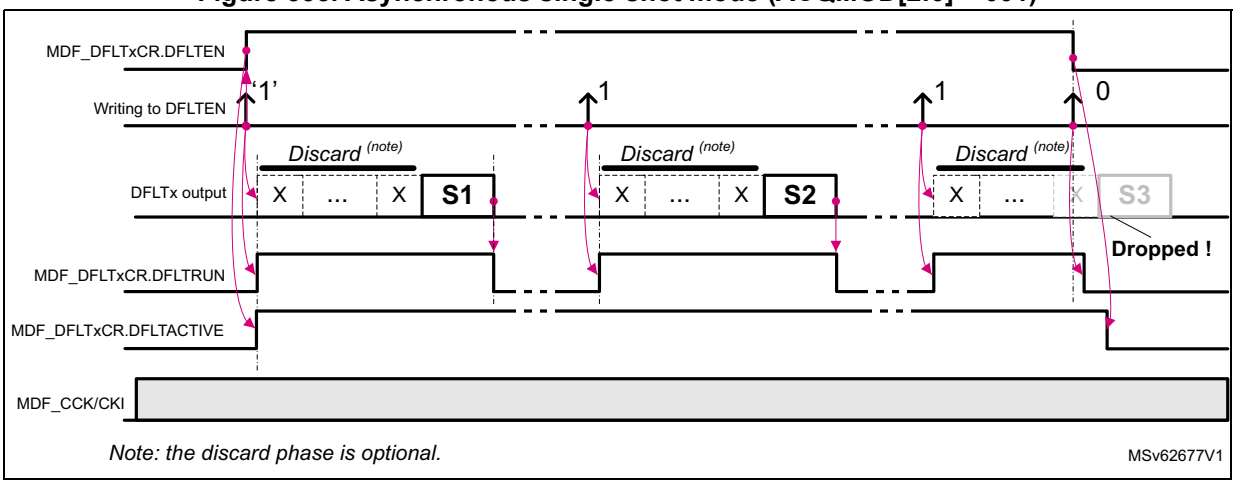
This sequence can be repeated every time a new data must be converted.

As shown in the *Figure 335*, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.

If the DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

Figure 335. Asynchronous single-shot mode (ACQMOD[2:0] = 001)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition on one or several filters by using the following trigger sources:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.

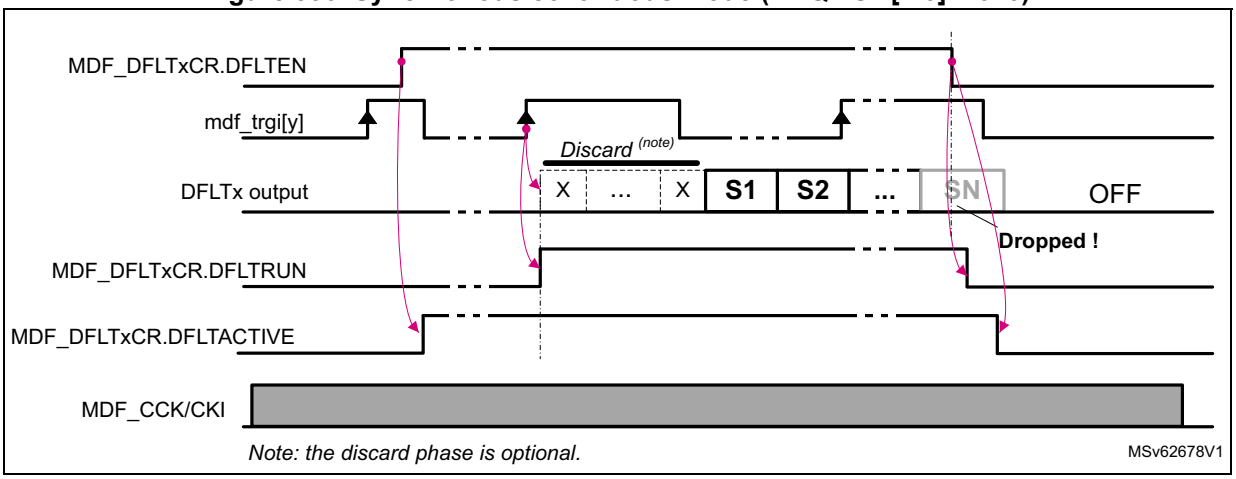
The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in *Table 286*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 010.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1 for the filters to enable.
8. When the trigger condition is met, the filters start the acquisition.

The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. The next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

Figure 336. Synchronous continuous mode (ACQMOD[2:0] = 010)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous single-shot acquisition mode

This mode allows the application to start a single acquisition on one or several filters by using the following trigger sources:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.

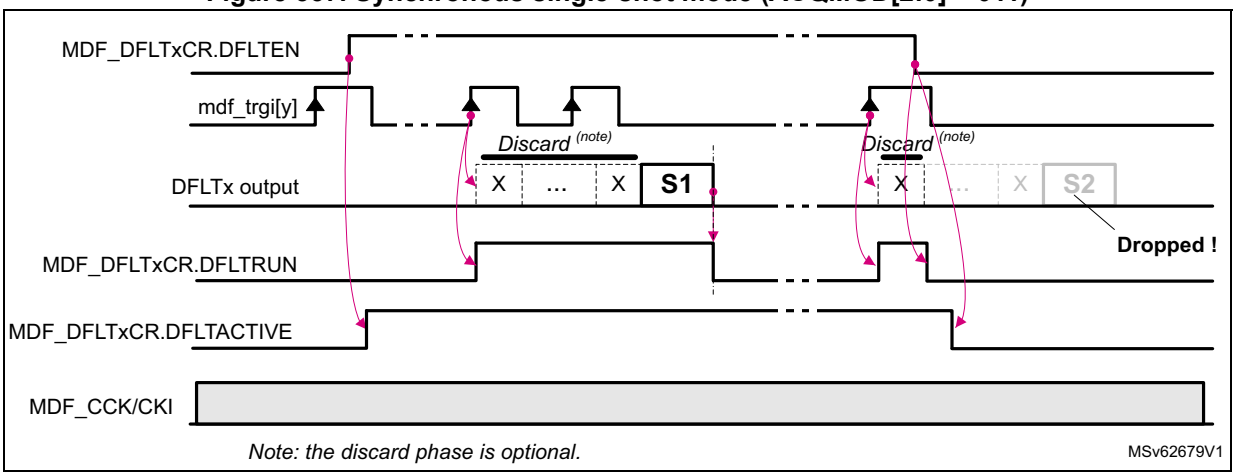
The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in *Table 286*).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter configuration and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated.
7. Set DFLTEN to 1 for the filters to enable.
8. Then when the trigger condition is met, the filters start the acquisition and provide one data to the RXFIFO, then the filters are ready to accept a new trigger.

TRGSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). Every time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

Figure 337. Synchronous single-shot mode (ACQMOD[2:0] = 011)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Figure 337 shows a case where DFLTEN is cleared to 0 while an acquisition is ongoing: thus the sample S2 is lost. This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.

Note: The ongoing DMA transfer is properly terminated.

Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition on one or several filters controlled by consecutive edges of one of the following trigger sources:

- one of the mdf_trg[13:0] signals
- TRGO bit

The window continuous acquisition mode is selected when ACQMOD[2:0] = 100.

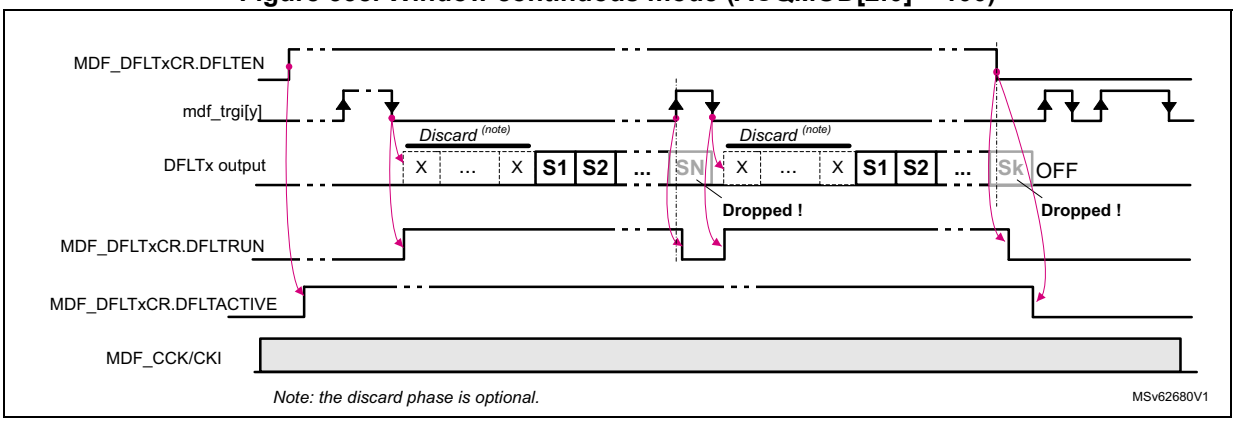
The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in *Table 286*).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated.
7. Set DFLTEN to 1 for the filters to enable.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 338 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the MDF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the MDF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the MDF waits again for a falling edge on the selected trigger input.

Figure 338. Window continuous mode (ACQMOD[2:0] = 100)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA

transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous snapshot acquisition mode

In the acquisition modes described on previous sections, the application must wait for filters settlings time or the end of conversion before getting a new valid sample. For applications very critical in latency, the last valid sample can be get immediately, with an information on the age of this sample by using the snapshot acquisition mode.

In snapshot mode, the DFLTx is continuously acquiring the samples, but the processed samples are not stored into the RXFIFO. When a trigger occurs, the last valid sample, the current decimation value of MCIC and the sample counter of the INT are stored in MDF_SNPS0DR.

The possible trigger sources are the following:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous snapshot acquisition mode is selected when ACQMOD[2:0] = 101.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in *Table 286*).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter settings and set the ACQMOD[2:0] to 101. FTH is usually cleared to 0 to receive an interrupt as soon as the RXFIFO is not empty.
4. Set the SITFEN bit of the requested data interfaces to 1.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated,
7. Set DFLTEN to 1 for the filters to enable.

When the trigger condition is met,

1. The MDF stores the last valid data provided by the corresponding filter, the value of the MCIC decimation counter, and the counter value of INT if selected by SNPSFMT into a shadow register.
2. The snps_evt is activated, indicating that a data is ready. If SSDRIE is set to 1, the MDF requests the AHB clock.
3. When the AHB clock is available the shadow register is stored in *MDF snapshot data register x (MDF_SNPSxDR)* and an interrupt is generated.
4. In the interrupt sub-routine, the application must do the following:
   a) Read the data located in MDF_SNPSxDR.
   b) Clear the SSDRF flag by writing it to 1.

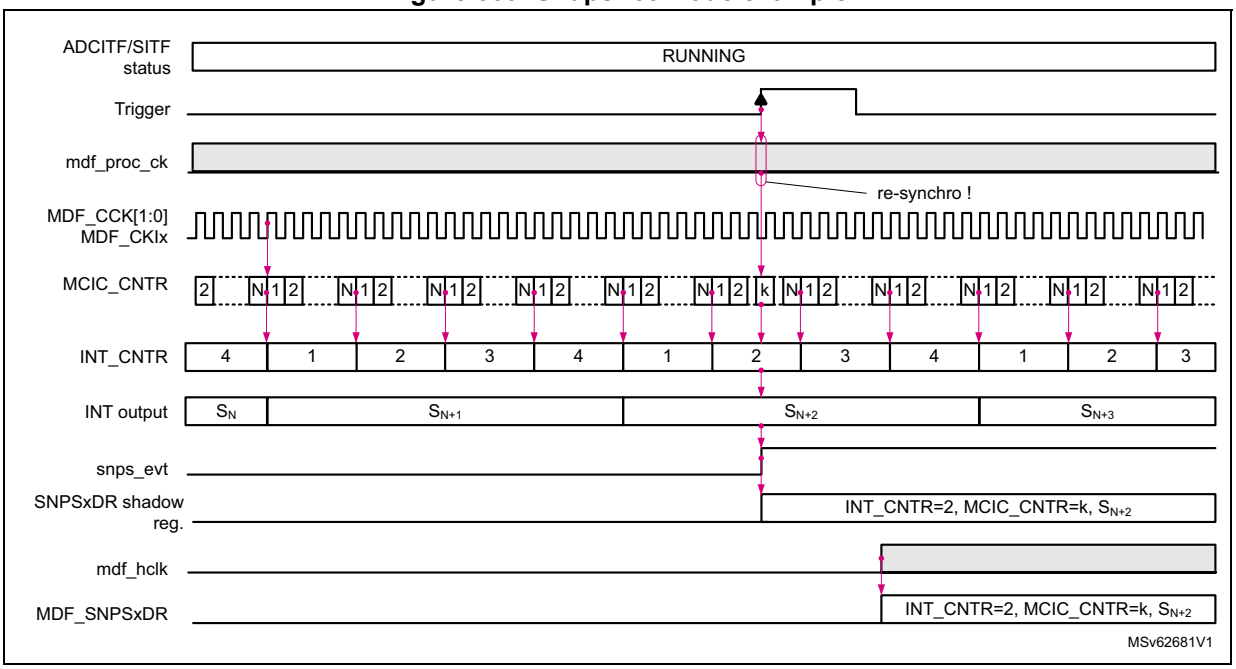
As shown in the *Figure 339*, in snapshot mode, when the trigger event occurs, it is resynchronized with the processing clock (mdf_proc_ck), the decimation counter of the MCIC (MCIC_CNTR), the integrator counter (INT_CNTR) and the last valid sample (S_{N+2}), are stored into a shadow register, and the snps_evt event is generated. When the AHB

clock is available, an interrupt is generated and the shadow register is copied in MDF_SNPSxDR. The application can read immediately the sample and the timing information.

The SSOVRF overrun flag is also available, allowing the application to check if an overrun condition occurs. A snapshot overrun condition is detected when the SSDRF flag is set to 1 while a new trigger event occurs.

In that case, the new trigger event is not taken into account. The application must clear the SSOVRF flag.

Figure 339. Snapshot mode example



Note: When an activated filter did not receive a data strobe, the filter is frozen. If the interface providing the stream is not enabled (SITF or ADCITF), the filter is frozen. Once a DFLT x is activated, CIC, HPF, IIR and INT are reinitialized. For each filter a status bit indicates if the filter is currently running or not.

Starting several filters synchronously

To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN is set to 0):

1. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
2. Set the SITFEN bit of the requested data interfaces to 1.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] to 0 (TRGO is selected).
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

To trigger a new acquisition (in case of single-shot), the application must do the following:

1. Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
2. Read TRGO until it is read to 0.
3. Set again TRGO to 1.

Discarded samples

The MDF offers the possibility to program the amount of samples to be discarded after each restart:

- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples

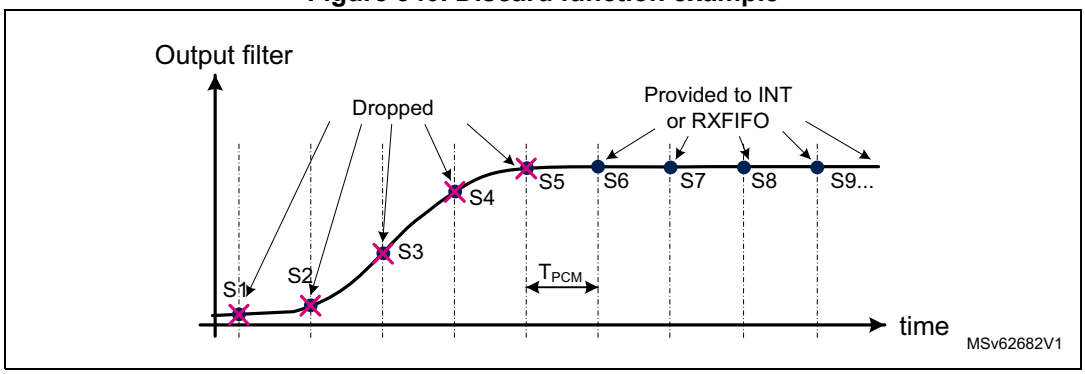
The discard function is controlled via NBDIS[7:0] as follows:

- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to *Figure 334* to *Figure 338*, *Figure 341* and *Figure 342*.

In the example shown in the figure below, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transfered to the RXFIFO (or INT block if enabled) is S6.

Figure 340. Discard function example



Warning: All filters working in interleaved DMA mode must have the same NBDIS[7:0] value.

Data interface activation

The data interfaces are enabled by setting the corresponding SITFEN or ADCITFEN bit to 1. Once the digital filter is enabled, it receives the serial data from the external ΣΔ modulator or parallel internal data sources (ADC).

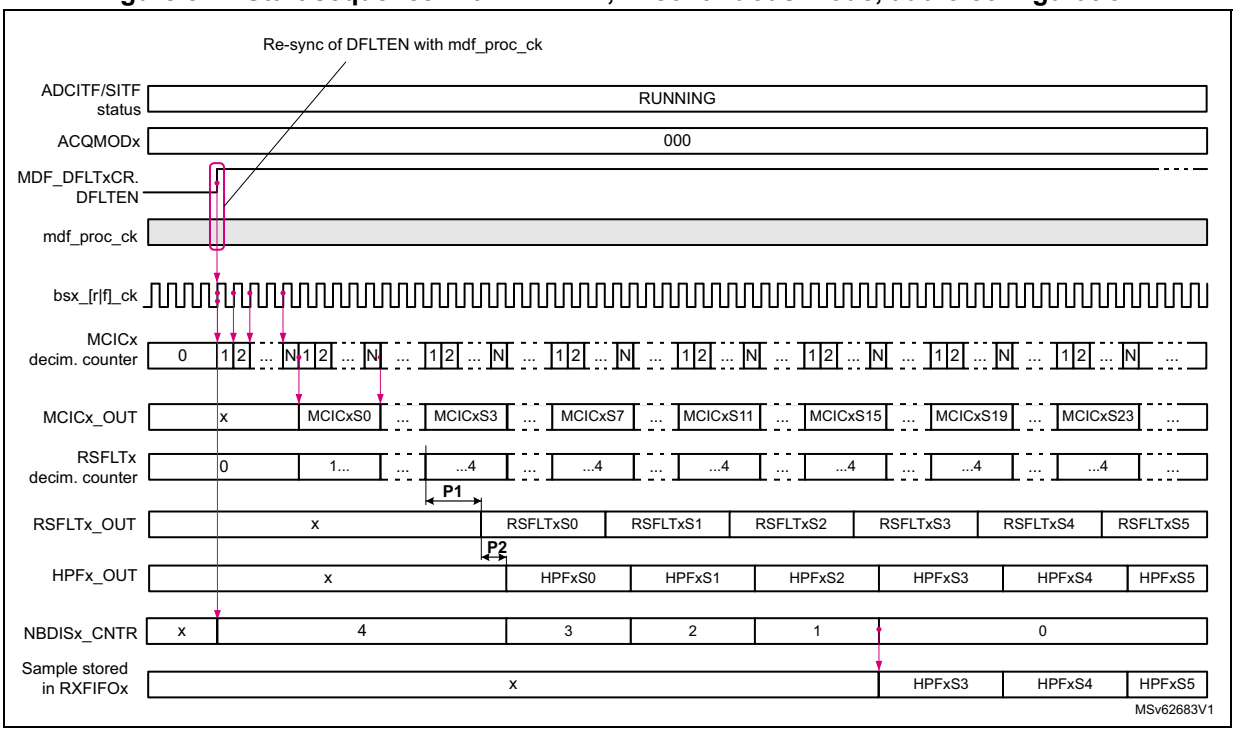
35.4.11 Start-up sequence examples

Figure 341 details an acquisition sequence start of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLTx is configured for audio application: MCIC, RSFLT and HPF activated.The data interface (SITFx or ADCITF) is assumed to be already activated.

Note: NBDIS[7:0] is set on purpose to a low value to simplify the drawing.

Figure 341. Start sequence with DFLTEN, in continuous mode, audio configuration



The DFLTEN bit is re-sampled into the MDF processing clock domain. When DFLTEN is detected high, the filter chain is enabled and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reaches its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC and delivers a sample to the HPF every time it processes four samples (decimation by 4) The RSFLT needs up to 24 cycles of mdf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0. This counter is decremented every time the HPF delivers a sample.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.

The example shown in *Figure 342* is based in a motor-control filter configuration:

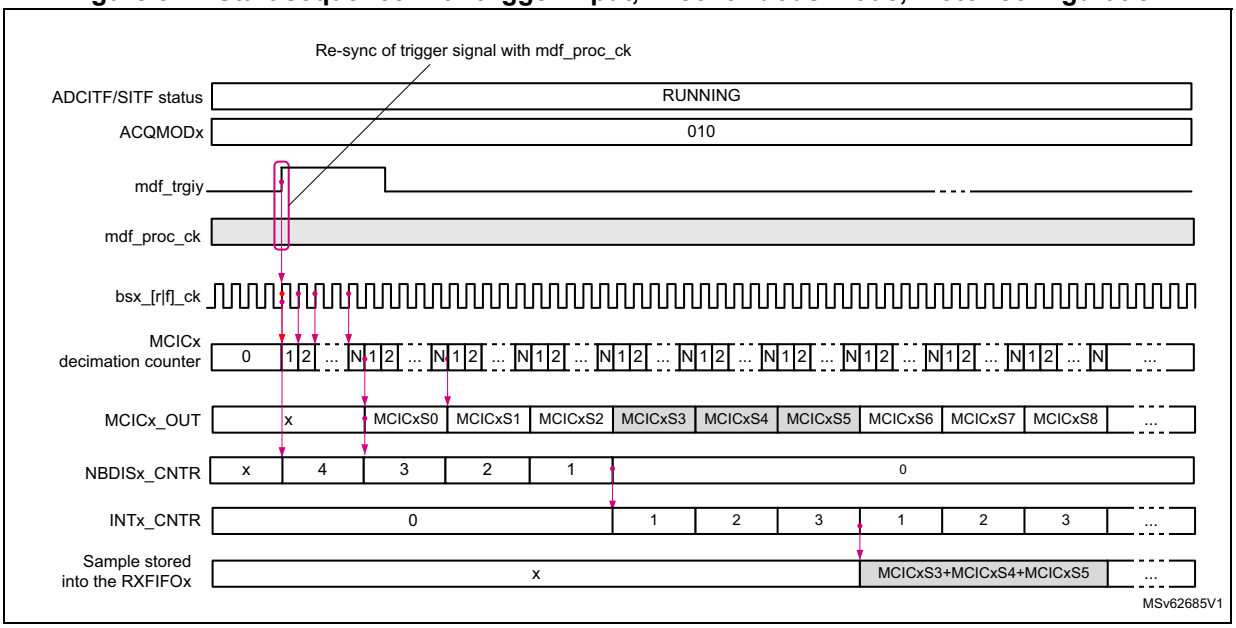
- MCIC and INT are enabled.
- SFLT and HPF are disabled.
- ACQMOD[2:0] is set to 1 and uses a mdf_trgiy input as trigger.
- NBDIS[7:0] is set to 3.
- INTVAL[6:0] is set to 2.

The mdf_trgiy input signal is re-sampled into the MDF processing clock domain to avoid any metastability issues. When the trigger condition is met (rising edge), the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reaches its programmed value N, a sample is available. The NBDIS function prevents the samples writing in the INT as long as NBDIS_CNTR does not reach 0. This counter is decremented every time the MCIC delivers a sample.

When NBDIS_CNTR reaches 0, the new samples are provided to the INT, that performs the integration of three consecutive samples and stores them into the RXFIFO.

Figure 342. Start sequence with trigger input, in continuous mode, motor configuration

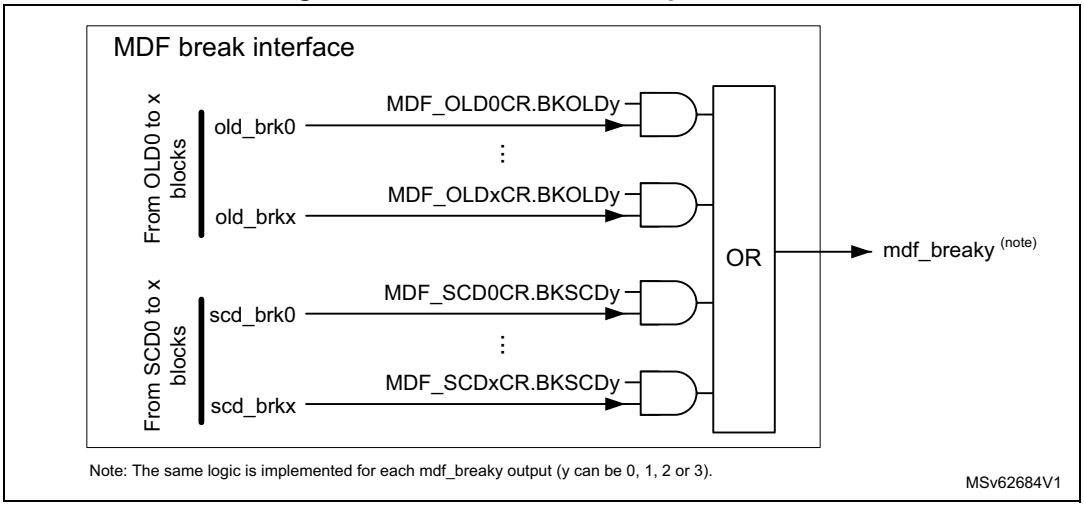


35.4.12 Break interface

The break interface merges the break events coming from the OLDx and SDCx blocks into four break signals connected to various peripherals of the product (see *Table 278* for details).

As shown in *Figure 343*, several blocks can share the same break line. A same block can also drive several break lines. The break interface is controlled via MDF_OLDxCR and MDF_SCDxCR.

Figure 343. Break interface simplified view



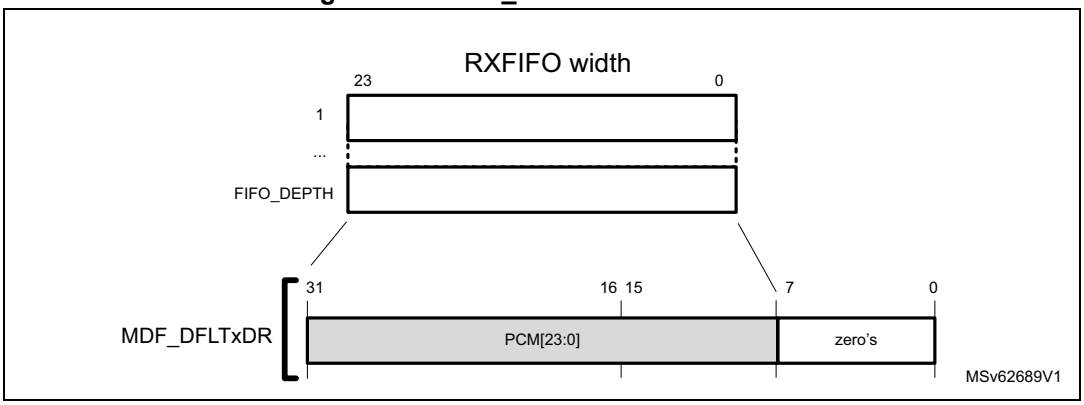
35.4.13 Data transfer to memory

Data format

The samples processed by DFLTx are stored into a RXFIFO. The application can read the samples stored into the FIFOs via the *MDF digital filter data register x (MDF_DFLTxDR)*. The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The MDF provides 24-bit left-aligned data. Performing a 16-bit access to MDF_DFLTxDR allows the application to get the 16 most significant bits. Performing a 32-bit access to MDF_DFLTxDR allows the application to get a 24-bit data size.

Figure 344. MDF_DFLTxDR data format



Data re-synchronization

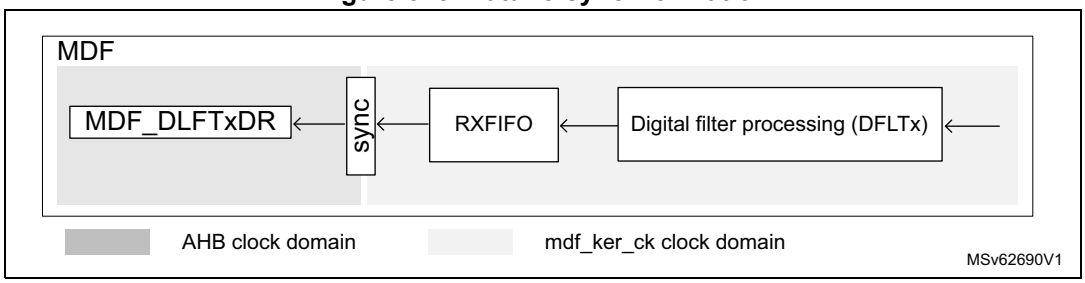
The samples stored into the RXFIFOs can be transferred into the memory by using either DMA requests or interrupt signaling.

Note: The RXFIFOs are located into the mdf_ker_ck clock domain, while MDF_DFLTxDR *are located into the mdf_hclk (AHB) clock domain.*

When the AHB clock is available, if MDF_DFLTxDR is empty and if a sample is available into the RXFIFO, this sample is transferred into MDF_DFLTxDR.

The sample transfer from the RXFIFO to MDF_DFLTxDR takes two periods of the AHB clock (mdf_hclk) and two periods of the mdf_ker_ck clock. The MDF inserts automatically wait-states if the application performs a read operation of MDF_DFLTxDR while the transfer of the new sample from the RXFIFO to MDF_DFLTxDR is not yet completed.

Figure 345. Data re-synchronization



The MDF can also combine two transfer types: the independent-transfer and the interleaved-transfer modes.

Independent-transfer mode

In this mode, each RXFIFO has its own DMA channel and its own FTHF flag event.

Both single and burst DMA transfers are supported in this mode, but the application must care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

In addition, the application can select the RXFIFO threshold (FTH bit) to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth / 2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the corresponding DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the corresponding RXFIFO is not empty.

The DMA mode of the RXFIFOx is enabled via the corresponding DMAEN bit in the *MDF digital filter control register x (MDF_DFLTxCR)*.

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in MDF_DFLTxDR, the corresponding FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as MDF_DFLTxDR is read.
- If FTH = 1, as soon as one of the RXFIFO reaches the threshold level and a data is available into MDF_DFLTxDR, the corresponding FTHF is set, allowing the generation of an interrupt. The FTHF flag is released as soon as one data is read. FTHF is set again if the threshold condition is met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE / 2 data.

The independent-transfer mode must be used when the sample rates provided by each filter paths are not perfectly synchronous, or when the streams are independent. This situation may occur for example:

- when SITF is in SLAVE mode and each external sensor provides its own sampling clock

- when the decimation ratios of the DFLTx are not the same
- when all the streams are not starting at the same time

Interleaved-transfer mode

This mode optimizes the DMA request resources by sharing a single DMA request with several RXFIFOs.

Only single DMA transfers are supported in this mode.

In interleaved-transfer mode, FTH cannot be used and only the FTHF of RXFIFO0 is available for the interrupt signaling.

For the DMA transfer, when all the RXFIFOs working in interleaved-transfer mode are not empty, some DMA requests are generated in order to read sequentially one sample of each RXFIFOs, via MDF_DFLT0DR.

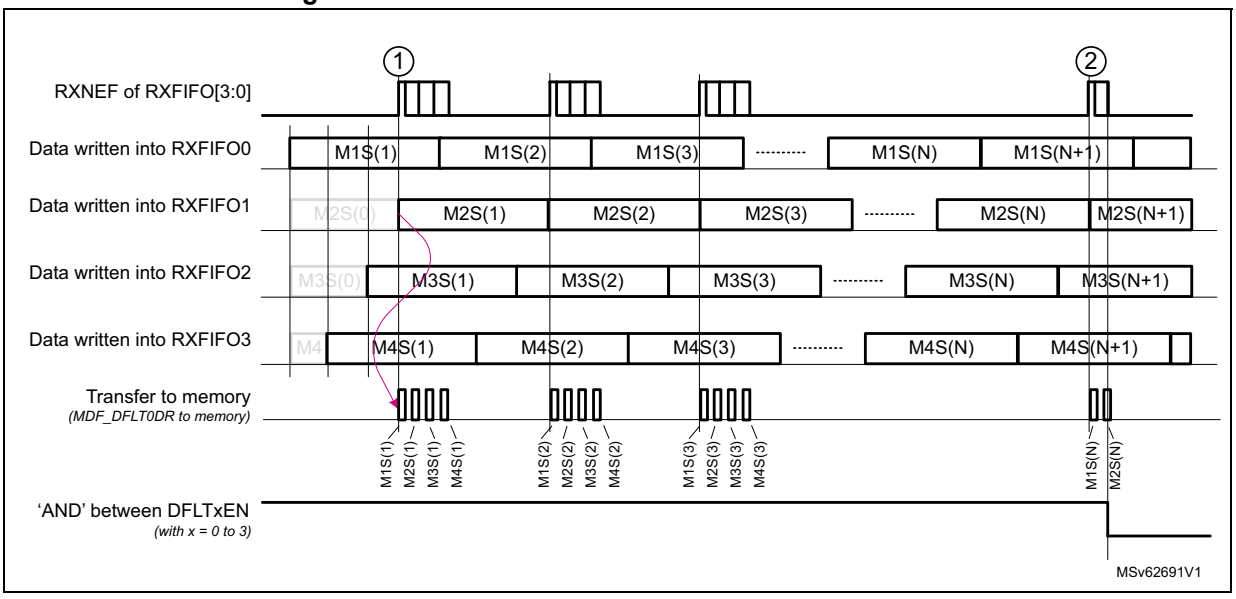
For the RXFIFOs working in interleaved-transfer mode, the DMA channel is enabled by setting to 1 DMAEN in MDF_DFLT0DR and by defining the amount of RXFIFOs working in interleaved mode via ILVNB[3:0]. DMAEN for the other RXFIFOs working in interleaved-transfer mode (RXFIFO 1 to ILVNB[3:0]) are not taken into account.

Figure 346 shows four RXFIFOs working in interleaved-transfer mode. Each RXFIFO has a delay due to the programming of the DLY block.

When all the RXFIFOs have at least one sample available (in this example the last FIFO receiving a sample is RXFIFO1), the MDF requests the data transfer to the memory (see 1 in *Figure 346*). In this figure, the DMA is assumed to be used for the data transfer to memory.

The acquisition can be simply stopped by setting DFTLEN to 0 for one of the filter configured in interleaved-transfer mode. In the example, when a DFLTEN is set to 0 (see 2 in *Figure 346*), the transfer to memory is immediately stopped. Samples M2S(N), M3S(N) and M4S(N) may be lost.

Figure 346. Data transfer in interleaved-transfer mode



In interrupt mode, when all the RXFIFOs working in interleaved-transfer mode have a data ready, the FTHF flag of RXFIFO0 is asserted to allow the interrupt generation. The application is then supposed to read sequentially one sample of each RXFIFOs, via MDF_DFLT0DR. The FTHF event is released when the first data is read.

For the RXFIFOs working in interleaved-transfer mode, the interrupt mode is enabled by setting FTHIE to 1 in MDF_DFLT0DR and by defining the amount of RXFIFOs working in interleaved-transfer mode via ILVNB[3:0]. FTHIE of the other RXFIFOs working in interleaved-transfer mode (RXFIFO1 to ILVNB[3:0]) are not taken into account.

The interleaved-transfer mode can only be applied starting at RXFIFO0 up to RXFIFOk. The number of RXFIFOs working in interleaved-transfer mode are defined by ILVNB[3:0].

When ILVNB[3:0] = 0, all RXFIFOs work in independent-transfer mode.

The interleaved-transfer mode can be used only for digital filters delivering samples perfectly synchronous each other. This is typically the case of sound capture with an array of digital microphones sharing the same bitstream clock.

Caution: To make the MDF working properly in interleaved-transfer mode, the following rules must be respected:

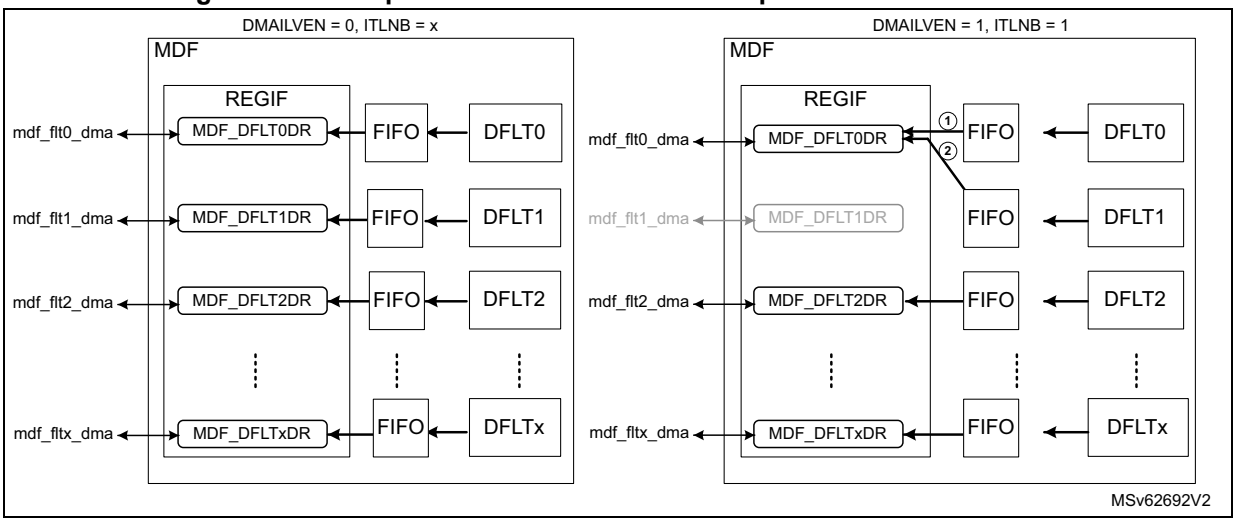
- All filters working in interleaved-transfer mode must be all synchronized together, meaning that all filters must select the same ACQMOD[2:0] (must be equal to 010 or 011), the same trigger source and the same trigger sensitivity.
- All filters working in interleaved-transfer mode must have the same configuration.
- All sensors providing the data for the filters working in interleaved-transfer mode must use the same bitstream clock frequency.
- The maximum delay difference applied with SPKDLY[6:0] for the filters working in interleaved-transfer mode must remain strictly lower than the RXFIFO depth. Normally this delay does not need to exceed one T_{PCM} period.

Note: Both independent- and interleaved-transfer modes can work in parallel: for example, the first RXFIFOs (RXFIFO0 to RXFIFOk) may work in interleaved-transfer mode when the others (RXFIFO(k+1) to RXFIFO(N)) works in independent-transfer mode.

If the AHB clock is not present when a data transfer must be performed, the MDF first requests the AHB clock (refer to Section 35.4.5: Clock generator (CKGEN) for details).

The figure below shows the data path for a configuration in independent-transfer mode (left-hand figure) and a configuration mixing both independent- and interleaved-transfer modes (right-hand figure).

Figure 347. Data path for interleaved- and independent-transfer modes



In the right-hand figure, the DFLT0 and DFLT1 filters are configured in interleaved-transfer mode. For those filters, FTH is no longer taken into account by the hardware. The samples provided by DFLT0 and DFLT1 are read from MDF_DFLT0DR. When both RXFIFOs are no longer empty, the MDF generates two DMA requests to read the sample from DFLT0 and the sample from DFLT1. If both RXFIFOs are not empty again, the same sequence is triggered.

Note: When one of the filter working in interleaved-transfer mode is disabled, the data transfer to memory of all filters in interleaved-transfer mode is stopped immediately as well.

RXFIFO overrun

A RXFIFO overrun condition is detected when the RXFIFO is full and a new sample from the DFLTx must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

Figure 348 shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.

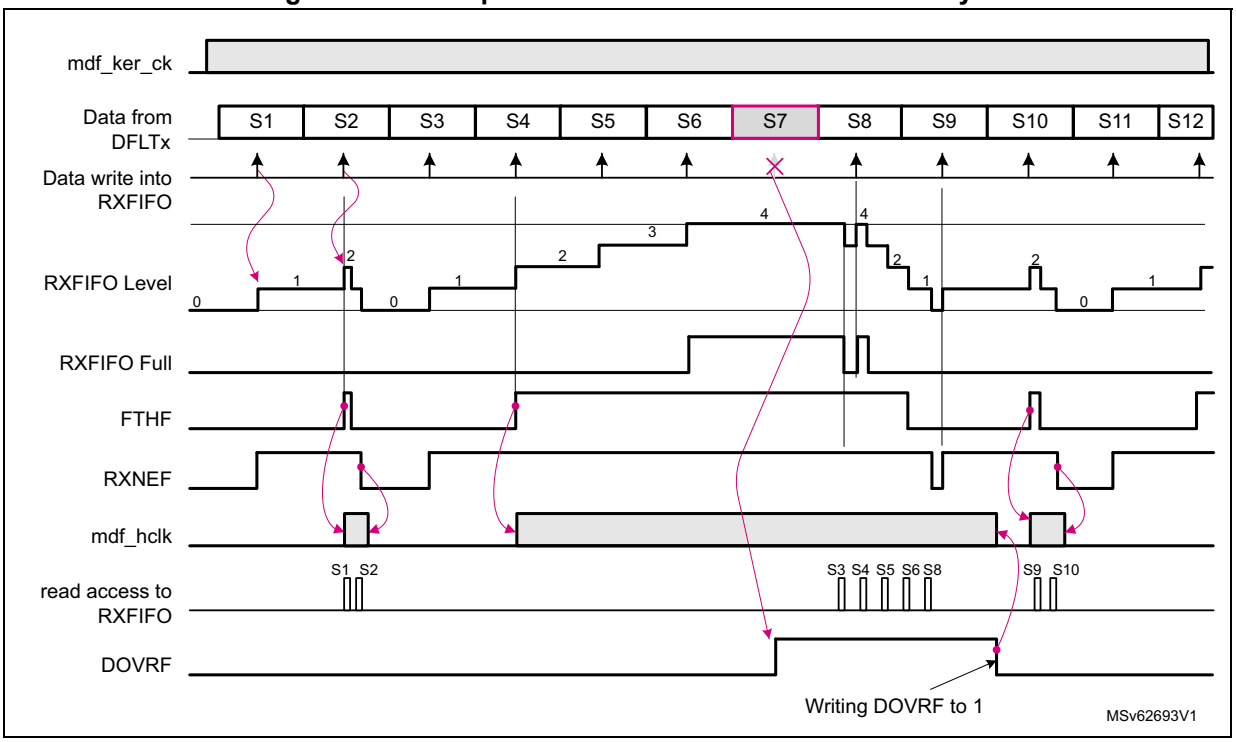
The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO and the MDF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the mdf_hclk line, the gray boxes indicate that the MDF requested the AHB clock. The figure below shows the AHB clock available only when the MDF requests it. In real applications, the AHB clock may also be present if the MDF does not request it.

Figure 348. Example of overflow and transfer to memory



Note: If the MDF works in interleaved-transfer mode, the application must check the overrun status of all RXFIFOs that works in interleaved-transfer mode.

35.4.14 Autonomous mode

The MDF can work even if the AHB bus clock is not available (Stop modes). The MDF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the MDF receives a kernel clock if the selected clock source is an oscillator available in Stop mode

In Stop mode, the MDF receives the AHB clock if the following conditions are met:

- The MDF autonomous mode is enabled in the RCC.
- The MDF requests the AHB clock, in the following situations:
  - when the MDF must transfer data into the memory via the DMA

    The data are directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the MDF must generate an interrupt

    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is generated.The AHB clock request is maintained as long as an enabled interrupt

flag is active. More precisely, when an interrupt must be generated, the MDF requests the AHB clock.

35.4.15 Register protection

The MDF embeds some hardware protection to prevent invalid situations. The table below shows the list of write-protected and unprotected fields.

Table 287. Register protection summary

Registers	Unprotected fields	Write-protected fields	Write-protection condition
MDF global control register (MDF_GCR)	TRGO	ILVNB[3:0]	DFLTACTIVE0 = 1
MDF clock generator control register (MDF_CKGCR)	CKGDEN CCK0EN CCK1EN	PROCDIV[6:0], CCKDIV[3:0], CKGMOD, TRGSRC[3:0], TRGSENS, CCK[1:0]DIR	CKGACTIVE = 1
MDF serial interface control register x (MDF_SITFxCR)	SITFEN	STH[4:0], SITFMOD[1:0], SCKSRC[1:0]	SITFACTIVEx = 1
MDF bitstream matrix control register x (MDF_BSMXxCR)	-	BSSEL[4:0]	DFLTACTIVEx = 1 or SCDACTIVEx = 1 or OLDACTIVEx = 1
MDF digital filter control register x (MDF_DFLTxCR)	DFLTEN	NBDIS[7:0], TRGSRC[3:0], TRGSENS, FTH, DMAEN, SNPSFMT, ACQMOD[2:0]	DFLTACTIVEx = 1
MDF digital filter configuration register x (MDF_DFLTxCICR)	SCALE[5:0]	MCICD[8:0], CICMOD[2:0], DATSRC[1:0]	
MDF reshape filter configuration register x (MDF_DFLTxRSFR)	-	All fields	
MDF integrator configuration register x (MDF_DFLTxINTR)	-	All fields	
MDF out-of limit detector control register x (MDF_OLDxCR)	OLDEN	ACICD[4:0], ACICN[1:0],THINB BKOLD[3:0]	OLDACTIVEx = 1
MDF OLDx low threshold register x (MDF_OLDxTHLR)	-	All fields	
MDF OLDx high threshold register x (MDF_OLDxTHHR)	-	All fields	
MDF delay control register x (MDF_DLYxCR)	-	SKPDLY[6:0]	SKPBF = 1
MDF short circuit detector control register x (MDF_SCDxCR)	SCDEN	BKSCD[3:0], SCDT[7:0]	SCDACTIVEx = 1
MDF DFLTx interrupt enable register x (MDF_DFLTxIER)	All fields	-	-

Table 287. Register protection summary (continued)

Registers	Unprotected fields	Write-protected fields	Write-protection condition
MDF DFLTx interrupt status register x (MDF_DFLTxISR)	All fields	-	-
MDF offset error compensation control register x (MDF_OECxCR)	OFFSET[25:0]	-	-

All the MDF processing is performed in the mdf_proc_ck clock domain. For that reason, enabling or disabling a MDF sub-block may take some time due to the re-synchronization between the AHB clock domain and the mdf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected bitfield, the application must follow this sequence:

1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for more details.

35.5 MDF low-power modes

Table 288. Effect of low-power modes on MDF

Mode	Description
Sleep	No effect. MDF interrupts cause the device to exit Sleep mode.
Stop(1)	The MDF registers content is kept. If the MDF is clocked by an internal oscillator available in Stop mode, the MDF remains active. The interrupts cause the device to exit Stop mode.
Standby	The MDF is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 35.3: MDF implementation* for details about Stop modes supported by the MDF.

35.6 MDF interrupts

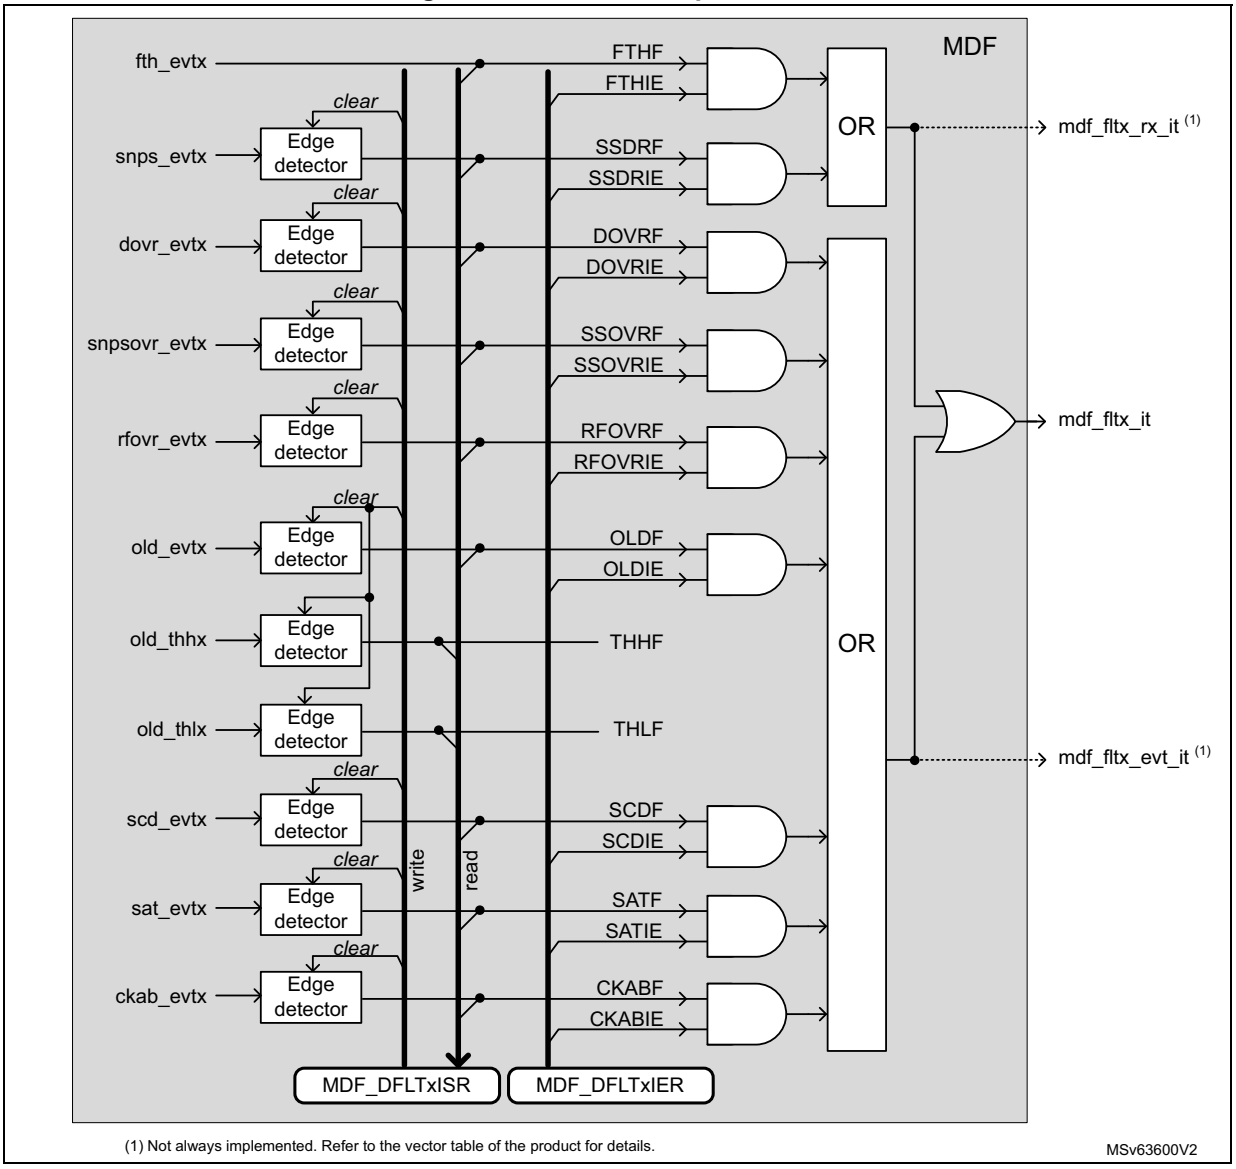
To increase the CPU performance, the MDF offers the following interrupt lines per digital filter:

- receive interrupt MDF_FLTx_RX (mdf_fltx_rx_it)
- event interrupt MDF_FLTx_EVT (mdf_fltx_evt_it)
- a combination of both interrupts MDF_FLTx (mdf_fltx_it)

Note: Interrupts are not always connected to the device (see Section 35.3: MDF implementation for more details).
The status flags are available even if the corresponding interrupt enable flag is not enabled.

The interrupt interface is controlled via the *MDF DFLTx interrupt enable register x (MDF_DFLTxIER)* and the *MDF DFLTx interrupt status register x (MDF_DFLTxISR)*.

Figure 349. MDF interrupt interface



The table below shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

Table 289. MDF interrupt requests

Interrupt vectors		Interrupt event	Event flag	Event/interrupt clearing method	Exit Sleep mode	Exit Stop modes[1]	Exit Standby mode
MDF_FLTx[2]	MDF_FLTx_RX[3]	RXFIFO threshold reached	FTHF	Read MDF_DFLTxDR until RXFIFO level is lower than the threshold.	Yes	Yes	No
		Snapshot data ready	SSDRF	Write SSDRF to 1.			
	MDF_FLTx_EVT[4]	Snapshot data overrun	SSOVRF	Write SSOVRF to 1.			
		RXFIFO overrun	DOVRF	Write DOVRF to 1.			
		RSFLT overrun	RFOVRF	Write RFOVRF to 1.			
		Short-circuit detector	SCDF	Write SCDF to 1.			
		Saturation detection	SATF	Write SATF to 1.			
		Channel clock absence detection	CKABF	Write CKABF to 1.			
		Out-of-limit detector	OLDF	Write OLDF to 1.			
-	-		THHF	Write OLDF to 1.	-	-	-
-	-		THLF	Write OLDF to 1.	-	-	-

1. Refer to *Section 35.3: MDF implementation* for details.
2. MDF_FLTx vector corresponds to the assertion of mdf_fltx_it signal
3. MDF_FLTx_RX vector corresponds to the assertion of mdf_fltx_rx signal.
4. MDF_FLTx_EVT vector corresponds to the assertion of mdf_fltx_evt signal.

35.7 MDF application informations

35.7.1 MDF configuration examples for audio capture

Table 290 gives some examples of the MDF settings for the digital microphones, focusing on 16 and 48 kHz output data rate. In these examples, the following is expected:

- The INT block is bypassed (INTVAL = 0).
- The offset error compensation is disabled (OFFSET = 0).

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (mdf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple and a good image rejection.

Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

Table 290. Examples of MDF settings for microphone capture

Configuration	mdf_ker_ck (MHz)	PROCDIV + 1	CCKDIV + 1	CIC order (1)	MCICD + 1	SCALE	RSFLTBYP	RSFLTD	HPFBYP	-	mdf_proc_ck (MHz)	Total dec. ratio	F_{RS} (kHz)	F_{MDF_CCKx} (MHz)	F_{PCM} (kHz)
#1	1.024	1	2	4	64	0x2D (- 8.5 dB)	1	x	x	=>	1.024	64	-	0.512	8
#2		1	2	5	32	0x2B (- 14.5 dB)						32	-		16
#3		1	2	5	16	0x01 (+ 3.5 dB)	0	0				64	32		8
#4	2.048	1	2	5	16	0x01 (+ 3.5 dB)	0	0			2.048	64	64	1.024	16
#5	3.072	1	6	5	8	0x0B (+ 33.6 dB)	0	0			3.072	32	32	0.512	8
#6		2	2	5	12	0x06 (+ 18.1 dB)						48	64	0.768	16
#7		1	2	5	24	0x2C (- 12 dB)						96		1.536	
#8	4.096	1	2	5	32	0x27 (- 26.6 dB)	0	0			4.096	128	64	2.048	16
#9	6.144	3	2	5	16	0x02 (+ 6.0 dB)	0	0			2.048	64	64	1.024	16
#10		2	2	5	24	0x2C (- 12 dB)					3.072	96		1.536	
#11		1	2	5	16	0x01 (+ 3.5 dB)					6.144	64	192	3.072	48
#12	7.680	1	2	5	20	0x2E (- 6.0 dB)	0	0			7.680	80	192	3.840	48

1. CICMOD = 100 for CIC order equal to 4. CICMOD = 101 for CIC order equal to 5.

35.7.2 Programming examples

This example describes how to capture sound from four microphones, assuming that each microphone pair shares the same data line. The MDF_SD0 and MDF_SD2 data lines are used. The microphone clock is provided by the MDF via MDF_CCK0 pin.

Table 291. Programming sequence

Operations	Comments
Adjust the proper kernel clock frequency via the RCC block	Assuming that the RCC is programmed to provide a kernel clock (mdf_ker_ck) of 12.288 MHz
Select the proper MDF kernel clock source via the RCC block	Refer to the RCC of the product.
Enable the MDF clocks via the RCC block	Refer to the RCC of the product.
Reset the MDF via the RCC block	Refer to the RCC of the product.
AFMUX programming	Program the AFMUX to select MDF_SD0, MDF_SD2 and MDF_CCK0 function.

Table 291. Programming sequence (continued)

Operations	Comments
Enable MDF processing clock: MDF_CKGCR = 0x0103 0023	PROCDIV = 1 (division by 2): mdf_proc_ck frequency is 6.144 MHz. CCKDIV = 3 (division by 4): MDF_CCK0 clock frequency is 1.536 MHz. The MDF_CCK0 pad is set in output and generates a clock so that the microphones can exit from low-power mode.
Serial interfaces configuration: MDF_SITF0CR = 0x0000 1F01 MDF_SITF2CR = 0x0000 1F01	SCKSRC = 0 to select MDF_CCK0 as serial clock. SIFTMOD = 0 to select LF_MASTER mode. Clock absence feature is not working in this mode. The serial interfaces are enabled.
Bitstream matrix configuration: MDF_BSMX0CR = 0x0000 0000 MDF_BSMX1CR = 0x0000 0001 MDF_BSMX2CR = 0x0000 0004 MDF_BSMX3CR = 0x0000 0005	DFLT0 filter takes the bitstream of SITF0, sampled on rising edge. DFLT1 filter takes the bitstream of SITF0, sampled on falling edge. DFLT2 filter takes the bitstream of SITF2, sampled on rising edge. DFLT3 filter takes the bitstream of SITF2, sampled on falling edge.
Filters configuration (CIC): MDF_DFLT0CICR = 0x02C0 1750 MDF_DFLT1CICR = 0x02C0 1750 MDF_DFLT2CICR = 0x02C0 1750 MDF_DFLT3CICR = 0x02C0 1750	SCALE = 0x2C (- 12 dB) to avoid any saturation MCICD = 0x17 (decimation by 24) CICMOD = 5 to select a $Sinc^5$ DATSCR = 0 to select data coming from BSMX
Filters configuration (RSFLT and HPF): MDF_DFLT0RSFR = 0x0000 0100 MDF_DFLT1RSFR = 0x0000 0100 MDF_DFLT2RSFR = 0x0000 0100 MDF_DFLT3RSFR = 0x0000 0100	HPFC = 1: cut-off frequency of 16 kHz * 0.00125 = 20 Hz HPFBYP = 0: HPF not bypassed RSFLTD = 0: RSFLT decimates by 4 RSFLTBYP = 0: RSFLT is not bypassed
Filters configuration (INT): MDF_DFLT0INTR = 0x0000 0000 MDF_DFLT1INTR = 0x0000 0000 MDF_DFLT2INTR = 0x0000 0000 MDF_DFLT3INTR = 0x0000 0000	INTVAL = 0: INT filter not used Other parameter is not significant.
Micro delay adjust: MDF_DLY0CR = 0x0000 0005 MDF_DLY0CR = 0x0000 0012 MDF_DLY0CR = 0x0000 0023 MDF_DLY0CR = 0x0000 0000	Initial micro-delay for each microphone, values just given as example
Offset error correction: MDF_OEC0CR = 0x0000 0000 MDF_OEC1CR = 0x0000 0000 MDF_OEC2CR = 0x0000 0000 MDF_OEC3CR = 0x0000 0000	No correction. DC offset is removed by HPF.

Table 291. Programming sequence (continued)

Operations	Comments
Short circuit detection: MDF_SCD0CR = 0x0000 0000 MDF_SCD1CR = 0x0000 0000 MDF_SCD2CR = 0x0000 0000 MDF_SCD3CR = 0x0000 0000	SCD function for each filter is disabled.
Enable interrupt events: MDF_DFLT0IER = 0x0000 0202 MDF_DFLT1IER = 0x0000 0202 MDF_DFLT2IER = 0x0000 0202 MDF_DFLT3IER = 0x0000 0202	Enable the interrupt event the application wants to handle. In this example, the SATIE and DOVRIE bits are set to 1 to have an interrupt if a saturation or an data overflow occurs.
Digital filter control: MDF_DFLT0CR = 0x0000 0027 MDF_DFLT1CR = 0x0000 0027 MDF_DFLT2CR = 0x0000 0027 MDF_DFLT3CR = 0x0000 0027 Wait for DFLTACTIVE = 0 for the filters	NBDIS = 0: no samples discarded TRGSRC = 0: TRGO selected as trigger source TRGSENS = 0: Trigger on rising edge ACQMOD = 2: Synchronous continuous acquisition mode DMAEN = 1: DMA interface enabled DFLTEN = 1: digital filter enabled
Clear status flags: MDF_DFLT0ISR = 0x0000 0FFF MDF_DFLT1ISR = 0x0000 0FFF MDF_DFLT2ISR = 0x0000 0FFF MDF_DFLT3ISR = 0x0000 0FFF	Clear all the status flags before running the filters.
Program the DMA Enable the DMA	The DMA must be programmed in order to read the data inside MDF_DFLT0DR every time a DMA request is generated. Note that when the MDF is in interleaved acquisition mode, data of filters 0, 1, 2, and 3 are read via MDF_DFLT0DR register.
Start acquisition: MDF_GCR = 0x0000 0031	ILVNB = 3: interleaved mode with DFLT0,1,2, and 3 TRGO = 1 to trigger the acquisition of all filters waiting for TRGO rising edge event

35.7.3 Connection examples

Figure 350 shows simple connection examples of the MDF to external sensors:

- Picture on the left: four digital microphones connected to the MDF

  In this connection, DMIC1 is intended to be used alone. This is why it uses a dedicated clock (MDF_CCK0). DMIC1 is also connected to a dedicated data line in case the application intends to power-down DMIC2/3/4, when only DMIC1 is used. If the application keeps DMIC2/3/4 powered, DMIC2 and DMIC1 can share the same data line, reducing the connection to four I/Os.

  If the power consumption is not an issue, when a single microphone is used, all the microphones can be connected to the same common clock (MDF_CCK0) and each

microphone pair can share the same data line. In this case, only three I/Os are required.

In this example, the data transfer to memory can be performed either using the interleaved- or the independent-transfer mode.

- Picture in the center: sensor providing several data lines with a common clock

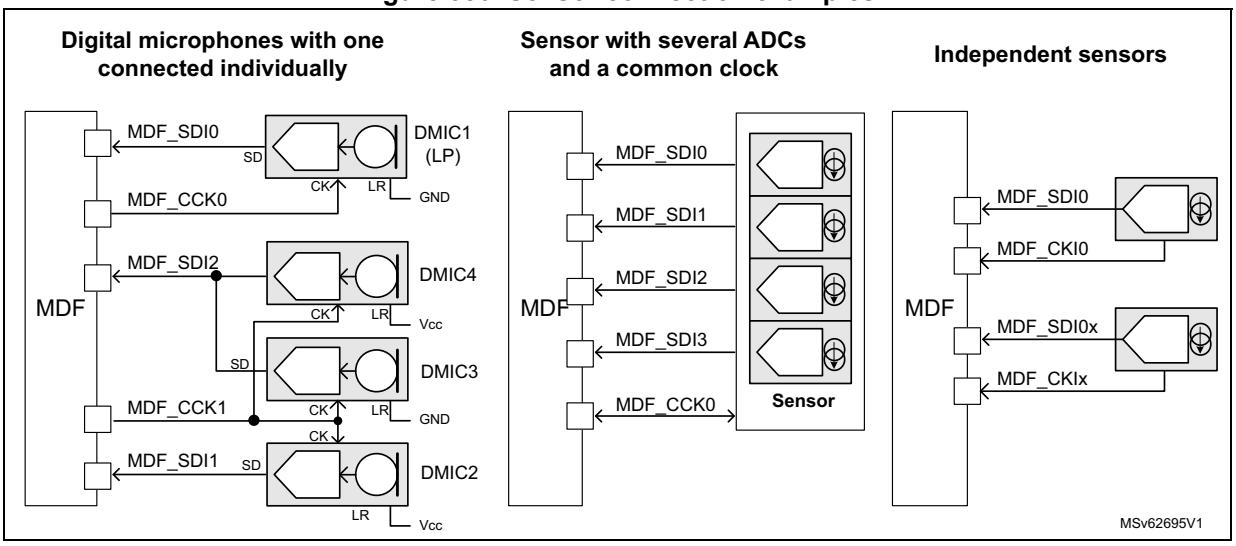
  Each data line can represent different parameters (such as current or voltage). The common clock can be provided either by the sensor or by the MDF. The data line can be shared or not by two sensors if the sensor allows it. In the figure below, the sensor does not allow the sharing of the data lines.

  In this example, the data transfer to memory can be performed either using the interleaved- or independent-transfer mode.

- Picture on the right: two independent sensors connected to the MDF

  Each of them has its dedicated clock and data lines. In this case, the data transfer to memory must use the independent-transfer mode.

Figure 350. Sensor connection examples



35.7.4 Global frequency response

Figure 351 shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enable with a cut-off frequency of 40 Hz

The figure below shows the theoretical frequency response using a CIC4 and a CIC5.

Figure 351. Global frequency response

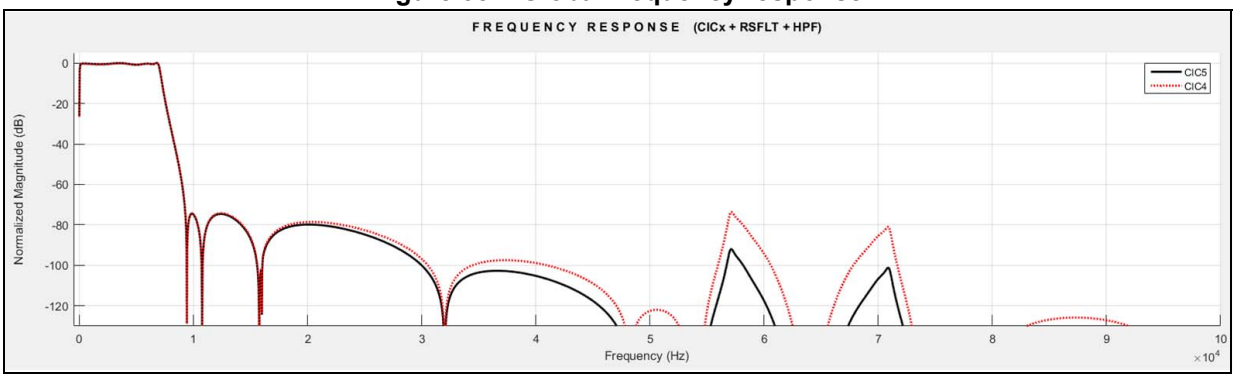


Figure 352 shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

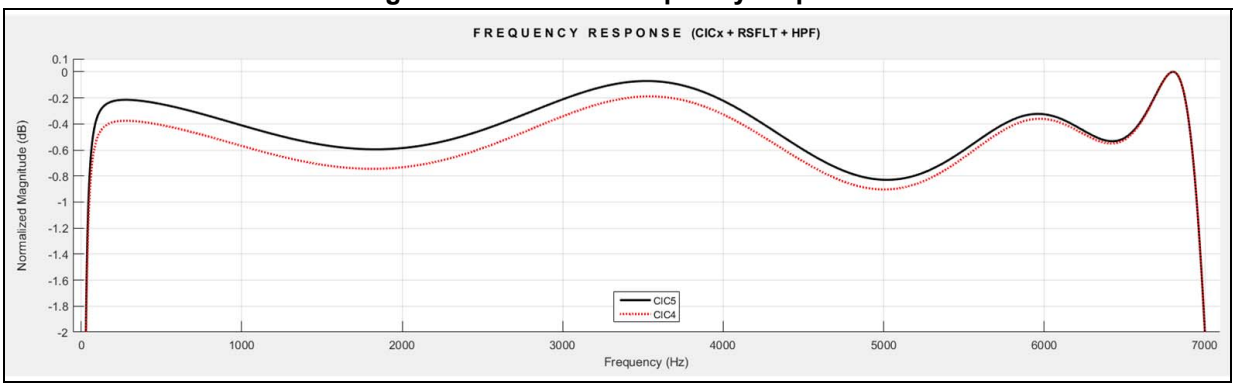
- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enable with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 for CIC4.

The -3 dB cut-off frequency is 7061 Hz.

Figure 352. Detailed frequency response



35.7.5 Total MDF gain

This section details how to compute the signal level provided by the MDF according to the filter settings. The formula does not take into account the filters transfer function.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50 % of the maximum level, has a - 6 dBFS level (6 dB below full scale).

For example, for the MDF offering a final data width of 24 bits, a signal having an amplitude of 2 * 10^6 LSB has a level of:

$$20 \times \log_{10}\left(\frac{2 \times 10^6}{2^{(24-1)}}\right) = -12.45 \text{ dBFS}$$

In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left(\frac{\ln(Amp)}{\ln(2)} + 1\right) \text{ bits}$$

One bit need to be added for negative values.

So a signal having an amplitude of 2 * 10^6 LSB, has a data size of 21.9 bits.

CIC gain

The CIC gain (G_{CIC} and GdB_{CIC}) can be deduced from the following formula giving data size in bits (DS_{CIC}).

$$DS_{CIC} = (N \times \log_2(D1)) + DS_{IN}$$

And the bit growth is:

$$BG_{CIC} = (N \times \log_2(D1))$$

where N represents the CIC order (selected by CICMOD[2:0]), and D1 is the decimation ratio (given by MCICD).

DS_{IN} represents the data size (in bits) of the input signal.

Warning: DS_{CIC} is very important for CIC filters. In order to work fine, DS_{CIC} must not exceed 26 bits.

$$G_{CIC} = 2^{(BG_{CIC})} = (D1)^N$$

which gives, in decibels:

$$GdB_{CIC} = 20 \times \log_{10}((D1)^N)$$

Note: The same formulas are valid for the ACIC.

Data size at SCALE output

The data size at SCALE output (including the CIC gain) is a key information as the RSFLT starts to have some saturations if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.

If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted. The resulting data size is given by:

$$DS_{SCALE} = N \times \log_2(D1) + \log_2\left(10^{\frac{GDB_{SCALE}}{20}}\right) + DS_{IN}$$

The data size at SCALE output (DS_{SCALE}) is expressed in bits and GdB_{SCALE} represents the gain selected by SCALE[5:0], in dB.

RSFLT gain

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.5 dB must be considered. Typically, the RSFLT increases the bit size by BG_{RSFLT}:

$$BG_{RSFLT} = 10^{\frac{9.5\ dB}{20}} = 2.98 = 1.6\ bits$$

INT gain

The INT block can also introduce a gain if the rescaling value is different from the integration value.

$$G_{INT} = \frac{IVAL}{IDIV}$$

and:

$$GdB_{INT} = 20 \times \log_{10}\left(\frac{IVAL}{IDIV}\right)$$

The bit growth of the INT is then given by the following formula:

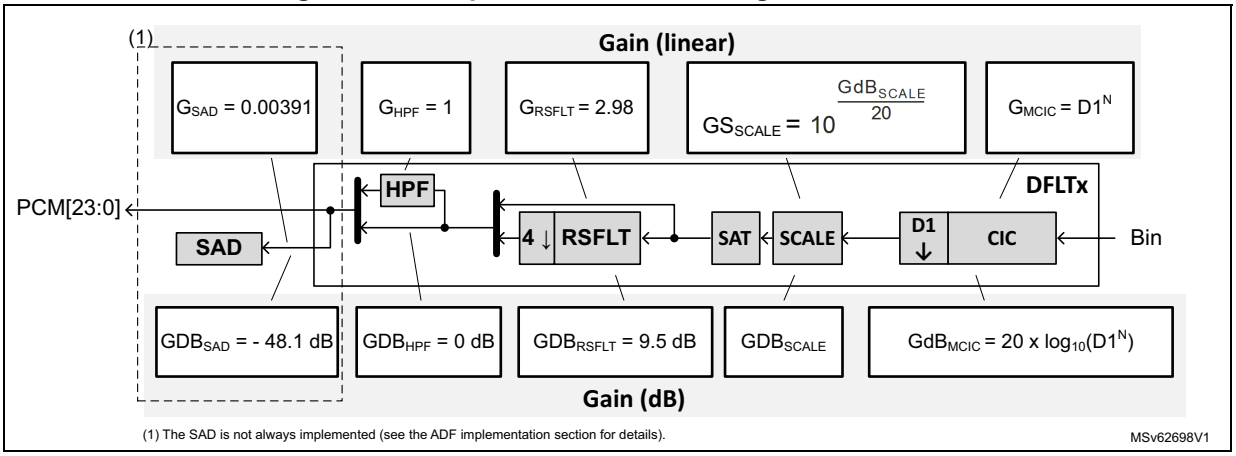
$$BG_{INT} = \log_2\left(\frac{IVAL}{IDIV}\right)$$

IVAL represents the integration value selected by INTVAL[6:0], and IDIV represents the integrator output division selected by INTDIV[1:0].

Note: The HPF filter has a gain of 0 dB.

The figure below shows a simplified view of the filter path, and gives for each significant component the expression of the bit growth and the gain.

Figure 353. Simplified DFLT view with gain information



The table below summarizes the final data size for different filter configurations.

Table 292. Output signal levels

Filter configurations	Final signal level (dBFS)	Final signal size (bits)
CIC + RSFLT (+ HPF)	$SdB_{OUT} = 20 \times \log_{10}\left(\frac{2^{DS_{OUT}}}{2^{24}}\right)$	$DS_{OUT} = DS_{SCALE} + 1.6$ bits DS_{SCALE} must be lower than 22 bits.
CIC + RSFLT (+ HPF) + INT		$DS_{OUT} = DS_{SCALE} + BG_{INT} + 1.6$ bits DS_{SCALE} must be lower than 22 bits.
CIC (+ HPF) + INT		$DS_{OUT} = DS_{SCALE} + BG_{INT}$ DS_{SCALE} must be lower than 24 bits.

Example using the main filter chain

If the MDF filter is programmed as follows:

- The input signal is coming from a serial interface (DS_{IN} = 1 bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to -12 dB.
- RSFLT is enabled and the decimation by four is enabled.
- HPF is enabled.
- INT is disabled.

Check first the data size at CIC output:

$$DS_{CIC} = (5 \times \log_2(24)) + 1 \text{ bit} = 23.92 \text{ bits}$$

The size is lower than 26 bits, so the CIC works in good conditions.

The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a signal 22 bits max to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

$$DS_{SCALE} = DS_{CIC} + \log_2\left(10^{\frac{-12}{20}}\right) = 23.92 - 1.99 = 21.93 \text{ bits}$$

At the end, the final signal amplitude is:

$$DS_{OUT} = DS_{SCALE} + 1.6 \text{ bits} = (21.93 + 1.6) = 23.52 \text{ bits}$$

or

$$SDB_{OUT} = 20 \times \log_{10}\left(\frac{2^{23.52}}{2^{24}}\right) = -2.84 \text{ dBFS}$$

The RSFLT ripple a margin of about ± 0.41 dB (in this configuration) must be considered.

Example using the OLD filter chain

In the following example, the application wants to trigger an OLD event when the voltage coming from a shunt resistor reaches ± 200 mV.

Hypothesis:

- The ΣΔ sensor is specified to support a full-scale signal of ± 350 mV.
- The ACIC decimation ratio (D2) is fixed to 32.
- The ACIC order (N) is fixed to 3.

The ΣΔ sensor provides a full-scale digital signal (amplitude of one bit) for a signal higher or equal to ± 350 mV. If the input signal is equal 200 mV, then the digital signal amplitude provided by the sensor is 200 / 350 = 0.571.

The gain of the ACIC filter is:

$G_{CIC} = (D2)^N = 32^3 = 32768$

A signal having an amplitude of 200 mV at sensor input has then an amplitude of about 32768 * 0.571 = 18725 LSB at ACIC output.

OLDTHH must be set to 18725 and OLDTHL must be set to -18725.

35.8 MDF registers

All the MDF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

The registers are described for the MDF instance having the biggest number of filters. For registers related to filters, the number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

35.8.1 MDF global control register (MDF_GCR)

Address offset: 0x000

Reset value: 0x0000 0000

This register is used for controls common to all digital filters.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ILVNB[3:0]				Res.	Res.	Res.	TRGO
								rw	rw	rw	rw				rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **ILVNB[3:0]**: Interleaved number

This bitfield is set and reset by software. it enables or disables the interleaved-transfer mode and defines how many digital filters work in this mode.
This bitfield cannot be changed when DFLTEN = 1 in MDF_DFLT0CR.
0000: Interleaved-transfer mode disabled
0001: Data from DFLT0 and DFLT1 are interleaved.
0010: Data from DFLT0, DFLT1 and DFLT2 are interleaved.
...
1111: Data from DFLT0 to DFLT15 are interleaved.

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TRGO**: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also able to synchronize several MDF together by controlling the mdf_trgo signal.
0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.
1: Write 1 generates a positive pulse on mdf_trgo signal and triggers the acquisition on the enabled filters having ACQMOD[2:0] = 0x1 and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.

35.8.2 MDF clock generator control register (MDF_CKGCR)

Address offset: 0x004

Reset value: 0x0000 0000

This register is used to control the clock generator. The mdf_proc_ck clock must be enabled before enabling other MDF parts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CKGACTIVE	PROCDIV[6:0]							Res.	Res.	Res.	Res.	CCKDIV[3:0]			
r	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRGSRC[3:0]				Res.	Res.	Res.	TRGSENS	Res.	CCK1DIR	CCK0DIR	CKGMOD	Res.	CCK1EN	CCK0EN	CKGDEN
rw	rw	rw	rw				rw		rw	rw	rw		rw	rw	rw

Bit 31 **CKGACTIVE**: Clock generator active flag

This bit is set and cleared by hardware. This flag must be used by the application to check if the clock generator is effectively enabled (active) or not. The protected fields of this function can only be updated when CKGACTIVE = 0 (refer to *Section 35.4.15* for details). The delay between a transition on CKGDEN and a transition on CKGACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: The clock generator is not active and can be configured if needed.

1: The clock generator is active and protected fields cannot be configured.

Bits 30:24 **PROCDIV[6:0]**: Divider to control the serial interface clock

This bitfield is set and reset by software. It is used to adjust the frequency of the clock provided to the SITF.

$$F_{mdf_itf_ck} = \frac{F_{mdf_ker_ck}}{(PROCDIV + 1)}$$

This bitfield must not be changed if one of the filters is enabled (DFTEN = 1).

0: mdf_ker_ck provided to the SITF

1: mdf_ker_ck/2 provided to the SITF

2: mdf_ker_ck/3 provided to the SITF

...

127: mdf_ker_ck/128 provided to the SITF

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CCKDIV[3:0]**: Divider to control the MDF_CCK clock

This bitfield is set and reset by software. It is used to adjust the frequency of the MDF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the MDF_CCK is given by the following formula:

$$F_{MDF_CCK} = \frac{F_{mdf_ker_ck}}{(PROCDIV + 1) \times (CCKDIV + 1)}$$

This bitfield must not be changed if one of the filters is enabled (DFTEN = 1).

0000: The MDF_CCK clock is mdf_proc_ck.

0001: The MDF_CCK clock is mdf_proc_ck / 2.

0010: The MDF_CCK clock is mdf_proc_ck / 3.

...

1111: The MDF_CCK clock is mdf_proc_ck / 16.

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software.It is used to select which external signals trigger for the corresponding filter. This bitfield is not significant if CKGMOD = 0.

000x: TRGO selected

0010: mdf_trg[0] selected

0011: mdf_trg[1] selected

...

1111: mdf_trg[13] selected

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details.)

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

0: A rising edge event triggers the activation of CKGEN dividers.

1: A falling edge even triggers the activation of CKGEN dividers.

Note: When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge. This bit can be write-protected (refer to Section 35.4.15 for details).

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: MDF_CCK1 direction

This bit is set and reset by software.It is used to control the direction of the MDF_CCK1 pin.

0: MDF_CCK1 pin direction is in input.

1: MDF_CCK1 pin direction is in output.

Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bit 5 **CCK0DIR**: MDF_CCK0 direction

This bit is set and reset by software.It is used to control the direction of the MDF_CCK0.

0: MDF_CCK0 pin direction is in input.

1: MDF_CCK0 pin direction is in output.

Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bit 4 **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if one of the filters is enabled (DFTEN = 1).

0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.

1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: MDF_CCK1 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the MDF_CCK1 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the MDF_CCK1 pad

Bit 1 **CCK0EN**: MDF_CCK0 clock enable

This bit is set and reset by software.It is used to control the generation of the bitstream clock on the MDF_CCK0 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the MDF_CCK0 pad

Bit 0 **CKGDEN**: CKGEN dividers enable

This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.

0: CKGEN dividers disabled

1: CKGEN dividers enabled

35.8.3 MDF serial interface control register x (MDF_SITFxCR)

Address offset: 0x080 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 1F00

This register is used to control the serial interfaces (SITFx). The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw	rw	rw			rw	rw		rw	rw	rw

Bit 31 **SITFACTIVE**: Serial interface active flag

This bit is set and cleared by hardware. It is used by the application to check if the serial interface is effectively enabled (active) or not. The protected fields of this function can only be updated when the SITFACTIVE is set to 0 (refer to *Section 35.4.15* for details).

The delay between a transition on SITFEN and a transition on SITFACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: The serial interface is not active and can be configured if needed.

1: The serial interface is active and protected fields cannot be configured.

Bits 30:13 Reserved, must be kept at reset value.

Bits 12:8 **STH[4:0]**: Manchester symbol threshold/SPI threshold

This bitfield is set and cleared by software. It is used for Manchester mode to define the expected symbol threshold levels (refer to *Manchester mode* for details on computation).

In addition this bitfield is used to define the timeout value for the clock absence detection in Normal SPI mode. STH[4:0] values lower than four are invalid.

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **SITFMOD[1:0]**: Serial interface type

This bitfield is set and cleared by software. it is used to define the serial interface type.

00: LF_MASTER SPI mode

01: Normal SPI mode

10: Manchester mode: rising edge = logic 0, falling edge = logic 1

11: Manchester mode: rising edge = logic 1, falling edge = logic 0

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **SCKSRC[1:0]**: Serial clock source

This bitfield is set and cleared by software. it is used to select the clock source of the serial interface.

00: Serial clock source is MDF_CCK0.

01: Serial clock source is MDF_CCK1.

1x: Serial clock source is MDF_CKIx (not allowed in LF_MASTER SPI mode).

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bit 0 **SITFEN**: Serial interface enable

This bit is et and cleared by software. It is used to enable/disable the serial interface.

0: Serial interface disabled

1: Serial interface enabled

35.8.4 MDF bitstream matrix control register x (MDF_BSMXxCR)

Address offset: 0x084 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to select the bitstream to be provided to the corresponding digital filter and to the SCD. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw	rw	rw	rw

Bit 31 **BSMXACTIVE**: BSMX active flag

This bit is set and cleared by hardware. It is used by the application to check if the BSMX is effectively enabled (active) or not. BSSEL[4:0] can only be updated when the BSMXACTIVE is set to 0. Th is BSMXACTIVE flag is a logical OR between OLDACTIVE, DFLTACTIVE, and SCDACTIVE flags. Both of them must be set to 0 in order update BSSEL[4:0] bitfield.

0: BSMX is not active and can be configured if needed.

1: BSMX is active and protected fields cannot be configured.

Bits 30:5 Reserved, must be kept at reset value.

Bits 4:0 **BSSEL[4:0]**: Bitstream Selection

This bitfield is set and cleared by software. It is used to select the bitstream to be processed for DFLTx and SCDx. The size of this bitfield depends on the number of DFLTx instantiated. If this bitfield selects a not instantiated input, the MDF selects the valid stream bsx_f having the higher index number.

00000: bs0_r provided to DFLTx and SCDx

00001: bs0_f provided to DFLTx and SCDx

00010: bs1_r provided to DFLTx and SCDx (if instantiated)

00011: bs1_f provided to DFLTx and SCDx (if instantiated)

...

11110: bs15_r provided to DFLTx and SCDx (if instantiated)

11111: bs15_f provided to DFLTx and SCDx (if instantiated)

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

35.8.5 MDF digital filter control register x (MDF_DFLTxCR)

Address offset: 0x088 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

Bit 31 **DFLTACTIVE**: Digital filter active flag

This bit is set and cleared by hardware. It indicates if the digital filter is active: can be running or waiting for events.

0: Digital filter not active (can be re-enabled again, via DFLTEN, if needed)

1: Digital filter active

Bit 30 **DFLTRUN**: Digital filter run status flag

This bit is set and cleared by hardware. It indicates if the digital filter is running or not.

0: Digital filter not running and ready to accept a new trigger event

1: Digital filter running

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 **NBDIS[7:0]**: Number of samples to be discarded

This bitfield is set and cleared by software. it is used to define the number of samples to be discarded every time the DFLTx is re-started.

0: No sample discarded

1: 1 sample discarded

2: 2 samples discarded

...

255: 255 samples discarded

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **SNPSFMT**: Snapshot data format

This bit is set and cleared by software. It is used to select the data format for the snapshot mode.

0: Integrator counter (INT_CNT) not inserted into MDF_SNPSxDR, leaving a data resolution of 23 bits

1: Integrator counter (INT_CNT) inserted at position [15:9] of MDF_SNPSxDR, leaving a data resolution of 16 bits.

Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection
This bitfield is set and cleared by software. It is used to select which external signals trigger the corresponding filter.
0000: TRGO selected
0001: OLDx event selected
0010: mdf_trg[0] selected
...
1111: mdf_trg[13] selected
Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: Digital filter trigger sensitivity selection
this bit is set and cleared by software. It is used to select the trigger sensitivity of the external signals
0: A rising edge event triggers the acquisition.
1: A falling edge even triggers the acquisition.
Note: When the trigger source is TRGO or OLDx event, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge, when OLDx event is selected, the sensitivity is forced to rising edge.
This bit can be write-protected (refer to Section 35.4.15 for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: Digital filter trigger mode
This bitfield is set and cleared by software. It is used to select the filter trigger mode.
000: Asynchronous continuous acquisition mode
001: Asynchronous single-shot acquisition mode
010: Synchronous continuous acquisition mode
011: Synchronous, single-shot acquisition mode
100: Window continuous acquisition mode
101: Synchronous snapshot mode
Others: same a 000
Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTH**: RXFIFO threshold selection
This bit is set and cleared by software. It is used to select the RXFIFO threshold. This bit is not significant for RXFIFOs working in interleaved-transfer mode (see *Interleaved-transfer mode* for details).
0: RXFIFO threshold event generated when the RXFIFO is not empty
1: RXFIFO threshold event generated when the RXFIFO is half-full
Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bit 1 **DMAEN**: DMA requests enable
This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory.
0: DMA interface for the corresponding digital filter disabled
1: DMA interface for the corresponding digital filter enabled
Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bit 0 **DFLTEN**: Digital filter enable

This bit is set and cleared by software. It is used to control the start of acquisition of the corresponding digital filter path. This bit behavior depends on ACQMOD[2:0]and external events. The serial or parallel interface delivering the samples must be enabled as well.

0: Acquisition immediately stopped

1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x or 100.

35.8.6 MDF digital filter configuration register x (MDF_DFLTxCICR)

Address offset: 0x08C + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to control the main CIC filter.The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw			rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **SCALE[5:0]**: Scaling factor selection

This bitfield is set and cleared by software. It is used to select the gain to be applied at CIC output (refer to *Table 283* for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this bitfield informs the application on the current gain value.

000000: 0 dB

000001: + 3.5 dB

000010: + 6 dB or shift left by 1 bit

...

011000: + 72 dB or shift left by 12 bits

100000: - 48.2 dB or shift right by 8 bits (default value)

100001: - 44.6 dB

100010: - 42.1 dB or shift right by 7 bits

100011: - 38.6 dB

...

101110: - 6 dB or shift right by 1 bit

101111: - 2.5 dB

Others: Reserved

Bits 19:17 Reserved, must be kept at reset value.

Bits 16:8 **MCICD[8:0]**: CIC decimation ratio selection
This bitfield is set and cleared by software. It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by (CICDEC+1).
0: Decimation ratio is 2.
1: Decimation ratio is 2.
2: Decimation ratio is 3..
3: Decimation ratio is 4
...
511: Decimation ratio is 512.
Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **CICMOD[2:0]**: Select the CIC mode
This bitfield is set and cleared by software.It is used to select the configuration and the order of the MCIC. When CICMOD[2:0] = 0xx, the CIC is split into two filters: the main CIC (MCIC) and the auxiliary CIC (ACIC, used for the out-off limit detector).
000: CIC split in two filters and MCIC configured in FastSinc filter
001: CIC split in two filters and MCIC configured in $Sinc^1$ filter
010: CIC split in two filters and MCIC configured in $Sinc^2$ filter
011: CIC split in two filters and MCIC configured in $Sinc^3$ filter
100: CIC configured in single $Sinc^4$ filter
others: CIC configured in single $Sinc^5$ filter
Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **DATSRC[1:0]**: Source data for the digital filter
This bitfield is set and cleared by software.
0x: Stream coming from the BSMX selected
10: Stream coming from the ADCITF1 selected
11: Stream coming from the ADCITF2 selected
Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

35.8.7 MDF reshape filter configuration register x (MDF_DFLTxRSFR)

Address offset: 0x090 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to control the reshape and HPF filters. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

						rw	rw	rw			rw				rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:8 **HPFC[1:0]**: High-pass filter cut-off frequency

This bitfield is set and cleared by software. It is used to select the cut-off frequency of the high-pass filter. F_{PCM} represents the sampling frequency at HPF input.

00: Cut-off frequency = 0.000625 x F_{PCM}

01: Cut-off frequency = 0.00125 x F_{PCM}

10: Cut-off frequency = 0.00250 x F_{PCM}

11: Cut-off frequency = 0.00950 x F_{PCM}

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bit 7 **HPFBYP**: High-pass filter bypass

This bit is set and cleared by software. It is used to bypass the high-pass filter.

0: HPF not bypassed (default value)

1: HPF bypassed

Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **RSFLTD**: Reshaper filter decimation ratio

This bit is set and cleared by software. It is used to select the decimation ratio for the reshape filter.

0: Decimation ratio is 4 (default value).

1: Decimation ratio is 1.

Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RSFLTBYP**: Reshaper filter bypass

This bit is set and cleared by software. It is used to bypass the reshape filter and its decimation block.

0: Reshape filter not bypassed (default value)

1: Reshape filter bypassed

Note: This bit can be write-protected (refer to Section 35.4.15 for details).

35.8.8 MDF integrator configuration register x (MDF_DFLTxINTR)

Address offset: 0x094 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to the integrator (INT) settings. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	INTVAL[6:0]							Res.	Res.	INTDIV[1:0]	
					rw	rw	rw	rw	rw	rw	rw			rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:4 **INTVAL[6:0]**: Integration value selection

This bitfield is set and cleared by software. It is used to select the integration value.

0: The integration value is 1, meaning bypass mode (default after reset).

1: The integration value is 2.

2: The integration value is 3.

...

127: The integration value is 128.

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **INTDIV[1:0]**: Integrator output division

This bitfield is set and cleared by software. It is used to rescale the signal at the integrator output in order keep the data width lower than 24 bits.

00: The integrator data outputs are divided by 128 (default value).

01: The integrator data outputs are divided by 32.

10: The integrator data outputs are divided by 4.

11: The integrator data outputs are not divided.

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

35.8.9 MDF out-of limit detector control register x (MDF_OLDxCR)

Address offset: 0x098 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to configure the OLDx.The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OLDACTIVE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACICD[4:0]					Res.
r										rw	rw	rw	rw	rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

		rw	rw					rw	rw	rw	rw			rw	rw

Bit 31 **OLDACTIVE**: OLDx active flag

This bit is set and cleared by hardware. It is used to check if the OLDx is effectively enabled (active) or not. The protected fields and registers of this function can only be updated when the OLDACTIVE is set to 0 (refer to *Section 35.4.15* for details).

The delay between a transition on OLDEN and a transition on OLDACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: OLDx not active and can be configured if needed

1: OLDx active and protected fields cannot be configured

Bits 30:22 Reserved, must be kept at reset value.

Bits 21:17 **ACICD[4:0]**: OLDx CIC decimation ratio selection
This bitfield is set and cleared by software. It is used to select the decimation ratio of the ACIC. It is only taken into account by the MDF when CICMOD[2:0] = 0xx. The decimation ratio is given by (ACICD + 1).
0: Decimation ratio is 1.
1: Decimation ratio is 2.
2: Decimation ratio is 3.
3: Decimation ratio is 4.
...
31: Decimation ratio is 32.
Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 16:14 Reserved, must be kept at reset value.

Bits 13:12 **ACICN[1:0]**: OLDx CIC order selection
This bitfield is set and cleared by software. It is used to select the ACIC type and order. It is only taken into account by the MDF when CICMOD[2:0] = 0xx.
00: FastSinc filter type
01: $Sinc^1$ filter type
10: $Sinc^2$ filter type
11: $Sinc^3$ filter type
Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **BKOLD[3:0]**: Break signal assignment for out-of limit detector
This bitfield is set and cleared by software.
BKOLD[i] = 0: Break signal (mdf_break[i]) not assigned to threshold event
BKOLD[i] = 1: Break signal (mdf_break[i]) assigned to threshold event
Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **THINB**: Threshold In band
This bit is set and cleared by software.
0: The OLDx generates an event if the signal is lower than OLDTHL or higher than OLDTHH (default value).
1: The OLDx generates an event if the signal is lower than OLDTHH and higher than OLDTHL.
Note: This bit can be write-protected (refer to Section 35.4.15 for details).

Bit 0 **OLDEN**: OLDx enable
This bit is set and cleared by software.
0: OLDx disabled (default value)
1: OLDx enabled, including the ACIC filter working in continuous mode

35.8.10 MDF OLDx low threshold register x (MDF_OLDxTHLR)

Address offset: 0x09C + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used for the adjustment of the out-off-limit low threshold. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **OLDTHL[25:0]**: OLD low threshold value

This bitfield is set and cleared by software. OLDTHL represents a 26-bit signed value. The real threshold compared to the signal provided by the filter is OLDTHL.

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

35.8.11 MDF OLDx high threshold register x (MDF_OLDxTHHR)

Address offset: 0x0A0 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used for the adjustment of the OLDx high threshold. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

OLDTHH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **OLDTHH[25:0]**: OLDx high threshold value

This bitfield is set and cleared by software. OLDTHH represents a 26-bit signed value. The real threshold compared to the signal provided by the filter is OLDTHH.

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

35.8.12 MDF delay control register x (MDF_DLYxCR)

Address offset: 0x0A4 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used for the adjustment stream delays. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SKPDLY[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bit 31 **SKPBF**: Skip busy flag

This bit is set and cleared by hardware. It is used to control if the delay sequence is completed.

0: MDF ready to accept a new value into SKPDLY[6:0]

1: Last valid SKPDLY[6:0] still under processing

Bits 30:7 Reserved, must be kept at reset value.

Bits 6:0 **SKPDLY[6:0]**: Delay to apply to a bitstream

This bitfield is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this bitfield, if SKPBF = 0 and the corresponding DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.

0: No input sample skipped

1: 1 input sample skipped

...

127: 127 input samples skipped

35.8.13 MDF short circuit detector control register x (MDF_SCDxCR)

Address offset: 0x0A8 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used for the adjustment stream delays. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw					rw	rw	rw	rw				rw

Bit 31 **SCDACTIVE**: SCDx active flag

This bit is set and cleared by hardware. It is used to check if the SCDx is effectively enabled (active) or not. The protected fields of this function can only be updated when the SCDACTIVE is set to 0 (refer to *Section 35.4.15* for details).

The delay between a transition on SCDEN and a transition on SCDACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: SCDx not active and can be configured if needed

1: SCDx active and protected fields cannot be configured

Bits 30:20 Reserved, must be kept at reset value.

Bits 19:12 **SCDT[7:0]**: SCDx threshold

This bitfield is set and cleared by software. These bits are written by software to define the threshold counter for SCDx. If this value is reached, a short-circuit detector event occurs on a given input stream.

0: 2 consecutive 1's or 0's generate an event.

1: 2 consecutive 1's or 0's generate an event.

2: 3 consecutive 1's or 0's generate an event.

...

255: 256 consecutive 1's or 0's generate an event.

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **BKSCD[3:0]**: Break signal assignment for short circuit detector

This bitfield is set and cleared by software.

BKSCD[i] = 0: Break signal (mdf_break[i]) not assigned to this SCD event

BKSCD[i] = 1: Break signal (mdf_break[i]) assigned to this SCD event

Note: This bitfield can be write-protected (refer to Section 35.4.15 for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **SCDEN**: SCDx enable

This bit is set and cleared by software.

0: SCDx disabled

1: SCDx enabled,

35.8.14 MDF DFLT0 interrupt enable register 0 (MDF_DFLT0IER)

Address offset: 0x0AC

Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

Bit 11 **RFOVRIE**: Reshape filter overrun interrupt enable
This bit is set and cleared by software.
0: Reshape filter overrun interrupt disabled
1: Reshape filter overrun interrupt enabled

Bit 10 **CKABIE**: Clock absence detection interrupt enable
This bit is set and cleared by software.
0: Clock absence interrupt disabled
1: Clock absence interrupt enabled

Bit 9 **SATIE**: Saturation detection interrupt enable
This bit is set and cleared by software.
0: Saturation interrupt disabled
1: Saturation interrupt enabled

Bit 8 **SCDIE**: SCD0 interrupt enable
This bit is set and cleared by software.
0: SCD0 interrupt disabled
1: SCD0 interrupt enabled

Bit 7 **SSOVRIE**: Snapshot overrun interrupt enable
This bit is set and cleared by software.
0: Snapshot overrun interrupt disabled
1: Snapshot overrun interrupt enabled

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **OLDIE**: OLD0 interrupt enable
This bit is set and cleared by software.
0: OLD0 event interrupt disabled
1: OLD0 event interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SSDRIE**: Snapshot data ready interrupt enable
This bit is set and cleared by software.
0: Snapshot data ready interrupt disabled
1: Snapshot data ready interrupt enabled

Bit 1 **DOVRIE**: Data overflow interrupt enable
This bit is set and cleared by software.
0: Data overflow interrupt disabled
1: Data overflow interrupt enabled

Bit 0 **FTHIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
0: RXFIFO threshold interrupt disabled
1: RXFIFO threshold interrupt enabled

35.8.15 MDF DFLTx interrupt enable register x (MDF_DFLTxIER)

Address offset: 0x12C + 0x80 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 0000

This register is used for allowing or not, the events to generate an interrupt. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bit 8 **SCDF**: Short-circuit detector flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no SCD0 event is detected. Write 0 has no effect.
1: Read 1 means that a SCD0 event is detected. Write 1 clears this flag.

Bit 7 **SSOVRF**: Snapshot overrun flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no snapshot overrun event is detected. Write 0 has no effect.
1: Read 1 means that a snapshot overrun event is detected. Write 1 clears this flag.

Bit 6 **THHF**: High-threshold status flag

This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the high-threshold comparator when the last OLD0 event occurred. This bit gives additional information on the conditions triggering the last OLD0 event. It can be cleared by writing OLDF flag to 1.

0: The signal was lower than OLDTHH when the last OLD0 event occurred.

1: The signal was higher than OLDTHH when the last OLD0 event occurred.

Bit 5 **THLF**: Low-threshold status flag

This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the low-threshold comparator when the last OLD0 event occurred. This bit gives additional information on the conditions triggering the last OLD0 event. It can be cleared by writing OLDF flag to 1.

0: The signal was higher than OLDTHL when the last OLD0 event occurred.

1: The signal was lower than OLDTHL when the last OLD0 event occurred.

Bit 4 **OLDF**: OLD0 flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no OLD0 event is detected. Write 0 has no effect.

1: Read 1 means that an OLD0 event is detected Write 1 clears THHF, THLF and OLDF.

Bit 3 **RXNEF**: RXFIFO not-empty flag

this bit is set and cleared by hardware according to the RXFIFO level.

0: RXFIFO empty

1: RXFIFO not empty

Bit 2 **SSDRF**: Snapshot data ready flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no data is available. Write 0 has no effect.

1: Read 1 means that a new data is available. Write 1 clears this flag.

Bit 1 **DOVRF**: Data overflow flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no overflow is detected. Write 0 has no effect.

1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag

This bit is set by hardware and cleared by hardware when the RXFIFO level is lower than the threshold.

0: RXFIFO threshold not reached

1: RXFIFO threshold reached

35.8.17 MDF DFLTx interrupt status register x (MDF_DFLTxISR)

Address offset: 0x130 + 0x80 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 0000

This register contains the status flags for each digital filter path. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	RFOVRF	CKABF	SATF	SCDF	SSOVRF	THHF	THLF	OLDF	RXNEF	SSDRF	DOVRF	FTHF
				rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	r	r	rc_w1	r	rc_w1	rc_w1	r

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bit 8 **SCDF**: Short-circuit detector flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no SCD event is detected. Write 0 has no effect.
1: Read 1 means that a SCD event is detected. Write 1 clears this flag.

Bit 7 **SSOVRF**: Snapshot overrun flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no snapshot overrun event is detected. Write 0 has no effect.
1: Read 1 means that a snapshot overrun event is detected. Write 1 clears this flag.

Bit 6 **THHF**: High-threshold status flag
This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the high-threshold comparator when the last OLDx event occurred. This bit gives additional information on the conditions triggering the last OLDx event. It can be cleared by writing OLDF flag to 1.
0: The signal was lower than OLDTHH when the last OLDx event occurred.
1: The signal was higher than OLDTHH when the last OLDx event occurred.

Bit 5 **THLF**: Low-threshold status flag

This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the low-threshold comparator when the last OLDx event occurred. This bit gives additional information on the conditions triggering the last OLDx event. It can be cleared by writing OLDF flag to 1.

0: The signal was higher than OLDTHL when the last OLDx event occurred.

1: The signal was lower than OLDTHL when the last OLDx event occurred.

Bit 4 **OLDF**: OLDx flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no OLDx event is detected. Write 0 has no effect.

1: Read 1 means that an OLDx event is detected Write 1 clears THHF, THLF and OLDF.

Bit 3 **RXNEF**: RXFIFO not-empty flag

this bit is set and cleared by hardware according to the RXFIFO level.

0: RXFIFO empty

1: RXFIFO not empty

Bit 2 **SSDRF**: Snapshot data ready flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no data is available. Write 0 has no effect.

1: Read 1 means that a new data is available. Write 1 clears this flag.

Bit 1 **DOVRF**: Data overflow flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no overflow is detected. Write 0 has no effect.

1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag

This bit is set by hardware and cleared by hardware when the RXFIFO level is lower than the threshold.

0: RXFIFO threshold not reached

1: RXFIFO threshold reached

35.8.18 MDF offset error compensation control register x (MDF_OECxCR)

Address offset: 0x0B4 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register contains the offset compensation value. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	OFFSET[25:16]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **OFFSET[25:0]**: Offset error compensation
This bitfield is set and cleared by software. If the application attempts to write a new offset value while the previous one is not yet applied, this new offset value is ignored. Reading back this bitfield informs the application on the current offset value.
This bitfield represents the value to be subtracted to the signal before going to the SCALE.

35.8.19 MDF snapshot data register x (MDF_SNPSxDR)

Address offset: 0x0EC + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to read the data processed by each digital filter in snapshot mode. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **SDR[15:0]**: Contains the 16 MSB of the last valid data processed by the digital filter.

Bits 15:9 **EXTSDR[6:0]**: Extended data size
If SNPSFMT = 0, this bitfield contains the bits 7 to 1 of the last valid data processed by the digital filter.
If SNPSFMT = 1, this bitfield contains the INT accumulator counter value when the last trigger event occurs (INT_CNT).

Bits 8:0 **MCICDC[8:0]**: Contains the MCIC decimation counter value when the last trigger event occurs (MCIC_CNT)

35.8.20 MDF digital filter data register x (MDF_DFLTxDR)

Address offset: 0x0F0 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to read the data processed by each digital filter. The number of registers is equal to the amount of filters. Refer to *Section 35.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

36 Audio digital filter (ADF)

36.1 ADF introduction

The audio digital filter (ADF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- metering

The ADF features one digital serial interface (SITF0) and one digital filter (DFLT0) with flexible digital processing options in order to offer up to 24-bit final resolution.

The ADF serial interface supports several standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

The ADF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition, it is possible to insert a high-pass filter.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter bypass, filter order, decimation ratio. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A sound activity detector (SAD) is available for the detection of sounds or voice signals. The SAD is connected at the output of the DFLT0. Several parameters can be programmed in order to adjust properly the SAD to the sound environment. The SAD strongly reduces the power consumption by preventing the storage of samples into the system memory, as long as the observed signal does not match the programmed criteria.

The digital processing is performed using only the kernel clock. The ADF requests the bus interface clock (AHB clock) only when data must be transfered or when a specific event requests the attention of the system processor.

36.2 ADF main features

- AHB Interface
- 1 serial digital input:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- 1 flexible digital filter path including:
  - A MCIC filter configurable in $Sinc^4$ or $Sinc^5$ filter with an adjustable decimation ratio
  - A reshape filter to improve the out-off band rejection and in-band ripple

  - A high-pass filter to cancel the DC offset
  - Gain control
  - Saturation blocks
- Clock absence detector
- Sound activity detector
- 24-bit signed output data resolution
- Continuous or single conversion
- Possibility to delay the selected bitstream
- One trigger input
- Autonomous functionality in Stop mode(s)
- DMA can be used to read the conversion data
- Interrupts services

36.3 ADF implementation

The devices embed one MDF instance and one ADF instance, both being digital filters with common features.

Table 294. ADF features (1)

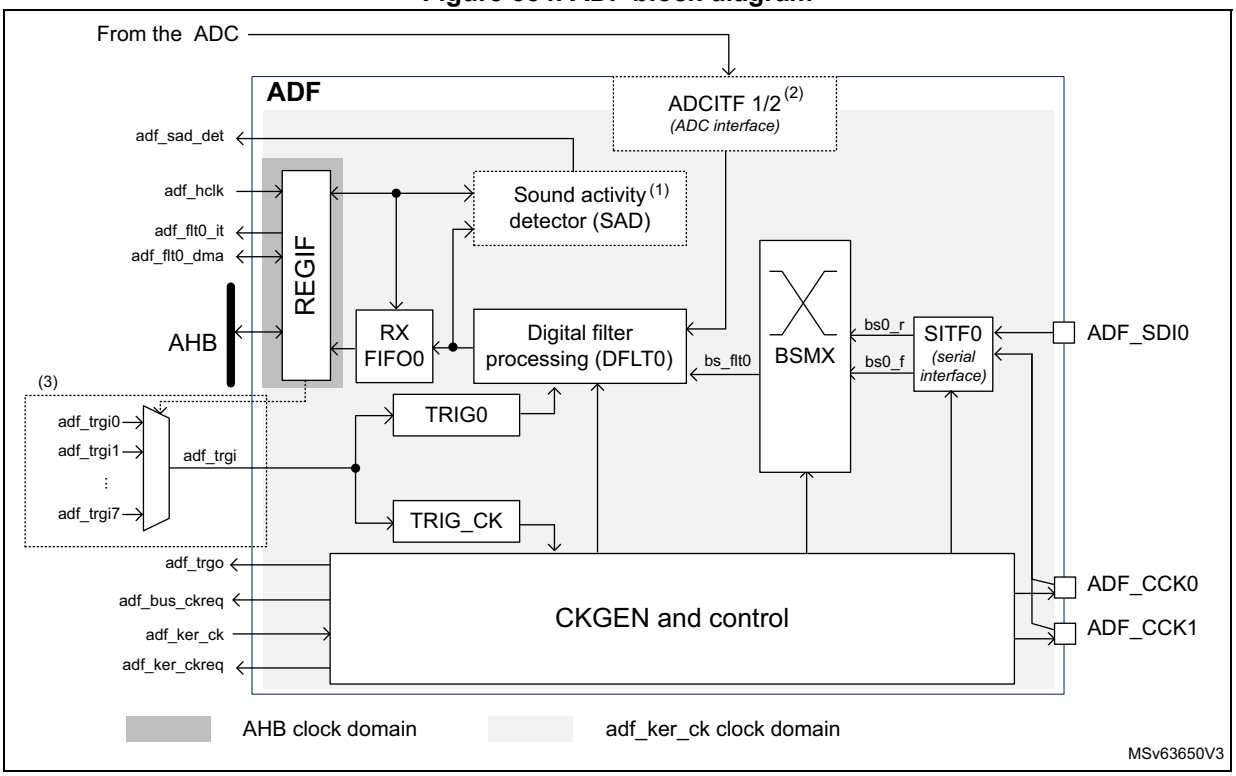
ADF modes/features	ADF
Number of filters (DFLT) and serial interfaces (SITF)	1
ADF_CKI[x] connected to pins	-
Sound activity detection (SAD)	X
RXFIFO depth (number of 24-bit words)	4
Number of trigger inputs	1
ADC connected to ADCITF1	-
ADC connected to ADCITF2	-
Motor dedicated features (SCD, OLD, OEC, INT, snapshot, break)	-
Main path with CIC4, CIC5	X
Main path with CIC1,2, 3 or FastSinc	-
RSFLT, HPF, SAT, SCALE, DLY, Discard functions	X
Global interrupts ADF_FLT[0:0] (adf_flt_it[0:0])	X
Receive interrupts ADF_RX[0:0] (adf_rx_it[0:0])	-
Event interrupts ADF_EVT[0:0] (adf_evt_it[0:0])	-
Autonomous in Stop mode	X(2)
Only DMA of filter 0 connected	-
All DMA channels connected	X

1. ‘X’ = supported, ‘-’ = not supported.
2. Only in Stop SVOS high mode.

36.4 ADF functional description

36.4.1 ADF block diagram

Figure 354. ADF block diagram



1. Refer to *Section 36.3: ADF implementation* to check if the SAD is available.
2. Refer to *Section 36.3: ADF implementation* to check if the ADCITF is available, and which ADCs are connected.
3. The number of trigger inputs depends on the product. Refer to *Table 297* for details.

36.4.2 ADF pins and internal signals

Table 295. ADF external pins

Pin name	Pin type	Remarks
ADF_SDI0	Input	Data signal from external sensors
ADF_CCKy (y = 0,1)	Input/output	Clock outputs for external sensor, or common clock input from external sensors

Table 296. ADF internal signals

Signal name	Signal type	Remarks
adf_trgi	Input	Trigger inputs to control the acquisition (see *Table 297: ADF trigger connections* for details)
adf_trgo	Output	Trigger output for synchronizing with other MDF instances

Table 296. ADF internal signals (continued)

Signal name	Signal type	Remarks
adf_flt0_dma	Input/output	DMA request/acknowledge signals for the ADF processing chain
adf_flt0_it	Output	Global interrupt signals
adf_bus_ckreq	Output	Bus interface clock request output
adf_ker_ckreq	Output	Kernel clock request output
adf_ker_ck	Input	Kernel clock input
adf_hclk	Input	AHB bus interface clock input
adf_sad_det	Output	SAD sound detection: 1 means that detecting sound
adf_adcitf1_dat[15:0]	Input	ADCITF1 data input
adf_adcitf2_dat[15:0]	Input	ADCITF2 data input

Table 297. ADF trigger connections

Trigger name	Direction	Trigger source/destination
adf_trgi	Input	From exti15
adf_trgo	Output	mdf_trgi13
adf_sad_det	Output	mdf_trgi12

36.4.3 Serial input interface (SITF)

The SITF0 input interface allows the connection of the external sensor to the digital filter via the bitstream matrix (BSMX). The SITF0 can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The data from the serial interface is routed to the filter in order to perform the PDM to PCM conversion and the sound activity detection.

The serial interface is enabled by setting the SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external ΣΔ modulator.

Note: Before enabling the *serial interface, the user must insure that the adf_proc_ck is already enabled (see Section 36.4.5: Clock generator (CKGEN) for details).*

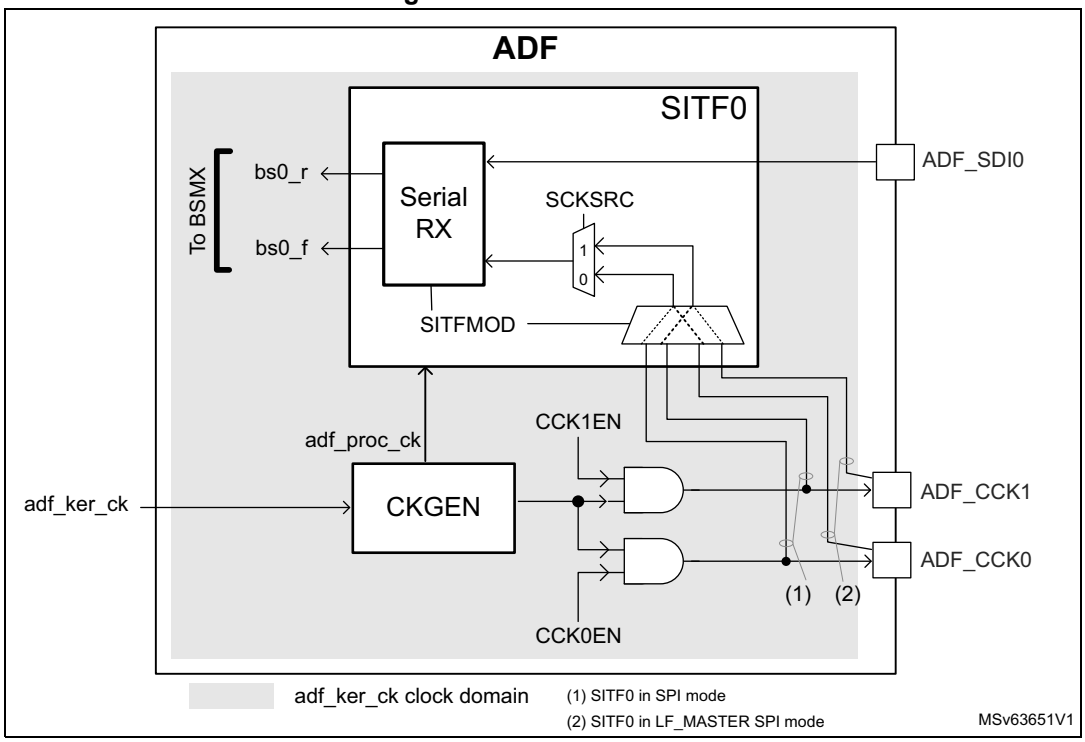
The SITF0 is controlled via the *ADF serial interface control register 0 (ADF_SITF0CR)*.

As shown in the *Figure 355*, ADF_CCK0 or ADF_CCK1 can be selected as clock source, in order to sample the incoming bitstream:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on the ADF_CCK0 or ADF_CCK1 pin.
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source is the clock directly provided by the CCKDIV to the ADF_CCK0 or ADF_CCK1 pin.

See *Table 298* for additional information.

Figure 355. SITF overview



LF_MASTER and normal SPI modes

The LF_MASTER SPI mode is a special mode allowing the use of an adf_proc_ck clock frequency, only two times bigger than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

In LF_MASTER SPI mode, the ADF must provide the bitstream clock to the external sensors via ADF_CCK0 and ADF_CCK1 pins. The ADF receives the bitstream data via the serial data input ADF_SDI0.

For the SITF0, the application must select the same clock than the one provided to the external sensor (ADF_CCK0 or ADF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the adf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select ADF_CCK0 or ADF_CCK1 clock for the capture of the data received via the ADF_SDI0 pin.

The ADF can generate a clock to the sensors via ADF_CCK0 or ADF_CCK1 if needed.

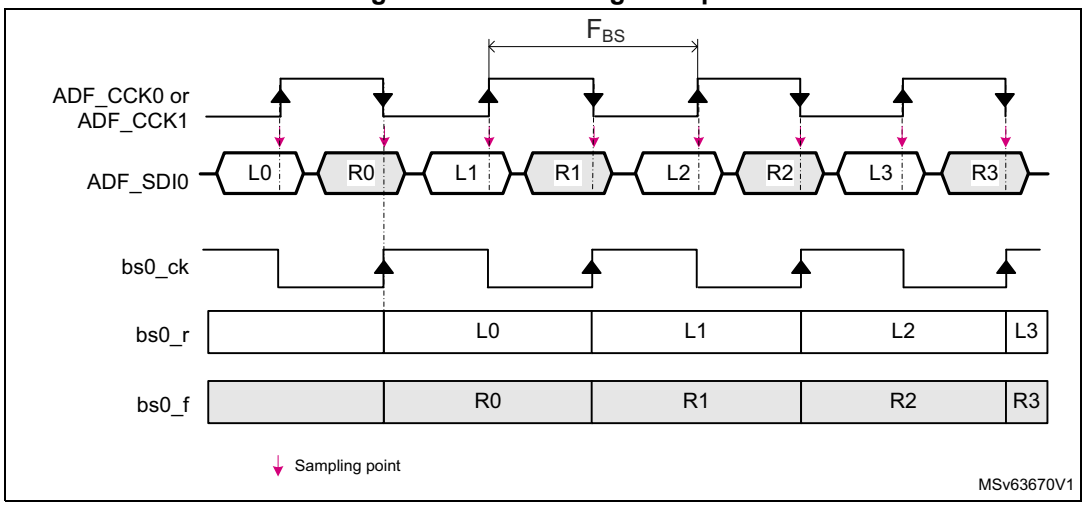
For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITF0 always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bs0_f)
- bitstream received using the bitstream clock rising edge (bs0_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.

Figure 356. SPI timing example



To properly synchronize/receive the data stream, the adf_proc_ck frequency must be adjusted according to the constraints listed in *Table 299*.

Clock absence detection

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] bitfield of the SITF0. If the ADF does not detect clock transitions for a duration of STH[4:0] x $T_{adf_proc_ck}$, then the CKABF flag is set.

An interrupt can be generated if CKABIE is set to 1. The STH[4:0] bitfield is in the *ADF serial interface control register 0 (ADF_SITF0CR)*.

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.

   If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF = 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

Note: The clock absence detection feature is not available in the LF_MASTER SPI mode.

Manchester mode

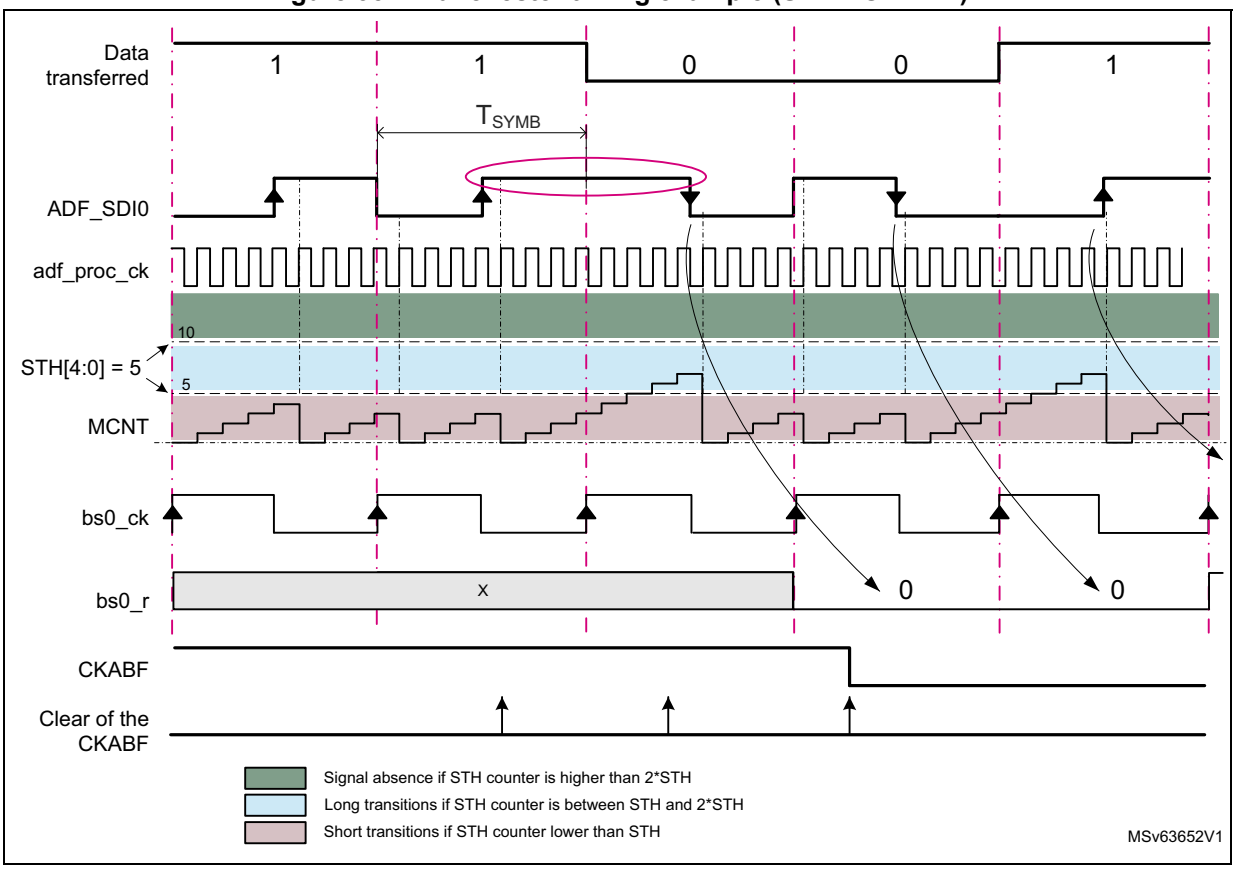
In Manchester coded format, the ADF receives data stream from the external sensor via the ADF_SDI0 pin only.

The ADF_CCK0 and ADF_CCK1 pins are not needed in this mode.

Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bs0_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0

Figure 357. Manchester timing example (SITFMOD = 11)



To decode the incoming Manchester stream, the user must program STH[4:0] in the *ADF serial interface control register 0 (ADF_SITF0CR)*. The STH[4:0] bitfield is used by the SITF0 to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the ADF_SDI0 input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. *Figure 357* shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate (T_{SYMB}) must respect the following formula:

$$(STH + 1) \times T_{adf_proc_ck} < T_{SYMB} < (2 \times STH \times T_{adf_proc_ck})$$

It is recommended to compute STH as follows:

$$STH[4:0] = round\left(\frac{(2 \times OVR) - 1}{3}\right)$$

where OVR represents the ratio between the adf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the adf_proc_ck clock must be adjusted according to the constraints listed in *Table 299*.

The clock absence flag CKABF is set to 1 when no transition is detected during more than 2 x STH[4:0] x $T_{adf_proc_ck}$, or when the SITF0 is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.

When the serial interface is enabled, the ADF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the *Figure 357*) is detected.

The end of the synchronization phase can be checked by following the software sequence:

1. Clear the CKABF flag in the *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)* by writing CKABF bit to 1. If the serial interface is not yet synchronized the hardware immediately set the CKABF flag to 1.
2. Read the CKABF flag:
   – If CKABF= 1, go back to step 1.
   – If CKABF = 0, the Manchester interface is synchronized and provides valid data.

Programming example

In the following example, the ADF kernel clock frequency ($F_{adf_ker_ck}$) is 100 MHz and the received Manchester stream is at about 6 MHz (F_{SYMB}):

1. Provide a valid adf_proc_ck to the SITF0.

   The adf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).

   PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, $F_{adf_proc_ck}$ = 50 MHz (8.33 times higher than the Manchester symbol frequency).
2. Compute STH.

   OVR is given by: OVR = $F_{adf_proc_ck}$ / F_{SYMB} = 50 MHz / 6 MHz = 8.33.

   Then STH[4:0] = $\text{round}\left(\frac{(2 \times 8.33) - 1}{3}\right) = 5$

   The minimum allowed frequency for the Manchester stream is then:

   1 / (2 × STH × $T_{adf_proc_ck}$) = 1 / (10 x 20 ns) = 5 MHz

   The maximum allowed frequency for the Manchester stream is then:

   1 / ((STH+1) × $T_{adf_proc_ck}$) = 1 / (6 x 20 ns) = 8.33 MHz

36.4.4 ADC slave interface (ADCITF)

The ADCs are not always connected to the ADF. Refer to *Section 36.3* to check the situation for this product.

The ADF allows the connection of up to two ADCs to the filter path. For the filter, the DATSRC[1:0] bitfield in the *ADF digital filer configuration register 0 (ADF_DFLT0CICR)* allows the application to select data from the ADCs.

Warning: The ADF does not support receiving interleaved data from one of the ADCITF input.

36.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the ADF:

- AHB clock (adf_hclk) used for the register interface
- kernel clock (adf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

These clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the ADF_CCK0 and ADF_CCK1 pins. All those clocks are generated from the adf_ker_ck.

The processing clock (adf_proc_ck) is used to run all the signal processing and to re-sample the incoming serial or parallel stream.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the ADF_CCK0 and ADF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).

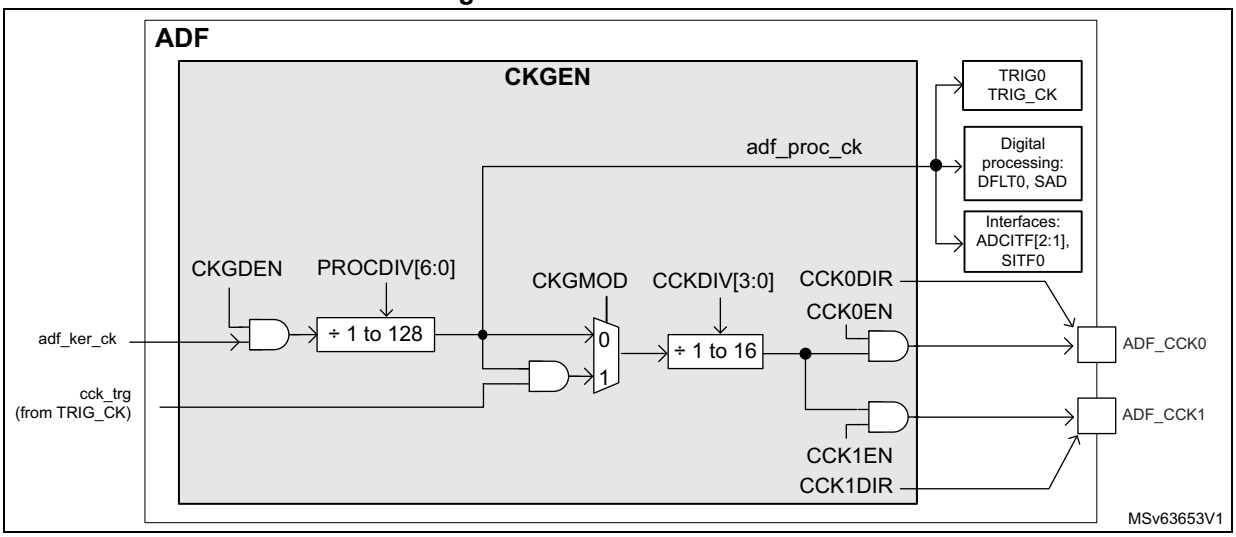
The adf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All the bits and fields controlling the CKGEN are in the *ADF clock generator control register (ADF_CKGCR)*.

Figure 358. CKGEN overview



The trigger logic for CKGEN is handled by the block TRG_CK. As shown in *Figure 363*, the CCKDIV divider can be triggered on the rising or falling edge of an external trigger source. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the ADF_CCKy (y = 0,1) clock of several ADF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the ADF_CCK0 or ADF_CCK1 pin thanks to CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

Table 298. Control of the common clock generation(1)

CCKyEN	CCKyDIR	Description
0	0	The ADF_CCKy pin is in input. An external clock can be connected to the ADF_CCKy pin and used by the SITF0 in order to decode the serial stream
0	1	The ADF_CCKy pin is in output. No clock is generated. The ADF_CCKy pin is driven low.
1	1	The ADF_CCKy pin is in output. A clock is generated on the ADF_CCKy pin. The SITF0 can use this pin as clock source in order to decode the serial stream

1. The configuration with CCKyEN = 1 and CCyDIR = 0 is not shown must be avoided (no interest).

Note: The adf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITF0 or DFLT0).

CKGEN activation sequence example

1. Set CKGDEN to 0.
2. Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
3. Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0], TRGSENS, CCK1EN and CCK0EN.
4. Set CKGDEN to 1.

When needed, at any moment, CCK[1:0]EN bitfield value can be changed without disabling the clock generator.

Clock frequency constraints

Table 299 shows the frequency constraints to receive and process properly the samples.

Note: The reshape filter (RSFLT) needs up to 24 cycles of adf_proc_ck clock to process one sample.

Table 299. Clock constraints with respect to the incoming stream(1)

SITF0 mode	ADF clock constraints	
	With RSFLT disabled	With RSFLT enabled
LF_MASTER SPI	F_{ADF_CCKy} max frequency limited to 5 MHz	
	$F_{adf_proc_ck} > 2 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 2 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$
MASTER SPI SLAVE SPI	F_{ADF_CKx} max frequency limited to 25 MHz	
	$F_{adf_proc_ck} > 4 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 4 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$
Manchester	F_{SYMB} max frequency limited to 20 MHz	
	$F_{adf_proc_ck} > 6 \times F_{SYMB}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 6 \times F_{SYMB}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$

1. F_{ADF_CCKy} represents the frequency of clock received via ADF_CCKy, or generated via ADF_CCKy. F_{SYMB} represents the frequency of the received symbol rate for Manchester mode.

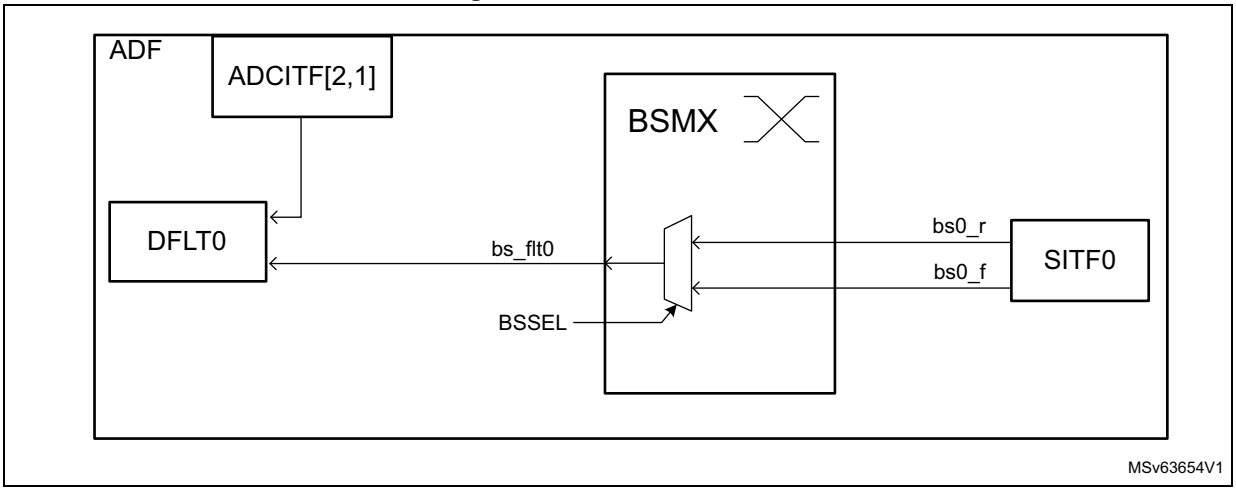
36.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from the serial interface SITF0 and provides the selected stream to the digital filter DFLT0.

As shown in *Figure 354*, the SITF0 provides two bitstreams (bs0_r and bs0_f) to the BSMX.

The application to select the wanted stream via the *ADF bitstream matrix control register 0 (ADF_BSMX0CR)*. This selection is intended to be static.

Figure 359. BSMX overview



BSMX programming sequence example

The BSSEL[4:0] bitfield cannot be changed if the DFLT0 is enabled. The following steps are needed to change the value of BSMX:

1. Set DFLTEN of DFLT0 to 0.
2. Wait for BSMXACTIVE = 0.
3. Program BSSEL[4:0].
4. Set DFLTEN of DFLT0 to 1.

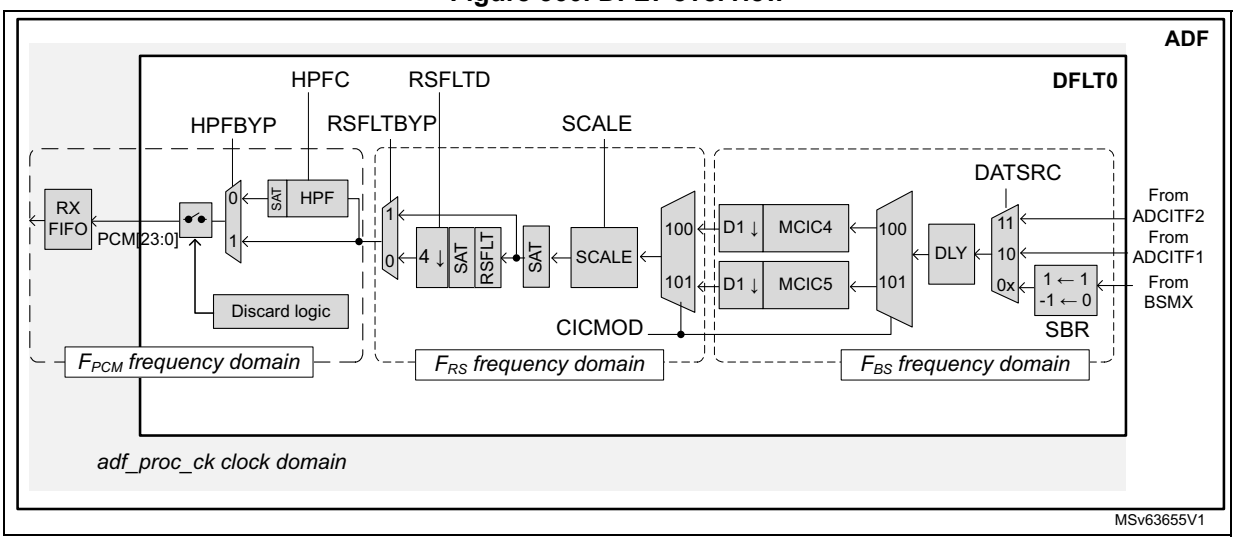
36.4.7 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- clock skipper delay (DLY)
- MCIC decimation filter that can be configured in $Sinc^4$ or $Sinc^5$
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- receive RXFIFO

Figure 360 shows the filter path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

Figure 360. DFLT overview



Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.

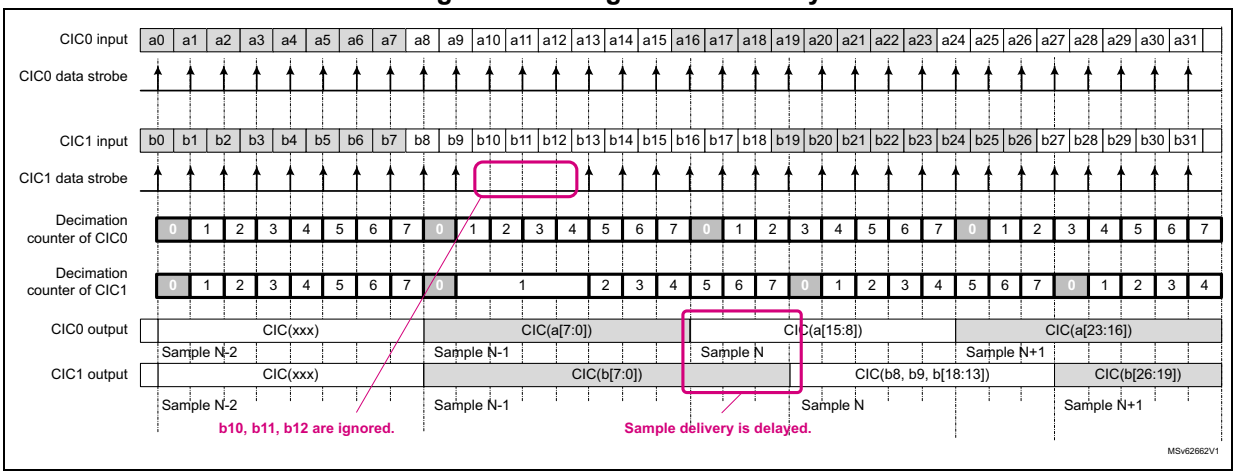
This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate must be applied to the incoming stream. This feature can be used when the ADF is synchronized with another MDF instance (if present in the product) for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is done by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

Table 361 shows an example on how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another MDF instance (if present in the product).

Figure 361. Programmable delay



The CIC of the ADF (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is built from input samples a[23:16] while the sample N+1 of CIC1 is built from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

Note: When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the DFLT0 is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the DFLT0 is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

   When the ADF skipped the amount of wanted data strobes, then SKPBF goes back to 0.
3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

The effect of the delay performed with this mechanism is cumulative as long as the ADF is enabled. If the application performs a D1 delay followed by a D2 delay, then all other active filters are delayed by D1 + D2.

Note: If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

Cascaded-integrator-comb (CIC) filter

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a $Sinc^N$ function, this is why they are often called Sinc filters.

The Sinc^N digital filter embedded into the ADF can be configurable in Sinc^4 or Sinc^5, according to CICMOD:

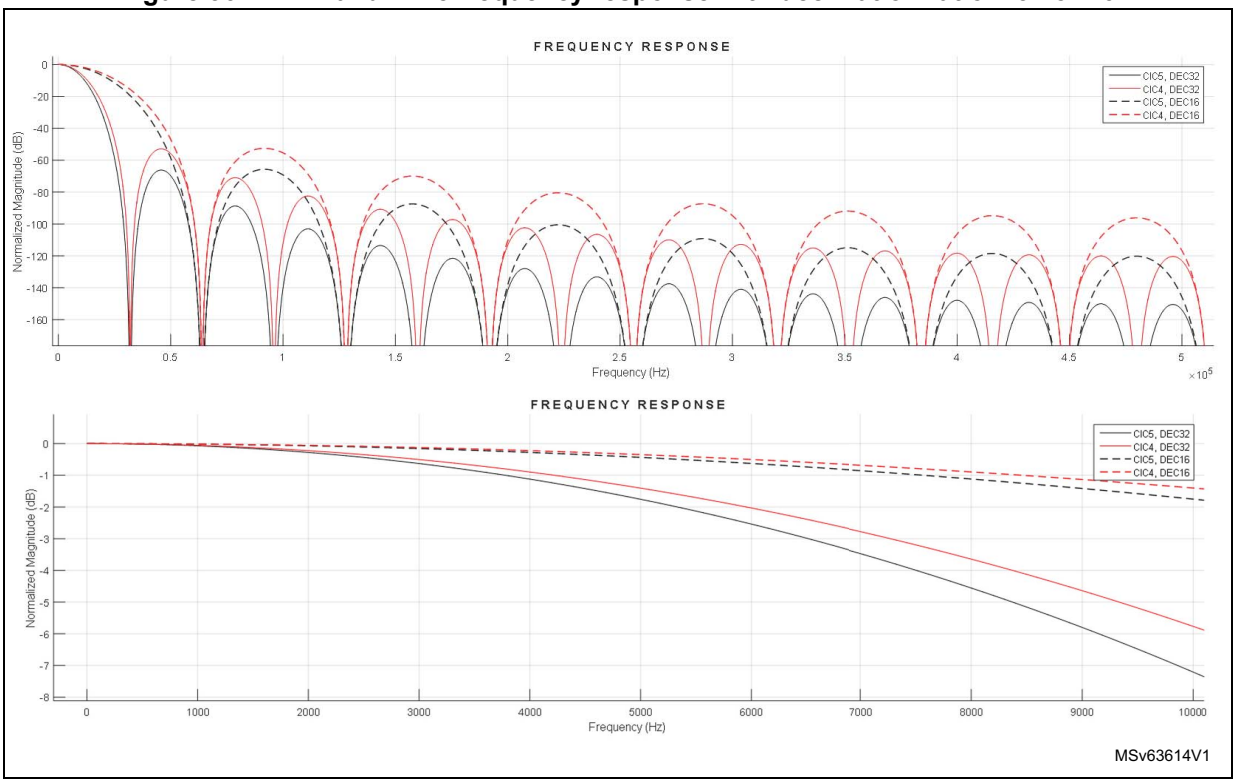
- If CICMOD[2:0] = 4, Sinc^4 is selected.
- If CICMOD[2:0] = 5, Sinc^5 is selected.

The filters have the following transfer function:

$$H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^N$$

where N can be 4 or 5, and D is the decimation ratio. D is equal to MCICD+1.

Figure 362. CIC4 and CIC5 frequency response with decimation ratio = 32 or 16



CIC output data size

The size of samples delivered by the CIC (DS_{CIC}), depends on the following parameters:

- CIC order (N)
- CIC decimation ratio (D)
- data size of the input stream (DSIN)

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (DS_{CIC}) according to the parameters above.

$$DS_{CIC} = \left(\frac{N \times Ln(D)}{Ln(2)}\right) + DS_{IN}$$

and the CIC gain is given by this formula:

$$G_{CIC} = (D)^N$$

The decimation ratio can be adjusted from 2 to 512 for the CIC filter.

Table 300 gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

Note: DS_{IN} = 1 bit for a serial bitstream, but can be up to 16 bits when coming from the ADCITF.

Table 300. Data size according to CIC order and CIC decimation values

Decimation	Data size (bits) when DS_{IN} = 1 bit (data from SITF0)		Data size (bits) when DS_{IN} = 12 bits (data from ADCITF)	
	Sinc^4	Sinc^5	Sinc^4	Sinc^5
4	9	11	20	22
8	13	16	24	-
10	15	18	26	-
12	16	19	-	-
16	17	21	-	-
20	19	23	-	-
24	20	24	-	-
32	21	26	-	-
48	24	-	-	-
64	25	-	-	-
76	26	-	-	-

Note: For a full-scale input signal, the decimation ratio must not exceed 76 for a Sinc^4 and 32 for a Sinc^5.

The LSB parts of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-off band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

Scaling (SCALE) and saturation (SAT)

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (- 48.2 dB), and can be increased by up to 12 bits (+ 72.2 dB).

The gain is adjusted by the SCALE[5:0] bitfield in the *ADF digital filer configuration register 0 (ADF_DFLT0CICR)*.

SCALE[5:0] can be changed even if the DFLT0 is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of adf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

Table 301 shows the possible gain values.

Table 301. Possible gain values

SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)
0x20	- 48.2	0x2B	- 14.5	0x06	+ 18.1	0x11	+ 51.7
0x21	- 44.6	0x2C	- 12.0	0x07	+ 21.6	0x12	+ 54.2
0x22	- 42.1	0x2D	- 8.5	0x08	+ 24.1	0x13	+ 57.7
0x23	- 38.6	0x2E	- 6.0	0x09	+ 27.6	0x14	+ 60.2
0x24	- 36.1	0x2F	- 2.5	0x0A	+ 30.1	0x15	+ 63.7
0x25	- 32.6	0x00	0.0	0x0B	+ 33.6	0x16	+ 66.2
0x26	- 30.1	0x01	+ 3.5	0x0C	+ 36.1	0x17	+ 69.7
0x27	- 26.6	0x02	+ 6.0	0x0D	+ 39.6	0x18	+ 72.2
0x28	- 24.1	0x03	+ 9.5	0x0E	+ 42.1	-	-
0x29	- 20.6	0x04	+ 12.0	0x0F	+ 45.7	-	-
0x2A	- 18.1	0x05	+ 15.6	0x10	+ 48.2	-	-

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The ADF performs saturation operations at the following levels:

- after the SCALE block (performed by the SAT block): The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the *ADF DFLT0 interrupt enable register (ADF_DFLT0IER)* and *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)*.

Gain adjustment policy

To get the best ADF performances, it is important to properly adjust the gain value via SCALE[5:0].

A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full-scale, for the maximum input signal.

A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

$$\frac{LN(SIN_{pp} \cdot D^N)}{LN(2)} < 26$$

where N represents the CIC order, D the decimation ratio and SIN_{pp} the maximum peak-to-peak amplitude of the input signal.

SIN_{pp}can take:

– a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF0

– A maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048), for samples coming from a 12-bit ADC

Example: a $Sinc^4$ can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

$$\frac{LN(0.7 \cdot 96^4)}{LN(2)} \sim 25.82 \text{ bits} < 26 \text{ bits}$$

2. Adjust the SCALE value.

   To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

   The SCALE value in dB must be selected using this formula:

$$SCALE_{dB} < 20 \cdot \log 10\left(\frac{2^{NB}}{SIN_{pp} \cdot D^{N}}\right)$$

   where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. $SCALE_{dB}$ represents the gain value selected by SCALE[5:0].

   Example: For a $Sinc^4$ with a decimation ratio of 96 and a SIN_{pp} of 0.7.

   – If the RSFLT is bypassed:

$$20 \cdot \log 10\left(\frac{2^{24}}{0.7 \cdot 96^{4}}\right) \sim -11 \text{ dB}$$

     $SCALE_{dB}$ value must be lower than - 11 dB, the closest lower value is - 12dB (SCALE[5:0] = 0x2C).

   – If the RSFLT is enabled:

$$20 \cdot \log 10\left(\frac{2^{22}}{0.7 \cdot 96^{4}}\right) \sim -23 \text{ dB}$$

     $SCALE_{dB}$ value must be lower than - 23 dB, the closest lower value is - 24.1 dB (SCALE[5:0] = 0x28).

   If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

Table 302 proposes gain values for different filter configurations, when the data comes from the SITF0, according to the MCIC order, and the MCIC decimation ratio. This table is not exhaustive and considers a full-scale input signal (see *Section 36.7.5: Total ADF gain* for details).

Table 302. Recommended maximum gain values versus CIC decimation ratios

CIC decimation ratio	Gain settings (dB) for configuration SITF + CICx + RSFLT (+ HPF)		Gain settings (dB) for configuration SITF + CICx (+ HPF)	
	CIC5	CIC4	CIC5	CIC4
8	33.6	51.7	45.7	63.7
12	18.1	39.6	30.1	51.7
16	3.5	27.6	15.6	39.6
20	- 6.0	21.6	6.0	33.6
24	- 12.0	15.6	0	27.6
28	- 20.6	9.5	- 8.5	21.6

Table 302. Recommended maximum gain values versus CIC decimation ratios (continued)

CIC decimation ratio	Gain settings (dB) for configuration SITF + CICx + RSFLT (+ HPF)		Gain settings (dB) for configuration SITF + CICx (+ HPF)	
	CIC5	CIC4	CIC5	CIC4
32	- 26.6	3.5	- 4.5	15.6
48	-	- 8.5	-	3.5
64	-	- 20.6	-	- 8.5

Reshaping filter (RSFLT)

In addition to the CIC, the ADF offers a reshaping IIR filter mainly dedicated to the audio application, but also usable in other applications.

When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLTD bit in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

The RSFLT can be bypassed by setting RSFBYP to 1 in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

Table 303 shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency (F_C) depends on the sample rates at its input (F_{RS}), and is given by the following formula:

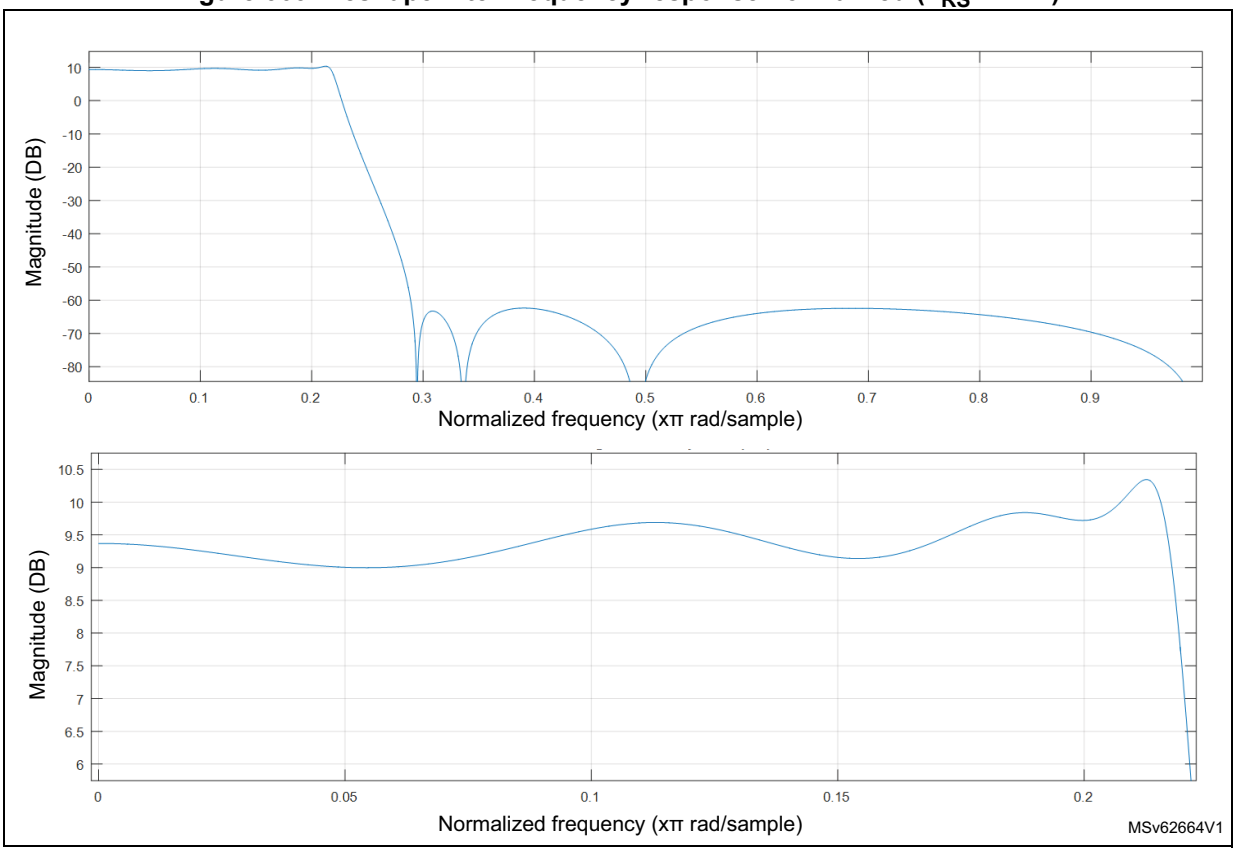
$$F_C = 0.111 \times F_{RS}$$

Table 303. Most common microphone settings

Sample rate (kHz) at RSFLT (F_{RS})	Pass band (kHz)	D2	PCM sampling rate (kHz)
32	3.55	4	8
64	7.1	4	16
128	14.2	4	32
192	21.3	4	48

Table 363 shows the frequency response of the reshape filter.

Figure 363. Reshape filter frequency response normalized (F_{RS} / 2 = 1)



The RSFLT gain is close to 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of adf_proc_ck clock to process one sample at F_{RS}. When the RSFLT is enabled, the application must insure that the adf_proc_ck is at least 24 times faster F_{RS}.

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new samples while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provides a faster adf_proc_ck clock to the RSFLT.

High-pass filter (HPF)

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source that must be removed from the final data.

The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*, among the following values:

- 0.000625 x F_{PCM}
- 0.00125 x F_{PCM}
- 0.00250 x F_{PCM}
- 0.00950 x F_{PCM}

Table 304. HPF 3 dB cut-off frequency examples

HPFC	3 dB cut-off frequency for common F_{PCM} frequencies (Hz)		
	F_{PCM} = 8 kHz	F_{PCM} = 16 kHz	F_{PCM} = 48 kHz
0	5	10	30
1	10	20	60
2	20	40	120
3	76	152	456

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

36.4.8 Digital filter acquisition modes

The ADF offers the following modes to perform a data capture:

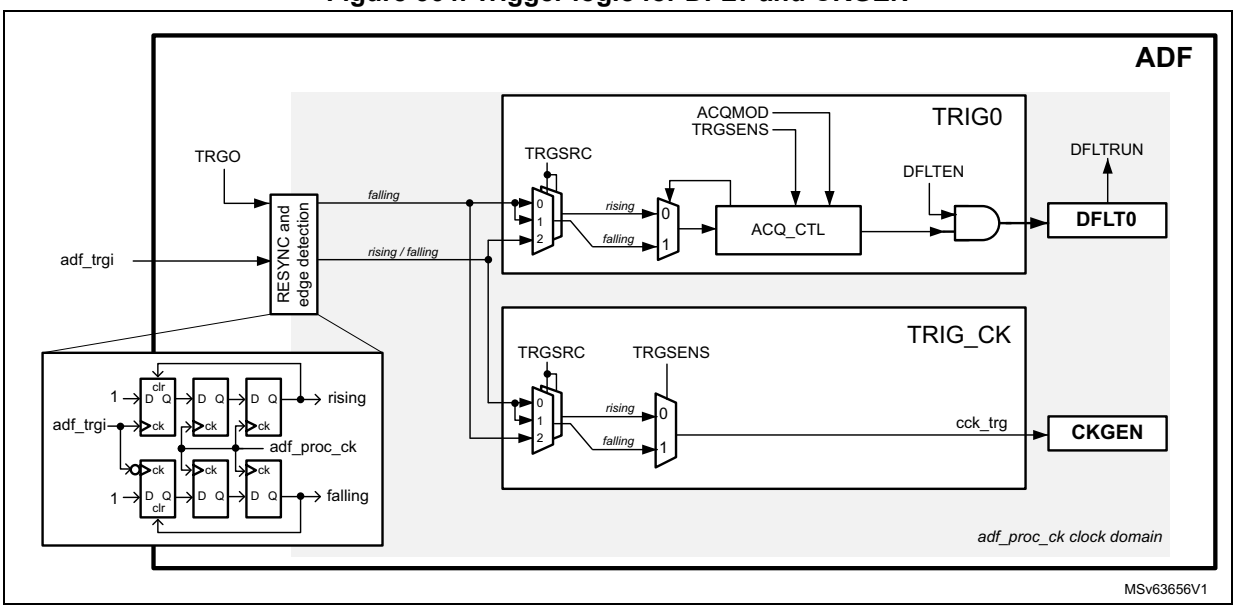
- asynchronous continuous acquisition mode
- asynchronous single-shot acquisition mode
- synchronous continuous acquisition mode
- synchronous single-shot acquisition mode
- window continuous acquisition mode

Note: To perform a data capture, the filter, the interface providing the data (SITF0 or ADCITF) and the CKGEN must be enabled. If needed, the ADF_CCK0 or ADF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This action resets the filter and flushes the RXFIFO. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filter is reset.

Table 364 shows a simplified view of the trigger logic available for each filter and for the clock generator.

Figure 364. Trigger logic for DFLT and CKGEN



A block common to all TRIG blocks performs the rising and falling edges detection and the re-synchronization of the input trigger to the adf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the adf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select adf_trgi or TRGO bit as trigger sources. The TRGO bit is in the *ADF global control register (ADF_GCR)*.

The edge sensitivity can also be selected.

Asynchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition by simply writing the DFLTEN bit to 1.

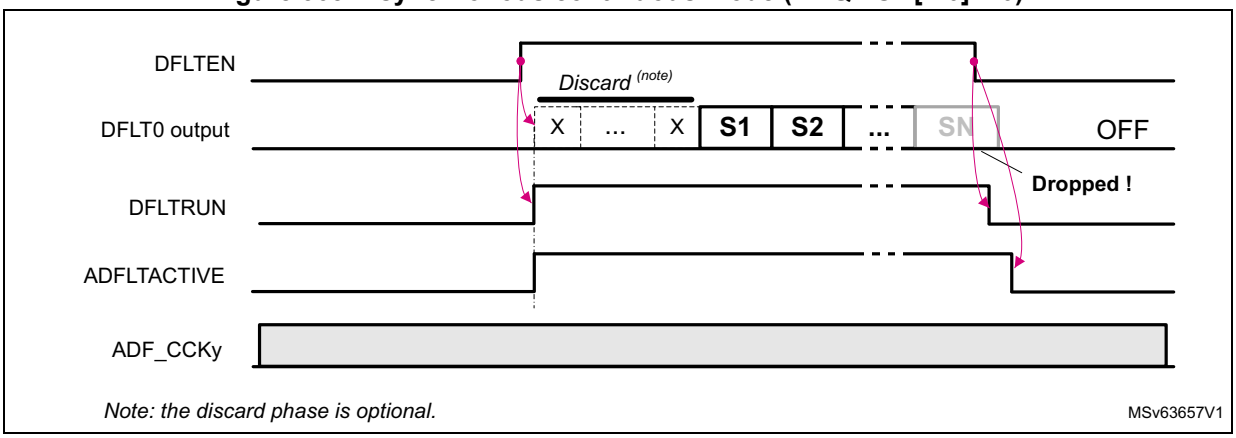
The asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN) so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 308*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the serial data interface.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the acquisition sequence starts immediately.

Figure 365 shows a simplified example of the samples generated by the DFLT0.

Figure 365. Asynchronous continuous mode (ACQMOD[2:0] = 0)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Asynchronous single-shot acquisition mode

This mode allows the application to start the acquisition of one sample by simply writing the DFLTEN bit to 1.

The asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 308*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, the application must:

1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.

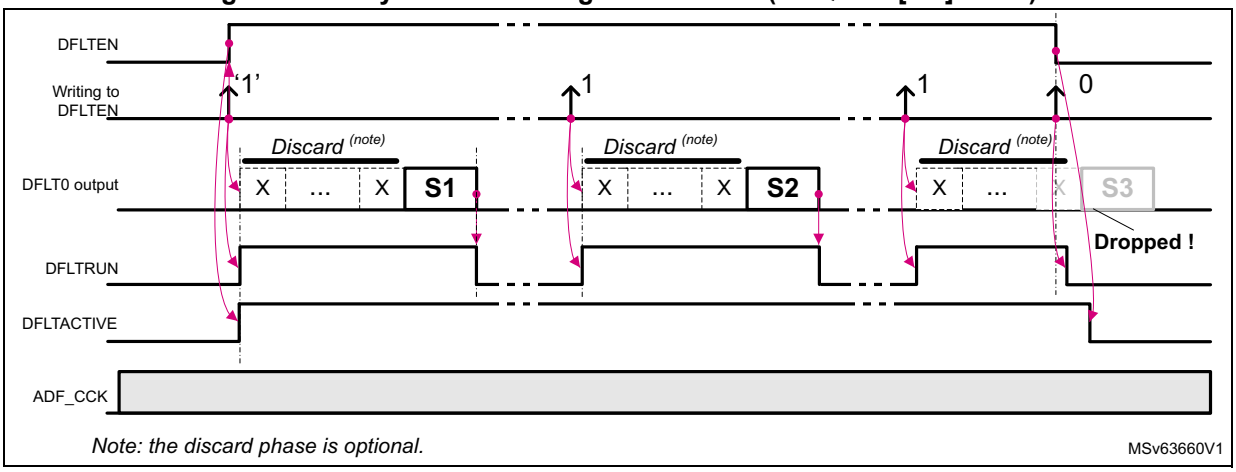
This sequence can be repeated every time a new data must be converted.

As shown in *Figure 365*, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.

If DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

Figure 366. Asynchronous single-shot mode (ACQMOD[2:0] = 001)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.

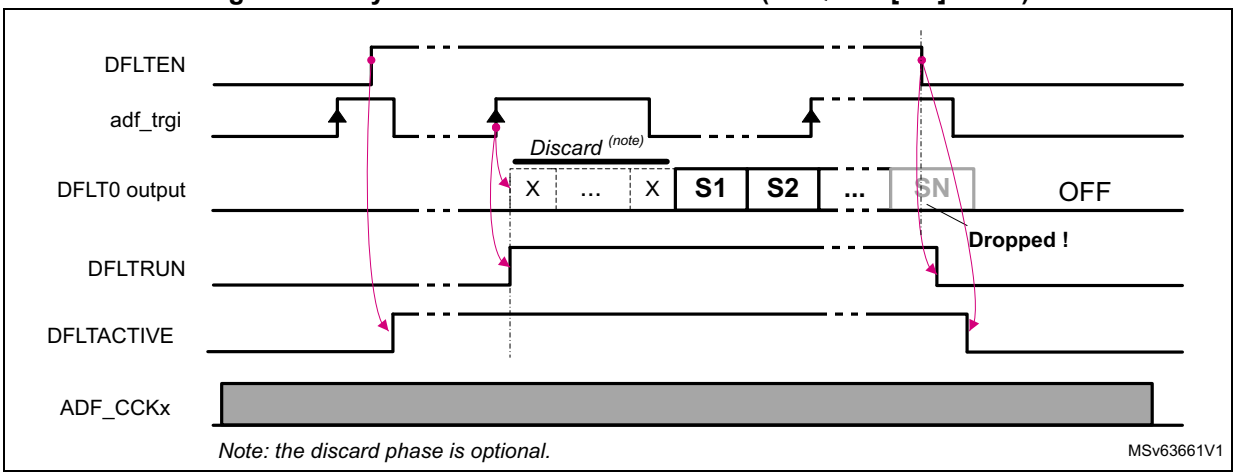
The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 308*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 010.
4. Set to 1 the bit SITFEN.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition.

The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

Figure 367 shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. Then the next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

Figure 367. Synchronous continuous mode (ACQMOD[2:0] = 010)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous single-shot acquisition mode

This mode allows the application to start a single acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.

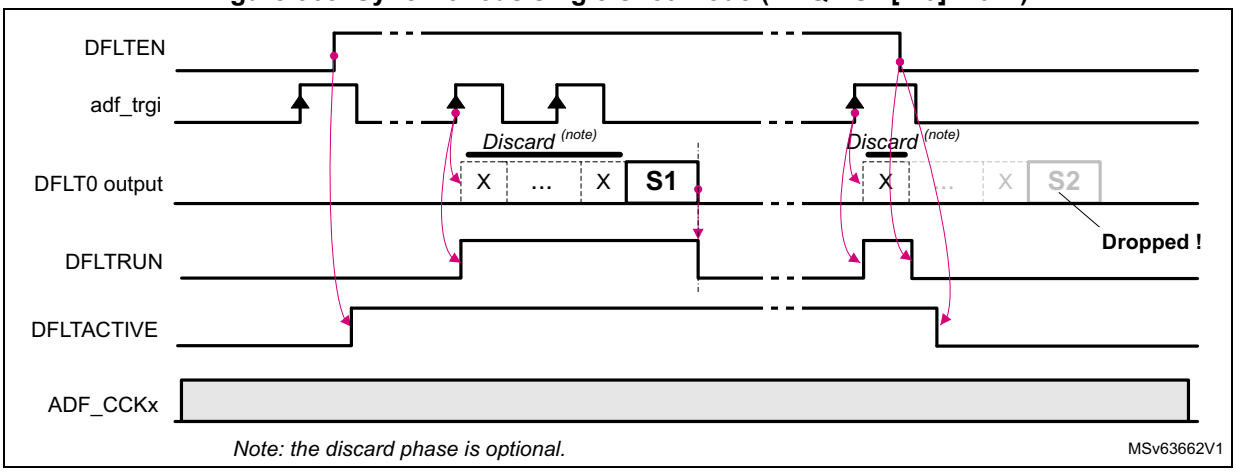
The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 308*).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition and provides one data to the RXFIFO, then the filter is ready to accept a new trigger.

TRGSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing, or if DFLTEN is set to 0.

Figure 368 shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). Every-time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

Figure 368. Synchronous single-shot mode (ACQMOD[2:0] = 011)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Figure 367 shows a case where the DFLTEN is set to 0 while an acquisition is ongoing (the sample S2 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.

Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition controlled by consecutive edges of one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The window continuous acquisition mode is selected when ACQMOD[2:0] = 100.

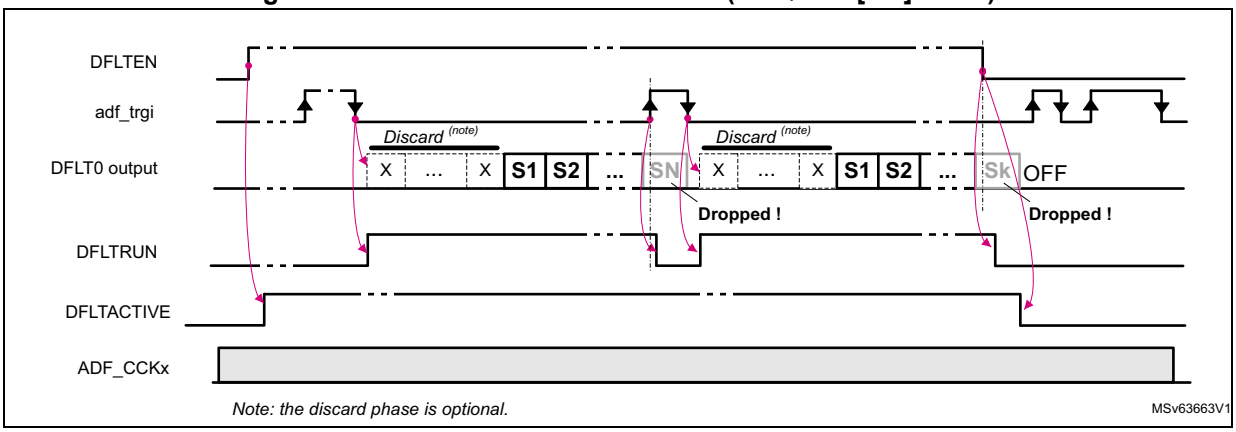
The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 308*).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 369 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the ADF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the ADF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the ADF waits again for a falling edge on the selected trigger input.

Figure 369. Window continuous mode (ACQMOD[2:0] = 100)



Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Starting several filters synchronously

If the ADF is used with MDF instances (if present in the product), it is possible to start simultaneously the acquisition of all the filters. This synchronization capability depends on the way the triggers are connected in the product. Generally, an ADF is able to trigger MDF instances, if its adf_trgo signal is connected as trigger input to those blocks (see *Section 36.4.2: ADF pins and internal signals* to check trigger capabilities).

In the following programming example, one ADF has its adf_trgo signal connected to some MDFs. To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN bits of the filters are set to 0):

On MDFs receiving the adf_trgo trigger:

1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] in order to select the adf_trgo trigger input.
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.

On the ADF generating the adf_trgo trigger:

1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK[1:0] clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. Set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. Set TRGSRC[3:0] to 0 (TRGO selected).
5. Set TRGSENS to 0 (rising edge).
6. Set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

To trigger a new acquisition (in case of single-shot) the application must do the following:

1. Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
2. Read TRGO until it is read to 0.
3. Set again the bit TRGO to 1.

Discarded samples

The ADF offers the possibility to program the amount of samples to be discarded after each restart:

- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples

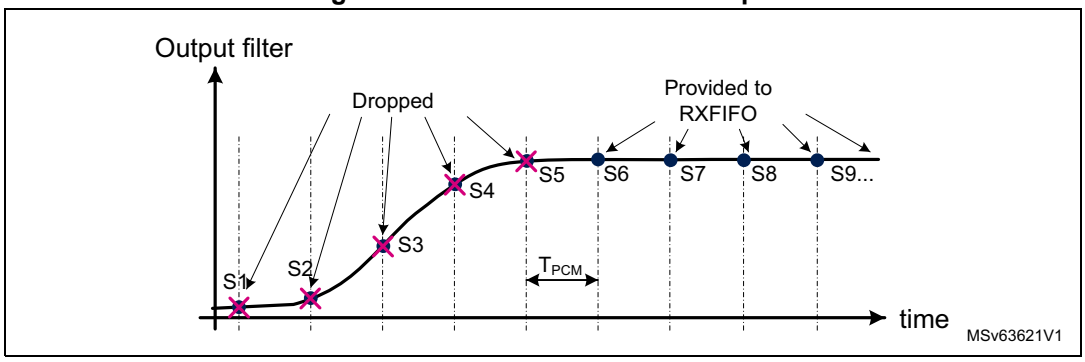
The discard function is controlled via NBDIS[7:0] as follows:

- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to *Figure 364* to *Figure 368*, and *Figure 370*.

In the example shown in *Figure 370*, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transfered to the RXFIFO is S6.

Figure 370. Discard function example



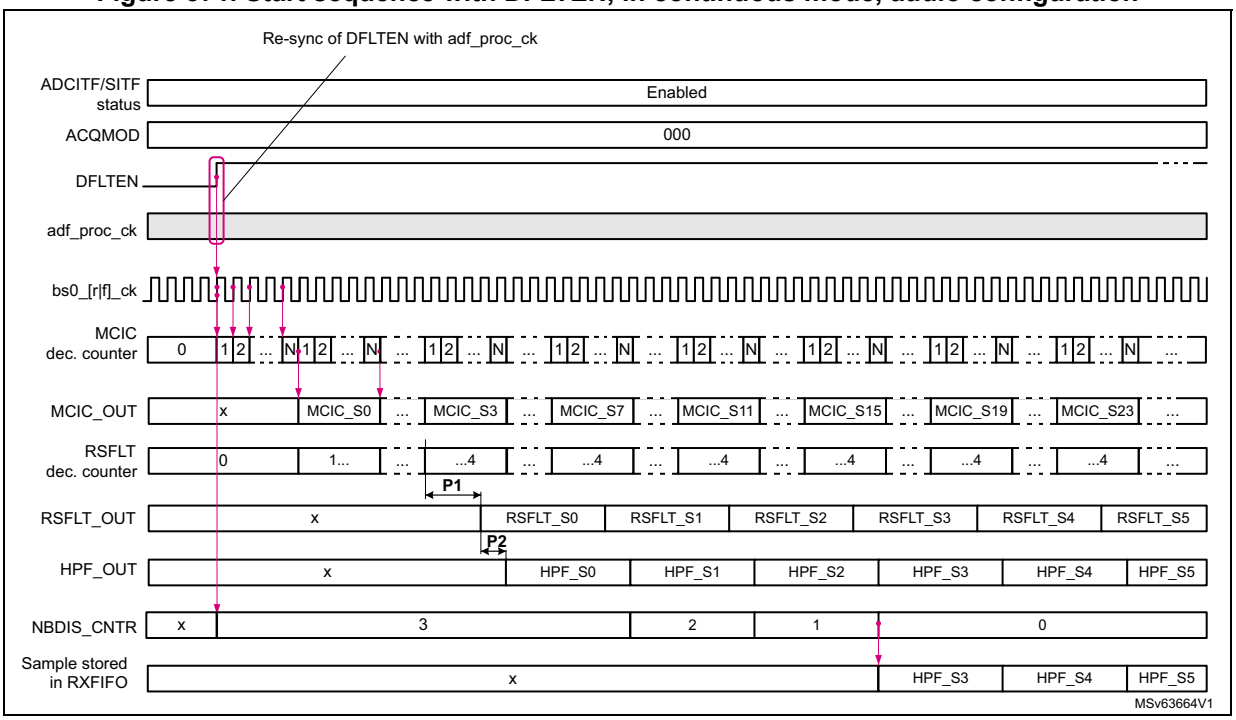
36.4.9 Start-up sequence examples

Figure 371 details a start of acquisition sequence of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLT0 is configured for audio application: MCIC, RSFLT and HPF activated.The data interface (SITF0 or ADCITF) is assumed to be already activated.

Note: NBDIS[7:0] is set on purpose to a small value to simplify the drawing.

Figure 371. Start sequence with DFLTEN, in continuous mode, audio configuration



The DFLTEN bit is re-sampled into the ADF processing clock domain. When DFLTEN is detected high, the filter chain is enabled, and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reached its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC, and delivers a sample to the HPF every-time it processes four samples (decimation by 4). The RSFLT needs up to 24 cycles of adf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.

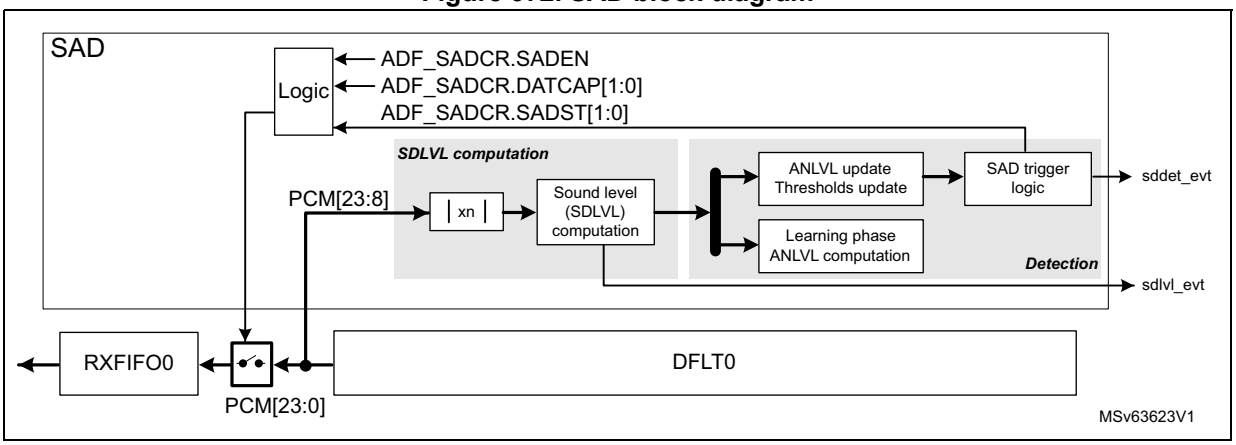
36.4.10 Sound activity detection (SAD)

The SAD is based on the computation of the ambient noise level (ANLVL) and of the short-term sound level (SDLVL). The SAD offers the following ways to detect a sound:

- when the SDLVL reaches a threshold referenced to the ambient noise level
- when the SDLVL reaches a fixed threshold
- when the ANLVL reaches a fixed threshold

As shown in *Figure 372*, the SAD takes the 16 MSB samples from the DFLT0 output.

Figure 372. SAD block diagram



The SAD is highly configurable, and the application can adjust several parameters:

- SAD detection behavior (SADMOD)
- number of samples used to compute the sound level (FRSIZE)
- number of frames used to compute the ambient noise level during the learning phase (LFRNB)
- slope of the ambient noise estimator (ANSLP)
- minimum expected ambient noise level (ANMIN)
- threshold level (SNTHR)
- threshold hysteresis (HYSTEN)
- hangover window in order to filter spurious transitions between DETECT and MONITOR states (HGOVR)
- data capture mode (DATCAP)

SAD detection behavior

The SAD can use the following ways to detect a sound, selected by SADMOD[1:0]:

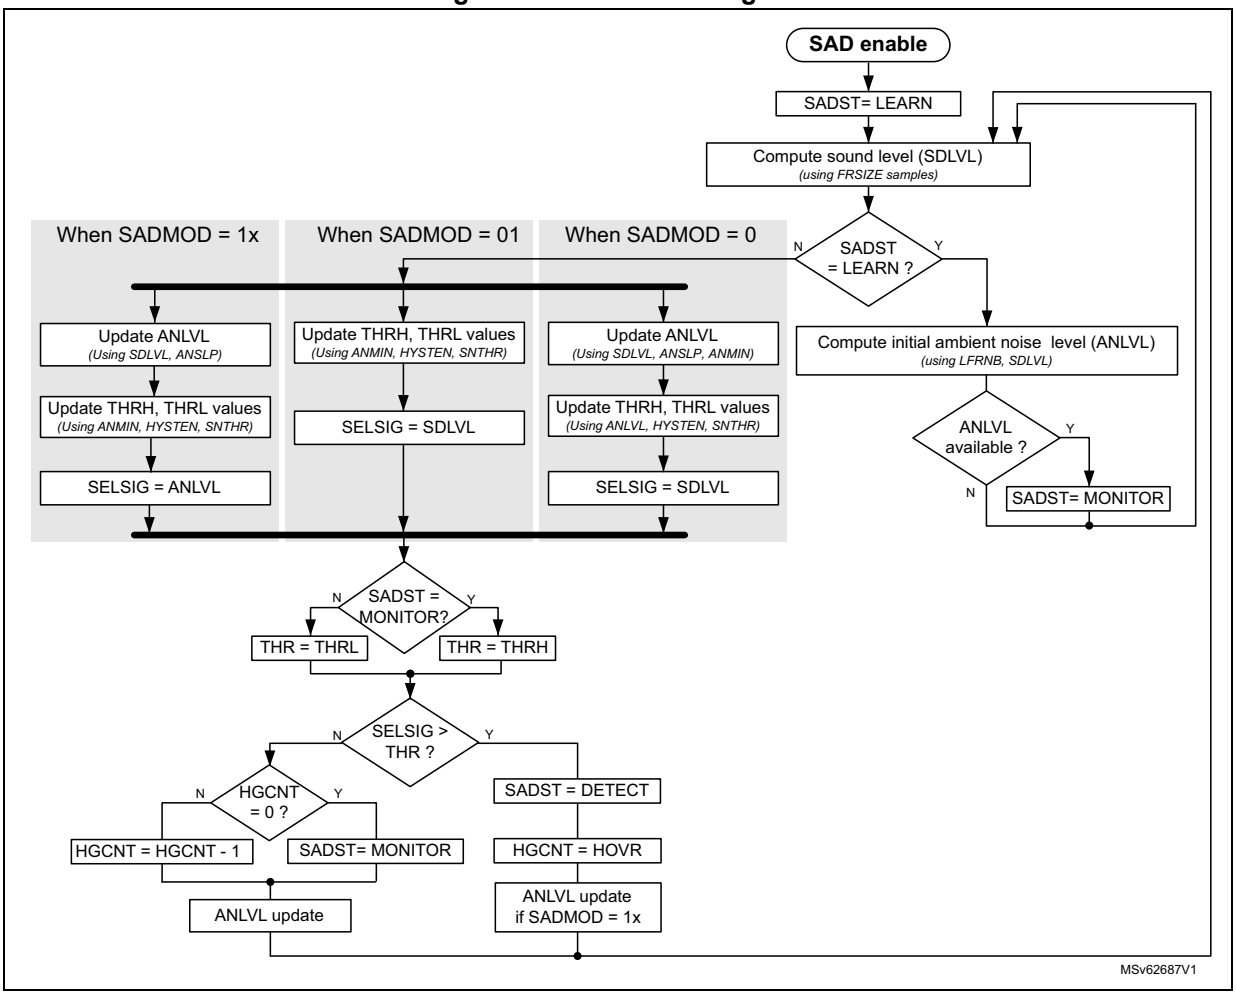
- When SADMOD[1:0] = 0, the SAD works like a voice-activity detection. In this mode, the SAD estimates the ambient noise level according to the computed sound level values. The threshold of the trigger is elaborated from the estimated ambient noise. Finally the current sound level is compared to this threshold. In a first approximation, the SAD triggers if the peak-to-average value of the input signal reaches a level defined by SNTHR[3:0].
- When SADMOD[1:0] = 01, the SAD compares the current sound level (SDLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode allows a fast SAD reaction as the amount of samples used to compute the sound level can be configured via FRSIZE[2:0].
- When SADMOD[1:0] = 1x, the SAD compares the estimated ambient noise level (ANLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode avoids unwanted triggers, due to peak levels, but the SAD reacts more slowly to an input signal variation. It is nevertheless possible to adjust the reaction time via FRSIZE[2:0] and ANSLP[2:0].

SAD states

As shown in *Figure 372*, the SAD works as follows:

1. When enabled (SADEN = 1), the SAD is first in LEARN state to perform a first estimation of the ambient noise level.
2. The SAD continuously computes the short-term sound level (SDLVL) using the samples provided by the DFLT0. The amount of samples used to compute the sound level is given by FRSIZE[2:0]. The samples processed by the DFLT0 can be transferred into the memory or not depending on DATCAP[1:0] value.
3. The initial ambient noise level (ANLVL) is computed using the consecutive sound level values. The application can define how much sound level values are used to perform the computation of this initial ambient noise estimation (LFRNB).
4. When the initial ambient noise level (ANLVL) is computed, the SAD switches to the MONITOR state.
5. Every time a new short-term sound level value is available, the SAD updates the ambient noise level and the thresholds according to the selected detection mode.
6. If the SAD triggers, then the following happens:
   – The SAD switches to DETECT state.
   – The sddet_evt event is asserted.
   – The adf_sad_det signal is set to high.
7. The hangover function insures that the DETECT state is maintained even if the sound level goes below the threshold level for a time given by HGOVR.

Figure 373. SAD flow diagram



Sound level computation (SDLVL)

Once enabled, the SAD computes continuously the sound level value. The sound level represents the average of the absolute value of an amount of PCM samples given by FRSIZE[2:0].

$$SDLVL = \frac{1}{N_{FRSIZE}} \times \sum_{n=1}^{N_{FRSIZE}} |PCM(n)|$$

where N_{FRSIZE} is the amount of PCM samples given by FRSIZE[2:0].

Ambient noise estimation (ANLVL)

The ambient noise level (ANLVL) is computed when SADMOD[1:0] is 00 or 10.

The ambient noise level is computed differently according to the state of the SAD as detailed below:

- ANLVL computation during the LEARN state

  Every time the SAD is enabled, a learning phase is initiated in order to estimate a first value of the ambient noise level. During this phase, the SAD cannot trigger.

  During the LEARN phase, the ambient noise level is computed as follows:

$$ANLVL = \frac{1}{N_{LFRNB}} \times \sum_{n=1}^{N_{LFRNB}} |SDLVL(n)|$$

  where N_{LFRNB} is the amount of frames given by LFRNB[2:0] bitfield.

- ANLVL computation during the MONITOR or DETECT state

  When the learning phase is completed, the SAD updates the ambient noise level in the following way:

  – The SAD computes the new possible values for the ambient noise level:

    ANLVL_UP = ANLVL * (1+2^(ANSLP-12))

    ANLVL_DN = ANLVL * (1-2^(ANSLP-10))

  – The ANLVL takes the ANLVL_DN value if the current sound level is lower than ANLVL_DN, otherwise ANLVL takes the value of ANLVL_UP.

    The ANLVL is not updated if the current sound level is higher than the threshold level, except if SADMOD[1:0] = 10.

  – When SADMOD[1:0] = 0, if the new ANLVL value is lower than ANMIN[12:0], ANLVL is replaced by ANMIN.

  The slope of the noise estimator can be adjusted to optimize the detection of the wanted signal. This slope is adjusted via ANSLP[2:0] in the *ADF SAD configuration register (ADF_SADCFGR)*.

Table 305 shows the allowed values according to the frame size and the sampling rate of the data observed by the SAD. The recommended values when the SADMOD[1:0] = 0 are the ones into the gray shaded cells.

Table 305. ANSLP values versus FRSIZE and sampling rates

FRSIZE	ANSLP values for Fs = 8 kHz			ANSLP values for Fs = 16 kHz		
	Slow(1)	typical(2)	Fast(3)	Slow(1)	typical(2)	Fast(3)
0 (8 samples)	0	1	2	-	0	1
1 (16 samples)	1	2	3	0	1	2
2 (32 samples)	2	3	4	1	2	3
3 (64 samples)	3	4	5	2	3	4
4 (128 samples)	4	5	6	3	4	5
5 (256 samples)	5	6	7	4	5	6
6 (512 samples)	6	7	-	5	6	7

1. The slow slope is equal to - 8.5 dB/s for the negative slope and + 2.1 dB/s for the positive slope.
2. The typical slope is equal to - 17.1 dB/s for the negative slope and + 4.2 dB/s for the positive slope.
3. The fast slope is equal to - 34.2 dB/s for the negative slope and + 8.5 dB/s for the positive slope.

The slopes can also be computed using the following formulas:

$$SLC_{UP} = 20 \times \frac{F_s}{F_{SIZE}} \times \log 10(1 + 2^{(ANSLP - 12)})$$

$$SLC_{DN} = 20 \times \frac{F_s}{F_{SIZE}} \times \log 10(1 - 2^{(ANSLP - 10)})$$

where F_S is the sampling rate of the stream observed by the SAD and F_{SIZE} is the frame size defined by FRSIZE[2:0].

Threshold computation

The way the threshold value is computed depends on SADMOD[1:0]:

- If SADMOD[1:0] = 0, THRH is obtained by multiplying the current ANLVL value with the gain defined in SNTHR[3:0].

  $$THR_H = ANLVL \times 10^{\frac{GdB_{SNTHR}}{20}}$$

  This threshold value is then compared to the current sound level (SDLVL).
- If SADMOD[1:0] = 01, THRH is obtained by multiplying the current ANMIN[12:0] with the gain defined by SNTHR[3:0].

  $$THR_H = ANMIN \times 10^{\frac{GdB_{SNTHR}}{20}}$$

  This threshold value is then compared to the current sound level (SDLVL).

- If SADMOD[1:0] = 1x, THRH is obtained by multiplying the current ANMIN[12:0] by 4.

$$THR_H = ANMIN \times 4$$

This threshold value is then compared to:

$$ANLVL \times 10^{\frac{GdB_{SNTHR}}{20}}$$

The hysteresis mode can be enabled to reduce the spurious transitions between MONITOR and DETECT states. In hysteresis mode (HYSTEN = 1), the following threshold values are used:

- THRH when the SAD is in MONITOR state.
- THRL when the SAD is in DETECT state.

Table 306 shows the thresholds values according to SNTHR.

Table 306. Threshold values according SNTHR(1)

SNTHR[3:0]	THR_H		THR_L		Comments
0	LVL + 3.5 dB	LVL x 1.5	LVL + 3.5 dB	LVL x 1.5	No hysteresis
1	LVL + 6.0 dB	LVL x 2	LVL + 3.5 dB	LVL x 1.5	Hysteresis of 2.5 dB
2	LVL + 9.5 dB	LVL x 3	LVL + 6.0 dB	LVL x 2	Hysteresis of 3.5 dB
3	LVL + 12.0 dB	LVL x 4	LVL + 9.5 dB	LVL x 3	Hysteresis of 2.5 dB
4	LVL + 15.6 dB	LVL x 6	LVL + 12.0 dB	LVL x 4	Hysteresis of 3.5 dB
5	LVL + 18.1 dB	LVL x 8	LVL + 15.6 dB	LVL x 6	Hysteresis of 2.5 dB
6	LVL + 21.6 dB	LVL x 12	LVL + 18.1 dB	LVL x 8	Hysteresis of 3.5 dB
7	LVL + 24.1 dB	LVL x 16	LVL + 21.6 dB	LVL x 12	Hysteresis of 2.5 dB
8	LVL + 27.6 dB	LVL x 24	LVL + 24.1dB	LVL x 16	Hysteresis of 3.5 dB
9	LVL + 30.1 dB	LVL x 32	LVL + 27.6dB	LVL x 24	Hysteresis of 2.5 dB

1. LVL must be replaced by ANLVL when SADMOD[1:0] = 0 and by ANMIN for other SADMOD[1:0] values.

When the hysteresis function is disabled, the SAD always use THRH.

Note: The hysteresis mode must not be used when SADMOD[1:0] = 1x.

Trigger logic

The signal compared to this threshold depends also on SADMOD[1:0].

The trigger condition is reached when the selected signal (SELSIG) is bigger than the threshold level.

If the trigger condition is met, the following happens:

- The SAD switches to DETECT state.
- The SAD refreshes the hangover counter with HGOVR.
- The sddet_evt event is asserted if the SAD transits from MONITOR to DETECT.

- The adf_sad_det signal is set to high.

The SAD remains in DETECT state as long as the trigger condition is met or the hangover down-counter is different from 0.

The sddet_evt event indicates when the SAD enters and/or exits the DETECT state. This event is used to generate an interrupt when a sound is detected or when a sound is no longer detected:

- When DETCFG = 0, the application receives an event only when the SAD enters the DETECT state.
- When DETCFG = 1, the application receives an event when the SAD enters or exits the DETECT state.

The adf_sad_det signal remains high as long as the SAD is in DETECT state.

The SAD also provides a flag indicating that a new sound level value is available (SDLVLF). The last computed sound level (SDLVL[14:0]) is available in the *ADF SAD sound level register (ADF_SADSDLVR)*, and the last computed ambient noise level (ANLVL[14:0]), in the *ADF SAD ambient noise level register (ADF_SADANLVR)*.

Note: The SAD can work even when the AHB clock is not present. In that case, the SAD does not update SDLVL[14:0] and ANLVL[14:0].

To get the latest valid SDLVL[14:0] and ANLVL[14:0] values, the application must read the ADF_SADSDLVR, and ADF_SADANLVR registers, when the SDLVLF flag goes high. This can be done in the following ways:

- by polling the SDLVLF flag:
  a) Clear the SDLVLF flag by writing SDLVLF to 1.
  b) Wait for SDLVLF = 1, by reading ADF_DFLTxISR.
  c) Read ADF_SADSDLVR and ADF_SADANLVR.
  d) Clear SDLVLF by writing it to 1.
  e) Go to step 2 if other values must to be read.
- by generating an interrupt:
  a) Read ADF_DFLTxISR.
  b) If SDLVLF = 1, read ADF_SADSDLVR and ADF_SADANLVR, and clear SDLVLF by writing it to 1.
  c) Handle other status flags and exit from ISR.

Sample transfer to memory

The SAD offers the following options to control the samples transfer from DFLT0 to the system memory:

- If DATCAP[1:0] = 1x, the samples are transferred into the system memory as soon as DFLT0 and SAD are enabled. The transfer does not depend on the SAD state.
- If DATCAP[1:0] = 01, the samples are transferred into the system memory when the SAD detects a sound (when the SAD is in DETECT state), assuming that DFLT0 and SAD are enabled.
- If DATCAP[1:0] = 0, the samples are not transferred into the memory. This mode can be used if the application only wants to observe but does not need samples for other processing.

Note: DATCAP[1:0] is taken into account only when the SADEN = 1. For example, if the SAD configuration is DATCAP[1:0] = 0, SADEN = DFLTEN = 1, and if the application sets now SADEN to 0, the samples provided by the DFLT0 are transferred to the RXFIFO.

Programming recommendations

To make the SAD function working properly, the ADF must be programmed as follows:

1. Provide the proper kernel clock (adf_ker_ck) to the ADF.
2. Configure the CKGEN and enable it.
3. Configure the SITF and enable it (note that microphones have a settling time of several milliseconds).
4. Configure the DFLT0. A typical setting is the following:
   - CIC5 with a decimation ratio of 12, 16 or 24
   - RSFLT with a decimation ratio of 4
   - HPF with HPFC = 2 or 3

   For a very-low power implementation, the RSFLT can be bypassed.
5. Set SADEN to 0.
6. Wait for SADACTIVE = 0. If SADEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
7. Configure the SAD as follows:
   - Set DATCAP[1:0] to 0, if the application does not want to store the samples into the system memory.
   - Set DATCAP[1:0] to 01, if the application wants to store the samples into the system memory only when the SAD detects a sound.
   - Set DATCAP[1:0] to 11, if the application wants to store the samples into the system memory continuously.
8. Configure the DMA (optional).
9. Enable the SAD.
10. Enable the DFLT0.

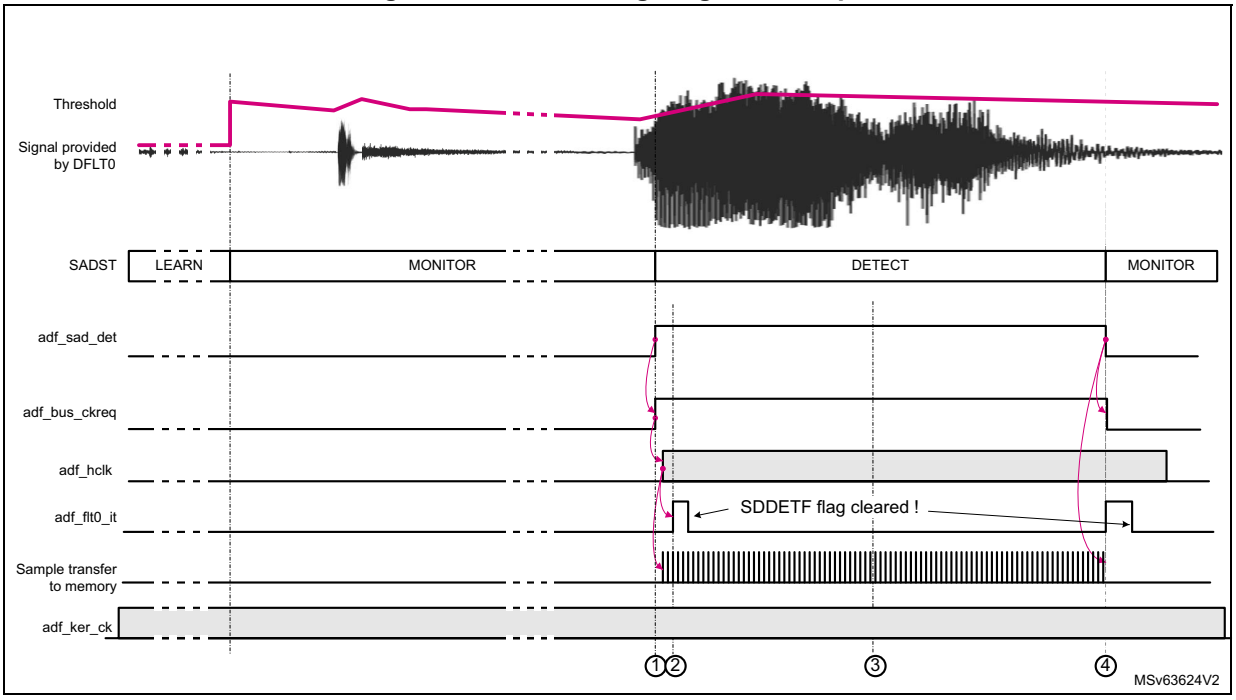
Figure 373 shows a simplified timing diagram when the SAD works with DATCAP[1:0] = 01.

Thanks to the kernel clock (adf_ker_ck), the SAD continuously monitors the audio signal provided by the DFLT0. The threshold is also continuously updated according to the ambient noise level estimation.

- When the SAD detects a sound higher than the programmed threshold (1), the ADF requests the bus clock (adf_bus_ckreq asserted).
- When the bus clock is available (see 2 in *Figure 373*) then:
  - The data transfer to the memory is triggered.
  - The event interrupt (adf_evt_it) can be generated.
- In this example, the event interrupt (adf_evt_it) is used to wake up the application. The interrupt line is released by clearing SDDETF by writing 1 to it.
- As long as the SAD remains in DETECT state, the application waits to get enough samples and calls, for example the keyword recognition algorithm (see 3 in *Figure 373*).
- In the case shown in *Figure 374*, the SAD state (SADST) goes back to MONITOR before the keyword is recognized. If DETCFG is set to 1, an event signals when the SAD goes back to MONITOR state. The SAD stops the transfer of samples into the

memory and the application can clean up the receive buffer for the next detection (see 4 in *Figure 373*).

Figure 374. SAD timing diagram example



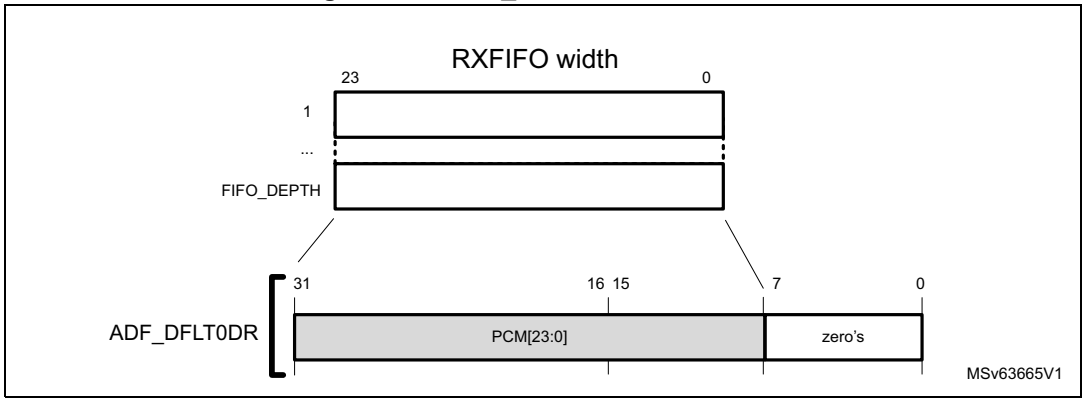
36.4.11 Data transfer to memory

Data format

The samples processed by DFLT0 are stored into a RXFIFO. The application can read the samples stored into these FIFOs via the *ADF digital filter data register 0 (ADF_DFLT0DR)*. The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The ADF provides 24-bit left-aligned data. Performing a 16-bit access to ADF_DFLT0DR allows the application to get the 16 most significant bits. Performing a 32-bit access to ADF_DFLT0DR allows the application to get a 24-bit data size.

Figure 375. ADF_DFLTxDR data format



Data re-synchronization

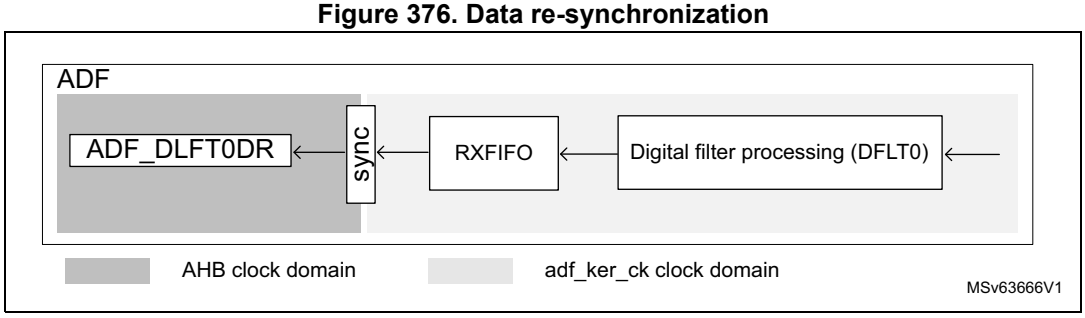
The samples stored into the RXFIFO can be transferred into the memory by using either DMA requests or interrupt signaling.

Note: The RXFIFO is located into the adf_ker_ck clock domain, while ADF_DFLT0DR *is located into the adf_hclk (AHB) clock domain.*

When the AHB clock is available, if ADF_DFLT0DR is empty and if a sample is available into the RXFIFO, this sample is transferred into ADF_DFLT0DR.

The sample transfer from the RXFIFO to ADF_DFLT0DR takes two periods of the AHB clock (adf_hclk) and two periods of the adf_ker_ck clock. The ADF inserts automatically wait-states if the application performs a read operation of ADF_DFLT0DR while the transfer of the new sample from the RXFIFO to ADF_DFLT0DR is not yet completed.

Figure 376. Data re-synchronization



Data transfer

The content of the RXFIFO can be transfered to the memory either by using a DMA channel or interrupt services.

Both single and burst, DMA transfers are supported by the ADF, but the application has to care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

Note: The burst mode is not available in all products (see the DMA section to check if the product supports it).

In addition, the application can select the RXFIFO threshold (FTH bit) in order to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth/2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the RXFIFO is not empty.

The DMA mode of the RXFIFO is enabled via the DMAEN bit in ADF_DFLT0DR.

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as ADF_DFLT0DR is read.
- If FTH = 1, as soon as the RXFIFO reaches the threshold level and a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as one data is read. FTHF is set again if the threshold condition is

met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE/2 data.

RXFIFO overrun

A RXFIFO overrun condition is detected when the RXFIFO is full, and a new sample from the DFLT0 must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

Figure 377 shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.

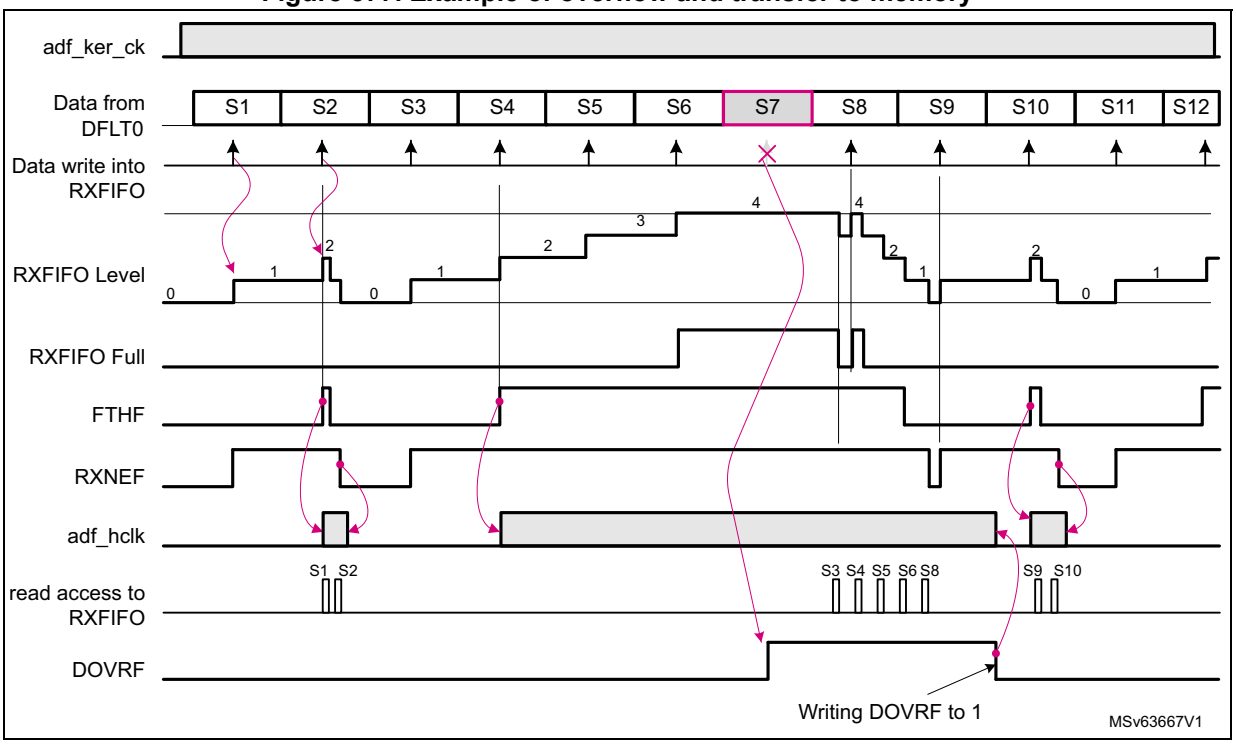
The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO, and the ADF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the adf_hclk line, the gray boxes indicate that the ADF requested the AHB clock. *Figure 377* shows the AHB clock available only when the ADF requests it. In real applications, the AHB clock may also be present if the ADF does not request it.

Figure 377. Example of overflow and transfer to memory



36.4.12 Autonomous mode

The ADF can work even if the AHB bus clock is not available (Stop modes). The ADF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the ADF receives a kernel clock if the following conditions are met:

- The ADF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.

In Stop mode, the ADF receives the AHB clock if the following conditions are met:

- The ADF autonomous mode is enabled in the RCC.
- The ADF requests the AHB clock in the following situations:
  - when the ADF must transfer data into memory via the DMA

    The data is directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the ADF needs to generate an interrupt

    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is generated.The AHB clock request is maintained as long as an enabled interrupt flag is still active.

36.4.13 Register protection

The ADF embeds some hardware protection to prevent invalid situations.
Table 307 shows the list of write-protected and unprotected fields.

Table 307. Register protection summary

Registers	Unprotected fields	Write-protected fields	Write-protection condition
ADF global control register (ADF_GCR)	TRGO	-	DFLTACTIVE0 = 1
ADF clock generator control register (ADF_CKGCR)	CKGDEN CCK0EN CCK1EN	PROCDIV[6:0], CCKDIV[3:0], CKGMOD, TRGSRC[3:0], TRGSENS, CCK[1:0]DIR	CKGACTIVE = 1
ADF serial interface control register 0 (ADF_SITF0CR)	SITFEN	STH[4:0], SITFMOD[1:0], SCKSRC[1:0]	SITFACTIVEx = 1
ADF bitstream matrix control register 0 (ADF_BSMX0CR)	-	BSSEL[4:0]	DFLTACTIVEx = 1
ADF digital filter control register 0 (ADF_DFLT0CR)	DFLTEN	NBDIS[7:0], TRGSRC[3:0], TRGSENS, FTH, DMAEN, SNPSFMT, ACQMOD[2:0]	DFLTACTIVEx = 1
ADF digital filer configuration register 0 (ADF_DFLT0CICR)	SCALE[5:0]	MCICD[8:0], CICMOD[2:0], DATSRC[1:0]	
ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)	-	All fields	
ADF delay control register 0 (ADF_DLY0CR)	-	SKPDLY[6:0]	SKPBF = 1

Table 307. Register protection summary (continued)

Registers	Unprotected fields	Write-protected fields	Write-protection condition
ADF DFLT0 interrupt enable register (ADF_DFLT0IER)	All fields	-	-
ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)	All fields	-	-
ADF SAD control register (ADF_SADCR)	SADEN	FRSIZE[2:0], DETCFG, SADMOD[1:0], HYSTEN, DATCAP[1:0]	SADACTIVE = 1
ADF SAD configuration register (ADF_SADCFGR)	-	ANMIN[12:0], SNTHR[3:0], HGOVR[3:0], LFRNB[2:0], ANSLP[2:0]	SADACTIVE = 1

All the ADF processing is performed in the adf_proc_ck clock domain. For that reason, enabling or disabling an ADF sub-block may take some time due to the re-synchronization between the AHB clock domain and the adf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected bitfield, the application must follow this sequence:

1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for details.

36.5 ADF low-power modes

Table 308. Effect of low-power modes on ADF

Mode	Description
Sleep	No effect. ADF interrupts cause the device to exit the Sleep mode.
Stop(1)	The ADF registers content is kept. Thanks to the kernel clock request feature, if the ADF is clocked by an internal oscillator available in Stop mode, the ADF remains active. The interrupts cause the device to exit Stop mode.
Standby	The ADF is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 36.3: ADF implementation* for details about Stop modes supported by the ADF.

36.6 ADF interrupts

To increase the CPU performance, the ADF offers an interrupt line (adf_flt0_it), sensitive to several events.

Note: The status flags are available even if the corresponding interrupt enable flag is not enabled.

The interrupt interface is controlled via the *ADF DFLT0 interrupt enable register (ADF_DFLT0IER)* and the *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)*.

Figure 378. ADF interrupt interface

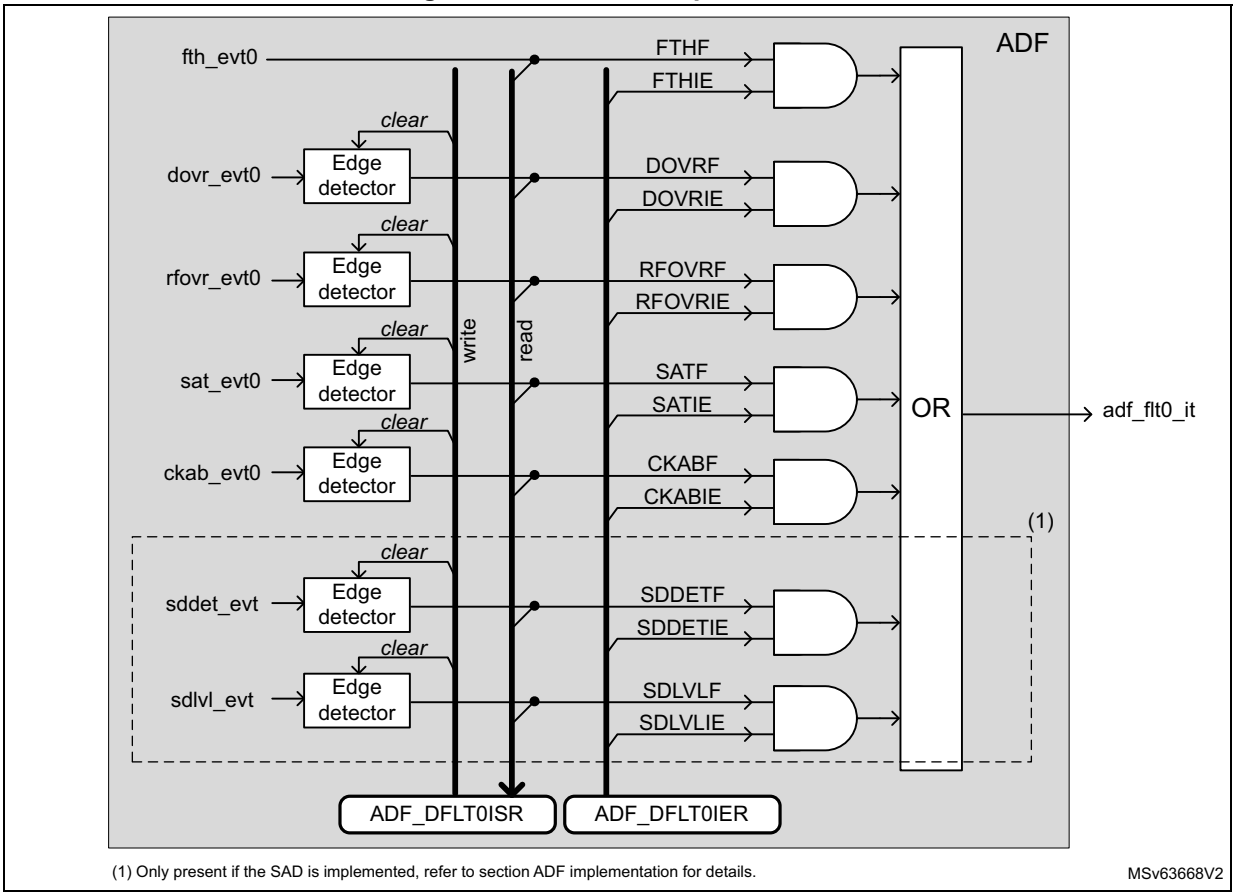


Table 309 shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

Table 309. ADF interrupt requests

Interrupt vector	Interrupt event	Event flag	Event/interrupt clearing method	Exit Sleep mode	Exit Stop modes(1)	Exit Standby mode
ADF_FLT0(2)	RXFIFO threshold reached	FTHF	Read ADF_DFLT0DR until RXFIFO level is lower than the threshold.	Yes	Yes	No
	RXFIFO overrun	DOVRF	Write DOVRF to 1.			
	RSFLT overrun	RFOVRF	Write RFOVRF to 1.			
	Saturation detection	SATF	Write SATF to 1.			
	Channel clock absence detection	CKABF	Write CKABF to 1.			
	SAD: sound detected	SDDETF	Write SDDETF to 1.			
	SAD: sound level value available	SDLVLF	Write SDLVLF to 1.			

1. Refer to *Section 36.3: ADF implementation* for details.
2. ADF_FLT0 vector corresponds to the assertion of adf_flt0_it signal.

36.7 ADF application information

36.7.1 ADF configuration examples for audio capture

Table 310 gives some examples of the ADF settings for the digital microphones, focusing on 16 and 48 kHz output data rate.

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (adf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple, and a good image rejection.

Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

Table 310. Examples of ADF settings for microphone capture

Configuration	adf_ker_ck (MHz)	PROCDIV + 1	CCKDIV + 1	CIC order (1)	MCICD + 1	SCALE	RSFLTBYP	RSFLTD	HPFBYP	-	adf_proc_ck (MHz)	Total dec. ratio	F_{RS} (kHz)	F_{ADF_CCKx} (MHz)	F_{PCM} (kHz)
#1	1.024	1	2	4	64	0x2D (- 8.5 dB)	1	x	x	=>	1.024	64	-	0.512	8
#2		1	2	5	32	0x2B (- 14.5 dB)						32	-		16
#3		1	2	5	16	0x01 (+ 3.5 dB)	0	0				64	32		8
#4	2.048	1	2	5	16	0x01 (+ 3.5 dB)	0	0			2.048	64	64	1.024	16
#5	3.072	1	6	5	8	0x0B (+ 33.6 dB)	0	0			3.072	32	32	0.512	8
#6		2	2	5	12	0x06 (+ 18.1 dB)						48	64	0.768	16
#7		1	2	5	24	0x2C (- 12 dB)						96		1.536	
#8	4.096	1	2	5	32	0x27 (- 26.6 dB)	0	0			4.096	128	64	2.048	16
#9	6.144	3	2	5	16	0x02 (+ 6.0 dB)	0	0			2.048	64	64	1.024	16
#10		2	2	5	24	0x2C (- 12 dB)					3.072	96		1.536	
#11		1	2	5	16	0x01 (+ 3.5 dB)					6.144	64	192	3.072	48
#12	7.680	1	2	5	20	0x2E (- 6.0 dB)	0	0			7.680	80	192	3.840	48

1. CICMOD = 100 for CIC order equal to 4. CICMOD = 101 for CIC order equal to 5.

36.7.2 Programming examples

Example 1

This example describes the programming of ADF for the capture of a signal coming from a digital microphone, using only the CIC4, with a decimation of 48, assuming that the kernel clock is 1.536 MHz. Typically, this configuration can be used to detect sound using the SAD.

Table 311. Programming sequence (CIC4)

Operations	Comments
Adjust the proper kernel clock frequency via the RCC	Assuming that the RCC is programmed to provide a kernel clock (adf_ker_ck) of 1.536 MHz coming from a RC oscillator.
Select the proper ADF kernel clock source via the RCC	Refer to the RCC of the product.
Enable the ADF clocks via the RCC	Refer to the RCC of the product.
Reset the ADF via the RCC	Refer to the RCC of the product.
AFMUX programming	Program the AFMUX to select ADF_SD0 and ADF_CCK0 functions.
Enable ADF processing clock: ADF_CKGCR = 0x0001 0023	PROCDIV = 0 (bypass): adf_proc_ck frequency is 1.536 MHz. CCKDIV = 1 (division by 2): ADF_CCK0 clock frequency is 768 kHz. The ADF_CCK0 pin is set in output and generates a clock so that the microphone can exit from low-power mode.
Serial interfaces configuration: ADF_SITF0CR = 0x0000 1F01	SCKSRC = 0 to select ADF_CCK0 as serial clock. SIFTMOD = 0 to select LF_MASTER SPI mode. Clock absence feature is not working in this mode. The serial interface is enabled.
Bitstream matrix configuration: ADF_BSMX0CR = 0x0000 0000	DFLT0 filter takes the bitstream of SITF0, sampled on rising edge
Filters configuration (CIC): ADF_DFLT0CICR = 0x0040 2F40	SCALE = 0x04 (12 dB): RSFLT is not enabled. Note that the gain is 8.5 dB, higher than recommended in order to improve signal accuracy for the SAD. Saturation is not an issue in this case, as only the detection of a signal much lower than the full scale is needed. MCICD = 0x2F (decimation by 48) CICMOD = 4 to select a $Sinc^4$ DATSCR = 0 to select data coming from BSMX
Filters configuration (RSFLT and HPF): ADF_DFLT0RSFR = 0x0000 0301	HPFC = 3: cut-off frequency of 16kHz * 0.0095 = 152 Hz HPFBYP = 0: HPF not bypassed RSFLTBYP = 1: RSFLT bypassed
Micro delay adjust: ADF_DLY0CR = 0x0000 0000	Not used in this example
Enable interrupt events: ADF_DFLT0IER = 0x0000 1000	Enable the interrupt events the application wants to handle. In this example, SDDETIE is set to 1 to have an interrupt if a sound is detected.

Table 311. Programming sequence (CIC4) (continued)

Operations	Comments
SAD setting: ADF_SADCR = 0x0000 1400	SADMOD = 1: Trigger based on sound level values FRSIZE = 4: Sound level computed on 128 samples HYSTEN = 0: No hysteresis DETCFG = 0: interrupt generated when the SAD enters in DETECT state DATCAP = 0: samples not transferred to memory SADEN = 0: SAD not yet enabled
SAD setting: ADF_SADCFGR = 0x0025 0001	ANMIN = 0x25: Sound threshold of 37 * 10^SNTHR/20 = 74 LSB(1) HGOVR = 0: four frames (4 x 128 = 512 samples) LFRNB = 0: Learning phase set to two frames. Not useful in this mode. ANSLP = 0: Not used in this mode SNTHR = 1: Threshold set to 6 dB (see ANMIN)
Clear status flags: ADF_DFLT0ISR = 0x0000 0FFF	Clear all the status flags before running the ADF
Enable the SAD: ADF_SADCR = 0x0000 1401 Wait for SADACTIVE flag = 1	Enable first the SAD, in order to be sure that data transfer to memory are blocked by the SAD.
Enable the filter: ADF_DFLT0CR = 0x0000 0001	NBDIS = 0: no samples discarded ACQMOD = 0: Asynchronous continuous acquisition mode DMAEN = 0: DMA interface not used DFLTEN = 1: Filter enabled

1. SNTHR and ANMIN values are computed using the same approach than in *Threshold programming with SADMOD = 01* (detection of a sound higher than 63 dBSPL).

Example 2

This example describes the programming of ADF for the capture of a signal coming from a digital microphone, using the CIC5, and the RSFLT, with a total decimation of 64.

Table 312. Programming sequence (CIC5)

Operations	Comments
Adjust the proper kernel clock frequency via the RCC	Assuming that the RCC is programmed to provide a kernel clock (adf_ker_ck) of 6.144 MHz
Select the proper ADF kernel clock source via the RCC	Refer to the RCC of the product.
Enable the ADF clocks via the RCC	Refer to the RCC of the product.
Reset the ADF via the RCC	Refer to the RCC of the product.
AFMUX programming	Program the AFMUX to select ADF_SD0 and ADF_CCK0 functions.
Enable ADF processing clock: ADF_CKGCR = 0x0201 0023	PROCDIV = 2 (division by 3): adf_proc_ck frequency is 6.144 MHz. CCKDIV = 1 (division by 2): ADF_CCK0 clock frequency is 1.024 MHz. The ADF_CCK0 pin is set in output and generates a clock so that the microphone can exit from low-power mode.

Table 312. Programming sequence (CIC5) (continued)

Operations	Comments
Serial interfaces configuration: ADF_SITF0CR = 0x0000 1F01	SCKSRC = 0 to select ADF_CCK0 as serial clock. SIFTMOD = 0 to select LF_MASTER SIPI mode. Clock absence feature is not working in this mode. The serial interface is enabled.
Bitstream matrix configuration: ADF_BSMX0CR = 0x0000 0000	DFLT0 filter takes the bitstream of SITF0, sampled on rising edge
Digital filter control: ADF_DFLT0CR = 0x0000 0006	NBDIS = 0: no samples discarded ACQMOD = 0: Asynchronous continuous acquisition mode DMAEN = 1: DMA interface not used DFLTEN = 0: Filter disabled FTH = 1: RXFIFO half-full
Filters configuration (CIC): ADF_DFLT0CICR = 0x0010 0F50	SCALE = 0x01(+3.5 dB): Output limited to 22 bits due to RSFLT. MCICD = 0xF (decimation by 16) CICMOD = 5 to select a $Sinc^5$ DATSCR = 0 to select data coming from BSMX
Filters configuration (RSFLT and HPF): ADF_DFLT0RSFR = 0x0000 0200	HPFC = 2: cut-off frequency of 16 kHz * 0.0025 = 40 Hz HPFBYP = 0: HPF not bypassed RSFLTBYP = 0: RSFLT not bypassed RSFLTD = 0: Decimation by 4
Micro delay adjust: ADF_DLY0CR = 0x0000 0000	Not used in this example
Enable interrupt events: ADF_DFLT0IER = x	Enable the interrupt events the application wants to handle.
Clear status flags: ADF_DFLT0ISR = 0x0000 0FFF	Clear all the status flags before running the ADF
Program the DMA Enable the DMA	The DMA must be programmed in order to read the data inside the ADF_DLT0DR register every time a DMA request is generated.
Start acquisition: ADF_DFLT0CR = 0x0000 0007	The ADF starts to filter data.

36.7.3 Connection examples

Figure 378 shows simple connection examples of the ADF to external sensors.

- Picture on the left: two digital microphones connected to the ADF

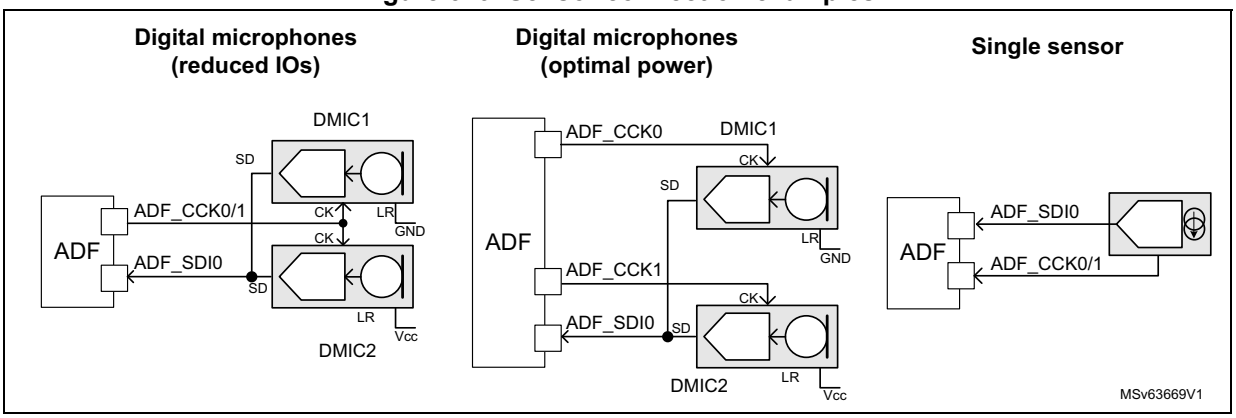
  In this connection, the amount of connections is optimized; DMIC1 and DMIC2 are sharing the same data line, and the same clock line. BSMX allows the application to connect the digital filter either to DMIC1 or to DMIC2. In this configuration when one of the microphone is used, the other is activated as well, as they share the same clock.
- Picture in the center: two digital microphones connected to the ADF

  In this connection, DMIC1 and DMIC2 are sharing the same data line, but have a dedicated clock line. BSMX allows the application to connect the filter either to DMIC1 or to DMIC2. When the application wants to use a microphone, it is possible to keep the other in low-power mode by forcing its clock line to 0 (CCKyEN = 0, CCKyDIR = 1).

- Picture on the right: single sensor connected to the ADF

  It is also possible to configure the CCK0 and CCK1 pins to input in order to connect sensors providing the clock.

Figure 379. Sensor connection examples



36.7.4 Global frequency response

Figure 379 shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 40 Hz

Figure 380 shows the theoretical frequency response using a CIC4 and a CIC5.

Figure 380. Global frequency response

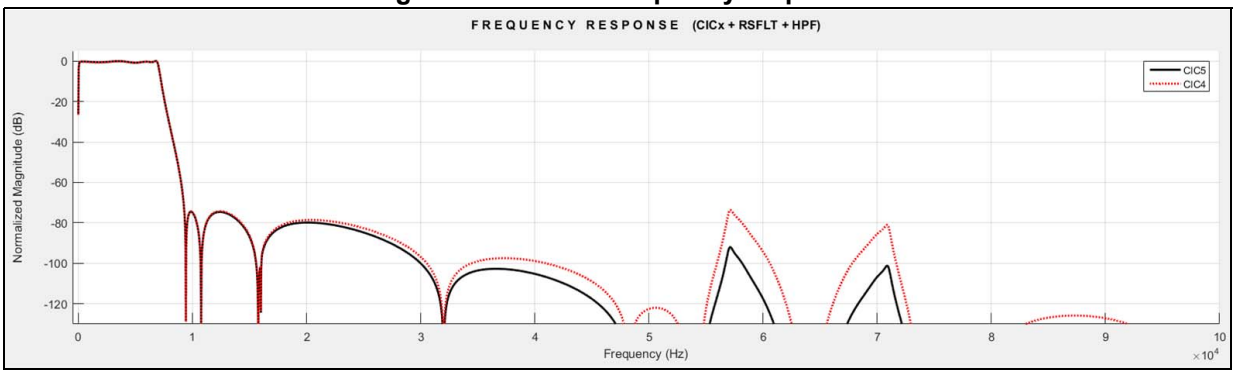


Figure 381 shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

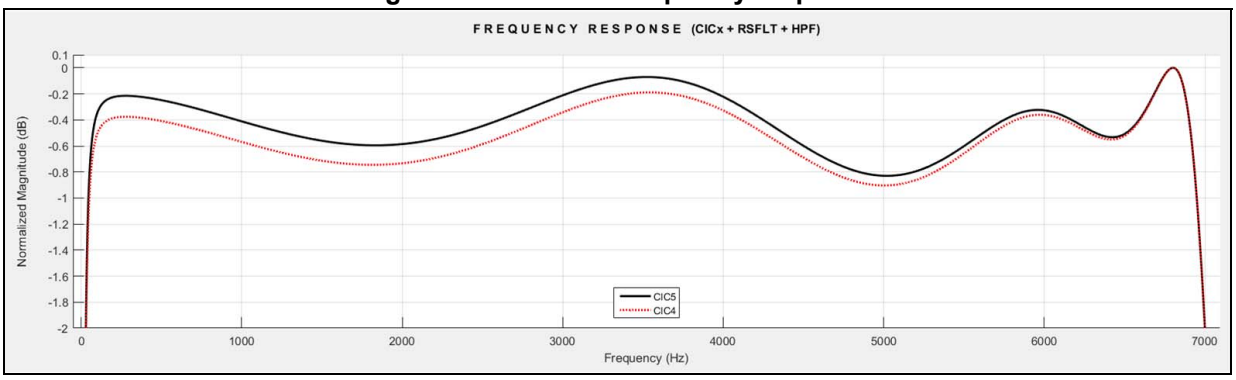
- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 dB for CIC4.

The - 3 dB cut-off frequency is 7061 Hz.

Figure 381. Detailed frequency response



36.7.5 Total ADF gain

This section details how to compute the signal level provided by the ADF according to the filter settings.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50 % of the maximum level, has a − 6 dBFS level (6 dB below full scale).

For example, for the ADF offering a final data width of 24 bits, a signal having an amplitude of 2 * 10^6 LSB has a level of:

$$20 \times \log_{10}\left(\frac{2 \times 10^6}{2^{(24-1)}}\right) = -12.45 \text{ dBFS}$$

In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left(\frac{\ln(Amp)}{\ln(2)} + 1\right) \text{ bits}$$

One bit need to be added for negative values.

So a signal having an amplitude of 2 * 10^6 LSB, has a data size of 21.9 bits.

CIC gain

The CIC gain (G_{CIC} and GdB_{CIC}) can be deduced from the following formula giving data size in bits (DS_{CIC}).

$$DS_{CIC} = (N \times \log_2(D1)) + DSin$$

where N represents the CIC order (selected by CICMOD[2:0]), and D1 is the decimation ratio (given by MCICD[8:0]).

DSin represents the data size (in bits) of the signal at CIC input.

Warning: DS_{CIC} is very important for CIC filter. In order to work fine, DS_{CIC} must not exceed 26 bits.

The CIC gain G_{CIC} is given by:

$$G_{CIC} = (D1)^N$$

which gives in decibels:

$$GdB_{CIC} = 20 \times \log_{10}((D1)^N)$$

Data size at SCALE output

The data size at SCALE output (including the CIC gain), is a key information as the RSFLT starts to have some saturations, if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.

If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted.

The signal amplitude at SCALE output is:

$$Asout_{SCALE} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times Asin_{DFLT}$$

GdB_{SCALE} represents the gain selected by SCALE[5:0], in dB.

$Asout_{SCALE}$ is the signal amplitude at SCALE output (in LSB), and $Asin_{DFLT}$ is the signal amplitude at CIC input (LSB).

$$DS_{SCALE} = \frac{\ln(Asout_{SCALE})}{\ln(2)} + 1$$

The data size at SCALE output (DS_{SCALE}) is expressed in bits.

RSFLT gain

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.41 dB must be considered.

$$G_{RSFLT} = 10^{\frac{9.5\ dB}{20}} = 2.98 \text{ typical}$$

Note: The HPF filter has a gain of 0 dB.

SAD gain

The SAD is using only the 16 MSB on the signal, as a consequence, from the SAD point of view, the truncation from 24 to 16 bits can be seen as an attenuation.

$GdB_{SAD} = -48.1dB$

and

$G_{SAD} = 0.003906$

The *Figure 382* shows a simplified view of the filter path and gives, for each significant component, the expression of the bit growth and the gain.

Figure 382. Simplified DFLT view with gain information

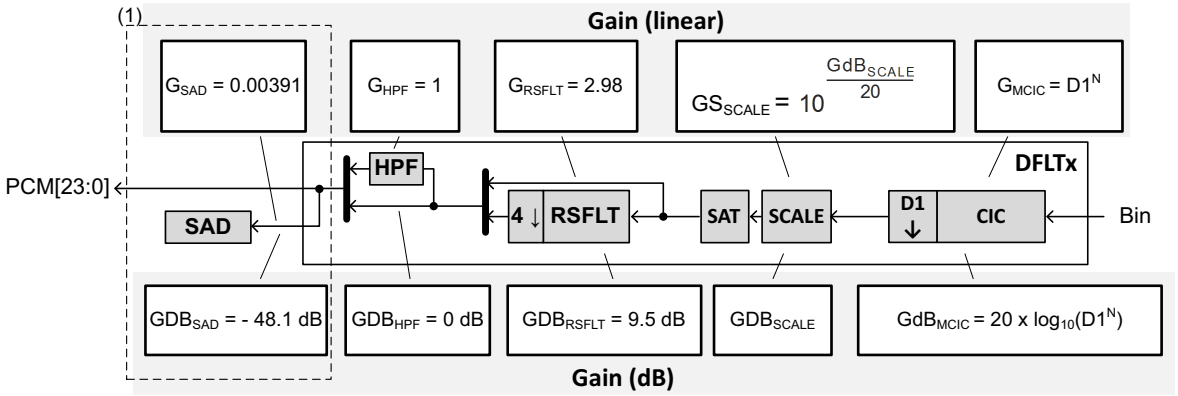


Table 313 summarizes of the final data size for different filter configurations.

Table 313. Output signal levels

Filter configurations	Final signal amplitude (LSB)
CIC + RSFLT + HPF + SAD	Samples provided to the RXFIFO: $Asout_{RXFIFO} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times Asin_{DFLT}$ Samples provided to the SAD: $Asout_{SAD} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times 0.003906 \times Asin_{DFLT}$ DS_{SCALE} must be lower than 22 bits
CIC + RSFLT (+ HPF)	$ASout_{HPF} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times Asin_{DFLT}$ DS_{SCALE} must be lower than 22 bits
CIC (+ HPF)	$ASout_{HPF} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times Asin_{DFLT}$ DS_{SCALE} must be lower than 24 bits

Example using the main filter chain

If the ADF filter is programmed as follows:

- The input signal is coming from a serial interface ($Dsin_{RSFLT}$ = 1 bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to - 12 dB.
- RSFLT enabled, and the decimation by four is enabled.
- HPF is enabled.

Check first the data size at CIC output:

$$DS_{CIC} = (5 \times \log_2(24)) + 1 \text{ bit} = 23.92 \text{ bits}$$

The size is lower than 26 bits, so the CIC works in good conditions.

The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a 22-bit max signal to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

$$Asout_{SCALE} = 24^5 \times 10^{\frac{-12}{20}} \times 1 = 2.10^6$$

$$DS_{SCALE} = \frac{\ln(2.10^6)}{\ln(2)} + 1 = 21.93 \text{ bits}$$

If a higher gain is used, the RSFLT may saturate the output signal for strong input signals.

At the end, the final signal amplitude is:

$$Asout_{HPF} = 24^5 \times 10^{\frac{-12}{20}} \times 10^{\frac{9.5}{20}} \times 1 = 5.9711 \times 10^6$$

$$Dsout_{HPF} = \left(\frac{\ln(5.9711 \times 10^6)}{\ln(2)} + 1\right) = 23.51 \text{ bits}$$

or:

$$SDB_{OUT} = 20 \times \log_{10}\left(\frac{2^{23.51}}{2^{24}}\right) = -2.84 \text{ dBFS}$$

36.7.6 How to compute SAD thresholds

The SAD does not compute the RMS value of the converted signal, but the average of the absolute values. As a consequence, the estimated level differs from the RMS value of the signal:

- For a sine signal having an RMS value of 1, the SAD computes a level of 0.9.
- For a white or pink noise signal having an RMS value of 1, the SAD computes a level of about 0.8.

Note: FRSIZE[2:0] has a big influence on the accuracy of the level estimation: big FRSIZE[2:0] values give better results.

Threshold programming with SADMOD = 01

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 63 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02.

The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 63 dBSPL produces a digital signal of about:
- 26 dBFS - (94 - 63) = - 57 dBFS.

- SCALE value adjustment

  For this example, the filter configuration is the following:
  - CIC5 with a decimation by 16
  - RSFLT enabled with a decimation by 4
  - HPF enabled

  A SCALE value of 3.5 dB is recommended for this configuration. As DFTL0 provides samples only used for a sound detection (samples not provided to the application), a bigger gain value can be applied: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 15.6 dB).
- Input signal amplitude

  The input signal is - 57 dBFS, corresponding to an amplitude

  Asin = $10^{(-57/20)}$ = 0.00141 LSB.
- Signal level at SAD input

  The total filter gain for the SAD is:

$$G_{SAD} = 16^5 \times 10^{\frac{15.6}{20}} \times 10^{\frac{9.5}{20}} \times \frac{1}{256} = 73.68 \times 10^3 \text{ or } 97.3 \text{ dB}$$

  The signal amplitude received by the SAD is:

$$Ain_{SAD} = 0.00141 \times G_{SAD} \sim 104 \text{ LSB}$$

  The gain can be increased if the expected amplitude is too small. For the targeted application, 104 LSB is fine.

  If the input signal is expected to be a sine, the sound level for a signal amplitude of 104 LSB is:

$$SDLVL = \frac{Ain_{SAD} \times \sqrt{2}}{2} \times 0.9 \sim 66 \text{ LSB}$$

  where 0.9 is the correction factor to apply with respect to the RMS value.
- Program the trigger value

ANMIN and SNTHR must be programmed to trigger the SAD when the input signal level reaches 66 LSB.

For SADMOD[1:0] = 01, the threshold value is given by:

$$THRH = ANMIN \times 10^{\frac{GdB_{SNTHR}}{20}}$$

where GdB_{SNTHR} represents the decibel value selected by SNTHR[3:0].

When SNTHR[3:0] = 6 dB for example, this formula becomes:

$$THRH = 2 \times ANMIN$$

So ANMIN = THRH/2 = 66 /2 = 33 LSB.

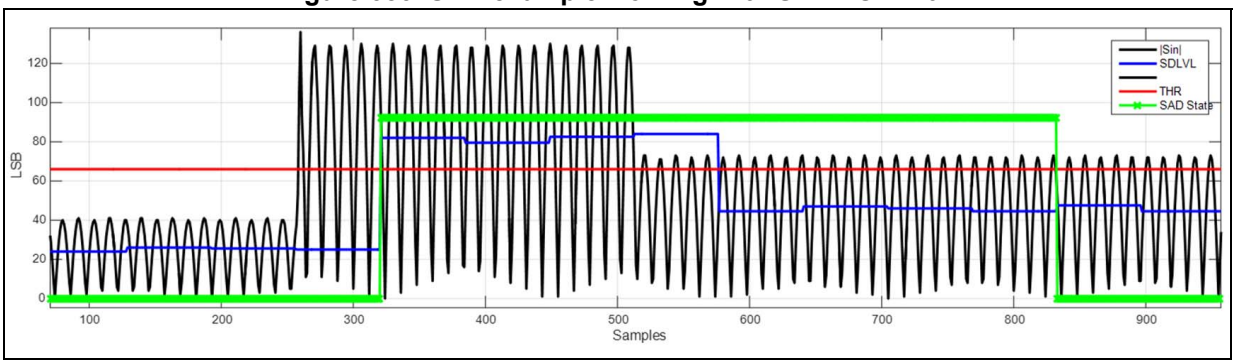
In *Figure 382*, the trigger value (THRH in red) is fixed to 66 LSB. The input signal is at - 65dBFS during 256 samples, then its value goes to - 55 dB for 256 samples, and finally it is reduced to - 60 dBFS.

The blue curve is showing the sound level estimation (SDLVL) versus time. Fluctuation on the estimated value can be observed due to windowing effect of FRSIZE samples.

The SAD DETECT state (when green signal is high) is maintained during four additional frames due to hangover function value.

In this example ANSLP = FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 33.

Figure 383. SAD example working with SADMOD = 01



Threshold programming with SADMOD = 1x

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 57 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02. The sensitivity of this microphone is typically - 26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 57 dBSPL produces a digital signal of about:
- 26 dBFS - (94-63) = - 63 dBFS.

- Adjust SCALE value

  For this example, the filter configuration is the following:

  – CIC4 with a decimation by 48

– RSFLT bypassed
– HPF enabled

A SCALE value of 3.5 dB is recommended for this configuration. The samples provided by DFTL0 are only used for a sound detection, without providing the samples to the application, a bigger gain value can be provided: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 24 dB).

- Input signal amplitude

  The input signal is - 63 dBFS, corresponding to an amplitude:

  Asin = $10^{(-63/20)}$ = 0.000708 LSB.

- Signal level at SAD input

  The total filter gain for the SAD is:

$$G_{SAD} = 48^4 \times 10^{\frac{24}{20}} \times 0.003906 = 328.6 \times 10^3 \text{ or } 110.3 \text{ dB}$$

The signal amplitude received by the SAD is:

$$Ain_{SAD} = 0.000708 \times G_{SAD} \sim 232 \text{ LSB}$$

The gain can be increased if the expected amplitude is too small.

If the input signal is expected to be a sine, the sound level for a signal amplitude of 232 LSB is:

$$SDLVL = \frac{Ain_{SAD} \times \sqrt{2}}{2} \times 0.9 \sim 148 \text{ LSB}$$

where 0.9 is the correction factor to apply with respect to the RMS value.

Note: ANLVL converges to average of SDLVL values, with a long constant time.
So SDLVL ~ ANLVL = 148 LSB for a constant input signal at 57 dBSPL.

- Programming trigger value

  For SADMOD = 1', the SAD compares the estimated ambient noise multiplied by the gain selected by SNTHR[3:0] to ANMIN[12:0] * 4.

  For simplification, SNTHR[3:0] is set to 1 (6 dB), meaning that ANLVL is multiplied by two.

  The SAD triggers if 2 * ANLVL > THRH.

  In this mode,

$$THRH = 4 \times ANMIN$$

So the SAD triggers if:

$$ANLVL > 2 \times ANMIN$$

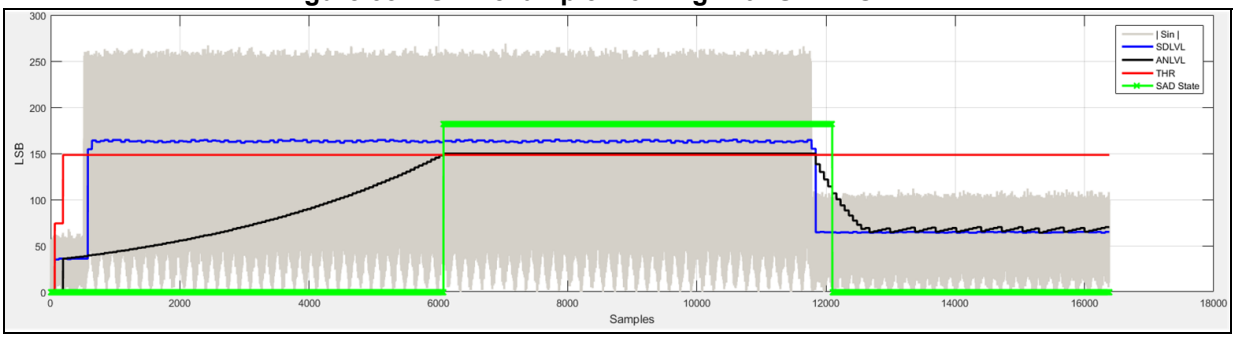
So ANMIN = 148 / 2 = 74 LSB

In *Figure 383*, the trigger value (THRH in red) is fixed to 148 LSB. The input signal is at - 75 dBFS during 512 samples, then its value goes to - 62 dB for 11000 samples, and finally it is reduced to - 70 dBFS.

The blue curve shows the sound level estimation (SDLVL) versus time. The black curve shows the ambient noise estimation versus time, increasing or decreasing logarithmically. During the learning phase, it reaches the SDLVL value.

In this example ANSLP = 6, FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 74.

Figure 384. SAD example working with SADMOD = 1x



36.8 ADF registers

All the ADF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

36.8.1 ADF global control register (ADF_GCR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRGO
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TRGO**: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also used to synchronize several ADF together by controlling the adf_trgo signal.

0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.

1: Write 1 generates a positive pulse on the adf_trgo signal and triggers the acquisition on enabled filter having their ACQMOD[2:0] = 01x and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.

36.8.2 ADF clock generator control register (ADF_CKGCR)

Address offset: 0x004

Reset value: 0x0000 0000

This register is used to control the clock generator. The clock adf_proc_ck must be enabled before enabling other ADF parts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CKGACTIVE	PROCDIV[6:0]							Res.	Res.	Res.	Res.	CCKDIV[3:0]			
r	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRGSRC[3:0]				Res.	Res.	Res.	TRGSENS	Res.	CCK1DIR	CCK0DIR	CKGMOD	Res.	CCK1EN	CCK0EN	CKGDEN
rw	rw	rw	rw				rw		rw	rw	rw		rw	rw	rw

Bit 31 **CKGACTIVE**: Clock generator active flag

This bit is set and cleared by hardware. Ii is used by the application to check if the clock generator is effectively enabled (active) or not. The protected fields of this function can only be updated when CKGACTIVE = 0 (see *Section 36.4.13: Register protection* for details).

The delay between a transition on CKGDEN and a transition on CKGACTIVE is two periods of AHB clock and two 2 periods of adf_proc_ck.

0: The clock generator is not active and can be configured if needed.

1: The clock generator is active and protected fields cannot be configured.

Bits 30:24 **PROCDIV[6:0]**: Divider to control the serial interface clock

This bitfield is set and reset by software. It is used to adjust the frequency of the clock provided to the SITF.

$$F_{adf_itf_ck} = \frac{F_{adf_ker_ck}}{(PROCDIV + 1)}$$

This bitfield must not be changed if the filter is enabled (DFTEN = 1).

0: adf_ker_ck provided to the SITF

1: adf_ker_ck / 2 provided to the SITF

2: adf_ker_ck / 3 provided to the SITF

...

127: adf_ker_ck / 128 provided to the SITF

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CCKDIV[3:0]**: Divider to control the ADF_CCK clock

This bitfield is set and reset by software. It is used to adjust the frequency of the ADF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the ADF_CCK is given by the following formula:

$$F_{ADF_CCK} = \frac{F_{adf_ker_ck}}{(PROCDIV + 1) \times (CCKDIV + 1)}$$

This bitfield must not be changed if the filter is enabled (DFTEN = 1).

0000: The ADF_CCK clock is adf_proc_ck.

0001: The ADF_CCK clock is adf_proc_ck / 2.

0010: The ADF_CCK clock is adf_proc_ck / 3.

...

1111: The ADF_CCK clock is adf_proc_ck / 16.

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger the corresponding filter. This bitfield is not significant if the CKGMOD = 0.

000x: TRGO selected

0010: adf_trg1 selected

Others: Reserved

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

0: A rising edge event triggers the activation of CKGEN dividers.

1: A falling edge even triggers the activation of CKGEN dividers.

Note: When the trigger source is TRGO, the sensitivity is forced to falling edge, thus TRGSENS value is not taken into account. This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: ADF_CCK1 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK1 pin.

0: The ADF_CCK1 pin direction is in input.

1: The ADF_CCK1 pin direction is in output.

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 5 **CCK0DIR**: ADF_CCK0 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK0 pin.

0: The ADF_CCK0 pin direction is in input.

1: The ADF_CCK0 pin direction is in output.

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 4 **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if the filter is enabled (DFTEN = 1).

0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.

1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: ADF_CCK1 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK1 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the ADF_CCK1 pin.

Bit 1 **CCK0EN**: ADF_CCK0 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK0 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the ADF_CCK0 pin

Bit 0 **CKGDEN**: CKGEN dividers enable

This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.

0: CKGEN dividers disabled

1: CKGEN dividers enabled

36.8.3 ADF serial interface control register 0 (ADF_SITF0CR)

Address offset: 0x080

Reset value: 0x0000 1F00

This register is used to control the serial interface SITF0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **SITFACTIVE**: Serial interface active flag

This bit is set and cleared by hardware. It is used by the application to check if the serial interface is effectively enabled (active) or not. The protected fields of this function can only be updated when SITFACTIVE is set to 0 (see *Section 36.4.13: Register protection* for details).

The delay between a transition on SITFEN and a transition on SITFACTIVE is two periods of AHB clock and two periods of adf_proc_ck.

0: The serial interface is not active, and can be configured if needed.

1: The serial interface is active and protected fields cannot be configured.

Bits 30:13 Reserved, must be kept at reset value.

Bits 12:8 **STH[4:0]**: Manchester symbol threshold/SPI threshold

This bitfield is set and cleared by software. It is used for Manchester mode to define the expected symbol threshold levels (see *Manchester mode* for details on computation).

In addition this bitfield is used to define the timeout value for the clock absence detection in Normal SPI mode. STH[4:0] values lower than four are invalid.

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **SITFMOD[1:0]**: Serial interface type
This bitfield is set and cleared by software. It is used to define the serial interface type.
00: LF_MASTER SPI mode
01: Normal SPI mode
10: Manchester mode: rising edge = logic 0, falling edge = logic 1
11: Manchester mode: rising edge = logic 1, falling edge = logic 0
Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **SCKSRC[1:0]**: Serial clock source
This bitfield is set and cleared by software. It is used to select the clock source of the serial interface.
00: Serial clock source is ADF_CCK0.
01: Serial clock source is ADF_CCK1.
others: reserved
Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 0 **SITFEN**: Serial interface enable
This bit is set and cleared by software. It is used to enable/disable the serial interface.
0: Serial interface disabled
1: Serial interface enabled

36.8.4 ADF bitstream matrix control register 0 (ADF_BSMX0CR)

Address offset: 0x084

Reset value: 0x0000 0000

This register is used to select the bitstream to be provided to DFLT0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw	rw	rw	rw

Bit 31 **BSMXACTIVE**: BSMX active flag
This bit is set and cleared by hardware. It is used by the application to check if the BSMX is effectively enabled (active) or not. BSSEL[4:0] can only be updated when BSMXACTIVE is set to 0. This BSMXACTIVE flag cannot go to 0 if DFLT0 is enabled.
0: BSMX is not active and can be configured if needed.
1: BSMX is active and protected fields cannot be configured.

Bits 30:5 Reserved, must be kept at reset value.

Bits 4:0 **BSSEL[4:0]**: Bitstream selection
This bitfield is set and cleared by software. It is used to select the bitstream to be processed for DFLT0.
00000: bs0_r provided to DFLT0
00001: bs0_f provided to DFLT0
others: reserved
Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

36.8.5 ADF digital filter control register 0 (ADF_DFLT0CR)

Address offset: 0x088

Reset value: 0x0000 0000

Bit 31 **DFLTACTIVE**: DFLT0 active flag

This bit is set and cleared by hardware. It indicates if DFLT0 is active: can be running or waiting for events.

0: DFLT0 not active (can be re-enabled again, via DFLTEN bit, if needed)

1: DFLT0 active

Bit 30 **DFLTRUN**: DFLT0 run status flag

This bit is set and cleared by hardware. It indicates if DFLT0 is running or not.

0: DFLT0 not running and ready to accept a new trigger event

1: DFLT0running

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 **NBDIS[7:0]**: Number of samples to be discarded

This bitfield is set and cleared by software. It is used to define the number of samples to be discarded every time DFLT0 is re-started.

0: No sample discarded

1: 1 sample discarded

2: 2 samples discarded

...

255: 255 samples discarded

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:12 **TRGSRC[3:0]**: DFLT0 trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger DFLT0.

0000: TRGO selected

0010: adf_trgi selected

Others: Reserved

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: DFLT0 trigger sensitivity selection

This bitfield is set and cleared by software. It is used to select the trigger sensitivity of the external signals

0: A rising edge event triggers the acquisition.

1: A falling edge even triggers the acquisition.

Note: When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge.
This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: DFLT0 trigger mode

This bitfield is set and cleared by software. It is used to select the filter trigger mode.

000: Asynchronous continuous acquisition mode

001: Asynchronous single-shot acquisition mode

010: Synchronous continuous acquisition mode

011: Synchronous single-shot acquisition mode

100: Window continuous acquisition mode

Others: Same as 000

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTH**: RXFIFO threshold selection

This bit is set and cleared by software. It is used to select the RXFIFO threshold.

0: RXFIFO threshold event generated when the RXFIFO is not empty

1: RXFIFO threshold event generated when the RXFIFO is half-full

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 1 **DMAEN**: DMA requests enable

This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory.

0: DMA interface for the corresponding digital filter disabled

1: DMA interface for the corresponding digital filter enabled

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 0 **DFLTEN**: DFLT0 enable

This bit is set and cleared by software. It is used to control the start of acquisition of the DFLT0 path. This bit behavior depends on ACQMOD[2:0] and external events. The serial or parallel interface delivering the samples must be enabled as well.

0: Acquisition immediately stopped

1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x.

36.8.6 ADF digital filer configuration register 0 (ADF_DFLT0CICR)

Address offset: 0x08C

Reset value: 0x0000 0000

This register is used to control the main CIC filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SCALE[5:0]						Res.	Res.	Res.	MCICD8

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCICD[7:0]								Res.	CICMOD[2:0]			Res.	Res.	DATSRC[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw			rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **SCALE[5:0]**: Scaling factor selection

This bitfield is set and cleared by software. It is used to select the gain to be applied at CIC output (see *Table 301* for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this bitfield informs the application on the current gain value.

000000: 0 dB
000001: + 3.5 dB
000010: + 6 dB or shift left by 1 bit
...
011000: + 72 dB or shift left by 12 bits
100000: - 48.2 dB or shift right by 8 bits (default value)
100001: - 44.6 dB

100011: - 38.6 dB
...
101110: -6 dB or shift right by 1 bit
101111: -2.5 dB
Others: Reserved

Bits 19:17 Reserved, must be kept at reset value.

Bits 16:8 **MCICD[8:0]**: CIC decimation ratio selection

This bitfield is set and cleared by software.It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by (CICDEC+1).

0: Decimation ratio is 2.
1: Decimation ratio is 2.
2: Decimation ratio is 3.
3: Decimation ratio is 4.
...
511: Decimation ratio is 512.

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **CICMOD[2:0]**: Select the CIC order
This bitfield is set and cleared by software. It is used to select the order of the MCIC.
100: MCIC configured in single $Sinc^4$ filter
101: MCIC configured in single $Sinc^5$ filter
Others: Reserved
Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **DATSRC[1:0]**: Source data for the digital filter
This bitfield is set and cleared by software.
0x: Stream coming from the BSMX selected
10: Stream coming from the ADCITF1 selected
11: Stream coming from the ADCITF2 selected
Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

36.8.7 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)

Address offset: 0x090

Reset value: 0x0000 0000

This register is used to control the reshape and HPF filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	HPFC[1:0]		HPFBYP	Res.	Res.	RSFLTD	Res.	Res.	Res.	RSFLTBYP
						rw	rw	rw			rw				rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:8 **HPFC[1:0]**: High-pass filter cut-off frequency
This bitfield is set and cleared by software. it is used to select the cut-off frequency of the high-pass filter. F_{PCM} represents the sampling frequency at HPF input.
00: Cut-off frequency = 0.000625 x FPCM
01: Cut-off frequency = 0.00125 x FPCM
10: Cut-off frequency = 0.00250 x FPCM
11: Cut-off frequency = 0.00950 x FPCM
Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 7 **HPFBYP**: High-pass filter bypass
This bit is set and cleared by software. It is used to bypass the high-pass filter.
0: HPF not bypassed (default value)
1: HPF bypassed
Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **RSFLTD**: Reshaper filter decimation ratio

This bit is set and cleared by software. It is used to select the decimation ratio for the reshape filter

0: Decimation ratio is 4 (default value).

1: Decimation ratio is 1.

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RSFLTBYP**: Reshaper filter bypass

This bit is set and cleared by software. It is used to bypass the reshape filter and its decimation block.

0: Reshape filter not bypassed (default value)

1: Reshape filter bypassed

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

36.8.8 ADF delay control register 0 (ADF_DLY0CR)

Address offset: 0x0A4

Reset value: 0x0000 0000

This register is used for the adjustment stream delays.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SKPBF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SKPDLY[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bit 31 **SKPBF**: Skip busy flag

This bit is set and cleared by hardware. It is used to control if the delay sequence is completed.

0: ADF ready to accept a new value into SKPDLY[6:0]

1: Last valid SKPDLY[6:0] still under precessing

Bits 30:7 Reserved, must be kept at reset value.

Bits 6:0 **SKPDLY[6:0]**: Delay to apply to a bitstream

This bitfield is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this bitfield, if SKPBF = 0 and DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.

0: No input sample skipped

1: 1 input sample skipped

...

127: 127 input samples skipped

36.8.9 ADF DFLT0 interrupt enable register (ADF_DFLT0IER)

Address offset: 0x0AC

Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SDLVLIE	SDDETIE	RFOVRIE	CKABIE	SATIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DOVRIE	FTHIE
		rw	rw	rw	rw	rw								rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SDLVLIE**: SAD sound-level value ready enable
This bit is set and cleared by software.
0: Sound-level-ready interrupt disabled
1: Sound-level-ready interrupt enabled

Bit 12 **SDDETIE**: Sound activity detection interrupt enable
This bit is set and cleared by software.
0: Sound-trigger interrupt disabled
1: Sound-trigger interrupt enabled

Bit 11 **RFOVRIE**: Reshape filter overrun interrupt enable
This bit is set and cleared by software.
0: Reshape filter overrun interrupt disabled
1: Reshape filter overrun interrupt enabled

Bit 10 **CKABIE**: Clock absence detection interrupt enable
This bit is set and cleared by software.
0: Clock absence interrupt disabled
1: Clock absence interrupt enabled

Bit 9 **SATIE**: Saturation detection interrupt enable
This bit is set and cleared by software.
0: Saturation interrupt disabled
1: Saturation interrupt enabled

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **DOVRIE**: Data overflow interrupt enable
This bit is set and cleared by software.
0: Data overflow interrupt disabled
1: Data overflow interrupt enabled

Bit 0 **FTHIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
0: RXFIFO threshold interrupt disabled
1: RXFIFO threshold interrupt enabled

36.8.10 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)

Address offset: 0x0B0

Reset value: 0x0000 0000

This register contains the status flags for the digital filter path.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SDLVLF	SDDETF	RFOVRF	CKABF	SATF	Res.	Res.	Res.	Res.	Res.	RXNEF	Res.	DOVRF	FTHF
		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1						r		rc_w1	r

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SDLVLF**: Sound level value ready flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that new sound level value is not ready. Write 0 has no effect.
1: Read 1 means that new sound level value is ready. Write 1 clears this flag.

Bit 12 **SDDETF**: Sound activity detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no sound activity is detected. Write 0 has no effect.
1: Read 1 means that sound activity is detected. Write 1 clears this flag.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **RXNEF**: RXFIFO not empty flag
This bit is set and cleared by hardware according to the RXFIFO level.
0: RXFIFO empty
1: RXFIFO not empty

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DOVRF**: Data overflow flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no overflow is detected. Write 0 has no effect.
1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag

This bit is set by hardware, and cleared by the hardware when the RXFIFO level is lower than the threshold.

0: RXFIFO threshold not reached

1: RXFIFO threshold reached

36.8.11 ADF SAD control register (ADF_SADCR)

Address offset: 0x0B8

Reset value: 0x0000 0000

This register is used for the configuration and the control of the sound activity detection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SADACTIVE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SADMOD[1:0]		Res.	FRSIZE[2:0]			HYSTEN	Res.	SADST[1:0]		DETCFG	DATCAP[1:0]		SADEN
		rw	rw		rw	rw	rw	rw		r	r	rw	rw	rw	rw

Bit 31 **SADACTIVE**: SAD Active flag

This bit is set and cleared by hardware. It is used to check if the SAD is effectively enabled (active) or not. The protected fields and registers of this function can only be updated when the SADACTIVE is set to 0 (see *Section 36.4.13: Register protection* for details).

The delay between a transition on SADEN and a transition on SADACTIVE is two periods of AHB clock and two periods of adf_proc_ck.

0: SAD not active and can be configured if needed

1: SAD active and protected fields cannot be configured.

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:12 **SADMOD[1:0]**: SAD working mode

This bitfield is set and cleared by software. It is used to define the way the SAD works.

00: Threshold value computed according to the estimated ambient noise

The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a voice activity detector.

01: Threshold value equal to ANMIN[12:0], multiplied by the gain selected by SNTHR[3:0]

The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a sound detector.

1x: Threshold value given by 4 x ANMIN[12:0]

The SAD triggers when the estimated ambient noise (ANLVL), multiplied by the gain selected by SNTHR[3:0] is bigger than the defined threshold. In this mode, the SAD is working like an ambient noise estimator. Hysteresis function cannot be used in this mode.

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **FRSIZE[2:0]**: Frame size

This bitfield is set and cleared by software. it is used to define the size of one frame and also to define how many samples are taken into account to compute the short-term signal level.

000: 8 PCM samples used to compute the short-term signal level

001: 16 PCM samples used to compute the short-term signal level

010: 32 PCM samples used to compute the short-term signal level

011: 64 PCM samples used to compute the short-term signal level

100: 128 PCM samples used to compute the short-term signal level

101: 256 PCM samples used to compute the short-term signal level

11x: 512 PCM samples used to compute the short-term signal level

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 7 **HYSTEN**: Hysteresis enable

This bit is set and cleared by software. It is used to enable/disable the hysteresis function (see *Table 301* for details). This bit must be kept to 0 when SADMOD[1:0] = 1x.

0: Hysteresis function disabled. THR_H is always used.

1: Hysteresis function enabled. THR_H is used for MONITOR to DETECT transition and THR_L is used for DETECT to MONITOR transition.

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **SADST[1:0]**: SAD state

This bitfield is set and cleared by hardware. It indicates the SAD state and is meaningful only when SADEN = 1. The SAD state can be:

- LEARN when the SAD is in learning phase or in SDLVL computation mode
- MONITOR when the SAD is in monitoring phase
- DETECT when the SAD detects a sound

00: SAD in LEARN state

01: SAD in MONITOR state

11: SAD in DETECT state

Bit 3 **DETCFG**: Sound trigger event configuration

This bit is set and cleared by software. It is used to define if the sddet_evt event is generated only when the SAD enters to MONITOR state or when the SAD enters or exits the DETECT state.

0: sddet_evt generated when SAD enters the MONITOR state

1: sddet_evt generated when SAD enters or exits the DETECT state

Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bits 2:1 **DATCAP[1:0]**: Data capture mode

This bitfield is set and cleared by software. It is used to define in which conditions, the samples provided by DLFT0 are stored into the memory.

00: Samples from DFLT0 not transfered into the memory

01: Samples from DFLT0 transfered into the memory when SAD is in DETECT state

1x: Samples from DFLT0 transfered into memory when SAD and DFLT0 are enabled

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 0 **SADEN**: Sound activity detector enable

This bit is set and cleared by software. It is used to enable/disable the SAD.

0: SAD disabled and SAD state reset

1: SAD enabled

36.8.12 ADF SAD configuration register (ADF_SADCFGR)

Address offset: 0x0BC

Reset value: 0x0000 0000

This register is used for the configuration of the sound activity detection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	ANMIN[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	HGOVR[2:0]			Res.	LFRNB[2:0]			Res.	ANSLP[2:0]			SNTHR[3:0]			
	rw	rw	rw		rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **ANMIN[12:0]**: Minimum noise level

This bitfield is set and cleared by software. It is used to define the minimum noise level and then the sensitivity. It represents a positive number.

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **HGOVR[2:0]**: Hangover time window

This bitfield is set and cleared by software. Once the SAD state is DETECT, this parameter is used to define the amount of time the sound is allowed to remain below the threshold, before switching the SAD to MONITOR state (see FRSIZE bitfield for the description of a frame).

000: SAD back to MONITOR state if sound is below threshold for 4 frames
001: SAD back to MONITOR state if sound is below threshold for 8 frames
010: SAD back to MONITOR state if sound is below threshold for 16 frames
011: SAD back to MONITOR state if sound is below threshold for 32 frames
100: SAD back to MONITOR state if sound is below threshold for 64 frames
101: SAD back to MONITOR state if sound is below threshold for 128 frames
110: SAD back to MONITOR state if sound is below threshold for 256 frames
111: SAD back to MONITOR state if sound is below threshold for 512 frames

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **LFRNB[2:0]**: Number of learning frames

This bitfield is set and cleared by software. It is used to define the number of learning frames to perform the first estimate of the noise level.

000: 2 frames used to compute the initial noise level
001: 4 frames used to compute the initial noise level
010: 8 frames used to compute the initial noise level
011: 16 frames used to compute the initial noise level
1xx: 32 frames used to compute the initial noise level

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ANSLP[2:0]**: Ambient noise slope control

This bitfield is set and cleared by software. It is used to define the positive and negative slope of the noise estimator, in charge of updating the ANLVL (see *Ambient noise estimation (ANLVL)* for information about programming this bitfield).

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

Bits 3:0 **SNTHR[3:0]**: Signal to noise threshold

This bitfield is set and cleared by software. It is used to define THR_H (and THR_L if hysteresis is enabled). See *Table 301* for details.

0000: THR_H is 3.5 dB higher than ANLVL
0001: THR_H is 6.0 dB higher than ANLVL
0010: THR_H is 9.5 dB higher than ANLVL
0011: THR_H is 12 dB higher than ANLVL
0100: THR_H is 15.6 dB higher than ANLVL
0101: THR_H is 18 dB higher than ANLVL
0110: THR_H is 21.6 dB higher than ANLVL
0111: THR_H is 24.1 dB higher than ANLVL
1000: THR_H is 27.6 dB higher than ANLVL
1001: THR_H is 30.1dB higher than ANLVL
others: Reserved

Note: This bitfield can be write-protected (see Section 36.4.13: Register protection for details).

36.8.13 ADF SAD sound level register (ADF_SADSDLVR)

Address offset: 0x0C0

Reset value: 0x0000 0000

This register contains the short-term sound-level computed by the SAD.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	SDLVL[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **SDLVL[14:0]**: Short term sound level

This bitfield is set by hardware. It contains the latest sound level computed by the SAD. To refresh this value, SDLVLF must be cleared.

36.8.14 ADF SAD ambient noise level register (ADF_SADANLVR)

Address offset: 0x0C4

Reset value: 0x0000 0000

This register contains the ambient noise level computed by the SAD.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	ANLVL[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **ANLVL[14:0]**: Ambient noise level estimation

This bitfield is set by hardware. It contains the latest ambient noise level computed by the SAD. To refresh this bitfield, the SDLVLF flag must be cleared.

36.8.15 ADF digital filter data register 0 (ADF_DFLT0DR)

Address offset: 0x0F0

Reset value: 0x0000 0000

This register is used to read the data processed by the digital filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3* for the register boundary addresses.

37 Camera subsystem

37.1 Introduction

The camera subsystem is built around a double path:

- a low-resolution path, with the DCMI and a low-frequency parallel interface. It supports sensors up to 24 Mpixel/s.
- a high-resolution path, with the DCMIPP and a high-frequency parallel interface or serial CSI-2 interface, either RGB or RawBayer. It targets sensors up to 5 Mpixels at 30 fps.

When plugging a camera sensor, it is recommended to use the DCMIPP, a higher performance pipe.

The previous DCMI is recommended only in two noticeable cases:

- to get a backward compatibility with former platforms that embed also the DCMI
- to input the pixels from a second camera sensor

Note: The DCMIPP inputs pixels from one sensor via the CSI-2 interface, while the DCMI gets pixels from the second sensor via the parallel interface.

The DCMI path offers the following summarized maximum features:

- Target sensor: 24 Mpixel/s 16 bpp (limited by the DMA)
- Parallel input: 80 MHz on 14-bit input capability
- Central DMA to extract and dump its pixels
- Software extraction of its pixel data

The DCMIPP path offers the following summarized maximum features:

- Target sensors: 5 Mpixel at 30 fps max
- Parallel input: 120 MHz on 16-bit input capability
- Serial input: CSI-2 @2.5 Gbps/lane on 2 data lanes
- ISP (image signal processor): demosaicing, exposure, white-balance, contrast, bad-pixel
- Application pipes: 2 pipes with crop, downsize, gamma, YUV conversion, YUV420

Some over-target use cases are possible, but with specific constraints:

- sensors with resolution above 5 Mpixels
- sensors with pixel rate above 150 Mpixel/s
- double sensors in parallel

37.2 Camera path main features

37.2.1 DCMI path main features

The DCMI path shows the following features:

- 8-, 10-, 12- or 14-bit parallel interface at 80 MHz (no I/O ReTime)
- Embedded/external line and frame synchronization
- Continuous or snapshot mode

- Crop feature
- Following data formats supported (dumped in memory, extracted by software):
  - 8-, 10-, 12-, 14-bit progressive video, either monochrome or RawBayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG (in fact, any default/byte data)

See *Section 38: Digital camera interface (DCMI)* for more details.

37.2.2 DCMIPP path main features

The DCMIPP path groups the DCMIPP pixel pipeline block, its included parallel interface, and the abutted CSI-2-Host and PHY.

The parallel interface shows the following features:

- Input rate: 120 MHz up to 16-bit capability (with I/O ReTime)
- Pixel format: RGB565, 888, YUV422, RawBayer/Mono 8/10/12/14
- Synchronization: embedded versus external line and frame synchronization

See *Section 39: Digital camera interface pixel pipeline (DCMIPP)* for more details.

The CSI-2 serial interface shows the following features:

- Standard: MIPI CSI2 v1.3
- Input rate: 2 data lanes @ 2.5 Gbps/lane
- Pixel rate: if RGB888: up to 200 Mpixel/s, if RawBayer 10: up to 333 Mpixel/s
- Pixel format: any MIPI CSI2 v1.3: RGB565, 888, YUV422, RawBayer
- Miscellaneous: interlaced video, interleaved packets, virtual channels

See *Section 40: CSI-2 Host (CSI)* for more details.

DCMIPP sizings and limitations

- Camera target: 5 Mpixels (typ. 2560x2048 or 2688x1944) before decimation
- Pipe resolution: 4094x4094 pixels max
  - Demosaicing: 2688 pixels wide max line-buffers (decimation available ahead)
  - Downsize: 2688 pixels wide max line-buffers
  - YUV420: 2688 pixels wide max line-buffers.
- Pipe pixel rate: 333 Mpixel/s peak.
- AXI FIFO: 5 Kbytes available, with a flexible allocation between all outputs.
- AXI master: AXI-64 bits @ 400 MHz, with FIFO for latencies up to 2 µs, 16 outstanding.

The DCMIPP provides three different pipes to process data:

- Pipe0: to dump data without any processing, branched before any ISP

  It is aimed at dumping metadata or statistics as-is from the sensor, or at dumping the full picture as RawBayer data, for a potential long but optimal software processing.
- Pipe1: main full-featured pipe (such as ISP, then downsize, YUV-multi-planar)

  It provides a picture ready for any application (such as display, video encode, or neural processing).

- Pipe2: ancillary semi-featured pipe

  Same ISP as pipe1, then downsize, but no YUV-multiplanar. It provides an RGB output for a display use, or neural processing if using RGB as input.

DCMIPP ISP capabilities common to pipe1 and 2, are the following:

- flow selection: parallel-vs-CSI2, CSI virtual packets
- capture mode: continuous versus snapshot mode
- pixel extraction: RGB565, 888, YUV422, RawBayer/Mono 8/10/12/14.
- statistic removal: to remove unused metadata (like statistics) from received pictures
- bad-pixel removal: automatic detection and correction of bad pixels from sensor array
- decimation: one pixel every 1/2/4/8, used to fit the max 2688 pixels
- exposure control: to amplify the exposure from 0.0 to 255.99x
- statistic extraction: average R,G,B,L values, dynamic bins
- demosaicing: to convert RawBayer to RGB, supports NIR patterns (2x2, 4x4)
- white-balance: to adapt to sensor white and global Illumination
- contrast: to enhance the contrast, via luminance

The DCMIPP application capabilities, replicated for pipe1 and 2, are listed below:

- cropping: to select a region of interest or stabilize the picture
- downsize: box-filtering, with any decimal ratio, up to 8x8 (64x64 with decimation)
- gamma conversion: predistortion with gamma = 2.2 for display purposes
- YUV color conversion: to convert to YUV to later store a video-friendly buffer (pipe1 only).
- YUV422/420: chroma subsampling to YUV422 or YUV420
- output streaming capability of three pixel pipes to a slave peripheral (VENC, NPU, or LP/HPDMA1), using a small multiline internal buffer located in the system memory
- regions of interest (ROI): draw capability of a colored rectangle around each ROI

Output pixel format:

- Pipe1 and 2: 888, 565, 422-1, Y8, ARGB and RGBA (coplanar only)
- Pipe1: to adds422-2, 420-2, 420-3 (multi-planar possibility)

The full features are detailed in *Section 38: Digital camera interface (DCMI)*.

37.3 Camera subsystem implementation

37.3.1 Hardware settings

The camera subsystem is implemented with the following specific settings:

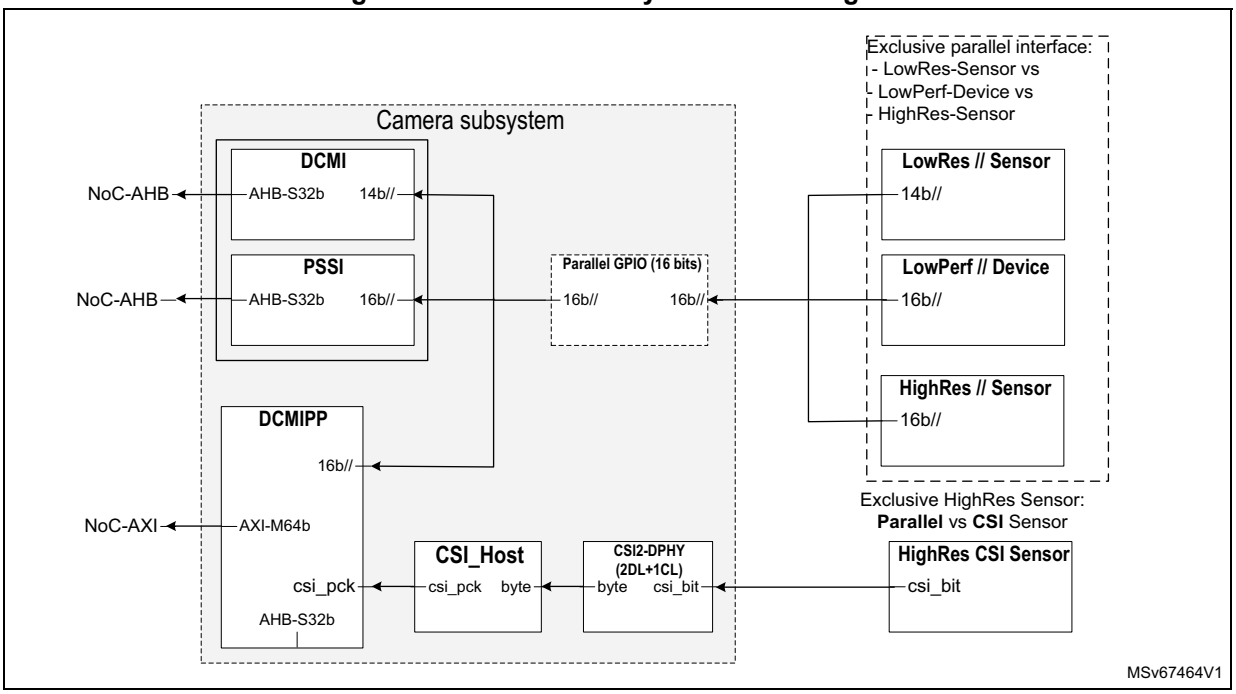
- CSI2: two data lanes (+ one clock lane) up to 2.5 Gbps/lane.
- DCMIPP FIFO: 5 Kbytes for AXI
- DCMIPP with the following subfeatures:
  - line-buffers: 2688 pixels (impacts the demosaicing, downsize, YUV420 conversion)
  - one dump pipe + two pixel pipes (pipe1 with YUV420/multi-planar only)

37.4 Camera subsystem functional description

37.4.1 Camera subsystem block diagram

The figure below shows the involved blocks in the camera subsystem.

Figure 385. Camera subsystem block diagram



Note: The PSSI is not used for camera purpose but rather for general-purpose parallel input (not described in this section).

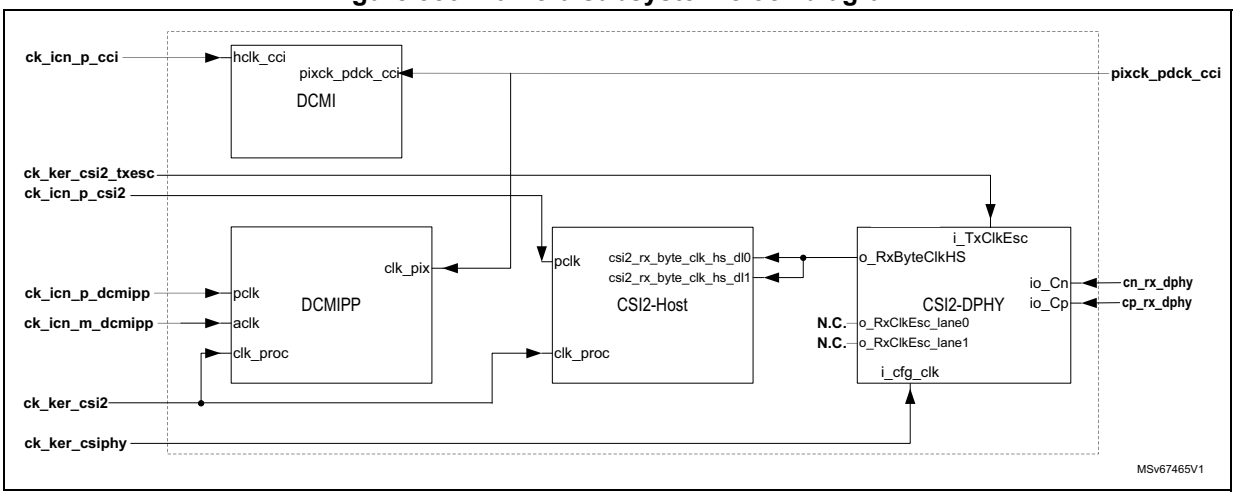
37.4.2 Camera subsystem pins and external signal interface

Details about the pins can be found in the respective block sections.

37.4.3 Camera subsystem reset and clocks

The clock diagram of the camera subsystem is shown in the figure below.

Figure 386. Camera subsystem clock diagram



The above camera subsystem has been implemented with the following clock max frequencies:

- DCMI // I/F (pixck_pdck_cci): 80 MHz (no I/O ReTime: async path from pads)
- DCMIPP // I/F (pixck_pdck_cci): 120 MHz (I/O ReTime mandatory)
- CSI2 bit clock (cn/p_rx_dphy): 1250 MHz (2.5 Gbps/lane)
- CSI2 byte clock (rxbyte_clkHS): 312.5 MHz
- CSI2 TxEsc clock (ck_ker_csi2_txesc): 20 MHz
- CSI2 Cfg clock (ck_ker_csiphy): 27 MHz
- Pixel clock (ck_ker_csi2): 333 MHz
- Register clocks (ck_icn_p_*): 200 MHz (all APB/AHB register files)
- AXI clock (ck_icn_m_dcmipp): 400 MHz

37.4.4 Streaming from the camera subsystem to slave peripherals

The DCMIPP in the camera subsystem can stream pixels to a set of slave peripherals NPU, HP/GPDMA, and VENC. This avoids to write the full frame into a frame buffer (and allocate this frame buffer).

The streaming is done via a small intermediate buffer in the system memory, organized in double ping-pong buffer. The double buffer must be a power-of-two amount of lines, with a recommended size of 16 lines high each.

The processing is as follows:

1. The DCMIPP starts writing into the first buffer.
2. After step 1 completion, the DCMIPP emits an hardware trigger signal to the slave peripheral, and continues to write to the second buffer.
3. At hardware trigger reception, the slave peripheral reads from the first buffer. It is expected to read and process the buffer faster than the DCMIPP fills the other.

4. After completing writing the second buffer, the DCMIPP emits again a trigger, and wraps back its write address counter to restart writing into the first buffer.
5. After finishing reading the second buffer, the slave peripheral wraps back reading into the first buffer.

All DCMIPP pipes can be streamed, but not to all slave peripherals:

- Pipe0 (dump pipe) can be streamed to HP/GPDMA.
- Pipe1 (main pixel pipe) can be streamed to HP/GPDMA, NPU, or VENC.
- Pipe2 (aux pixel pipe) can be streamed to HP/GPDMA or NPU.

The VENC can only get streamed from Pipe1 (only pipe that can output a YUV420 pixel format, needed for its H264 or JPG encode).

A same pipe can be streamed simultaneously to several peripherals if the resolution and pixel format match: after receiving the same broadcasted trigger, the various slave peripherals simply read in parallel from the same shared intermediate buffer.

More information about the streaming can be found in the respective peripheral sections:

- *Section 39: Digital camera interface pixel pipeline (DCMIPP)* (see pixel packing and streaming across a ping-pong buffer)
- *Section 20: Neural-ART accelerator™ (NPU)*
- *Section 18: High-performance direct memory access controller (HPDMA)*
- *Section 19: General purpose direct memory access controller (GPDMA)*
- *Section 45: Video encoder (VENC)*

37.4.5 Camera subsystem security

The security of the camera subsystem is based on the protection of its register map, and of its master access to the system interconnect, based on default RISUP and RIMU respectively.

More information can be found in *Section 3.5.3: RIF infrastructure*.

The RISUP differentiates the access right of accesses performed toward the following RIF protected peripheral ID (indexes refer to *Table 20: RISUP indexes*):

- DCMIPP: tag = DCMIPP for the configuration of pixel pipelines (index 93)
- CSI2-Host: tag = CSI2H for Host and PHY configurations (index 926)
- DCMI and PSSI: tag = DCMI for its configuration, and to retrieve pixels by DMA (index 94 and 95 respectively)

The RIMU (RIMU_AXI_DCMIPP) gives the access right to the DCMIPP AXI master: CID, S and P are set using the RIF RIMC_ATTR9 register (no inheritance from RISPU to RIMU).

- CID is set either by the RISA (RISUP86 register) of directly by software.

By default, the camera subsystem is expected to work in a nonsecure mode:

- DCMIPP, CSI2, DCMI, and PSSI are left unprotected, so that any OS software can configure and handle the camera subsystem.
- The AXI master can be configured with a DCMIPP CID = DISP or CID = VID to mention that the AXI write access of the camera subsystem contains pixels (like the display system).

For secure applications, the user can put the camera subsystem in S, P, or S-and-P mode, with the following impacts:

- As a benefit, the user is sure that the content of the dumped buffer does truly come from the camera sensor:

  The output of the DCMIPP is differentiated from other masters: only the DCMIPP can write into its buffer. This buffer content is known to come from the camera sensor, which makes impossible to fill-in (by software) a fake face to be recognized.
- The camera subsystem needs to be transfered to the secure software world (with the verification implications), or the system must make sure that the access rights of the DCMIPP cannot harm the system.

The above recommended non-protected settings are shown in *Table 315: Camera subsystem RIF peripheral ID*.

The table below lists vertically all camera subsystem blocks, and horizontally the associated RIF peripheral ID.

Table color legend for the recommended settings: gray for a permanently non-protected setting, blue for a temporarily protected versus non-protected, and pink for a permanently protected state: by default, all the settings are non-protected.

Table 315. Camera subsystem RIF peripheral ID

Subsystem	Block	Address range	Start address	RISUP - slave		
				94 and 95	93	92
				DCMI and PSSI	DCMIPP	CSI2H
Camera low resolution	DCMI	Configuration	0x0000	Y	-	-
		Pixel Rx	0x0A00	Y	-	-
		Configuration	0x0B00	Y	-	-
		Data in/out	0x0C00	Y	-	-
Camera high resolution	DCMIPP	Common configuration	0x0	-	Y	-
		P1 configuration	0x0	-	Y	-
		P2 configuration	0x0	-	Y	-
		P3 configuration	0x0	-	Y	-
	CSI	Configuration control	0x0000	-	-	Y
		Configuration wrap	0x1000	-	-	Y
		CSI DPHY-Rx (no register)	-	-	-	-

37.5 Camera subsystem programmable parameters

This section describes the configuration of the various main use cases supported by the camera subsystem. Its purpose is to provide the settings that are global to the camera subsystem, and not provided by the local relevant blocks.

The use cases supported by default are the following:

- low-resolution parallel camera, using the DCMI path (see *Section 37.5.1*)

- high-resolution parallel camera, using the DCMIPP path (see *Section 37.5.2*)
- high-resolution CSI2 camera, using the DCMIPP path (see *Section 37.5.3*)

Some over-target use cases are possible, but with specific constraints:

- sensors over target-resolution (above 5 Mpixels)

  The limiting factors are
  - the clock (related to max pixel rate)
  - AXI bandwidth (related to the pixel rate and pixel format of the active pipes)
  - line buffers of the demosaicing, downsize, and YUV420 chroma decimation (when active)

  To cope with these limitations, the decimation can be used, ahead of the pipes, to reduce the width and/or height of the frame, and/or deactivate the limiting operators, the demosaicing, downsize, YUV420.
- sensors over target pixel rate (above 150 Mpixel/s)
- double sensors like 3D camera (with their left and right sensors)

37.5.1 Low-resolution parallel camera and DCMI

This use case is recommended only for backward compatibility, or to grab pictures simultaneously from two sensors (a low and a high resolution).

The steps to setup this path are the following:

- Clock and reset
  - pixck_pdck_cci is provided by the sensor (via the PCB on the input I/O, 80 MHz max).
  - The RCC provides ck_icn_p_cci, that must be ≥ 2.5x pixck_pdck_cci due to the DCMI. The default clock is 200 MHz, which allows the input clock to be at 80 MHz.
  - *Section 20: Reset and clock control (RCC)* provides the needed details.
- DMA
  - The GPDMA and HPDMA retrieve pixels from the DCMI, that signals to the DMA that its FIFO is full and must be read-out.
  - *Section 18* and *Section 19* provide the needed details.

37.5.2 High-resolution parallel camera and DCMIPP

This is the default use case to grab a picture from a parallel camera (up to the target 5 Mpixels @30fps). Any RGB or RawBayer picture can be grabbed.

The steps to setup this path are the following:

- Clock and reset:
  - pixck_pdck_cci is provided by the sensor (via the PCB on the input I/O, 120 MHz max). Each pixel needs 1 to 3 cycles to get in.
  - ck_icn_p_dcmipp is provided by the RCC for the DCMIPP configuration (default 200 MHz).
  - ck_ker_csi2 is provided by the RCC for the pixel pipelines of the DCMIPP (default 200 MHz).
  - ck_icn_m_dcmipp is provided by the RCC for the DCMIPP AXI (default 400 MHz).

  - *Section 20: Reset and clock control (RCC)* provides the needed details.
- DCMIPP configuration:
  - Select the parallel interface as input interface.
  - Setup the DCMIPP (parallel interface, ISP, application path, AXI-plug) as described in *Section 39: Digital camera interface pixel pipeline (DCMIPP)*.

37.5.3 High-resolution CSI2 camera and DCMIPP

This is the default use-case to grab a picture from a CSI2 camera (up to the target 5 Mpixels @30 fps). Any RGB or RawBayer picture can be grabbed.

The steps to setup this path are the following:

- Clock and reset:
  - cn/p_rx_dphy are provided by the sensor (via the PCB on the input I/O, 1.25 GHz/2.5 Gbit/s max).
  - RxByteClkHS is automatically divided (1/8) from cn/p_rx_dphy (312.5 MHz max).
  - ck_icn_p_csi2 is provided by the RCC for the CSI2-Host configuration (default 200 MHz).
  - ck_icn_p_dcmipp is provided by the RCC for the DCMIPP configuration (default 200 MHz).
  - ck_ker_csiphy is provided by the RCC for CSI2-Host in low-power (default 20 MHz).
  - ck_ker_csi2_txesc is provided by the RCC for the TxEscape mode of CSI2 (default 27 MHz).
  - ck_ker_csi2 is provided by the RCC for the pixel pipelines of the DCMIPP (default 200 MHz).
  - ck_icn_m_dcmipp is provided by the RCC for the DCMIPP AXI (default 400 MHz).
  - *Section 20: Reset and clock control (RCC)* provides the needed details.
- CSI2-Host configuration:
  - Setup the CSI2-Host (such as packet type).
- DCMIPP configuration:
  - Select the CSI2 interface as input interface.
  - Setup the DCMIPP (CSI2, ISP, application path, AXI-plug) as described in *Section 39: Digital camera interface pixel pipeline (DCMIPP)*.

37.5.4 Sensors over target resolution

The sensors over the target resolution (5 Mpixels) are supported with the following restrictions:

- CSI2 interface must be used (parallel interface quickly limited with its 120 MHz performances).
- The sensor must be able to output its bit rate onto the available two data lanes of the CSI2 link. It is recommended to use RawBayer (less bit/pixel than RGB).
- Width and height must both remain below 4094 (up to 16 Mpixels can be reached).
- Decimation is located ahead of most processing, and can be used to decrease the grabbed resolution.
- Demosaicing is limited with a max width of 2688: if demosaicing needs to be activated (RawBayer input, RGB output), then the decimation must be used to fall under that 2688 pixel limit. There is no height limit.
- Downsize and YUV420 are limited (similarly as demosaicing) to 2688, and require a decimation ahead if they need to be activated. The horizontal downsize occurs before the vertical one: the first can be used to fall below the 2688 pixels limit, before being processed by the second.
- If all demosaicing, downsize, and YUV420 are disabled. Pictures up to 4094x4094 can be received and dumped by the AXI.

After taking into account these restrictions, the configuration itself is the same as for the default high-resolution CSI2 camera, described in previous section.

37.5.5 Sensors over target pixel rate

The sensors over the target pixel rate (150 Mpixel/s average, ~200 Mpixel/s peak) are supported with the following restrictions:

- The sensor must be able to output its bit rate onto the available two data lanes of the CSI2 link.
- The peak pixel rate must remain below (with some margin) the max 333 MHz of the DCMIPP pixel clock (with a 10% margin recommended).
- DCMIPP bandwidth and FIFO allocation must be able to dump this load: it is recommended to reduce the amount of parallel dumps (best not all Pipe0, Pipe1, and Pipe2 active simultaneously). In the DCMIPP plug, more FIFO and outstanding allocation can be made in favor of the working pipe.

After taking into account these restrictions, the configuration itself is the same as for the default high-resolution CSI2 camera, described in *Section 37.5.3*.

37.5.6 Double sensors

Two sensors are simultaneously and independently supported with the following restriction:

- One sensor must be low-resolution, so that it can use the DCMI (the other sensor uses the DCMIPP).
- Two input interfaces must be available: one sensor is CSI2, and the other parallel.

The configuration of the double sensors is the same as for the default low-resolution and default high-resolution sensors, described in previous sections.

37.6 Camera subsystem interrupts

Sections for each peripheral describe in details the provided interrupts.

37.7 Camera subsystem registers

All the registers are described in sections for each peripheral.

38 Digital camera interface (DCMI)

38.1 Introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

38.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

38.3 DCMI functional description

The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

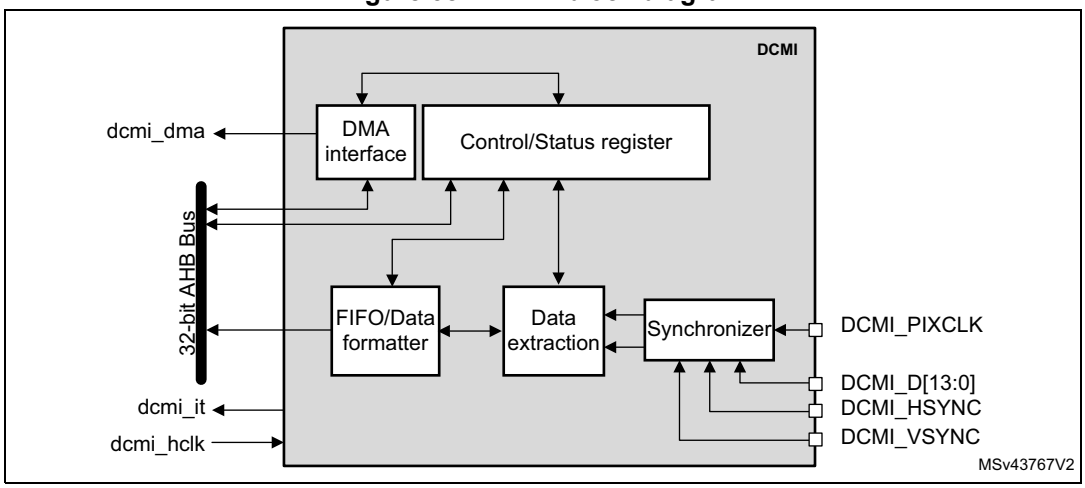
The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.

38.3.1 DCMI block diagram

Figure 387 shows the DCMI block diagram.

Figure 387. DCMI block diagram



38.3.2 DCMI pins and internal signals

The following table shows DCMI pins.

Table 316. DCMI input/output pins

Mode	Pin name	Signal type	Description
8 bits 10 bits 12 bits 14 bits	DCMI_D[7:0] DCMI_D[9:0] DCMI_D[11:0] DCMI_D[13:0]	Inputs	DCMI data
DCMI_PIXCLK		Input	Pixel clock
DCMI_HSYNC		Input	Horizontal synchronization / Data valid
DCMI_VSYNC		Input	Vertical synchronization

The following table shows DCMI internal signals.

Table 317. DCMI internal input/output signals

Internal signal name	Signal type	Description
dcmi_dma	Output	DCMI DMA request
dcmi_it	Output	DCMI interrupt request
dcmi_hclk	Input	DCMI interface clock

38.3.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

38.3.4 DCMI DMA interface

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

38.3.5 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

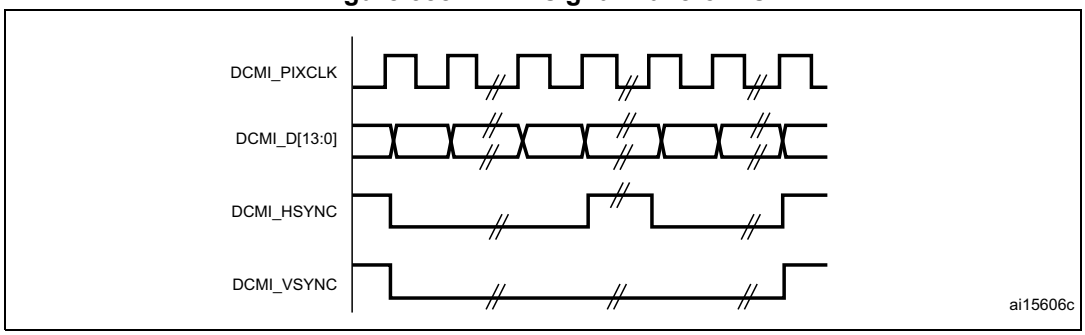
DCMI pins are shown in *Table 316*.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame

Figure 388. DCMI signal waveforms



1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

8-bit data

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.

Table 318. Positioning of captured data bytes in 32-bit words (8-bit width)

Byte address	31:24	23:16	15:8	7:0
0	D_{n+3}[7:0]	D_{n+2}[7:0]	D_{n+1}[7:0]	D_n[7:0]
4	D_{n+7}[7:0]	D_{n+6}[7:0]	D_{n+5}[7:0]	D_{n+4}[7:0]

10-bit data

When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 319. Positioning of captured data bytes in 32-bit words (10-bit width)

Byte address	31:26	25:16	15:10	9:0
0	0	D_{n+1}[9:0]	0	D_n[9:0]
4	0	D_{n+3}[9:0]	0	D_{n+2}[9:0]

12-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 320. Positioning of captured data bytes in 32-bit words (12-bit width)

Byte address	31:28	27:16	15:12	11:0
0	0	D_{n+1}[11:0]	0	D_n[11:0]
4	0	D_{n+3}[11:0]	0	D_{n+2}[11:0]

14-bit data

When EDM[1:0] = 11 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 321. Positioning of captured data bytes in 32-bit words (14-bit width)

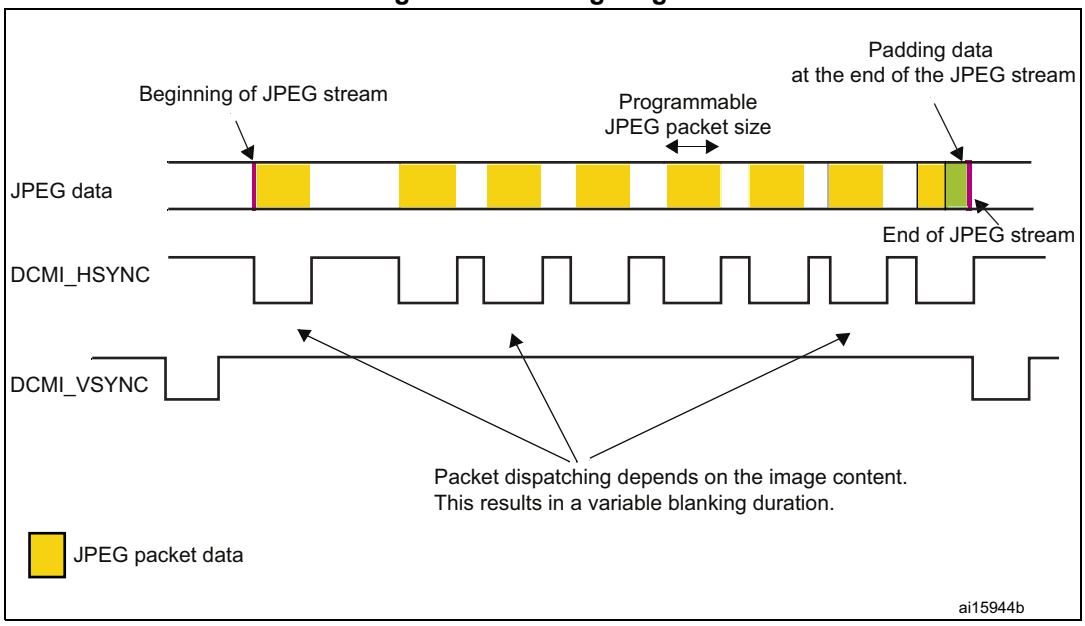
Byte address	31:30	29:16	15:14	13:0
0	0	D_{n+1}[13:0]	0	D_n[13:0]
4	0	D_{n+3}[13:0]	0	D_{n+2}[13:0]

38.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. *Figure 389* shows the corresponding timing diagram.

Figure 389. Timing diagram



Hardware synchronization mode

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and

capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are *not* used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable results and must not be used.

Note: Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).

- Mode 2

  Four embedded codes signal the following events
  - Frame start (FS)
  - Frame end (FE)
  - Line start (LS)
  - Line end (LE)

  The XY values in the 0xFF0000XY format of the four codes are programmable (see *Section 38.5.7: DCMI embedded synchronization code register (DCMI_ESCR)*).

  A 0xFF value programmed as a “frame end” means that all the unused codes are interpreted as valid frame end codes.

  In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.
- Mode 1

  An alternative coding is the camera mode 1. This mode is ITU656 compatible.

  The codes signal another set of events:
  - SAV (active line) - line start
  - EAV (active line) - line end
  - SAV (blanking) - end of line during interframe blanking period
  - EAV (blanking) - end of line during interframe blanking period

This mode can be supported by programming the following codes:

- FS $\leq$ 0xFF
- FE ≤ 0xFF
- LS ≤ SAV (active)
- LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. A bit can therefore be selected to compare in the embedded code and

detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

Example

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

38.3.7 DCMI capture modes

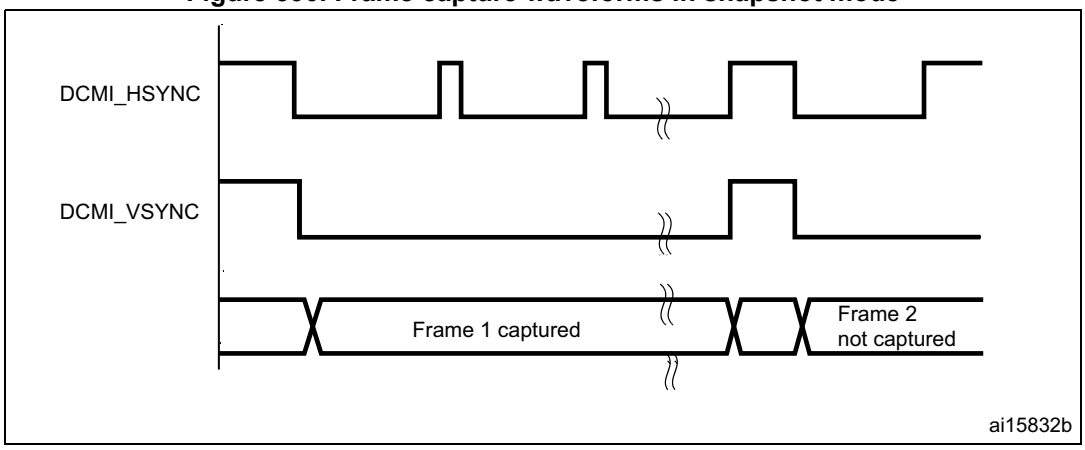
This interface supports two types of capture: snapshot (single frame) and continuous grab.

Snapshot mode (single frame)

In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

Figure 390. Frame capture waveforms in snapshot mode

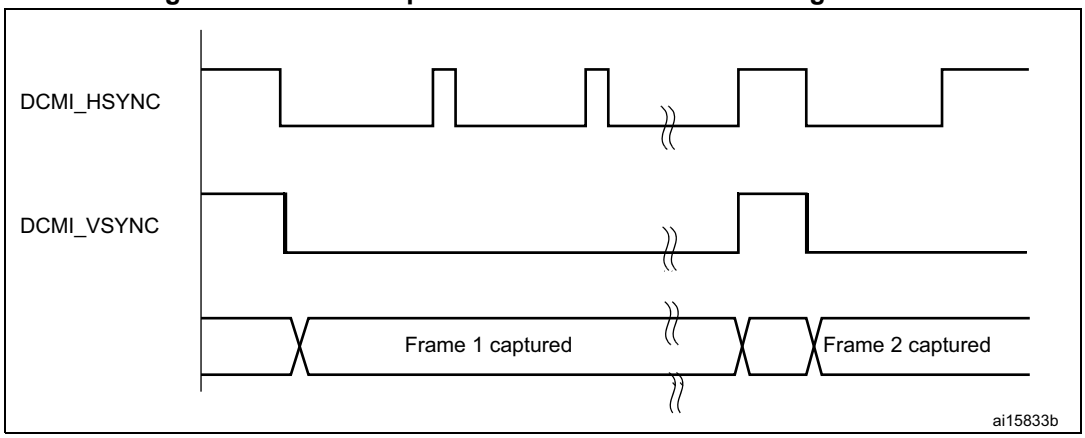


1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

Continuous grab mode

In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.

Figure 391. Frame capture waveforms in continuous grab mode



1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

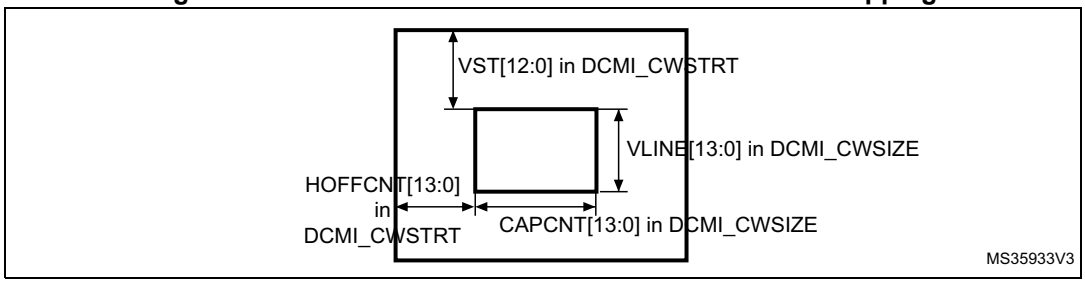
In continuous grab mode, the FCRC[1:0] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

Note: In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

38.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

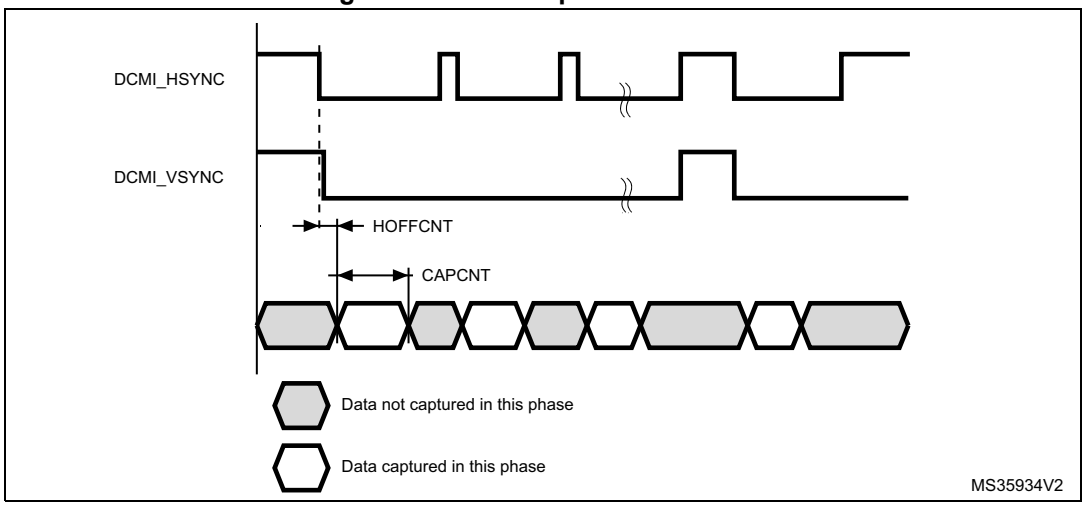
Figure 392. Coordinates and size of the window after cropping



These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.

If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

Figure 393. Data capture waveforms



1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

38.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in JPEG format.

38.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.

38.3.11 DCMI data format description

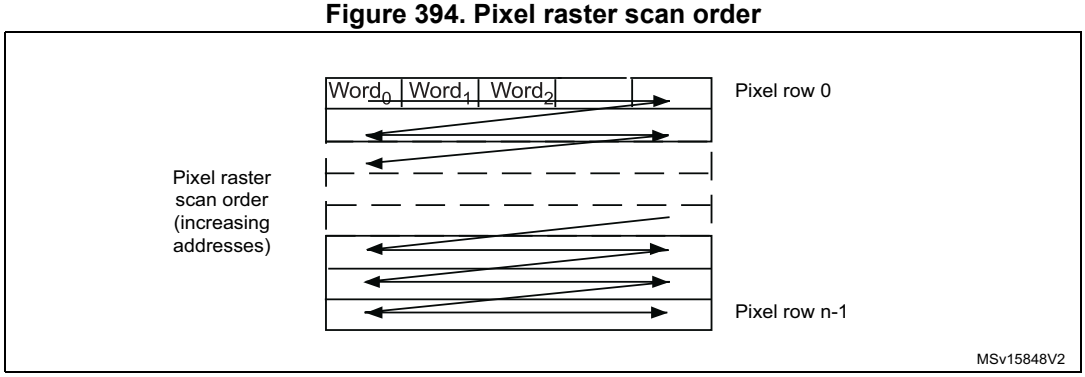
Data formats

The following types of data are supported:

- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred
- compressed data: JPEG

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

Figure 394. Pixel raster scan order



Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

Table 322. Data storage in monochrome progressive video format

Byte address	31:24	23:16	15:8	7:0
0	n + 3	n + 2	n + 1	n
4	n + 7	n + 6	n + 5	n + 4

RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGBRG)
- Optimized for display output

The RGB planar format is compatible with standard OS frame buffer display formats.

Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

Table 323. Data storage in RGB progressive video format

Byte address	31:27	26:21	20:16	15:11	10:5	4:0
0	Red n + 1	Green n + 1	Blue n + 1	Red n	Green n	Blue n
4	Red n + 4	Green n + 3	Blue n + 3	Red n + 2	Green n + 2	Blue n + 2

YCbCr format

Characteristics:

- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

Table 324. Data storage in YCbCr progressive video format

Byte address	31:24	23:16	15:8	7:0
0	Y n + 1	Cr n	Y n	Cb n
4	Y n + 3	Cr n + 2	Y n + 2	Cb n + 2

YCbCr format - Y only

Characteristics:

- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in *Table 325*.

The result is a monochrome image having the same resolution as the original YCbCr data.

Table 325. Data storage in YCbCr progressive video format - Y extraction mode

Byte address	31:24	23:16	15:8	7:0
0	Y n + 3	Y n + 2	Y n + 1	Y n
4	Y n + 7	Y n + 6	Y n + 5	Y n + 4

Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

38.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

Table 326. DCMI interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exits Sleep mode	Exists Stop and Standby modes
dcmi_it	End of line	LINE_RIS	LINE_IE	Set LINE_ISC	Yes	No
	End of frame capture	FRAME_RIS	FRAME_IE	Set FRAME_ISC	Yes	No
	Overrun of data reception	OVR_RIS	OVR_IE	Set OVR_ISC	Yes	No
	Synchronization frame	VSYNC_RIS	VSYNC_IE	Set VSYNC_ISC	Yes	No
	Detection of an error in the embedded synchronization frame detection	ERR_RIS	ERR_IE	Set ERR_ISC	Yes	No

38.5 DCMI registers

Refer to *Section 1.2 on page 156* for list of abbreviations used in register descriptions. All DCMI registers must be accessed as 32-bit words, otherwise a bus error occurs.

38.5.1 DCMI control register (DCMI_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OELS	LSM	OEBS	BSM[1:0]	
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ENABLE	Res.	Res.	EDM[1:0]		FCRC[1:0]		VSPOL	HSPOL	PCKPOL	ESS	JPEG	CROP	CM	CAPTURE
	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OELS:** Odd/Even Line Select (Line Select Start)

This bit works in conjunction with the LSM field (LSM = 1).

0: Interface captures first line after the frame start, second one being dropped.

1: Interface captures second line from the frame start, first one being dropped.

Bit 19 **LSM:** Line Select mode

0: Interface captures all received lines.

1: Interface captures one line out of two.

Bit 18 **OEBS:** Odd/Even Byte Select (Byte Select Start)

This bit works in conjunction with BSM field (BSM $\neq$ 00).

0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped.

1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped.

Bits 17:16 **BSM[1:0]:** Byte Select mode

00: Interface captures all received data.

01: Interface captures every other byte from the received data.

10: Interface captures one byte out of four.

11: Interface captures two bytes out of four.

Note: This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE:** DCMI enable

0: DCMI disabled

1: DCMI enabled

Note: The DCMI configuration registers must be programmed correctly before enabling this bit.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]:** Extended data mode

00: Interface captures 8-bit data on every pixel clock.

01: Interface captures 10-bit data on every pixel clock.

10: Interface captures 12-bit data on every pixel clock.

11: Interface captures 14-bit data on every pixel clock.

Bits 9:8 **FCRC[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.

00: All frames are captured.

01: Every alternate frame captured (50% bandwidth reduction)

10: One frame out of four captured (75% bandwidth reduction)

11: reserved

Bit 7 **VSPOL:** Vertical synchronization polarity

This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.

0: DCMI_VSYNC active low

1: DCMI_VSYNC active high

Bit 6 **HSPOL:** Horizontal synchronization polarity

This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.

0: DCMI_HSYNC active low

1: DCMI_HSYNC active high

Bit 5 **PCKPOL:** Pixel clock polarity

This bit configures the capture edge of the pixel clock.

0: Falling edge active

1: Rising edge active

Bit 4 **ESS:** Embedded synchronization select

0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.

1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.

Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.

This bit is disabled in JPEG mode.

Bit 3 **JPEG:** JPEG format

0: Uncompressed video format

1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 **CROP:** Crop feature

0: The full image is captured. In this case the total number of bytes in an image frame must be a multiple of four.

1: Only the data inside the window specified by the crop register is captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM:** Capture mode

0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.

Bit 0 **CAPTURE:** Capture enable

0: Capture disabled

1: Capture enabled

The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.

In snapshot mode, the CAPTURE bit is automatically cleared at the end of the first frame received.

In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit is effectively cleared after the frame end.

Note: The DMA controller and all DCMI configuration registers must be programmed correctly before enabling this bit.

38.5.2 DCMI status register (DCMI_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FNE	VSYNC	HSYNC
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FNE**: FIFO not empty

This bit gives the status of the FIFO.
1: FIFO contains valid data.
0: FIFO empty

Bit 1 **VSYNC**: Vertical synchronization

This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active frame
1: synchronization between frames
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

Bit 0 **HSYNC**: Horizontal synchronization

This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active line
1: synchronization between lines
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

38.5.3 DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_RIS	VSYNC_RIS	ERR_RIS	OVR_RIS	FRAME_RIS
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_RIS**: Line raw interrupt status

This bit gets set when the DCMI_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI_CR is set.

It is cleared by setting the LINE_ISC bit of the DCMI_ICR register.

Bit 3 **VSYNC_RIS**: DCMI_VSYNC raw interrupt status

This bit is set when the DCMI_VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI_CR.

It is cleared by setting the VSYNC_ISC bit of the DCMI_ICR register.

Bit 2 **ERR_RIS**: Synchronization error raw interrupt status

0: No synchronization error detected

1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by setting the ERR_ISC bit of the DCMI_ICR register.

Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_RIS**: Overrun raw interrupt status

0: No data buffer overrun occurred

1: A data buffer overrun occurred and the data FIFO is corrupted.

The bit is cleared by setting the OVR_ISC bit of the DCMI_ICR register.

Bit 0 **FRAME_RIS**: Capture complete raw interrupt status

0: No new capture

1: A frame has been captured.

This bit is set when a frame or window has been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).

The bit is cleared by setting the FRAME_ISC bit of the DCMI_ICR register.

38.5.4 DCMI interrupt enable register (DCMI_IER)

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_IE	VSYNC_IE	ERR_IE	OVR_IE	FRAME_IE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_IE**: Line interrupt enable
0: No interrupt generation when the line is received
1: An Interrupt is generated when a line has been completely received.

Bit 3 **VSYNC_IE**: DCMI_VSYNC interrupt enable
0: No interrupt generation
1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state.
The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR_IE**: Synchronization error interrupt enable
0: No interrupt generation
1: An interrupt is generated if the embedded synchronization codes are not received in the correct order.
Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_IE**: Overrun interrupt enable
0: No interrupt generation
1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received.

Bit 0 **FRAME_IE**: Capture complete interrupt enable
0: No interrupt generation
1: An interrupt is generated at the end of each received frame/crop window (in crop mode).

38.5.5 DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_MIS	VSYNC_MIS	ERR_MIS	OVR_MIS	FRAME_MIS
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_MIS**: Line masked interrupt status
This bit gives the status of the masked line interrupt.
0: No interrupt generation when the line is received
1: An Interrupt is generated when a line has been completely received and the LINE_IE bit is set in DCMI_IER.

Bit 3 **VSYNC_MIS**: VSYNC masked interrupt status

This bit gives the status of the masked VSYNC interrupt.

0: No interrupt is generated on DCMI_VSYNC transitions.

1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state and the VSYNC_IE bit is set in DCMI_IER.

The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR_MIS**: Synchronization error masked interrupt status

This bit gives the status of the masked synchronization error interrupt.

0: No interrupt is generated on a synchronization error.

1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR_IE bit in DCMI_IER is set.

Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_MIS**: Overrun masked interrupt status

This bit gives the status of the masked overflow interrupt.

0: No interrupt is generated on overrun.

1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR_IE bit is set in DCMI_IER.

Bit 0 **FRAME_MIS**: Capture complete masked interrupt status

This bit gives the status of the masked capture complete interrupt

0: No interrupt is generated after a complete capture.

1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME_IE bit is set in DCMI_IER.

38.5.6 DCMI interrupt clear register (DCMI_ICR)

The DCMI_ICR register is write-only. Setting a bit of this register clears the corresponding flag in the DCMI_RIS and DCMI_MIS registers. Writing 0 has no effect.

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_ISC	VSYNC_ISC	ERR_ISC	OVR_ISC	FRAME_ISC
											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_ISC**: line interrupt status clear

Setting this bit clears the LINE_RIS flag in the DCMI_RIS register.

Bit 3 **VSYNC_ISC**: Vertical Synchronization interrupt status clear

Setting this bit clears the VSYNC_RIS flag in the DCMI_RIS register.

Bit 2 **ERR_ISC**: Synchronization error interrupt status clear

Setting this bit clears the ERR_RIS flag in the DCMI_RIS register.

Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_ISC**: Overrun interrupt status clear
Setting this bit clears the OVR_RIS flag in the DCMI_RIS register.

Bit 0 **FRAME_ISC**: Capture complete interrupt status clear
Setting this bit clears the FRAME_RIS flag in the DCMI_RIS register.

38.5.7 DCMI embedded synchronization code register (DCMI_ESCR)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEC[7:0]								LEC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSC[7:0]								FSC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEC[7:0]**: Frame end delimiter code
This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.
If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code
This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code
This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code
This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.
If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

38.5.8 DCMI embedded synchronization unmask register (DCMI_ESUR)

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEU[7:0]								LEU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSU[7:0]								FSU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEU[7:0]**: Frame end delimiter unmask

This byte specifies the mask to be applied to the code of the frame end delimiter.
0: The corresponding bit in the FEC byte in DCMI_ESCR is masked while comparing the frame end delimiter with the received data.
1: The corresponding bit in the FEC byte in DCMI_ESCR is compared while comparing the frame end delimiter with the received data.

Bits 23:16 **LEU[7:0]**: Line end delimiter unmask

This byte specifies the mask to be applied to the code of the line end delimiter.
0: The corresponding bit in the LEC byte in DCMI_ESCR is masked while comparing the line end delimiter with the received data.
1: The corresponding bit in the LEC byte in DCMI_ESCR is compared while comparing the line end delimiter with the received data.

Bits 15:8 **LSU[7:0]**: Line start delimiter unmask

This byte specifies the mask to be applied to the code of the line start delimiter.
0: The corresponding bit in the LSC byte in DCMI_ESCR is masked while comparing the line start delimiter with the received data.
1: The corresponding bit in the LSC byte in DCMI_ESCR is compared while comparing the line start delimiter with the received data.

Bits 7:0 **FSU[7:0]**: Frame start delimiter unmask

This byte specifies the mask to be applied to the code of the frame start delimiter.
0: The corresponding bit in the FSC byte in DCMI_ESCR is masked while comparing the frame start delimiter with the received data.
1: The corresponding bit in the FSC byte in DCMI_ESCR is compared while comparing the frame start delimiter with the received data.

38.5.9 DCMI crop window start (DCMI_CWSTRT)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	VST[12:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	HOFFCNT[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **VST[12:0]**: Vertical start line count

The image capture starts with this line number. Previous line data are ignored.
0x0000: line 1
0x0001: line 2
0x0002: line 3
....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **HOFFCNT[13:0]**: Horizontal offset count

This value gives the number of pixel clocks to count before starting a capture.

38.5.10 DCMI crop window size (DCMI_CWSIZE)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	VLINE[13:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CAPCNT[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **VLINE[13:0]**: Vertical line count

This value gives the number of lines to be captured from the starting point.
0x0000: 1 line
0x0001: 2 lines
0x0002: 3 lines
....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **CAPCNT[13:0]**: Capture count

This value gives the number of pixel clocks to be captured from the starting point on the same line. It value must corresponds to word-aligned data for different widths of parallel interfaces.
0x0000: 1 pixel
0x0001: 2 pixels
0x0002: 3 pixels
....

38.5.11 DCMI data register (DCMI_DR)

Address offset: 0x28

Reset value: 0x0000 0000

The digital camera Interface packages all the received data in 32-bit format before requesting a DMA transfer. A 8-word deep FIFO is available to leave enough time for DMA transfers and avoid DMA overrun conditions.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BYTE3[7:0]								BYTE2[7:0]

Refer to *Section 2.3* for the register boundary addresses.

39 Digital camera interface pixel pipeline (DCMIPP)

39.1 Introduction

The DCMIPP is the pixel pipeline section of a high-resolution camera subsystem: it gets pixels from a parallel or a CSI interface, and after some processing (such as decimation, cropping, downsize, color conversion, gamma correction, auto-exposure) dumps them to the memory.

DCMIPP supports multiple types of external sensors, among others:

- dumb sensors (without internal ISP), which output raw Bayer pixels
- smart sensors (with an internal ISP), which usually output RGB or YUV pixels
- smart sensors with internal compression, which output a bit-stream (such as JPEG, or H264)
- sensors with interlaced video, which output their odd and even fields sequentially

The DCMIPP input interface integrates a parallel interface (up to 16 bits at 120 MHz, with internal/external synchronization), and makes it possible to abut an external CSI-2 host (one to two data lanes, up to 2.5 Gbps/lane).

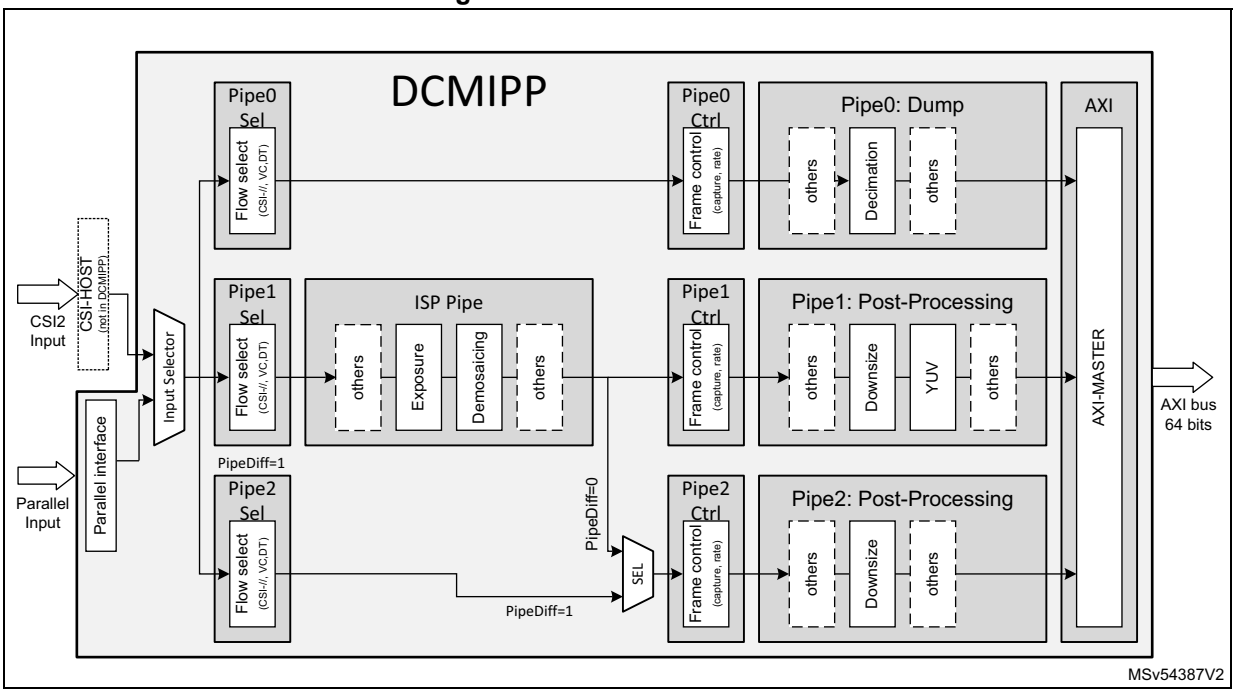
A first common part of the DCMIPP selects the input exclusively from the parallel or the CSI interfaces. Data go to dedicated pipeline(s) before they are sent to memory for further processing or display purposes.

Table 328. Available pipelines

ID	Function	Description
Pipe0	Dump pipe	Used to dump the received data as-is, without any processing (for example. without pixel extraction, no formatting), with an exception: it formats the CSI 10/12/14-bit raw Bayer components mapped unpacked into 16-bit memory words, to ease the job of a downstream application. 2D crop operation and basic decimation can be performed within this pipe.
Pipe1	Main pipe	Typically used for the main needs (such as video encode, software analysis, neural network), it allows to downsize the input, convert its color and dump to multiple pixel formats, including multi-planar ones. It can adapt the luminosity (gamma conversion) as well as auto-exposure and black level calibration based on its own embedded image processing functions, handling camera sensor without internal ISP. It can convert the raw Bayer to RGB (demosaicing). Pipe1 shares all the image processing functions with Pipe2.
Pipe2	Ancillary pipe	Typically used for ancillary needs (such as a permanent display), also allows to downsize the input and dump to several pixel formats, however restricted to coplanar ones (as specialized for display-like usage).

Figure 395 shows the DCMIPP main functions, namely the integrated parallel interface, the abutted CSI-2 host, the ISP functions in Pipe1 and shareable with Pipe2, the differentiated applicative post-processing pipelines with their crop, downsize, and pixel formatting.

Figure 395. DCMIPP overview



In the ISP processing, and therefore before the post-processing pipes (Pipe1 and Pipe2), the component dynamic is reduced to 8 bits per component. If the software intends to benefit of the wider dynamic, the input data must be dumped via Pipe0, which keeps the input pixel format (10/12/14 bpp) when storing them in memory.

Table 329. Glossary

Item	Definition
A	Alpha component, used to define transparency, opaque = 0xFF, for example ARGB.
3A (or AAA)	In ISP domain: acronym for AE-AF-AWB, algorithms automatically correcting pictures: – AE: automatic exposure control (adapts exposure or sensibility of sensor) – AF: automatic focus control (adapts the focus) – AWB: automatic white balance (adapts the color tones to have a white balance).
BPC	Bits per component (for example, RGB565 has five bits for the red component, hence 5 bpc)
BPP	Bits per pixel (for example, RGB565 has 16 bits per pixel, hence 16 bpp)
CSI	Camera serial interface, and its latest standard by MIPI®, the CSI-2 v1.3 (and v2.0)
DCMIPP_	Digital camera interface - Pixel pipeline
DT	Data type, used in the CSI-2 standard. The data type is a concept similar to the pixel format, but adds support for other data like the byte format.
Interlaced	Interlaced video: the field with odd lines is transmitted first, followed, after the last odd line, by the field with even lines. The two fields are thus consecutive but exclusive.
Interleaved	Interleaved packets, applies to CSI-2: two groups of packets transmitted by the sensor can be emitted mixed, as a packet granularity.

Table 329. Glossary (continued)

Item	Definition
ISP	Image signal processing: algorithms that retune the sensor output (through correction of pixels, demosaicing, lens-correction, light/contrast correction) to build a good quality picture.
NPU	Neural network processing engine (also known as NN, neural network).
Planar	Defines in how many sub-buffers a pixel buffer is split into: 1 (coplanar), 2 (semi-planar), 3 (full planar).
ROI	Region of interest (pixel box surrounding the region of interest)
VC	Virtual channel, used in the CSI-2 standard, makes it possible to simultaneously transmit up to four parallel flows (in CSI-2 v1.3) or more (in CSI-2 v2.0).
YUV444	Pixel format, YUV color reference, all three components (Y, U, V) given per pixel.
YUV422	Pixel format, YUV color reference, chroma component (U, V) sub-sampled 1/2 in X

39.2 DCMIPP main features

- Parallel input interface:
  - Pixel rate: up to 16 bits in parallel, 100 Mpixel/s (typically 1080p30, maximum 2048x2048 on processing pipelines after decimation).
  - Pixel format: RGB565, RGB888, YUV422, raw Bayer/Mono 8/10/12/14, and ByteStream (JPEG)
- CSI-2 host input interface:
  - Pixel rate: 32 bits in parallel at 200 Mpixel/s (typically 5 MPixel x30), supports MIPI® CSI-2 v1.3
  - Pixel format: all MIPI CSI-2 v1.3, among others RGB565, RGB888, YUV422, raw Bayer (see *Table 335*)
  - Abutted CSI-2 host IP: 1-to-2 DL at up to 2.5 Gbps/lane
  - Features: Interleaved packets, four virtual channels
- Pipeline maximum resolution:
  - Dimensioned for 5 Mpixel (typically 2560 x 2048 or 2688 x 1944) before decimation
  - Maximum pipe resolution: 4094 x 4094
  - Maximum demosaicing or downsize or YUV420 width: 2688 pixels
- Pipe pixel rate: 200 Mpixel/s peak (150 Mpixel/s average + blanking)
- Maximum frame per second (fps): typical examples are defined with 30 fps, it is possible to reach higher rates (for example 120 fps) by decreasing image resolution to guarantee the maximum pixel rate constraints.
- Flow selection and frame control:
  - CSI-2 interleaved packets supported (with some restrictions)
  - Capture mode in Continuous vs. Snapshot mode
- Byte-to-pixel conversion:
  - Enables the above flexible input pixel formats to be extracted and fed to pipes
  - Non-extracted pixel formats can still be dumped via Pipe0, to allow an ad-hoc software extraction
- Statistic removal:
  - To remove unused metadata (like statistics) from received pictures
- Bad pixel removal (automatic detection and correction of bad pixels from sensor array)
- Decimation of one pixel every 1/2/4/8:
  - Decimation to fit the demosaicing (maximum 2688 pixel width)
  - Raw Bayer format support, via a decimation of components (2 by 2)
- Integrated image processing block, which makes possible to connect very low cost camera modules without any embedded ISP
  - Black level calibration
  - Statistics extraction
    - > To extract average R, G, B, L values (for auto exposure and white balance)
    - > To sort any R, G, B, L value into 12 dynamic bins (for contrast enhancement)
  - Exposure control (amplifies the exposure up to 256x)
    - > To smoothly adapt to dark exposures

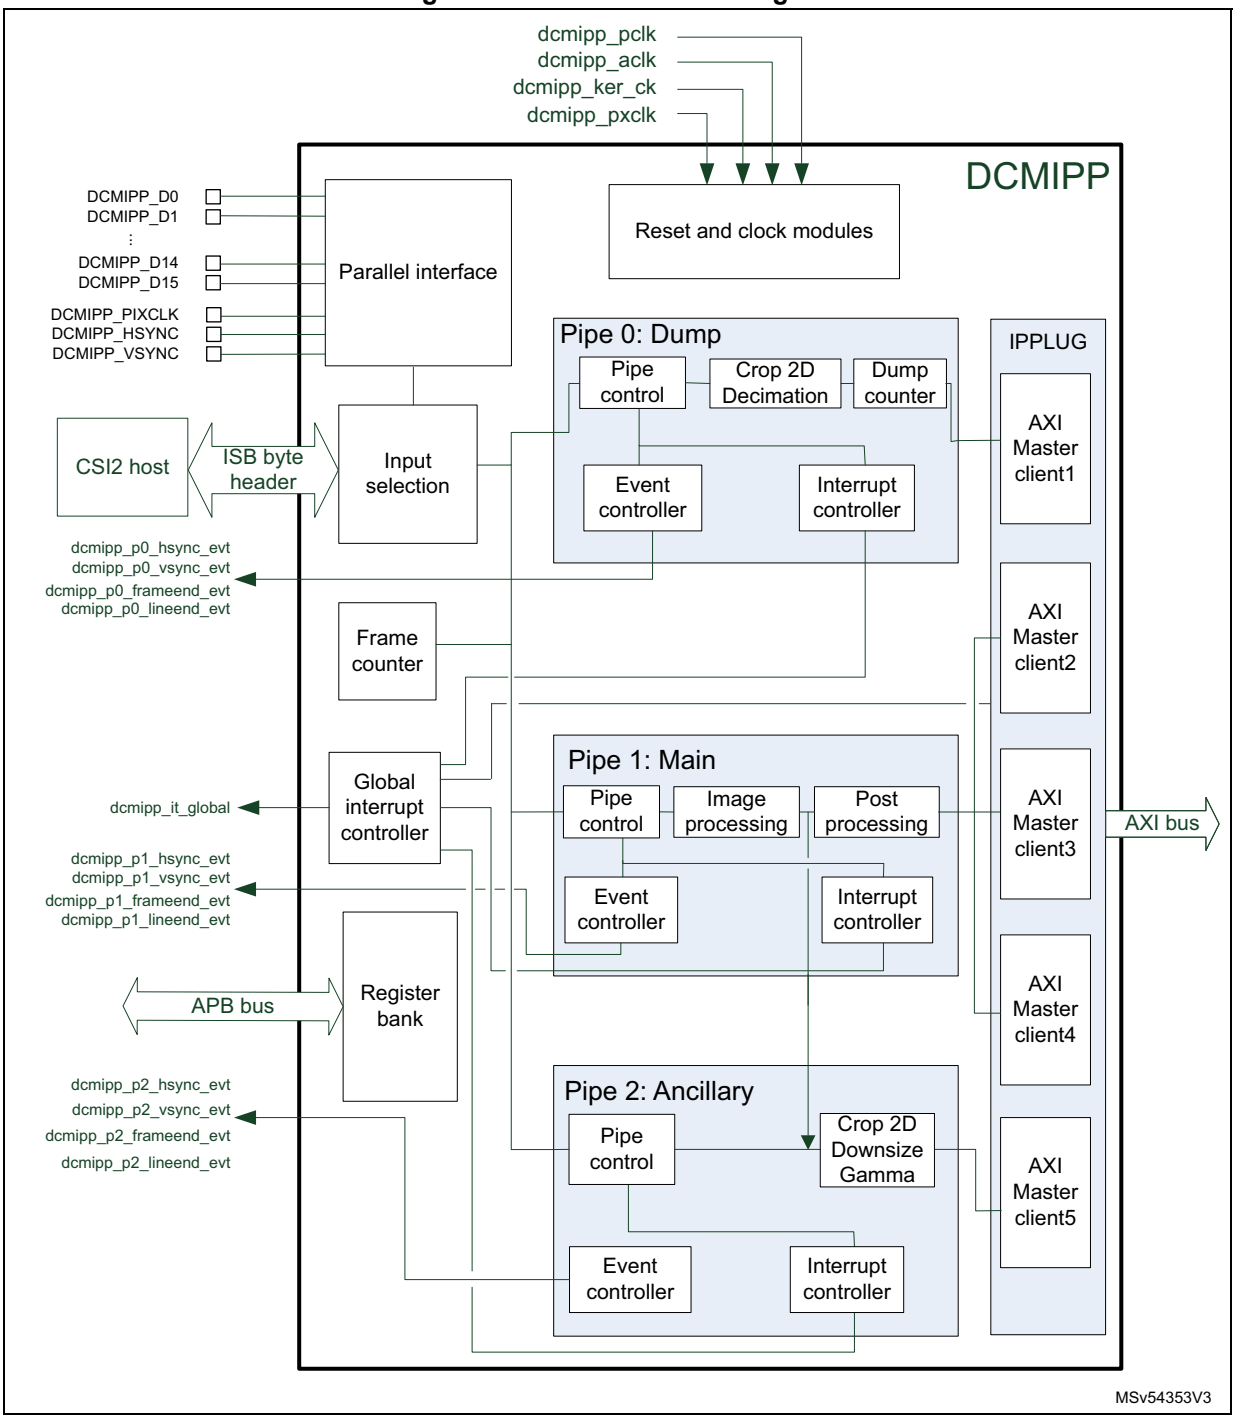
  - Raw Bayer to RGB conversion (demosaicing)
    - > Mid quality conversion for display and software analysis purposes (high quality conversion can be done in software upon trigger, for still-image only)
    - > Algorithm with a 4 x 3 heuristic analysis matrix
  - Color conversion to adapt to the sensor and tune the illumination
    - > Configurable coefficients, to map any linear tuning
  - Contrast enhancement
    - > Non-linear luminance tuning, linearized across eight luminance segments.
- Decimation on Pipe0 (dump pipe)
  - Pure sub-sampling, ratio 1 vs. 1, 2, 4 in X and ratio 1 vs. 1, 2 in Y (no X if CSI source)
- Parallel pipelines for parallel applications:
  - Pipe0 (for data dump) for a direct dump without processing
  - Pipe1 (for main usage) with downsize, ColorConv, decimation, multi-planar
  - Pipe2 (for ancillary usage) with downsize, decimation, coplanar
- Downsize
  - Decimation, optional pre-processing, sub-sampling ratio 1 vs. 1, 2, 4, 8 in X and Y
  - Box-filtering, with any decimal ratio up to 8x8, on Pipe1 and Pipe2
- Up to eight regions of interest (ROI) can be defined for displaying purpose (only supporting RGB data format)
  - Up to 64 line colors can be selected by the software, per ROI
  - Up to four line widths can be configurable (1, 2, 4, 8 pixels, common to all ROIs)
  - Pipe0 does not support ROI
- Gamma conversion for display:
  - Non-linear transform, with seven interpolated segments, with static coefficient for G = 2.2
- Color conversion 2 for RGB to YUV conversion:
  - to/from YUV: 12 coefficients (BT.601, 709, any), with optional range ext/clamp
- Output pixel format:
  - Pipe0: any data as-is, Y/Rb: 8/10/12/14 statistics, bit streams
  - Pipe2: 888, 565, 422-1, Y8, ARGB and RGBA (coplanar only)
  - Pipe1: adds 422-2, 420-2, 420-3 (multi-planar possible) to Pipe2 formats
- AXI master:
  - Output FIFOs to drain pixel/data to the memory (linked to the memory latency) from the pipe(s)
  - The unique AXI-Master interface implements one client per pipe, with semi- or multi-planar pipes using, respectively, two or three clients
  - Double buffer mode capab/ility per pipe
  - Address wrapping to write into a ping-pong buffer
- Overrun detection:
  - Notification in case of frame impacted by pixel congestion (no impact on the following frame if the congestion cause is solved)

39.3 DCMIPP functional description

39.3.1 DCMIPP block diagram

The block diagram of the DCMIPP is shown in *Figure 396*.

Figure 396. DCMIPP block diagram



39.3.2 DCMIPP pads and internal signals

Table 330. DCMIPP input/output pads

Pin name	Signal type	Description
DCMIPP_Dn (n = 0 to 15)	Input	Bit n of the parallel data bus coming from the camera sensor
DCMIPP_PIXCLK	Input	Pixel clock sent by the master (parallel camera sensor module)
DCMIPP_VSYNC	Input	VSYNC signal (vertical synchronization) coming from the camera sensor
DCMIPP_HSYNC	Input	HSYNC signal (horizontal synchronization) coming from the camera sensor

Table 331. DCMIPP input/output pins

Internal signal name	Signal type	Description
dcmipp_pclk	Input	DCMIPP APB clock (APB bus)
dcmipp_aclk	Input	DCMIPP AXI clock (AXI bus)
dcmipp_ker_ck	Input	Interface from the CSI2 host
dcmipp_it_global	Output	DCMIPP interrupts (refer to *Table 363* for the full list of interrupt sources)
dcmipp_p0_hsync_evt	Output	Pipe0 Hsync event
dcmipp_p0_vsync_evt		Pipe0 Vsync event
dcmipp_p0_frameend_evt		Pipe0 frame end event
dcmipp_p0_lineend_evt		Pipe0 line event
dcmipp_p1_hsync_evt	Output	Pipe1 Hsync event
dcmipp_p1_vsync_evt		Pipe1 Vsync event
dcmipp_p1_frameend_evt		Pipe1 frame end event
dcmipp_p1_lineend_evt		Pipe1 line event
dcmipp_p2_hsync_evt	Output	Pipe2 Hsync event
dcmipp_p2_vsync_evt		Pipe2 Vsync event
dcmipp_p2_frameend_evt		Pipe2 frame end event
dcmipp_p2_lineend_evt		Pipe2 line event

39.3.3 DCMIPP reset and clocks

Table 332. DCMIPP clocks

Domain	Clock	Maximum frequency	Comments
Parallel	dcmipp_pxclk	120 MHz	Up to 2x 120 MB/s in 16-bit mode
Pipeline	dcmipp_ker_ck	333 MHz	Up to 333 Mpixels/s (minus the blanking)
AXI bus	dcmipp_aclk	400 MHz	SoC AXI frequency
APB bus	dcmipp_pclk	200 MHz	SoC APB frequency

Table 333. DCMIPP resets

Domain	Reset type	Comments
Parallel + Pipeline	Asynchronous	Resynchronized internally on dcmipp_pxclk/dcmipp_ker_ck
AXI bus	Synchronous	Resets directly the dcmipp_aclk domain
APB bus	Synchronous	Resets directly the dcmipp_pclk domain

Clocks and pixel rate limitations

This paragraph lists the DCMIPP limitations and bottlenecks:

- The target is to sustain an average pixel rate (PixRateAvg):
  - A 5 Mpixel sensor at 30 fps requires 150 Mpixel/s (CSI-2 interface)
  - Higher resolution sensors can be supported, but with lower FPS (for example 10 Mpixels at 15 fps)
- Vertical and horizontal blanking:
  - The full system (sensor, interface, pipe, AXI) embeds limited capacity FIFOs. The idle times that the sensor inserts during its blanking periods impact all the downstream elements, including interface, pipe, and AXI. A pixel rate (PixRatePeak) higher than average must be used. The idle time due to the blanking can reach 33% of the frame duration, sometimes more (check sensor specification).
  - PixRatePeak = 1.33 * PixRateAvg = 200 Mpixel/s in our example.
- Parallel interface clock (dcmipp_pxclk):
  - On the parallel interface, pixels are received sequentially, in one, two or three cycles. The maximum implemented clock (120 MHz) constrains the peak pixel rate, depending on the ratio of cycles per pixel.
  - PixRatePeak ≤ dcmipp_pxclk / (1, 2 or 3) = 120 / (1, 2 or 3)
  - Clock frequency:
    - > dcmipp_pxclk ≤ dcmipp_ker_ck (due to resync interface between them)
    - > dcmipp_pxclk ≤ dcmipp_aclk
  - Consequences: see *Table 334*.

Table 334. Parallel interface maximum resolution (80 MHz)

Pixel		Transmission on the interface			Resolution (30 fps), including blanking	
Format	Width (bpp)	Width	Cycles/pixel	Pixel rate	Mpixel/frame	Example
Mono/raw	8	8	1	80	2.15	1080 p
	14	14	1	80	2.15	1080 p
RGB565	16	8	2	40	1.08	720 p
		16	1	80	2.15	1080 p
RGB888	24	8	3	27	0.72	qHD
		12	2	40	1.08	720 p
YUV422	16	16	1	80	2.15	1080 p
		16	2	40	1.08	720 p
YUV444	24	12	2	40	1.08	720 p
		16	2	40	1.08	720 p

  - Clock setting: dcmipp_pxclk ≥ PixRatePeak * Ratio(1,2,3)

- Pipe clock dcmipp_ker_ck (when using the CSI-2 host interface)
  - CSI-2 PHY provides data bit at the clk_bit rate, on DL parallel data lanes.
  - Rationale: internally, the CSI-2 host interface packs the serial stream on 32-bit words, resynchronized on the pipe clock (dcmipp_ker_ck).
  - Clock setting: dcmipp_ker_ck ≥ clk_bit * DL / 32 bpp = 156.25 MHz.
  - Rationale 2: The pixel pipe processes 1 pixel/clk, so that dcmipp_ker_ck must be higher than the wanted PixRatePeak.
  - Clock setting: dcmipp_ker_ck ≥ PixRatePeak.
  - For small footprint pixels (like Raw8), the DCMIPP is limited by its maximum dcmipp_ker_clk, and can be unable to handle the maximum CSI pixel rate (clk_bit * DL / 8 bpp for Raw8).
- Downsize:
  - The line buffer of the vertical downsize operator is limited to a width of 2688 pixels after the horizontal downsize operation, limiting the resolution, when the downsizing is active, to 2688 x 1944 (1944 is the usual maximum height with a width of 2688), thus 5.1 Mpixel.
  - If a camera resolution higher than 5 Mpixel is targeted, a basic decimation has to be performed to decrease the resolution to a maximum of 5 Mpixel before processing the downsizing operation.
- AXI clock:
  - The pixels must be reclocked from the processing to the AXI domain, resulting in
    > dcmipp_ker_ck ≤ dcmipp_aclk
  - The AXI bus must drain the running pipelines. The maximum footprint of pixel (or data) pipes is 32 bpp (Pipe1 and Pipe2) and 16 bpp (Pipe0). AXI is on 64 bits, with an efficiency of 8 / 9 for the typical 64-byte burst.
  - dcmipp_aclk ≥ dcmipp_ker_ck * (32 bpp + 32 bpp + 16 bpp) / (64bit / bus) * 9 / 8 (efficiency) = dcmipp_ker_ck * 1.4.

39.3.4 DCMIPP maximum resolution

The limitations related to the maximum resolution supported by the DCMIPP are:

- Maximum width and height across pipes: 4094 x 4094 pixels
  - Registers and counters are limited to 12 bits
- Maximum performance: 333 Mpixel/s on each pipe
  - Larger pixel rate can be used, but with less pipe active or lower memory latency
  - Maximum pixel rate on each pipe must remain below the pixel clock
- Maximum width on demosaicing: 2688 components wide
  - limitation related to the Line-buffer size
- Maximum width after downsize: 2688 pixels
  - limitation related to the Line-buffer size
- Maximum width for conversion to YUV420: 2688 pixels
  - limitation related to the Line-buffer size
- Max line stride: 32767 bytes
  - Registers and counters, to handle 4094 pixels x 32 bits x 2 (provision for interleaving)

39.3.5 DCMIPP minimum requirements for frame structure

DCMIPP imposes the following minimum requirements for the frame architecture:

Blanking phase

- Dump pipe
  - The minimal duration of the blanking between two frames must be an equivalent of 666 datawords of 32 bits
- Pixel pipe
  - Vertical blanking: minimum is 5 lines. If the line is less than 12 pixels, a minimum of 24 pixels equivalent for the vertical blanking parameter is requested
  - Horizontal blanking: a minimum duration of 12 pixels is required between two lines

Data image area

- Vertical image area: minimum one line (two lines if raw Bayer conversion is active)
- Horizontal image area: minimum two pixels
- The minimum total frame size is fixed to 36 pixels

39.3.6 Description of DCMIPP pixel format support

Table 335 lists the supported pixel formats in the input interfaces (parallel, CSI), as input to the pixel Pipe1 and Pipe2, and in the three output pipes.

Table 335. Supported pixel formats

Index (1)	Pixel format	BPP	Parallel input (clk/pix)(2)	CSI input	Pipe0 output (dump)	Pipe1 and Pipe2 input	Pipe1 output (main)	Pipe2 output (ancillary)
-	Bytes (CSI: long packets and user)	8	-	Y	Y	-	-	-
13(3)	Byte stream (JPEG, compressed video)	8	Y, 1	-	Y	-	-	-
14(4)	Other data	8 to 16(4)	Y, 1	-	Y	-	-	-
5	Raw6	6	(5)	Y(6)	Y(6)	-	-	-
5	Raw7	7	(5)	Y(6)	Y(6)	-	-	-
5	Raw8	8	Y, 1	Y	Y	Y	Y	Y
6	Raw10	10	Y, 1	Y	To 16 bpc	To 8 bpc	-	-
7	Raw12	12	Y, 1	Y	To 16 bpc	To 8 bpc	-	-
8	Raw14	14	Y, 1	Y	To 16 bpc	To 8 bpc	-	-
9	Mono8	8	Y, 1	-	Y	Y	Y	Y
10	Mono10	10	Y, 1	-	To 16 bpc	To 8 bpc	-	-
11	Mono12	12	Y, 1	-	To 16 bpc	To 8 bpc	-	-
12	Mono14	14	Y, 1	-	To 16 bpc	To 8 bpc	-	-
2	RGB444	12	(5)	Y	(5)	To 8 bpc	-	-
2	RGB555	15	(5)	Y	(5)	To 8 bpc	-	-

Table 335. Supported pixel formats (continued)

Index (1)	Pixel format	BPP	Parallel input (clk/pix)(2)	CSI input	Pipe0 output (dump)	Pipe1 and Pipe2 input	Pipe1 output (main)	Pipe2 output (ancillary)
2	RGB565	16	Y, 1, 2	Y	Y	To 8 bpc	Y	Y
3	RGB666	18	(5)	Y	(5)	To 8 bpc	-	-
4	RGB888 / YUV444(6)	24	Y, 2, 3	Y	Y	Y	Y	Y
-	xRGB888 / xYUV444(6)	32	-	-	Y	-	Y	Y
-	RGBx888 / YUVx444(6)	32	-	-	Y	-	Y	Y
1	YUV422-1 (YUYV)	16	Y, 1, 2	Y	Y	Y	Y	Y
-	YUV422-2	16	-	Y(6)	Y(6)	-	Y	-
-	YUV420-2 (NV21/NV12)	12	-	Y(6)	Y(6)	-	Y	-
-	YUV420-3 (YV12)	12	-	Y(6)	Y(6)	-	Y	-
-	YUV422 10 bpc	20	-	Y(6)	Y(6)	-	-	-
-	YUV420 10 bpc	15	-	Y(6)	Y(6)	-	-	-
-	Any other CSI-2	Any	-	Y(6)	Y(6)	-	-	-

1. Index is used to link the input pixel format to the DCMIPP_PRCR register. The index has a meaning only for camera connected with the parallel interface
2. Pixel formats on 16 bpp (like RGB565 or YUV422-1) can be received either on an 8-bit interface (using 2 cycles), or on a 16-bit input interface (using one cycle). Pixel formats on 24 bpp (like RGB888) can be received either on an 8-bit interface (using three cycles), or on a 12-bit input interface (using two cycles).
3. In Byte stream mode, the bytes are dumped consecutively with only a 32-bit padding (if needed) at the end of the frame (or JPEG stream). There is no 32-bit padding operation inside the stream until the VSYNC deassertion (end of frame, or end of JPEG stream).
4. If the data format is different from those in this table, user can choose “others” configuration into bit field FORMAT in the DCMIPP_PRCR register, using bit-field EDM to select how many data bits must be captured in one pixel clock. It is possible to capture two 8-bit data mapped on 16-bit parallel input data in a single cycle (for instance FORMAT = Others, EDM = 100, i.e. 16-bit capture on each pixel clock). Data are 32-bit padded at the end of a line to have a complete line aligned on 32-bit width.
5. On the parallel interface input, some sensor pixel formats are supported by the DCMIPP, by selecting a wider pixel format in DCMIPP, by mapping the sensor wires onto the MSB of the DCMIPP interface. On the input missing pins, it is recommended to replicate the sensor MSB pins onto the missing input LSB pins. This helps achieving full dynamic on the extended pixel format. The work-around can be applied on the following formats (sensor output on left, mapping on DCMIPP format on right):
   - Raw6: Raw8 with 1-cycle input, processed as a 8 bpp
   - Raw7: Raw8 with 1-cycle input, processed as a 8 bpp
   - RGB444: RGB565 with 1-cycle input, processed as a 16 bpp
   - RGB555: RGB565 with 1-cycle input, processed as a 16 bpp
   - RGB666: RGB888 with 3-cycle input, processed as a 24 bpp
6. The same bit mapping is used for the input RGB888 and YUV444, the input xRGB and xYUV, and similarly for the outputs. The difference between RGB and YUV is the color reference, set in the color conversion that occurs after the input or before the output.

39.4 DCMIPP input and flow control

This section describes the functional elements of the DCMIPP. For each, it details the features, the software configuration, and provides a software configuration example (when needed).

39.4.1 Parallel input interface

The parallel interface is a flexible pixel interface that clocks in a bus of 8- to 16-bit in parallel, with an externally provided clock, and adds vertical and horizontal synchronization, provided either with specific pins (external sync) or flagged via specific data (as in CCIR601).

Interface (all inputs)

- Clk: clock up to 120 MHz, internally named dcmipp_pxclk
- Data: 16 IO pins, up to 120 Mbps/pin, 8- to 16-bit, pixels potentially serialized
- HSync, VSync, but no enable (EN)

Features

- Horizontal and vertical synchronization:
  - External, via the HSync and VSync pins.
  - Internal, via the CCIR601 flagging.

  Data provided during the horizontal or vertical blanking cannot be captured.
- Input pixel format (see *Section 39.3.6*)
  - Binary stream like JPG
  - Single cycle data:
    - Raw Bayer and monochrome: 8/10/12/14 bits in parallel
    - YUV422, RGB565:16 bpp on 16 bits in parallel
  - Double-cycle data:
    - YUV422, RGB565:16 bpp on 8 bits in parallel
    - RGB888/YUV444: 24 bpp on 12 bits in parallel
  - Triple-cycle data:
    - RGB888/YUV444: 24 bpp on 8 bits in parallel
- Flexible input:
  - MSB-vs-LSB bits can be swapped to ease PCB placement
  - Cycle0-vs-Cycle1 can be swapped (for 2-cycle long pixels).
  - Red-vs-blue components can be swapped (for RGB, or U-vs-V for YUV), this last swap operates only on the pixel pipes and not the dump pipe.

Hardware synchronization mode

In this mode two synchronization signals (DCMIPP_HSYNC and DCMIPP_VSYNC) are used.

Depending on the camera module/mode, data can be transmitted during horizontal/vertical synchronization periods. DCMIPP_HSYNC/DCMIPP_VSYNC act as blanking signals, as all data received during DCMIPP_HSYNC/DCMIPP_VSYNC active periods are ignored.

To correctly transfer images in the RAM buffer, data transfer is synchronized with the DCMIPP_HSYNC/DCMIPP_VSYNC signals. When the hardware synchronization mode is selected, and capture is enabled (CPTREQ bit set in DCMIPP_PxFCTCR), data transfer is synchronized with the deassertion of the DCMIPP_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by the IP-Plug to successive buffers or the same/circular buffer.

Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using embedded 32-bit codes, using the 0x00/0xFF values not used in data anymore.There are four types of codes, all with 0xFF00 00XY format. The embedded synchronization codes are supported only in 8-bit parallel data capture (in the DCMIPP_PRCR register, the EDM[2:0] bits must be programmed to “000”). For other data widths, this mode generates unpredictable results.

Note: Camera modules generate up to eight synchronization codes when in interleaved mode, while the DCMIPP reacts to one single code. As a consequence, an interleaved flow with an embedded synchronization has one every other frame discarded as not detected.

Mode 2

Four embedded codes signal the following events:

- Frame start (FS)
- Frame end (FE)
- Line start (LS)
- Line end (LE)

The XY values in the 0xFF00 00XY format of these codes are programmable (see *Section 39.14.9*).

A 0xFF value programmed as a frame end means that all the unused codes are interpreted as valid frame end codes.

In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

Mode 1

An alternative coding is the camera mode 1. This mode is ITU656 compatible.

The codes signal another set of events:

- SAV (active line) - Line start
- EAV (active line) - Line end
- SAV (blanking) - Start of line during interframe blanking period
- EAV (blanking) - End of line during interframe blanking period

This mode can be supported by programming the following codes:

- FS ≤ 0xFF
- FE ≤ 0xFF
- LS ≤ SAV (active)
- LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. User can therefore select a bit to compare in the embedded code and detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

Example:

- FS = 0xA5
- Unmask code for FS = 0x10

In this case the frame start code is embedded in bit 4 of the frame start code.

Note: FEC sequence must be sent before the transfer of the first frame, otherwise other codes are not decoded and the first frame can be lost after the DCMIPP has been enabled. After the first FE sequence, the following frame is captured based on FS sequence.

Error conditions

Error conditions can be detected when using the embedding synchronization data modes. Flags PRERRF in DCMIPP_CMSR2 and ERRF in DCMIPP_PRSR are used for this function. An interruption can be triggered based on error detection if bit PRERRIE in DCMIPP_CMIER is set for the global interrupt (or bit ERRIE in DCMIPP_PRIER for a local interrupt line).

For instance, such kind of wrong sequences or values generate an error:

- FF 00 00 XY sequence detected with XY value different from the one set for FS/LS/FE/LE
- LS = 0xFF or LE = 0xFF
- If an LS or FS sequence follows an LS sequence

Software configuration

Table 336. DCMIPP_PRCR bit function

Bit ID	Function	Comments
ENABLE	Enables the parallel interface	Low-power mode when disabled.
PCKPOL	Defines clock polarity	– 0: Falling edge – 1: Rising edge
ESS	Defines if VSync and HSync synchronizations are provided by sideband (specific hardware IO) or by in-band (specific embedded codes) signals	– 0: Hardware (external) synchronization: using DCMIPP_HSYNC and DCMIPP_VSYNC pins. – 1: Embedded (internal) synchronization: using codes FSC, FEC, LSC, LEC and masks in registers DCMIPP_PRESCR and DCMIPP_PRESURy.
VSPOL, HSPOL	Defines the polarity of the IO DCMIPP_VSYNC and DCMIPP_HSYNC used for, respectively, the vertical and horizontal synchronization	– 0: Active low – 1: Active high
FORMAT	Defines the pixel format used on the IO DCMIPP_Dx	From 0 to 15
EDM	Defines the amount of valid bits received per cycle	8/10/12/14/16 bits
	The duration of a pixel is extracted by the bit-per-pixel (given by FORMAT) and bit-per-cycle (given by EDM) ratios	1, 2 or 3 cycles
SWAPBITS	Swaps the 16 bits of the parallel interface	15:0 becomes 0:15
SWAPCYCLES	Swaps, when a pixel is received in two cycles, the data from the first cycle with the data from the second cycle	Software must not activate it when a pixel is received in one or three cycles.
SWAPRB(1)	Swaps red (or V = Cr) with blue (or U = Cb) components	Operates only on pixel pipe, not on dump pipe.

1. DCMIPP_CMCR register.

The embedded synchronization codes are configured by means of DCMIPP_PRESCR and DCMIPP_PRESUR registers (see *Table 337*).

Table 337. DCMIPP_PRESCR and DCMIPP_PRESUR bit function

Bit ID	Function
FSC, FEC	Frame-start and frame-end synchronization, when embedded synchronization ESS = 1
FSU, FEU	Masks for FSC and FEC codes
LSC, LEC	Line-start and line-end synchronization, when embedded synchronization ESS = 1
LSU, LEU	Masks for LSC and LEC codes

Sequence of swap operations

The sequence of the SWAP operators on bits, cycles and RB (red vs. blue) is induced by their functionality:

- the swap on bits (MSB vs. LSB on IOs) occurs first, as operating on the IOs
- the swap on cycles occurs afterwards, as it operates on words already sampled by still raw
- the swap on the RB occurs last, as it operates on the final red and blue components.

39.4.2 Interface from CSI-2 host

The CSI-2 host and DPHY_RX (both external to the DCMIPP) provide the data from the CSI-2 camera sensor, forward them into the DCMIPP using the ISB byte header interface.

The ISB byte header features are:

- CSI-2 clock interface aligned with the DCMIPP processing clock (333 MHz)
- Data width: 32 bit (data and CSI headers are interleaved)
  - Frame synchronization short packet
  - Frame number, Data ID, and packet type are provided (see *Section 39.7.9*).
- Line Sync short packets are not received.
- Headers of data long packet:
  - Packet length, Data ID, and packet type are provided (see *Section 39.7.9*).
- Payloads of data long packet:
  - Data as 32-bit words, as collected by the CSI-2 host.
- Packet CRC is not received.

39.4.3 Input selection

Input selection block is ahead of any pipe to select the camera sensor module interface connected to the DCMIPP. Two interfaces are supported:

- Parallel interface: up to 16-bit parallel interface with physical synchronization signals (DCMIPP_VSYNC/DCMIPP_HSYNC) or software embedded ones (as in CCIR601).
- MIPI CSI-2 interface: Host ISB byte header internal connection from the CSI2 host controller placed in front of the DCMIPP.

Both interfaces are exclusive. The selected one is applied to all the input pipes.

The camera sensor interface is selected by means of bit INSEL of the DCMIPP_CMCR register.

39.4.4 Flow selection

The module, present in each pipe, handles the flow control around the CSI2 camera sensor interface. For each pipe, the software needs to configure which virtual channel (VC) and which Datatypes (DT) are processed by the pipe.

For Pipe0 and Pipe1, multiple Datatypes can be selected whereas only one virtual channel can be defined for a frame. Configuration can be changed frame by frame if the application requires it, offering some flexibility.

For Pipe2, when the pipe is independent with PIPEDIFF = 1, only one virtual channel and only one data type by frame can be selected.

The software has to reconfigure the flow selection module to handle interleaved frames from a sensor if it uses virtual channels as a mean to make the differentiation, accepting to lose frames since there can be only one virtual channel active for a given frame (it decreases the FPS).

Multiple cameras data flow can be received simultaneously through the CSI2 ISB header bus. For instance, for a system having two different camera data flows, it is possible to redirect one virtual channel on a pipe and the other one on the other pipe. It can be interesting to dump them on Pipe0, but only one frame over two since the flow selection block has to be reconfigured to switch from one VC to another one.

The flow selection module is used also to share some image processing features (demosaicing, color conversion, statistics, contrast enhancement, auto exposure, statistics removal and basic decimation) between Pipe1 and Pipe2, whatever the camera sensor interface solution (parallel interface or CSI2 interface): when bit PIPEDIFF in the DCMIPP_P1FSCR register is 0, or the input is on the parallel interface that provides unique flow, the Pipe2 samples pixels from the output of the ISP of Pipe1 (see *Figure 395*). PIPEDIFF must be reconfigured when Pipe1 and Pipe2 are disabled.

Software configuration

The following configurations must be set first, because static in the DCMIPP_PxFSCR registers:

Pipe0

- DTMODE[1:0]: Mode for CSI flow selection into that pipe
  - 0: only flow VC/DTIDA is forwarded in the pipe
  - 1: flows VC/DTIDA and/or VC/DTIDB are forwarded in the pipe
  - 2: all Datatypes of the selected virtual channel, except the VC/DTIDA or VC/DTIDB, are forwarded in the pipe
  - 3: all Datatypes of the selected virtual channel are forwarded in the pipe
- VC[1:0]: Virtual channel ID of the CSI flow to select for further processing on the pipe
- DTIDA[5:0]: Data type ID A to select in the CSI flow for further processing in the pipe
- DTIDB[5:0]: Data type ID B to select in the CSI flow for further processing in the pipe
- PIPEN: activation of the Pipes, to be set after the above configurations.

Pipe1

- DTMODE[1:0]: mode for CSI flow selection into that pipe
  - 0: only flow VC/DTIDA is forwarded in the pipe
  - 1: flows VC/DTIDA and VC/DTIDB are forwarded in the pipe
- VC[1:0]: virtual channel ID of the CSI flow to select for further processing on the pipe
- DTIDA[5:0]: data type ID A to select in the CSI flow for further processing in the pipe
- DTIDB[5:0]: data type ID B to select in the CSI flow for further processing in the pipe
- FDTFEN: when the DTIDx is detected depending on DTMODE, the software forces the data type format to the value set into FDTF[5:0] for the pixel pipe processing. It can be used, for instance, to address sensor 3D camera through specific bridge using CSI2 “user data type” to make distinction between left and right camera sensor (each camera has its own user data type value, but sharing the same pixel format).
- FDTF[5:0]: data type value to be forced
- PIPEDIFF: Pipe2 to take same input as Pipe1 or differentiated:
  - 0: Pipe1 and Pipe2 take the flow selection configuration of Pipe1. Pipe1 shares the image processing functions with Pipe2.
  - 1: Pipe1 and Pipe2 are considered as two independent pipes, without any shared configuration.
- PIPEN: activation of the pipes, to be set after the above configurations.

Pipe2

- VC[1:0]: Virtual channel ID of the CSI flow to select for further processing on the pipe.
- DTIDA[5:0]: Data type ID A to select in the CSI flow for further processing in the pipe
- FDTFEN: When the DTIDx is detected depending on DTMODE, the software forces the data type format to the value set into FDTF[5:0] for the pixel pipe processing. It can be used to address sensor 3D camera through specific bridge using CSI2 “user data type” to make distinction between left and right camera sensor for instance (each camera having its own user data type value, but sharing the same pixel format).
- FDTF[5:0]: Data type value to be forced
- PIPEN: activation of the pipes, to be set after the above configurations.

If PIPEDIFF = 0 in DCMIPP_P1FSCR, the configuration bits are directly those set in the DCMIPP_P1FSCR register.

The above bit fields are meaningful when PIPEDIFF = 1.

39.4.5 Frame counter

A frame counter is available for a tag purpose and counts all the frame received on the selected pipe.

The counter is 32-bit, read-only. It is active at least when bit PIPEN of the pipe to whom it is connected is enabled (PIPEN = 1).

It provides an (almost) unique frame number, with a loop time of 4.5 years (if 30 fps).

The counter can be incremented, depending on the PSFC in DCMIPP_CMCR, at the FrameStart event of the selected virtual channel, when a CSI-2 camera sensor is connected, or at the FrameStart event of the pipe when the camera sensor module is connected with parallel interface.

The frame counter is cleared by setting CFC in the DCMIPP_CMCR register.

Software configuration

The frame counter must be configured before it is used for the pipe. Software action(s) must be performed in the DCMIPP_CMCR register:

- Select on which pipe the frame counter is connected by configuring bit PSFC[1:0]
- Frame counter runs as soon as the selected pipe is active (PIPEN = 1)

Note: It is possible to have the Frame counter run on a pipe, while having the pipe not flowing any pixel: this is achieved with pipe enable active (PIPEN = 1) to have the frame counter run, but with CPTREQ = 0 to avoid any pixel flow.

39.4.6 Frame control

The module is replicated for each dump and pixel pipe. It handles the frame control and the capture of each pipe, grouping data into frames, and capturing them when requested.

Definitions

There are two notions of frame events

- Event used inside the hardware (provided by the input interfaces):
  - FrameStart: when a frame starts at the input of the pipes (at frame control)
    - > Parallel interface with VSync fall
    - > CSI-2 interface: SoF (Start-of-Frame) packet
  - FrameEnd: when a frame finishes at the input of pipes (at frame control)
    - > Parallel interface: VSync rise (End-of-Frame)
    - > CSI-2 interface: EoF (End-of-Frame) packet
- Events exposed to software via DCMIPP events and interrupts:
  - VSYNC
    - > When a frame starts, observed at the input of the pipes (at frame control)
    - > It indicates that the current frame has started and has sampled its shadow registers, and that the software can start to configure the next frame
    - > It is recommended to use that interrupt to trigger the software that reconfigures the DCMIPP.
  - FRAME END
    - > When a frame finishes, observed at the output of pipes (when the last pixel has been written on the AXI)
    - > It indicates that the current frame has finished writing all its data to memory, and that the application can immediately start using them
    - > It is recommended to use that interrupt to trigger the software that forwards the memory buffer to other applications

Features

- Frame delineation: allows to dump data with the required frame granularity.
  - Extracts, per pipe, the FrameStart and FrameEnd event, based on the input Start-of-Frame and End-of-Frame.
    - > The FrameStart immediately generates a VSYNC event.
    - > The FrameEnd ripples till the end of the pipe, at the pixel packer level, where it generates the FRAME event.
  - Based on the algorithm detailed in *Extraction algorithm for FrameStart and FrameEnd*.
- Capture mode: can capture a frame snapshot, or capture continuously.
- Capture rate: can capture all frames, or one out of 2, 4, 8. It is only active when the Capture mode is in Continuous mode.
- Frame status: stores infos about the last captured frame (PxLSTFRM, PxLSTLINE), re-sampled at the FrameEnd event.

Extraction algorithm for FrameStart and FrameEnd

The extraction of the FrameStart and FrameEnd is straightforward.

In CSI-2 mode, each pipe is handling a unique virtual channel ID by frame. In case of interleaved flow in input of the DCMIPP, the software can decide to:

- Dedicate each virtual channel on a single pipe in case of multiple pipes, each of them having its own virtual channel number selected
- Decide to decrease the FPS ratio by changing the pipe configuration swapping with the other virtual channel ID (mainly in case of single pipe)

The interlaced mode can be handled by the software in CSI-2 mode by changing the pipe configuration frame by frame.

The following usecases are supported and detailed in the figures below:

- Default single VC: straightforward behavior, support in both pixel and dump pipes (*Figure 397*)
- Overlapping VC (supported on a single pipe via the loss of one frame when switching)
  - It can be supported by affecting each VC on a dedicated pipe (*Figure 399*)
- Exclusive VC (supported in both pixel and dump pipes), see *Figure 398*:

The use cases with two exclusive VCs can be handled either using one single pipe, by reconfiguring it from frame to frame, or by splitting the flow on more than one pipe, each of them handling its own VC:

- each flow arrives exclusively in one pipe and is processed as an independent frame, with its Start-of-Frame and End-of-Frame
- FrameStart and FrameEnd are generated per VC flow.

Figure 397. VC flow processed by one pipe

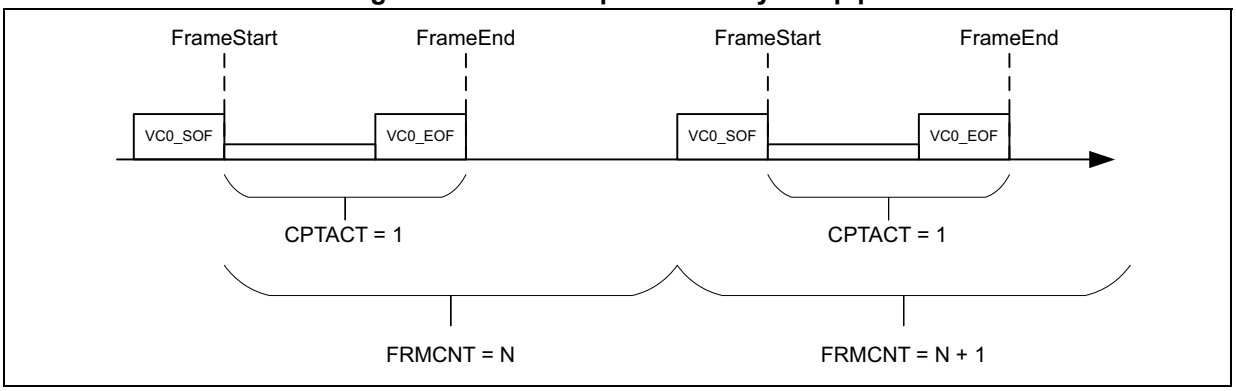


Figure 398. Two exclusive VC flows processed by one reconfigured pipe

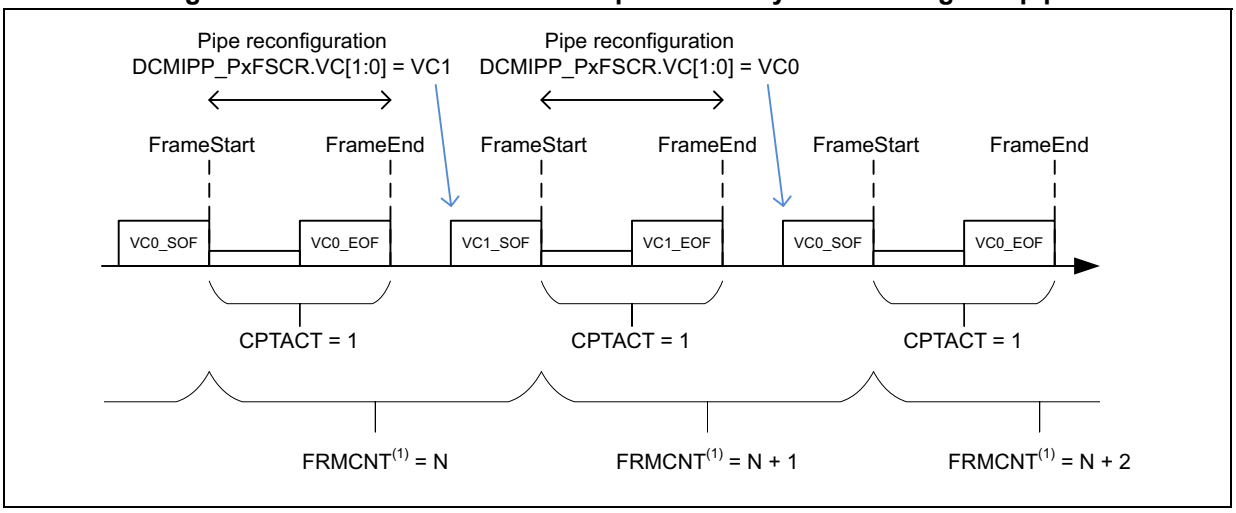
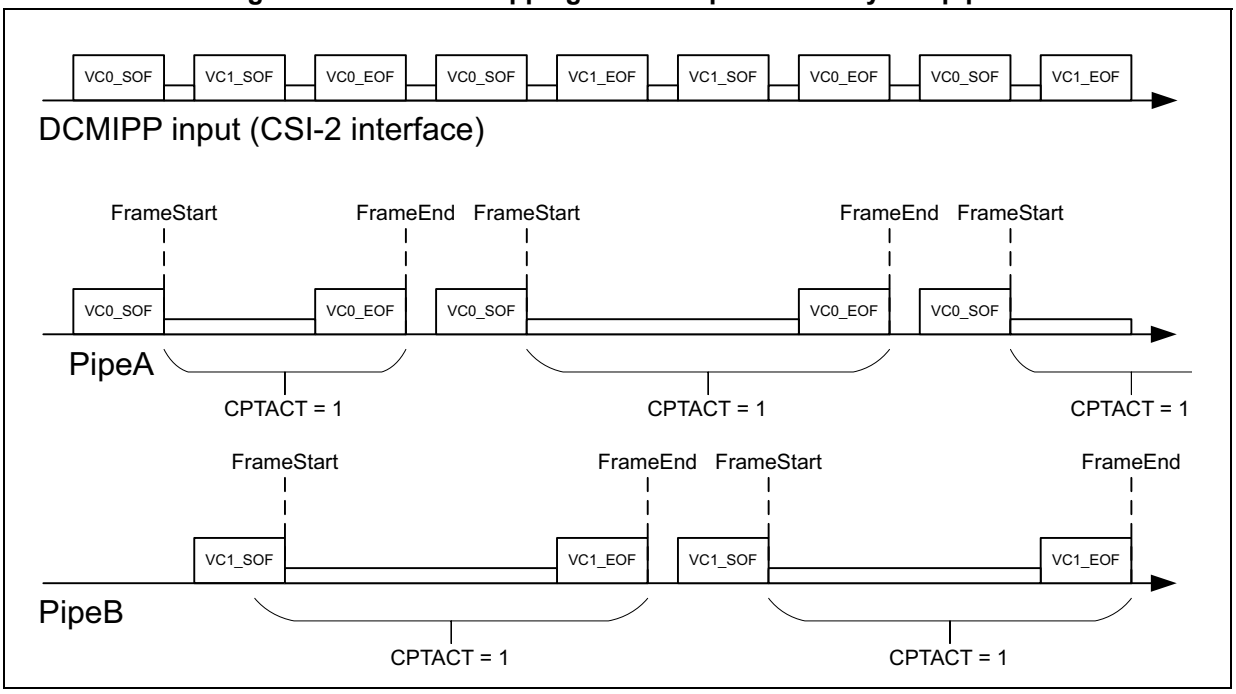


1. If frame counter is attached to the pipe and if reset is not requested when changing VC.

Figure 399. Two overlapping VC flows processed by two pipes



Use cases

The Continuous mode is typically used to send to display or to software-analysis a continuous stream of frames.

The Snapshot mode is typically used to dump a high-resolution frame.

The Frame rate mode is typically used for a low-power continuous analysis, where only one frame every eight is dumped and analyzed.

The frame informations are typically used for interlaced video use cases, where the sensors transmit alternatively odd and even fields (top vs. bottom), and where software must be able to retrieve the type of field. Depending on the sensor, it can be retrieved from:

- the VC-ID, if the sensor uses one VC for one field and another for the other
- the LSB of the counted number of lines in that frame (indicates if the number is odd or even)
- the LSB of the frame counter extracted from the CSI information (if counting this pipe), which can be odd or even.

Software configuration

The frame control supports two different capture modes:

- Snapshot mode: the software captures single frames
- Continuous mode: the software captures a continuous sequence.

The timing diagram of these two modes is shown in *Figure 400*.

Figure 400. Snapshot (CPTMODE = 1) and Continuous (CPTMODE = 0) capture modes

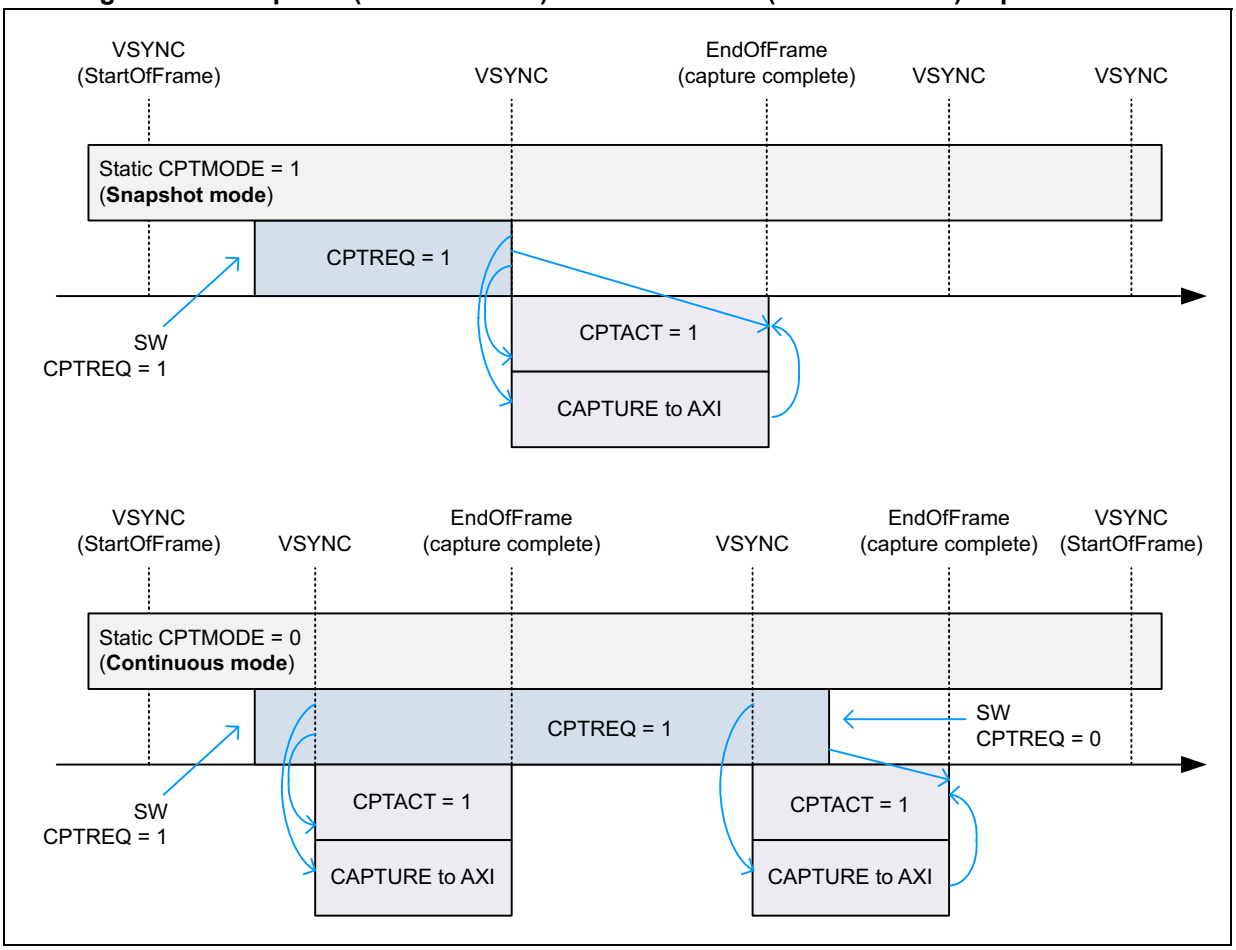


Table 338. DCMIPP_PxFCTCR bit function

Bit ID	Function	Values
CPTMODE	Capture mode	– 0: Continuous – 1: Snapshot
CPTREQ	Capture request	– 1: Capture requested
FRATE	Frame rate	– 0: Full rate capture – 1: 1/2-rate capture – 2: 1/4-rate capture – 3: 1/8-rate capture
CPTACT(1)	Capture status	– 1: Capture currently active

1. Bit read from the DCMIPP_PxSR register.

Configuration example

The software operations when using the Snapshot mode are the following:

1. Software sets CPTMODE = 1, to use the Snapshot mode.
2. Software sets PIPEN = 1, to let the flow selection send data to PipeN.
3. Software sets CPTREQ = 1, to request the capture of one frame.
4. At the first following VSync, the HW samples CPTREQ at 1, with the following impact:
   a) The capture effectively starts: pixels flow into the pipe and are dumped in memory.
   b) CPTACT is set to 1, to mention that a capture is currently ongoing, and that it is best to not modify the configuration of the pipe operators, unless shadowed.
   c) CPTREQ is reset to 0, so that only a single frame is dumped.
5. At the following capture complete interrupt
   a) CPTACT is reset to 0, to signal that the capture is over.
   b) The capture is complete, no more pixels are flowing, hence software can restart to update the configuration of non-shadowed registers without any issue, and use the captured pixels in memory. Depending upon the sensor blanking, this period can be short.
6. At the next VSync, CPTREQ usually is sampled at 0, so that no more frames are captured
   – As soon as CPTREQ is reset to 0 the software can set it again to 1, to request a capture at the following frame. It means that a continuous sequence of frame can be captured by setting again CPTREQ to 1, continuously frame after frame.

The software operations when using the Continuous mode are the following:

1. Software sets CPTMODE = 0, to use the Continuous mode.
2. Software sets PIPEN = 1, to let the flow selection send data to PipeN.
3. Software sets CPTREQ = 1, to request the continuous capture of frames.
4. At the first following VSync, CPTREQ is sampled at 1, with the following impact:
   – As in Snapshot mode, the capture starts, and CPTACT is set at 1.
   – Unlike the Snapshot mode, CPTREQ is not modified and remains at 1.
5. At the following capture complete interrupt:
   – As in Snapshot mode, CPTACT is reset to 0, capture stops, software can shortly reconfigure the pipes, and software can use the captured pixels.
6. At the next VSync, and as long as CPTREQ remains at 1, the capture restarts, similarly as described above.
7. To stop capturing later frames, software resets CPTREQ to 0.
   – An ongoing capture continues until completion.
8. At the next VSync, CPTREQ is sampled at 0, and the next capture does not restart.

39.4.7 Pipe deactivation

It is possible to abort a pipe to stop any frame acquisition and to potentially offer a mean to reprogram it completely (including non-shadowed registers), or to let it fully disabled for some time. The following operating mode has to be considered to correctly stop the pipe:

1. Disable the CPTREQ bit of the DCMIPP_PxFCTCR register of the corresponding pipe
2. Poll CPTACT = 0 status bit in the DCMIPP_CMSR1 register to check if the pipe is no longer active (idle state)
3. Disable PIPEN in the DCMIPP_PxFCTCR register.

When disabling the pipe, the last frame is processed completely by respecting the above operating mode.

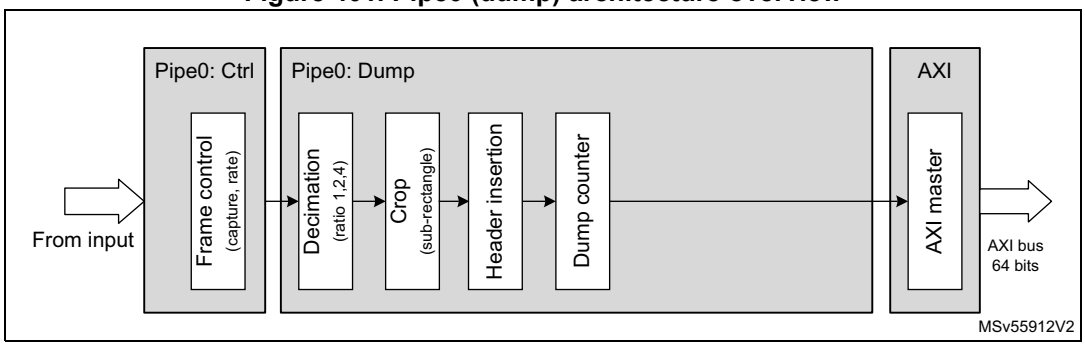
Note: To disable the parallel interface (PREN = 0 in the DCMIPP_PxFSCR), it is recommended to first disable the pipes considering the above operation mode, before switching off the parallel interface.

39.5 Pipe0 (dump pipe)

39.5.1 Overview

Pipe0 works as a dump pipe: it extracts data from the camera sensor module and dumps them (as-is) to the targeted memory, with some basic decimation and cropping 2D operations in between.

Figure 401. Pipe0 (dump) architecture overview



Pipe0 retrieves data from the camera sensor module connected to the DCMIPP through the 16-bit parallel interface or the CSI-2 interface, by means of the CSI-2 host controller peripheral. The selection between interfaces is managed by means of bit INSEL in the DCMIPP_CMCR register.

The flow selection chooses the virtual channels and data types to be processed by the pipe from the CSI2 host controller, see *Section 39.4.4* for more details.

The frame controller handles mainly the camera acquisition mode (continuous or snapshot, frame rate), see *Section 39.4.6* for more details.

When the input data from the camera is valid and supposed to be processed by Pipe0, 2D-cropping and decimation operations can be configured by the software. A dump counter combining with a limit amount of data to be set is offered to handle unknown length of data or to avoid the amount of data to be too wide within a frame.

Pipe0 can be reconfigured from time to time. Some events can be used to trigger the software reconfiguration routines (refer to *Section 39.13.2: Interrupts*).

It is also possible to write into the shadow registers within the processing of a frame. The values are loaded into the physical register based on the start of frame event.

39.5.2 Decimation

The decimation allows to cheaply downsize a frame.

Based on parallel interface camera module:

- Factor 1x, 2x, 4x at data/byte level depending on the configuration of bit field BSM[1:0] of the DCMIPP_P0PPCR register. The decimation is not working directly at pixel level, but it is based on either byte or 16-bit word granularity (for padded raw 10, for instance) to make equivalent decimation to one pixel out of two. Bit OEBS is used to start from the odd or even byte (or data) to capture first.
- The decimation can also be based on entire line, by capturing all the lines, or one line out of two thanks to bit LSM. Here, again, choice is given to the software to reject odd or even lines within the frame by configuring bit OELS.

When the camera sensor module is designed on CSI-2 interface, the decimation can be based filter out potentially, one line out of two. Indeed, each packet is by protocol composed for an entire line.

Note: Care must be taken when the CSI-2 header is dumped, as it is 32-bit wide, and it increases by one unit the data counter, taking part of the decimation. It is advised not to use the CSI header option when decimation takes place.

Table 339. DCMIPP_P0PPCR bit function

Bit ID	Function
BSM[1:0]	To select how much byte/data have to be captured within a line. This feature is available only for a parallel interface camera module.
OEBS	Allows the user to chose if the filtering starts from the odd or the even byte.
LSM	Possibility to filter out one line out of two.
OELS	The software can select if the filtering rejects the odd or even lines.

39.5.3 Crop/statistics selection/suppression

The dump pipe (Pipe0) has the capability to handle 2-D crop processing. The vertical cropping is based on line, thanks to HSYNC event (from the physical IOs or the embedded code detection if selected). It can be extracted from the CSI-2 packet information (each packet is one line wide by protocol).

The horizontal area on which the crop is applied is based on data (32-bit wide), and not on pixels since this pipe is not directly considering the pixels. It handles the data flow with 32-bit granularity. The CROP functionality is not supported when the pipe is convoying JPEG format. The ENABLE bit must be kept cleared into DCMIPP_P0SCSZR to avoid any unpredictable behavior.

The area to be captured within the frame has to be specified configuring the registers DCMIPP_P0SCSTR and DCMIPP_P0SCSZR. The starting point on the two axis are set accordingly as well as the width in both directions. It is possible to take the data inside or outside this area by means of bit POSNEG in the DCMIPP_P0SCSZR register. Some sensors can send sensor configuration data and statistics (histogram) on the very first and last lines of a frame. By specifying active the area outside of this window selection (POSNEG = 1), only statistic data are extracted by the way, and the software can decide to apply some processing on the data to correct, such as contrast or exposure.

Features

- 2D-Crop operation with granularity:
  - Lines in the vertical axis
  - 32-bit data in the horizontal axis
- Possibility to capture data inside or outside the defined window (valid image data or statistic data)
- Cropping with 0 value for HSIZE[11:0] or VSIZE[11:0] has no crop effect to the dimension for which the 0 value has been applied (vertical or horizontal axis).

Software configuration

Registers DCMIPP_P0SCSTR and DCMIPP_P0SCSZR have to be configured to set the crop feature into the dump pipe:

1. Configure the cropped horizontal starting point with HSTART[11:0] and the width with HSIZE[11:0] (both with a 32-bit data granularity).
2. Configure the cropped lines, starting at line VSTART[11:0] and with a height of VSIZE[11:0] (both with a line granularity)
3. If any value HSIZE or VSIZE is set to 0, the hardware does not consider crop operation in the vertical or horizontal dimension for which the 0 value has been applied, so that all the pixels in that dimension are sampled.
4. Select the inner or the outer part of the window for the data capture by configuring POSNEG bit.
5. Enable the crop feature setting ENABLE bit. This bit must be cleared when JPEG is selected as the input format for Pipe0.

Note: Cropping out the picture size (with too large HSTART or VSTART) leads to a not guaranteed processed frame.

39.5.4 Header insertion

The module works on the dump pipe(s) and it optionally inserts an header before the data of a former CSI packet.

Features

- Optionally inserts non-data information to help software interpreting the following data payload. The non-data info is Frame sync short packets and Header of data long packets (both non-data info into a 32-bit word), mapped as follows:
  - Frame sync short packet: defined by Frame type = SOF or EOF
    - > bits 31:16: Frame number
    - > bits 15:8: Reserved (forced to 0)
    - > bits 7:4: Virtual channel ID in CSI-2_v1.3, bits 7:6 = 00
    - > bits 3:0: Frame type (SOF = 0x1 or EOF = 0x2)
  - Header of data long packet (defined by below Frame type = DATA)
    - > bits 31:16: Amount of bytes in the payload
    - > bits 15:8: Data type ID in CSI-2_v1.3, bits 15:14 = 00
    - > bits 7:4: Virtual channel ID in CSI-2_v1.3, bits 7:6 = 00
    - > bits 3:0: Frame type (DATA = 0x0)

To keep consistency between the amount of bytes provided by the header versus those effectively dumped, it is recommended to not activate the header insertion simultaneously with the crop or decimation, as these functions modify the amount of dumped data.

When header insertion is active, the FrameEnd packet is dumped as a header, and is considered as the unique part of an additional line, inducing an event.

Software configuration

It is configured with the DCMIPP_P0PPCR register:

- HEADEREN:
  - 0: No header insertion
  - 1: Insertion of the headers, aligned on 32 bits.

39.5.5 Dump counter

The dump counter is present on dump pipe. It is used to count the amount of data that are dumped in that frame, and to potentially limit the amount dumped if too large. It allows the software to know the size of dumped buffer, and to make sure that no dump is made out of a preallocated buffer.

It is specifically useful when dumping a content whose length is unknown prior to reception, like an encoded JPG stream. When dumping a pixel frame, the size is known thanks to the configured width and height of the frame.

The counter is counting 32-bit data for almost all the input formats, even if the value is expressed in number of bytes. The counter increment is 4-bytes granularity for all formats except the JPEG byte stream input mode, for which the counter granularity is 8-bit because the application does not know the amount of dumped data.

Features

- Dump counter, counting the amount of bytes dumped. It counts the amount of dumped 32-bit words (the increment is 4), except when connected to a parallel interface camera and dumping a 8-bit data in byte stream mode (see FORMAT bit field in the DCMIPP_PRCR register), where it counts per byte (the increment is 1).
  - The counter saturates at 0x03FF_FFFF.
  - At FrameEnd, the counter value is recopied in a readable shadow register and the counter itself is reset to start the count of the next frame.
- Dump limit, that clamps the dumped words below a maximum limit:
  - If the counter reaches the limit, all following bytes are deleted until the next VSync.
  - The counter continues to count over the limit, to indicate how many bytes have been received and must have been dumped if not deleted.
- Interrupt limit is triggered when some bytes are deleted due to dump limit crossed.
- CSI headers, when dumped (HEADEREN = 1), participate to the counted and limited data volumes.
- Monochrome or raw Bayer padding (alignment of 10/12/14 bpp to 16 bpp) is also taken into account in data volumes.

Software configuration

Table 340. DCMIPP_P0DCCNTR and DCMIPP_P0DCLMTR bit function

Bit ID	Function
ENABLE	1: Enables the limit check.
CNT	Read-only, counts the amount of data with a 4-byte granularity for most of the input formats or with an 8-bit data granularity in JPEG byte stream mode selected into DCMIPP_PRCR.FORMAT). The counter increment is based on dumped data at the pipe output standpoint. The value is expressed in bytes, whatever the input format.
LIMIT	Gives the maximum amount of 32-bit data that can be dumped. Limit value 0 is inconsistent and the processed frame is not guaranteed if ENABLE bit is set.
LIMITIE	DCMIPP_PxIER.LIMITIE bit enables the interrupt.

Note: The dump counter sees the CSI-2 packet headers as normal 32-bit words. Raw Bayer and monochrome pixels on 10/12/14 bpc are padded onto 16 bits, and are thus slightly larger than their 10/12/14 bit size.

39.5.6 Double buffer mode

The dump pipe uses an AXI master interface to dump the data from the internal FIFO to the external memory. In the application, it is possible to handle frame data swapping memory area frame by frame. The double buffer mode fills up this function. There are two memory address registers set to initialize the base addresses of these memories areas. Each start of captured frame event swaps the memory base address to handle double buffering mode.

The double buffer mode can be used to allow post-processing on a buffer (frame buffer) while the other buffer is read to be displayed (display buffer).

Software configuration

Double buffering mode requires an activation, as well as addresses configuration, to define the two memory areas in which data are consecutively stored frame by frame at the output of the pipeline:

- DCMIPP_PxPPM0AR1 and DCMIPP_PxPPM0AR2 must be filled with the memory addresses associated to the double buffer memory locations.
- Bit DBM in the DCMIPP_PxPPCR register(s) is set to enable the double buffer mode.

39.6 Pipe1 (ISP part)

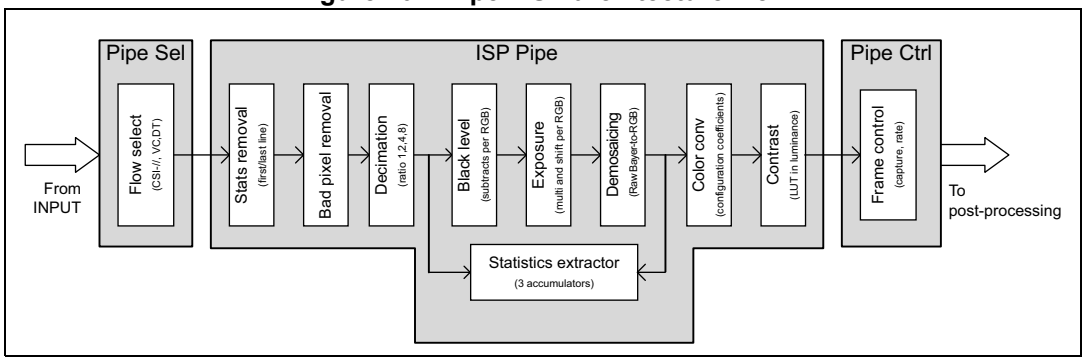
39.6.1 Overview

Pipe1 is a pixel pipeline in which some image processing (ISP) and post-processing functions are integrated, to relieve the software from very specific (time and memory consuming) operations. The ISP part implements functions like:

- Statistics removal within the dataflow
- Bad pixel detection to automatically remove noisy pixels
- Basic decimation to reduce high resolution camera sensor to fit with the image processing maximum resolution tolerance
- Auto exposure and statistics extraction based on pixel analysis
- Demosaicing algorithm to convert raw Bayer input pixels to RGB ones
- Color conversion and contrast enhancement functions

Pipe1 ISP block diagram is shown in *Figure 402*.

Figure 402. Pipe1 ISP architecture view



Pipe1 is the most featured pixel pipeline, even if the image processing functions can be shared with Pipe2 (refer to *Section 39.8.2*).

Pipe1 retrieves data from the camera sensor module connected to the DCMIPP with the 16-bit parallel interface or with the CSI-2 interface, thanks to the external CSI-2 host controller peripheral. The selection between interfaces is managed by means of bit INSEL in the DCMIPP_CMCR register.

The flow selection chooses the virtual channels and data types to be processed by the pipe from the CSI2 host controller. Refer to *Section 39.4.4: Flow selection* for more details.

The frame controller handles mainly the camera acquisition mode (continuous or snapshot, the frame rate). Refer to *Section 39.4.6: Frame control*.

Pipe1 can be reconfigured from time to time. Some events can be used to trigger the software reconfiguration routines (refer to *Section 39.13.2: Interrupts*).

It is also possible to write into the shadow registers during the processing of a frame. The values are loaded into the physical register based on the following start of frame event.

39.6.2 Byte-to-pixel conversion

The module works on the pixel pipes: it gets 32-bit words from the input (parallel or CSI) interfaces, extracts the pixels depending on the provided pixel format, and maps them onto

the triple-component pixel pipeline, that is 14 bpc at this stage (and 8 bpc later downstream).

Functionality

- Extracts various input pixel formats to a triple R, G, B lane
  - All CSI-2 formats of versions CSI v1.3 and v2.0 are supported, except Raw 6/7 bpc, YUV422-10 bpc, YUV420 (see *Table 335*)
- YUV420-to-YUV444 conversion is not supported
  - Pipe1 and Pipe2 cannot extract and process YUV420 pixels received from the CSI interface
- YUV422-to-YUV444 conversion:
  - Done by replication of the U and V components. It thus assumes that the location of the common chroma is defined at mid-distance between the two pixels.
- Extension of short triple component (RGB/YUV) to the output triple 8 bpc:
  - The extension is done by replicating the input MSB onto the missing output LSB. The replication onto the LSB allows to map any input dynamic on the full downstream dynamic.
  - Examples of 5 and 6 bpc extended to the output 8 bpc:
    - > Input Di[4:0]: Output Do = Di[4:0] and Di[4:2]
    - > Input Di[5:0]: Output Do = Di[5:0] and Di[5:4]
- Keeps as-is the single-components, usually wide:
  - The monochrome and raw Bayer 10/12/14 bpc are fed into the pipes as-is (the monochrome assumes a Y, with U = V = 128).

Software configuration

The used pixel format depends upon the source of the pixels:

- CSI-2 interface: the pixel format is embedded in the received CSI-2 packets, and defined in the data type field of the packet header.
  - When FDTFEN = 0, the byte-to-pixel conversion uses the data type provided by the CSI-2 packet, and works automatically, without need for any configuration.
  - When FDTFEN = 1, the data type is configured by software in the FDTF field.
- Parallel interface: the pixel format is determined by the source of the pixels, i.e. the camera sensor. The byte-to-pixel extracts the pixels based on the pixel format provided by the software in the parallel interface configuration, in the field of the DCMIPP_PRCR register.

39.6.3 Statistics removal

The module is used to removing potential statistic data inserted by a sensor, prior to starting the demosaicing conversion that is multi-pixel and would be impacted by remaining statistics. It is typically used by sensors with a parallel interface, which does not have any way to distinguish between statistics and pixel data. CSI-2 sensors typically split these flows using different virtual channel IDs.

Features

- Suppression of some of the first lines of the frame.
- Suppression of the last lines of the frame, after a configured line N.

Software configuration

Table 341. DCMIPP_P1SRCR bit function

Bit ID	Values	Comments
CROPEN	1: Active	If CROPEN = 0 all pixels are fed through.
FIRSTLINEDEL	0 to 7	Amount of first lines to delete when CROPEN = 1
LASTLINE	0 to 4094	Amount of lines to keep after the removed first lines. If LASTLINE is null, all remaining lines after FIRSTLINEDEL are fed through.

Configuration example

If the received frame contains four lines of statistics, followed by 100 lines of pixels and eight lines of ancillary data, the configuration to extract the 100 lines of pixels is the following:

- CROPEN = 1, to have the removal active
- FIRSTLINEDEL = 4, to remove the first four lines
- LASTLINE = 100, to keep the next 100 lines

39.6.4 Bad pixel removal

This module aims at detecting and correcting artifacts generated by a bad pixel on the sensor array. It is based on a correlation extraction, and not on fixed locations.

Functionality

- Works for raw Bayer flows only, as RGB flows are assumed as already processed.
- Scans all the arriving components, and extracts the horizontal continuity correlation versus the two left and two right neighbors, on both the local component and on the adjacent raw Bayer component:
  - if a component is seen as too light, it is declared as bad
  - too dark components are not extracted, to avoid false positives
- A component assumed bad is replaced by the horizontal average of its two neighbors (with the same component).

Software configuration

Table 342. DCMIPP_P1BPRCR and DCMIPP_P1BPRSR bit function

Bit ID	Function
ENABLE	– 1: Active – 0: No component checked nor replaced. To be enabled only for raw Bayer flows, as it corrupts RGB flows.
STRENGTH	3 bits, 0 (high tolerance) to 7 (aggressive detection)
BADCNT	12-bit counter, reporting the amount of bad components corrected. The counter saturates at its maximum value (4095). At FrameEnd, the counter is re-clocked (the read value remains stable one full frame), even if the frame is skipped (not captured), and reset to restart accumulation at the next frame.

Configuration example

A too aggressive bad pixel detection might detect false bad pixels and erroneously correct them (it can occur for very thin light vertical lines that cannot be distinguished from bad pixels in the implemented horizontal filter). To avoid such artifacts, it is advised to setup a software loop-back that tunes the filter strength so that the detected bad pixels remain within a predefined valid range.

Start configuration (or without software feedback loop):

- ENABLE = 1 (enabled)
- STRENGTH = 0 (high tolerance)

Software feedback loop:

Assumes a maximum amount of 100 bad pixels on the array (any other value can be used).

- BADCNT read: gets the amount of corrected bad pixels of the last frame
- Low-pass filter on the BADCNT, and/or hysteresis
  - BADCNT > 100: too aggressive, decrease STRENGTH
  - BADCNT < 30: too tolerant, increase STRENGTH (assuming there are bad pixel on the array)

Note: The expected amount of bad pixels (100 in the above example) can be set to other values, or made dependent upon the equivalent gain of the sensor (analog gain, exposure duration). A high-gain picture has more noisy pixels and can accept a more aggressive filter to smooth the noise, while a low-gain picture has mostly correct pixels, only very uncorrelated pixels need to be corrected.

39.6.5 Input decimation

The decimation makes it possible to cheaply downsize a frame, by a factor 2, 4, or 8, in both horizontal and vertical directions. It supports a special mode adapted to a raw Bayer format in input.

The decimation is redundant with the downsize, that brings a higher quality (the decimation discards the data of the dropped pixels, while the downsize averages all pixels and does not lose information).

The decimation has two main usages:

- Reduces the width of very high resolution sensors to one accepted by the raw Bayer-to-RGB conversion. Indeed, the raw Bayer-to-RGB embeds a line buffer that limits its processed images to a maximum width of 2688 pixels. The decimation makes possible, for instance, to plug a 12 Mpixel sensor (4000 x 3000), decimate its width by a factor 2x to 2000 pixels wide, and have it converted to RGB.
- Complements the downsize (limited to ratio of 8 x 8), to have a combined downsizing ratio of 64 x 64. It is recommended to have the largest ratio implemented in the downsize, and the decimation complement to that. For instance, for a ratio 30x, is it recommended to have a ratio 4x in decimation, and a ratio 30 / 4 = 7.5 in the downsize.

Features

- Forwards one item every 1, 2, 4, 8 pixels, independently, vertical and horizontal.
- Supports raw Bayer formats, where RG-GB components must remain grouped. In that mode the above forwarded items are not pixels, but a double component (for example R and G or G and B for a RGGB format), in both vertical and horizontal directions. For

instance, with a decimation of 2x, the input sequence R0, G0, R1, G1, R2, G2, R3, G3 gets forwarded as R0, G0, R2, G2 and not R0, R1, R2. The same applies vertically.

Software configuration

Table 343. DCMIPP_P1DECR bit function

Bit ID	Function	Value	Comments
HDEC[1:0]	Ratio (2 bits)	0	No decimation
		1	Ratio 1/2
		2	Ratio 1/4
		3	Ratio 1/8
VDEC[1:0]		0	No decimation
		1	Ratio 1/2
		2	Ratio 1/4
		3	Ratio 1/8

The raw Bayer mode in decimation is indirectly activated when the Datatype is defined as raw Bayer.

39.6.6 Black level calibration

This module suppresses a potential positive black level offset, which happens when the sensor sends non-null pixels when capturing a black picture.

Functionality

- Subtracts an offset from the R, G, B components.
- A different constant is used for R vs. G vs. B, including within raw Bayer pixels.

Software configuration

Table 344. DCMIPP_P1BLCCR bit function

Bit ID	Value	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components	-
BLCR	-	8-bit offset, for red
BLCG	-	8-bit offset, for green
BLCB	-	8-bit offset, for blue

The offset subtracted is aligned components MSB: for instance, if components are defined on 12 bits, the 8-bit offset subtracted for red is BLCR « 4.

Configuration example

It is possible to use the statistics extraction, to extract the long-term most-dark R, G, B components, and assign their darkness as black. Their RGB values become the black level offset for each RGB.

For a raw Bayer sensor with 12-bit components, if the measured black level offset for red is 64 (out of a maximum of 4095), configure BLCR as 16.

39.6.7 Exposure compensation and white-balance calibration

This module aims at compensating bad exposure (too short/dark or too long/light), and at compensating a bad color balance to recenter the colors to more white ones.

The exposure and white balance operations are purely linear, and do not distort colors if performed correctly.

Functionality

- Multiplies R, G, B by a configured floating-point constant.
- A different constant is used for R vs. G vs. B, including within raw Bayer pixels.

Software configuration

Table 345. DCMIPP_P1EXCR1 and DCMIPP_P1EXCR2 bit function

Bit ID	Value	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components	-
MULTR, SHFR	-	8-bit multiplier (mantissa), and up-shift value (0, 1, 2, 3, 4, 5, 6, 7) for red components.
MULTG, SHTG	-	8-bit multiplier and exponent, for green components.
MULTB, SHTB	-	8-bit multiplier and exponent, for blue components.

The idle setting (that sends out a similar value as input) is:

- MULTR = MULTG = MULTB = 128
- SHFR = SHFG = SHFB = 0

Similar idle couples are MULTx = 64 and SHFx = 1, or 32 and 2, or 16 and 3.

Configuration example for exposure alone

It is recommended to use the exposure control in conjunction with the contrast enhancement below in the pipe: the idea is to deliberately keep an exposure lower than ideal, to avoid burning the whites: the contrast enhancement, thanks to non-linear operator on luminance, lightens the dark pixels, and reduces the dynamic of the light pixels without burning them.

It is recommended to use the statistics to extract the average luminance across the whole frame (done best by extracting the R, G, B averages, and computing the luminance from the RGB).

The idea is to push the average output luminance to 128, or if working with the contrast enhancement too, to push it to a lower value, for instance 64.

When measuring an average luminance of 26 (target is 64), the exposure factor to apply is 64 / 26 = 2.5x = 1.25x * 2, hence the following configuration must be set:

- MULTR = MULTG = MULTB = 128 * 1.25 = 160
- SHFR = SHFG = SHFB = 1

Configuration example for an additional white balance

An example of easy way to recenter the colors is using the Gray-world algorithm.

This algorithm assumes that a default scene has an inherent balance of its red, green, and blue pixels, so that the average values of the red, green, and blue components across the ideal picture are the same. If the measured averages are not the same, it means that there has been a distortion of the white balance, that must be corrected by amplifying or reducing the red, green, and blue strengths in the exposure module, thanks to the differentiated red vs. green vs. blue multipliers and exponents.

In practice this is the same approach used for the exposure compensation, but, instead of forcing the output luminance to a default target (64 in the example), user must force the red, green, and blue averages towards the same exposure target.

As an example:

- Exposure target is defined as 64.
- Measured red is 26: red factor is 64 / 26 = 2.5x, hence MULTR = 160, SHFR = 1.
- Measured green is 32: green factor is 64 / 32 = 2.0x, hence MULTG = 128, SHFG = 1.
- Measured blue is 10: blue factor is 64 / 10 = 6.4x, hence MULTB = 205, SHFB = 2.

39.6.8 Demosaicing

The module works on the pixel pipes, and implements a mid-quality conversion from raw Bayer 8 bpp to an RGB 24 bpp, with no implicit half-sizing: the output RGB pixel rate is the same as the input component rate.

The conversion targets real-time but medium quality purposes, like display or low-resolution software analysis. For higher quality conversions, it is recommended to convert the raw Bayer in software, with higher quality algorithms but limited to non-real-time, thus still-picture applications.

The algorithm takes the surrounding 3 x 3 components in input, applies linear heuristics to determine the most likely missing components, and generates an output RGB888 pixel.

To provide the 3 x 3 input matrix to the algorithm, the demosaicing module embeds a double line-buffer, 2 x 2688 components wide. As such, it limits the maximum width of a converted demosaicing buffer to 2688 components/pixels wide. Wider camera sensor resolution can be connected and goes through the first decimation stage in front of the demosaicing operation.

Note: This demosaicing conversion algorithm can create some artifacts, like Zipper. Such artifacts are much reduced by a later downsizing or even suppressed for a 2 x 2 downsizing.

Applications like display, video encode, or software analysis usually require such a downsize, so the artifacts become invisible.

The underlying heuristic filters try to extract and adapt to edges, horizontal and vertical lines, and lone pixels.

Functionality

- Input pixel format: from 1 (raw Bayer) to three (RGB/YUV) components on 8 bits
- Max input width of 2688 components
- Demosaicing conversion:
  - 2-line buffer
  - provides a 3 x 3 matrix to the algorithm + one trailing component (2 left)
  - Extraction and optimization for specific shapes:
    - > Edges (on left, right, top, bottom)
    - > Lines (horizontal and vertical)
    - > Peaking (lone pixels detection)
- Output pixel format: three RGB components on 8 bits.

Software configuration

Table 346. DCMIPP_P1DMCR bit function

Bit ID	Values	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components.	If the camera sensor transmits an RGB or YUV frame and not raw Bayer, the demosaicing conversion must be disabled, by setting Enable = 0. All other parameters are ignored.
TYPE	– 0:RGGB – 1:GRBG – 2:GBRG – 3:BGGR	Default raw Bayer with three components (R, G, B)
EDGE	– 0: No edge detection, pure linear interpolation – 1 to 7: Relative algorithm strength (respectively 3, 4, 6, 8, 12, 16, 24)	-
LINEH	– 0: No horizontal line detection, pure linear interpolation – 1 to 7: Relative algorithm strength (respectively 3, 4, 6, 8, 12, 16, 24)	-
LINEV	– 0: No vertical line detection, pure linear interpolation – 1 to 7: Relative algorithm strength (respectively 3, 4, 6, 8, 12, 16, 24)	-
PEAK	– 0: No peak detection, pure linear interpolation – 1 to 7: Relative algorithm strength (respectively 3, 4, 6, 8, 12, 16, 24)	-

The four filters, EDGE, LINEH, LINEV, PEAK, improve the zoomed accuracy of the filtered picture (thus mostly luminance correctness, like no Zipper artifact), however at the expense of some chrominance blurring or distortion. Some scenes can require specific settings:

- Scenes where chrominance distortion is very visible (like a mostly black and white scene viewed by an RGB sensor) can require lower strength of the filters.
- On the opposite, scenes heavily loaded with geometric shapes (and thus source of artifacts) can require strengthening the filters.

Globally, 6/4/4/2 is a good compromise for the filter strength.

Configuration example

If the camera sensor is raw Bayer, with a grid with a red top-left pixel, the next configuration can be used:

- ENABLE = 1 to have the demosaicing active
- TYPE = 0 to have a top-red pixel, thus a RGGB grid
- EDGE, LINEH, LINEV, PEAK = (4, 4, 4, 4) as typical setting (so an internal strength of 8 for each parameter).

39.6.9 Color conversion

This module implements a color conversion with flexible (fully programmable coefficients), which can be used to map the following features:

- YUV-to-RGB: when the pixels of a YUV-sensor are used as RGB (display, GPU)
- RGB-to-YUV: when the pixels of a RGB-sensor are used by software (for example video encode)
- Tone change: to map special color references (sepia), emphasize some tone/colors
- Monochrome: to compute a monochrome from RGB/YUV with a specific linear mix
- Expansion: to handle a YUV (or RGB) expansion or compression
- Gamma: to emulate a gamma correction via a linear scale

Features

- Linear rotation of color space: 3 x 3 matrix + 3 x 1 column.
- Clamping optional on either [16 to 235] for Y, R, G, B and [16 to 240] for U, V.

Software configuration

Table 347. DCMIPP_PxCCyy (yy = R0, R1, G0, G1, B0, B1) bit function

Bit ID	Value	Comments
ENABLE	– 1: Activates the color conversion	-
CLAMP	– 1: Clamps the output pixel, when using a reduced dynamic	-
TYPE	– 1: Clamps as RGB – 0: Clamps as YUV	-

Table 347. DCMIPP_PxCCyy (yy = R0, R1, G0, G1, B0, B1) bit function (continued)

Bit ID	Value	Comments
Matrix3x3_Coeff	-	11 bits (sign, 2 int, 8 dec, with sign as complement to 2)
Added3x1_Coeff	-	10 bits (sign, 9 int, with sign as complement to 2)

Configuration example

Table 348 provides examples of the most used conversions:

- To / from RGB from/to YUV (as SDTV ITU-R BT.601 or HDTV BT.709).
- With a full (0 to 255) or a reduced (16 to 235) dynamic for Y and RGB, 16 to 240 for CbCr.
- Matrix fields are defined as XY bit fields in the color conversion coefficient registers, with X being the input R or G or B, and Y being the output R or G or B. For conversions to/from YUV, the R must be assumed as Cr (= V), G must be assumed as Y, and B must be assumed as Cb (= U).
- Coefficients are defined signed, and multiplied by 256 when there are decimals (the matrix coefficients). Negative values are on 11 bits: N11(val) = XOR (val, 0x7FF) + 1, on 10 bits for Added_Coeff: N10(val) = XOR (val, 0x3FF) + 1.

Table 348. Color conversion: examples of coefficients

Conversion	Output components	Input components				
RGB-255 to YUV601-255	-	R	G	B	Added	Clamping

	B	0	256	465	-232	[16 to 235]

39.6.10 Contrast enhancement

This module ends the image processing pipe. It makes possible to enhance the contrast of the frame, by non-linear emphasis of the luminance of the pixels, and to provide more luminance quantification steps at highly used luminances (usually central grays), by reducing the amount of quantification steps less used by the picture (usually the few very dark and very light pixels).

Functionality

- Inputs RGB from the pipe
- Computes the luminance of the local pixel
- Extracts the desired luminance increase/decrease factor, in function of the input luminance, non-linearly (using a look-up table)
- Multiplies the input RGB with the amplification factor
- Outputs the clamped RGB components on 8 bits

Software configuration

Table 349. DCMIPP_P1CTCR1,2,3 bit function

Bit ID	Values	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components	-
LUMx (x = 0 to 8, respectively inputs at 0, 32, 64, 96, 128, 160, 192, 224, 256)	0 to 63	Amplification factor: – LUMx = 8 halves the pixel luminance – LUMx = 16 does not modify the pixel luminance – LUMx = 32 doubles the pixel luminance

Configuration example

There are multiple approaches to handle contrasts.

It is possible to flatten the spectrum of luminance density (that is, to try have a similar amount of pixel per each segment of luminance), which is to fill each of the eight segments of luminance with 12.5% of the pixels of the frame.

An intermediate approach is to proceed with only the upper and lower half pixels: half of pixels must have a luminance below and another half above the mid-dynamic (128 for 8-bit components).

It is advised to use the statistics extraction module, sample the luminance after the exposure control (to avoid an impact on the exposure compensation), and sort it in the 12 available bins (refer to *Section 39.6.11*). From the extracted bins the user must linearly extrapolate the luminance of the median of the amount of pixels. The luminance of median pixel must be increased/decreased to be moved to the targeted output median luminance, which is recommended to be the median dynamic (128).

For instance, a 400 kpixels VGA picture can have 200 kpixels below a luminance of 64, and the other 200 kpixels above that value. The ideal luminance amplification factor can be set to 128 / 64 = 2x:

- pixels darker than 64 are lightened by a factor 2x
- pixels lighter than 64 are lightened a bit less, decreasingly
- pixel of luminance of 255 get an idle, 1x, factor.

The above assertions can be used to compute the LUMx values to configure:

- Ratio 2x from lum = 0 to 64:
  - LUM0 = LUM1 = LUM2 = 32.
- Decreasing ratio from 32 to 256, best exponentially decreasing:
  - LUM3 = 27
  - LUM4 = 23
  - LUM5 = 20
  - LUM6 = 18
  - LUM7 = 17
  - LUM8 = 16 (the maximum luminance, 256, must remain idle).

39.6.11 Statistics extraction

This module extracts several statistics across the frame, to provide inputs to the software image compensation algorithms, that configure feedbacks to the following implemented hardware modules: black level calibration, exposure compensation, white balance, and contrast enhancement.

The statistics are accumulated during a full frame, and sampled at the end of the frame, thus allows the software to have the full next frame to read the accumulated statistics, process them, define the adapted configuration for the hardware feedback modules, and to configure these modules.

Thanks the shadowing mechanism, the newly configuration parameters are active at the following frame, thus active at an average two frames after the statistics are accumulated. The statistics extraction block is considering all frames selected by means of the DCMIPP_P1FSCR configuration registers. Statistics block is running even when the frame is not supposed to be captured, respect to the DCMIPP_FCTCR configuration register.

The latency is not an issue, as the captured scene is expected to be almost static, and typical software compensation algorithms filter the statistic variations to avoid oscillations and visual artifacts (the low-pass filter typically has a one-second period).

Functionality

- Three statistics accumulators available, allowing three statistics extractions per frame.
  - Different types of statistics can be extracted frame over frame
- 32-bit accumulators, allowing to accumulate 8-bit samples over 16 Mpixels.
- Average mode, that extracts averages (accumulates component values)
  - Capability to discard extreme values (if value is <16 or >240, same for 32 or 64).
- Binning mode, which extracts presences (accumulates 256 per fit)
  - 12 available bins (values: <4, <8, <16, <32, <64, <128, and reverse to 256).
- Capability to define a sub-rectangle within the frame where statistics are extracted
  - Allows to focus the statistics on a specific region of interest.
- Raw Bayer supported, with the statistics using the specific locally available R, G, B components of the raw Bayer
- Statistics can be performed on either the input data (before any pixel modification) or after demosaicing, to benefit of a full RGB and thus luminance presence per pixel.

Software configuration

Table 350. DCMIPP_P1STyCR (y = 1, 2, 3), DCMIPP_P1STySR (y = 1, 2, 3), DCMIPP_P1STSTR and DCMIPP_P1STSZR bit function

Bit ID	Value	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components	-
MODE	– 0: Average mode	Values of pixels are accumulated as-is.
	– 1: Bin mode	Values of pixels are used to see if the pixel fits one of the 12 bins
SRC (3 bits)	– (R, G, B, L)_up	– Up: refers to sampling after decimation. – L: luma (Y') computed as R / 4 + G / 2 + B / 4 when receiving RGB pixels, (R or G or B) when in raw Bayer mode.
	– (R, G, B, L)_down	– Down: refers to sampling after demosaicing (raw Bayer to RGB conversion), thus after both the exposure and white balance compensation, and when true RGB components (and thus luminance components) are available.

Table 350. DCMIPP_P1STyCR (y = 1, 2, 3), DCMIPP_P1STySR (y = 1, 2, 3), DCMIPP_P1STSTR and DCMIPP_P1STSZR bit function (continued)

Bit ID		Value	Comments
BINS (2 bits)	MODE = Average	– 0: AllPixels: no components are rejected – 1: NoExt16: components are rejected if < 16 or ≥ 240 – 2: NoExt32: components are rejected if < 32 or ≥ 224 – 3: NoExt64: components are rejected if < 64 or ≥ 192	Enables to reject extreme data, not accumulated for statistics. Additional statistics (with MODE = Bin) are needed to count the amount of selected pixels. BINS = 0 is likely to be the most used setting.
	MODE = Bin	– 0: Low: Accu0 counts if V < 4, Accu1 if V < 8, Accu2 if V < 16 – 1: LowMid: Accu0 counts if V < 32, Accu1 if V < 64, Accu2 if V < 128 – 2: UpMid: Accu0 counts if V ≥ 128, Accu1 if V ≥ 192, Accu2 if V ≥ 224 – 3: Up: Accu0 counts if V ≥ 240, Accu1 if V ≥ 248, Accu2 if V ≥ 252	Counts the amount of components V.
CROPEN (1 bit)		– 1: Statistics extracted from sub-rectangle – 0: Statistics extracted from whole frame	-
VSTART (12 bits)		-	Upper position of rectangle, from which statistics are extracted.
HSTART (12 bits)		-	Left position of the rectangle, from which statistics are extracted.
VSIZE (12 bits)		-	Height of the sub-rectangle, from which statistics are extracted.
HSIZE (12 bits)		-	Width of the sub-rectangle, from which statistics are extracted.
ACCU (24 bits)		-	Result of the 32-bit accumulation, re-sampled at frame boundary, and divided by 256 to fit the ACCU width of 24 bits.

Note: If HSIZE or VSIZE = 0 when the CROPEN bit is set, the block internally forces the “0” value at the maximum for the corresponding bit field (i.e. 0xFFE).

Table 351. Statistics extraction: collected data vs. modes

Mode	Average		Bin	
SRC	RGB	Raw	RGB	Raw
R, G, B up	012 = R / G / B	012 = RGB / 0 / 0	012 = R / G / B	012 = RGB / 0 / 0
L up	012 = R / 4 + G / 2 + B / 4	012 = RGB + 0 + 0	012 = R / 4 + G / 2 + B / 4	012 = RGB + 0 + 0
R, G, B down	012 = R / G / B	-	012 = R / G / B	-
L down	012 = R / 4 + G / 2 + B / 4	-	012 = R / 4 + G / 2 + B / 4	-

Configuration example for exposure control

For exposure control and white balance calibration, user would typically extract the average values of the luminance, and of the R, G, B. It can be done in a single frame capture campaign, with the following settings:

- ENABLE = 1 (enabled)
- MODE = 0 (average mode)
- SRC = 0 for red, 1 for G, 2 for B (upper values, before processing)
- BINS = 0 (all pixel values)
- CROPEN = 1 (1 below: to select a 300 x 220 close to top-left corner: 10,10)
- VSTART = 10
- HSTART = 10
- VSIZE= 220
- HSIZE= 300

After one frame (after a VSync), the Accu0, Accu1, Accu2 counters contain, respectively, the average red, green, blue accumulated across the 300 x 220 rectangle.

The value to expect from the Accu0, Accu1, Accu2 can be computed according to the following hypotheses:

- Amount of pixels: 300 x 220 (or full frame if statistics has CROPEN = 0)
- Amount of components:
  - Raw Bayer-red: 1/4, as one pixel every four in raw Bayer has a red component.
  - Raw Bayer-green: 1/2, as one pixel every two in raw Bayer has a green component.
  - Raw Bayer-blue: 1/4, as one pixel every four in raw Bayer has a blue component.
  - RGB: 1, as all pixels contain R, G, B components.
- Average value on 8 bits: 128 typically for a mid-gray picture (RGB: 128, 128, 128).
- Re-sampling: 1/256 (re-sampling accumulator to ACCU at end of frame).

The expected values in the accumulators are:

- Accu0 (red): 300 x 220 / 4 x 128 / 256 = 8250
- Accu1 (green): 300 x 220 / 2 x 128 / 256 = 16500
- Accu2 (blue): 300 x 220 / 4 x 128 / 256 = 8250

Configuration example for contrast enhancement

For contrast enhancement, the amount of pixels with a luminance inside a bin is typically extracted. As statistics are extracted 3 by 3, and as 12 bins can be accumulated, data are extracted during four consecutive frames, with three different bins for each frame.

The typical configuration is the following:

- ENABLE = 1 (enabled)
- MODE = 1 (bin mode)
- SRC = 3 (upper value, luminance selected)
- BINS = 0 (then, at next frame 1, then 2, then 3)
- CROPEN = 0 (no stat sub-rectangle)

After one frame (after a VSync), Accu0, Accu1, Accu2 counters contain the amount of pixels fitting bins <4, <8, <16, respectively.

The value to expect from the Accu0, Accu1, Accu2 can be computed by multiplying the following:

- Amount of pixels: 640 x 480 (assuming a full frame resolution of VGA).
- Amount of components: 1 (all pixels contribute to the luminance, even in raw Bayer).
- All pixels contribute to the statistics, both in raw Bayer and in RGB. In raw Bayer, a fake statistics is extracted, assuming a RGB-balanced pixel (Gray-world algorithm).
- Average value for bins: 256 (as in Bin mode, 256 is added for each fitting presence).
- Re-sampling: 1/256 (at end of frame)

The resulting value in accumulators are:

- Accu0 (bin < 4): 640 x 480 x 1 x 256 / 256 x 1% = 3072 (assuming 1% of pixels have lum < 4)
- Accu1 (bin < 8): 640 x 480 x 1 x 256 / 256 x 3% = 9000 (assuming 3% of pixels have lum < 8)
- Accu2 (bin < 16): 640 x 480 x 1 x 256 / 256 x 8% = 24000 (assuming 8% of pixels have lum < 16)

At the following frame, with BINS = 1, the statistics for luminance <32, <64, <128 are extracted, providing figures like 72k (25%), 144k (50%), and 210k (75%).

Such values indicate a median luminance ~64, as 50% of the pixels have a luminance <64.

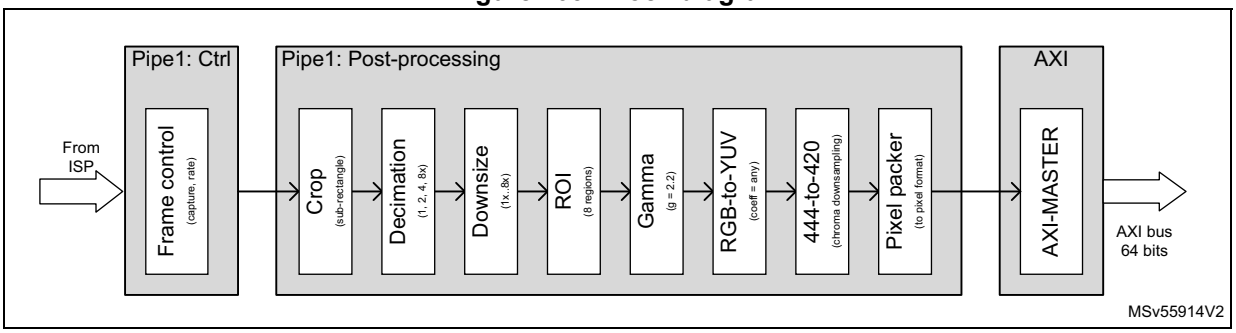
39.7 Pipe1 (post-processing part)

39.7.1 Overview

The post-processing Pipe1 (whose diagram is shown in *Figure 403*) is a pixel pipeline in which post-processing functions are integrated to relieve the software from very specific operations (time and memory consuming), like:

- Crop, to keep only the part of the picture required by the targeted application
- Decimation, as a cheap preprocessing before the downsize
- Downsize, to reduce the picture resolution (size reduction)
- ROI signaling
- Gamma correction before sending the data to the memory for further displaying operations
- YUV conversion with possible down-sampling option, to optimize the memory size needed to store the corresponding image or to match a YUV420 video encoder.

Figure 403. Block diagram



The applicative Pipe1 is the most featured pixel pipeline, even if the image processing functions can be shared with Pipe2 (refer to *Section 39.8.2*).

Pipe1 can be reconfigured from time to time. Some events can be used to trigger the software reconfiguration routines (refer to *Section 39.13.2*).

It is also possible to write into the shadow registers during the processing of a frame. The values are loaded into the physical register based on the following start of frame event.

39.7.2 Pixel 2D cropping

The pixel 2D cropping aims at extracting and forwarding a rectangle of pixels.

The cropping assigns an X and Y location to its input pixels, and selects a configured rectangle among the pixels, and forward the pixels of this rectangle farther in the pixel pipe. The pixels around the selected rectangle are discarded.

Functionality

- Counts lines thanks to HSync (if from parallel interface) or packets (if from CSI-2)
- Counts pixels inside a line
- Positive cropping (forwards a selected rectangle of pixels in the pipe)
- Cropping with 0 value for HSIZE[11:0] or VSIZE[11:0] forces the internal crop to get the maximum value on the parameter where the software sets to the 0 value

Software configuration

Table 352. DCMIPP_PxCRSTR and DCMIPP_PxCRSZR bit function

Bit ID	Values	Comments
ENABLE	– 1: Cropping active – 0: All data transmitted	-
HSTART, VSTART	0 to 4094	Top-left corner of the cropped rectangle.
HSIZE, VSIZE	0 to 4094	Width and height of the cropped rectangle. Can be larger than the received picture to grab everything.

If the cropped window is larger than the received window, only the received pixels are forwarded (no pixels are inserted to match the window size).

If the software sets 0 in one or both horizontal/vertical size bit fields (HSIZE, VSIZE), the crop forces internally the value to be at the maximum on the corresponding bit field.

Configuration example

To select a small rectangle (size 100 x 50), whose upper pixel is located at position (30, 10), provide the following setting:

- ENABLE = 1 to crop a sub-rectangle
- HSTART, VSTART = (30, 10) to start cropping at x = 30, y = 10 of the received picture
- HSIZE, VSIZE = (100, 50)

The most bottom-right selected pixels have a position (129, 59) from the received picture.

The frame forwarded is handled downstream in the pipe as a 100 x 50 frame.

39.7.3 Decimation pre-downsize

The decimation (prior to downsize) makes it possible to cheaply downsize a frame by a factor 2, 4, or 8x, in both horizontal and vertical directions.

The decimation is partially redundant with the downsize, that brings a higher quality (the decimation discards the data of the dropped pixels, while the downsize averages all pixels and does not lose information).

The decimation complements the downsize (limited to ratio of 8 x 8), to have a combined downsizing ratio of 64 x 64. It is recommended to have the largest ratio implemented in the higher quality downsize, and have needed the decimation complement to that. For instance, for a ratio 30x, is it recommended to have a ratio 4x in decimation, and a ratio 30 / 4 = 7.5 in the downsize.

Features

- Forwards one item (typically pixel) every 1, 2, 4, 8 pixels, independently vertical and horizontal.

Software configuration

Table 353. DCMIPP_PxDCCR bit function

Bit ID	Function	Value	Comments
HDEC[1:0]	Ratio (2 bits)	0	No decimation
		1	Ratio 1/2
		2	Ratio 1/4
		3	Ratio 1/8
VDEC[1:0]		0	No decimation
		1	Ratio 1/2
		2	Ratio 1/4
		3	Ratio 1/8

39.7.4 Downsize

This module implements a downsize based on box filtering, which allows ratios from 1x to 8x, independently, in both X and Y directions.

The box filter has properties close to a bilinear filter for small ratios (from 1x to 2x), but provides the advantage of avoiding some Moiré effect for higher ratios (from 2x to 8x) thanks to using all the samples.

Functionality

- Features:
  - Integer + decimal ratio, different vertically and horizontally.
  - Ratio: 1.0x to 8x
  - Limited to a maximum output buffer width of 2688 pixels due to the needed linebuffer.
- Operations:
  - Increments defined with 3.13 precision (<1 pixel error after maximum width of 4094)
  - Internal computations for filter defined with 3.3 precision
  - Accumulates skipped pixels to allow ratio up to 8x with saturation on 11 bits
  - Weighting of shared pixels, to allow good quality at ratio close to 1
  - Independent H filter, then V filter
  - Init phase: left of left-most pixel is aligned on input pixel (see below Pi0, Po0)

Software configuration

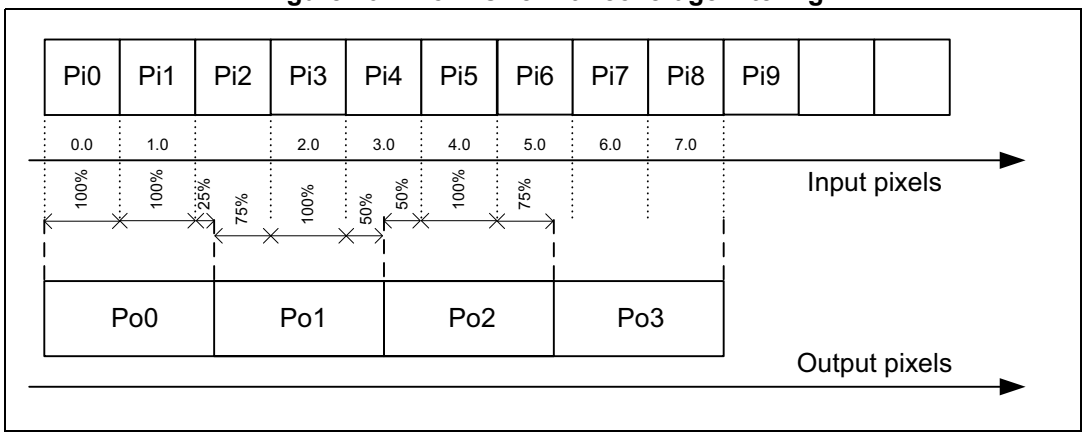
Table 354. DCMIPP_PxDSCR, DCMIPP_PxDSRTIOR, DCMIPP_PxDSSZR

Bit ID	Function	Values	Comments
ENABLE	-	– 1: Downsize active – 0: Transmission without downsize	-
HRATIO, VRATIO	Downsize ratio (respectively horizontally and vertically)	16-bit fields, used as unsigned 3 integer 13 decimal. Valid values are 8192 (= 1x) to 65535 (= 7.999x).	Key parameters that create output pixels. The optimal is computed as xRATIO = Floor (8192 * xRatioFloatingPoint), maximum value 65535 (x = H or V).
HDIV, VDIV	Inverted ratio, must be consistent with Ratio	10-bit fields, used as unsigned 10 decimal. Valid values are 128 (= inv8x) to 1023 (= inv1x).	A side parameter, impacts only the luminance of the output pixels. The optimal in function of xRATIO is xDIV = Floor((1024 * 8192 -1) / xRATIO) (x = H or V).
HSIZE, VSIZE	Final size after the downsize	-	The downsize filter clips pixels if the post-downsize size is not correct. The HSIZE and VSIZE are partially redundant vs. the cropping size divided by the downsize ratio. If VSIZE = 0 or HSIZE = 0, the filter is disabled in that dimension.

Figure 404 shows the principle of the computations:

- Po0 = (1.00 x Pi0 + 1.00 x Pi1 + 0.25 Pi2) / 2.25
- Po1 = (0.75 x Pi2 + 1.00 x Pi3 + 0.50 Pi4) / 2.25
- Po2 = (0.50 x Pi4 + 1.00 x Pi5 + 0.75 Pi6) / 2.25

Figure 404. Downsize with coverage filtering



Configuration example

- ENABLE = 1 to activate the downsize
- Downsize ratio 1x: HRATIO = VRATIO = 8192, HDIV = VDIV = 1023
- Downsize ratio 2x: HRATIO = VRATIO = 16384, HDIV = VDIV = 512
- Downsize ratio 3x: HRATIO = VRATIO = 24576, HDIV = VDIV = 341
- Downsize ratio 8x: HRATIO = VRATIO = 65535, HDIV = VDIV = 128

39.7.5 Regions of interest (ROIs)

Pixel pipes can defined up to eight different ROIs to highlight areas on a picture. The purpose of this feature is to draw one rectangle with user size defined for each enabled ROI.

There is no hardware processing within the defined area applied on the image. As the aim is to draw rectangles on a display, the ROI is supposed to be used when the data flow is RGB at the output of the image processing blocks.

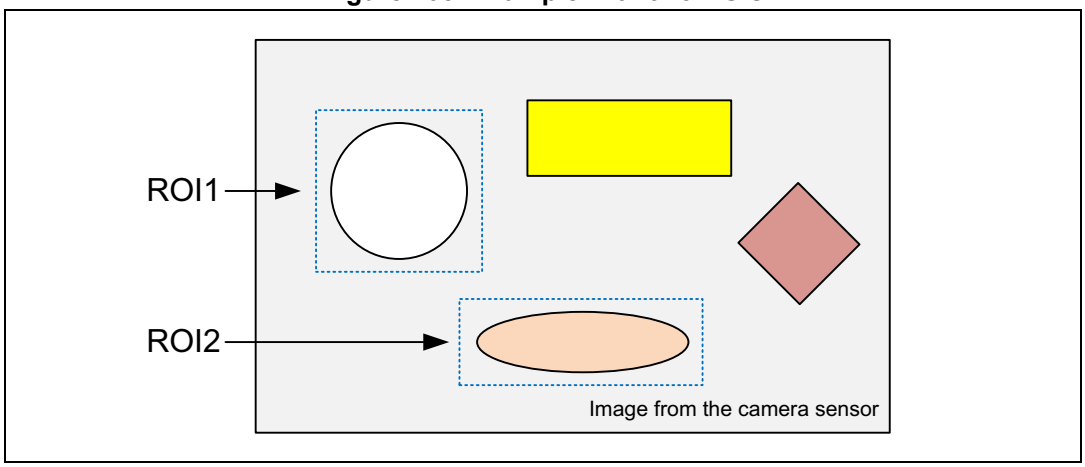
The line width is configurable commonly for each ROI thanks to bit-field ROILSZ[1:0] of the DCMIPP_PxCMRICR register. The color line is configurable per ROI to make easy visual distinction between each region of interest.

Each configuration is valid for a frame and it may be changed frame by frame by reprogramming the registers by software.

Each ROI can be enabled independently for displaying purpose.

Figure 405 shows a basic example of two ROIs displayed within a frame to isolate two flights (it is only visual information). The application can decide to crop the area to work on these two ROIs, by reprogramming the crop area for the next frames to make appropriate analysis linked to the application target.

Figure 405. Example with two ROIs



Software configuration

The first action is the configuration of DCMIPP_PxCMRICR, the common register to activate the ROI and to select the line width applied to all the active ROIs within a frame:

- ROIyEN (y = 1 to 8): each ROI can be enabled during the frame.
- ROILSZ: select the line width in pixel (1, 2, 4 or 8 pixels wide).

The second step is the configuration of each ROI, independently, through registers DCMIPP_PxRIyCR1 and DCMIPP_PxRIyCR2. The color line, among others, is set during this step.

- VSTART and HSTART bit fields allow to set the origin point of the rectangle for a given ROI. The origin is located on the top-left pixel, within the colored lines.
- VSIZE and HSIZE bit fields are used to set up the vertical and horizontal size in pixel for the area to draw. The size of the rectangle is measured the colored lines.
- CLR, CLG, CLB are used to select the color among 64. Each component has its two bits duplicated to 8-bit, to get an RGB888 at the output of the ROI block

39.7.6 Gamma conversion

This feature implements a gamma compression on each R, G, B component, using a static gamma exponent 2.2, to store gamma-compressed pictures, as defined in the sRGB standard.

Features

- The gamma is implemented as a 7-segment linear curve.
- It crosses the following way-points, in logarithm spacing:
  - (0,0)
  - (4,39)
  - (8,53)
  - (16,72)
  - (32,99)
  - (64,136)
  - (128,186)
  - (256,256)

Software configuration

ENABLE = 1 in the DCMIPP_PxGMCR registers activate the color conversion.

39.7.7 YUV conversion

This block is a replication of the one described in *Section 39.6.9*, used to convert RGB in YUV color format (basically, since the conversion YUV to RGB is assumed to be performed by the color conversion block into the image processing main function). Bit fields are the same of the color conversion module, only the register name and the memory mapping are different. The register functions are the same, the register names are DCMIPP_P1YUVxxx instead of DCMIPP_P1CCxx.

39.7.8 Chroma down-sampling

The Chroma down-sampling module reduces the chroma resolution from its arriving YUV444 format to the potential YUV420 output, and sends them to a different channel.

Features

- Downsizes in H first, if YUV420, with (0.5 + 0.5) filter
- Downsizes in V then, if YUV420, with (0.5 + 0.5) filter
- Memory: embeds one half-line buffer for each U and V

Software configuration

Configuration is indirectly taken from the pixel packing output format, located in the DCMIPP_PxPPCR register.

- The Chroma down-sampling is active when the output pixel format is YUV422-1, YUV422-2, YUV420-2, YUV420-3.

Output

- One to three channels: RGB/Y, UV (or U) and V.

39.7.9 Pixel packing

This module works on the dump pipe (Pipe0) and pixel pipes (Pipe1 .. N), setting the arriving pixels in memory words.

Features

- DBM addresses: double buffer mode with their associated address locations if the application need to swap memory address for one frame to the next one.
- Flexible pitch (line stride): width up to 4094 pixels, 32 bpp, potentially interleaved.
- Pixel format: all usual formats, as indicated in *Section 39.3.6* (Pipe1 allows semi-planar and full planar buffer, Pipe2 coplanar buffer only).
- Swap R-vs-B: swaps the red vs. the blue component.
- Padding: MSB vs. LSB padding of 10/12/14 bit onto 16 bit. (such formats are supported only on the dump pipe).
- Header enable: allows to dump (or not) the CSI packet headers, to allow software an easier extraction of data in case of Interleaved CSI packets in the captured buffer.
- Multi-line event: event generated (for DMA and INT) at each multiple of sent lines.
- Multi-line address wrapping: allows to write the full frame across a ping-pong buffer, thanks to wrapping back to the BaseAddress after a power-of-2 amount of lines.

Note: Some features (for example padding) are available only on the dump pipe, while others (like swap R-vs-B) are available only on the pixel pipes.

Table 355. DCMIPP_PxPPCR bit function

Bit ID	Function	Value	Comments
M0A, M1A, M2A	Base address of pixel buffer in memory, 32-bit wide, aligned on 16 bytes	-	The line alignment of the pixel buffers in memory is assumed on 16 bytes. Therefore the buffer base address (i.e. M0A, M1A, M2A) must be a multiple of 16 bytes, and similarly for line PITCH.
PITCH	Address jump from line to line, up to 32 Kbyte - 1.	-	Aligned on 16 bytes.

Table 355. DCMIPP_PxPPCR bit function (continued)

Bit ID	Function	Value	Comments
SWAPRB	Swaps R-vs-B components (and U-vs-V, same operation if Y mapped on G) available on pixel pipe and not on dump pipe.	-	-
HEADEREN	-	– 1: Dumps headers	Feature present only in dump pipe.
PAD	MSB vs. LSB padding of the raw Bayer and monochrome to 16 bpp.	– 0 (align on LSB): backward compatibility with the former DCMI IP – 1 (align on MSB): easier use by software or GPU	Applies only on the dump pipe and for the 10/12/14 (not 8)-bit pixels (the pixel pipe convert pixels into 8 bpc, and padding is therefore not relevant).
FORMAT	Output pixel format	-	– Pipe0: not defined as default input format used for dump. It allows unique formats ByteData, ByteHeader and Mono/raw Bayer 8/10/12/14. – Pipe1: adds semi- and multi-planar formats: YUV 422-2, 420-2, 420-3 if Alpha or X is dumped, they are forced at 255). – Pipe2: supports coplanar pixel formats xRGB8888 (=xYUV444), RGB888 (=YUV444), RGB565, YUV422-1 and Y8.
LINEMULT	Periodicity of the line (HSync) interrupt and event, as power of 2 of LINEMULT configuration (i.e. every 1, 2, ..,128 lines).	-	-
LMAWE	Enable line multi address wrapping (see *LMAWM*)	-	-
LMAWM	Periodicity of the address wrapping to BaseAddress, period given as power of 2 of LMAWM configuration (i.e. every 1, 2, ..,128 lines).	-	-

Double buffer mode

The dump pipe uses an AXI master interface to dump the data from the internal FIFO to the external memory. In the application, it is possible to handle frame data swapping memory area frame by frame. The double buffer mode fills up this function. There are two memory address registers set to initialize the base addresses of these memories areas. Each start of captured frame event swaps the memory base address to handle double buffering mode. The double buffer mode can be used to allow post-processing on a buffer (frame buffer), while the other buffer is read to be displayed (display buffer).

Software configuration

Double buffering mode requires an activation and addresses configuration to define the two memory areas in which data are consecutively stored frame by frame at the output of the pipeline:

- DCMIPP_PxPPM0AR1 and DCMIPP_PxPPM0AR2 must be filled with the memory addresses associated to the double buffer memory locations.
- Bit DBM in the DCMIPP_PxPPCR registers is set to enable the double buffer mode.

Streaming across a ping-pong buffer

The DCMIPP has the capability (pixel pipes only) to stream pixels to a slave IP (like VENC or any) without storing the full frame in the main memory, by writing to a short intermediate multi-line buffer. It can do so by configuring the LINEMULT, LMAWE and LMAWM fields.

As an example, the slave IP is a JPG encoder that expects to be provided lines of macroblocks (16x16 pixels). The DCMIPP writes into a double (ping-pong) buffer, with each 16 lines high.

The streaming flow is as follows:

1. At a start of frame, the DCMIPP writes its pixels at an incremented address starting at the buffer BaseAddress (M1A/M2A).
2. After having written 16 lines, it emits a hardware Line event (dcmipp1_pXline_evt). At the reception of this hardware trigger, the slaved IP (JPG encoder here) starts to read the first 16-line buffer at the BaseAddress, and to encode its pixels.
3. The DCMIPP continues to write at the following addresses, thus after line 16.
4. After having written another 16 lines, the DCMIPP emits another Line event, to that the slaved IP can read and process the following 16 lines (at BaseAddress + Line16).
5. The DCMIPP wraps back to the BaseAddress, writes the following lines (32 to 47) starting at this BaseAddress, and then sends a trigger to the slave IP to process these new 16 lines.

The needed configuration is the following one:

- LINEMULT = 0x4, to send an event after having written each 16 lines
- LMAWM = 0x5, to wrap the address after having written each 32 lines
- LMAWE = 1, to enable the address wrapping of the address.

39.7.10 Overrun detection

This logic handles flow-control hazards: the DCMIPP is provided a continuous flow of data (via parallel or CSI2 interfaces) without any wait/hold capability, while downstream of DCMIPP, the access to memory can be temporarily stuck.

In some cases the internal FIFOs of the DCMIPP get full and pixels may be deleted. The overrun detection logic handles such hazard at best.

Features

- Software gets warned in case of an hazard:
  - Interrupt OVR is triggered at the first deletion of a pixel, repeated at every frame, as long as the overrun hazard is present.
  - It is recommended to skip / trash the impacted frame:
    - > Overflowing pixels are deleted, so that when the access to memory resumes, the remaining of the line is discarded (not written out). The normal processing resumes at the start of the next line. Potentially, several full lines can get discarded.
- No Frame-to-Frame impact in case of an hazard:
  - VSync resets what is needed in the DCMIPP, so that any hazard on a previous frame has no impact at all on the pixels dumped in next frames.

Software configuration

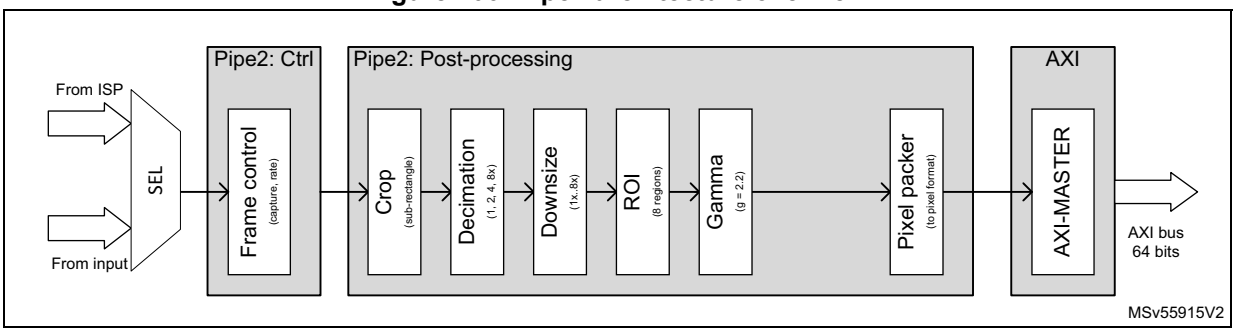
- Interrupt DCMIPP_PxSR.OVRF is warned in case of hazard.

39.8 Pipe2 (post-processing)

39.8.1 Overview

Pipe2, compared to Pipe1, is a lighter pixel pipeline offering no embedded image processing blocks. This pipe can work in standalone mode, or share the image processing functions with Pipe1 (refer to *Section 39.8.2*).

Figure 406. Pipe2 architecture overview



The main blocks (controller and post-processing general functions) of Pipe2 are almost the same as those of Pipe1. The flow selection and frame controller allow to configure Pipe2 behavior when it is used in standalone, meaning without image processing heritage from Pipe1. Refer to *Section 39.4.4* and *Section 39.4.5* for more details about the use cases and the configuration of the pipe.

The set of post-processing blocks is reduced compared to Pipe1, as neither the YUV conversion nor the down-sampling YUV444 to YUV420 are integrated in Pipe2. This pipe can have its own image crop area, its dedicated downsizing, and take benefit of the gamma correction, like Pipe1. Refer to *Section 39.7* and to its subsections for more details on how to use and configure by software these post-processing functions.

Software configuration

To use Pipe2 as a standalone pixel pipe, without any image processing functions shared with Pipe1, bit PIPEDIFF must be set in the DCMIPP_P1FSCR register. This bit has a meaning only when the flows can be differentiated, that is, when the camera connected and processed by the DCMIPP is a CSI2 camera interface.

In this non-shared mode, it is required that different flows are sent to Pipe1 and Pipe2, or a non-supported behavior can occur.

The flow to Pipe1 and the flow to Pipe2 may potentially be interleaved at packet level.

Pipe2 may be reconfigured time to time. Some events may be used to trigger the software reconfiguration routines (refer to *Section 39.13.2: Interrupts*).

It is possible also to write into the shadow registers within the processing of a frame. The values are loaded into the physical register based on the start of frame event.

39.8.2 Pipe1 and Pipe2 sharing image processing functions

Following the application, it may be interesting to share the image processing functions belonging to Pipe1 with Pipe2 when the dataflow is shared for both. One pipe may be used for display operation, and the other one used for statistics or software analysis. In this case PIPEDIFF bit of DCMIPP_P1FSCR register must be cleared.

If the CSI-2 module is connected to the DCMIPP, the VC DT and DTMODE of Pipe2 are the same as those configured into DCMIPP_P1FSCR register, making non relevant the values for these fields into the DCMIPP_P2FSCR register. However, bits CPTREQ and CPTMODE remain active into the DCMIPP_P2FCTCR register to control the flow inside Pipe2.

39.9 Application use cases

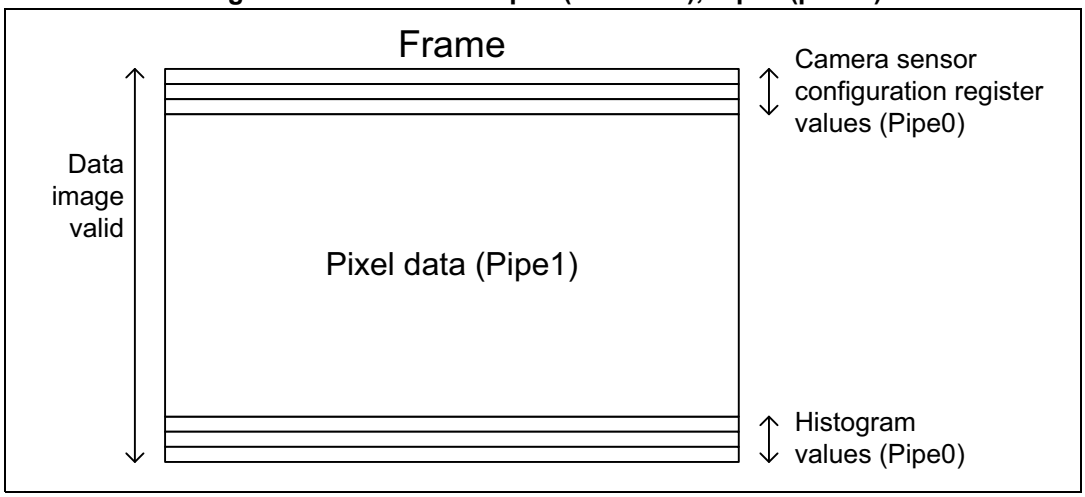
There are several application use cases that can fit the DCMIPP architecture, a few of them are described in this section.

39.9.1 Parallel interface camera sensor module

A parallel interface camera sensor can transfer images as well as statistics. It is easier to manage the software processing by splitting the statistics and the image data on different memory storages. Two pipes are used in such case, with Pipe0 extracting the statistics and Pipe1 dealing with the image data (whatever the data format supported by the DCMIPP). Both work in parallel on the same frame, frame by frame. Each output FIFO attached to the pipe conveys the data on the targeted memory for further processing.

The camera sensor module may use some lines of the frame to transfer statistics or sensor configuration data. These lines can be placed at the beginning and at the end of the frame (see *Figure 407*), even if there is no real standard.

Figure 407. Use case: Pipe0 (statistics), Pipe1 (pixels)



Software configuration

- Pipe0: select the crop area to extract statistics only
  - Configure HSTART[11:0] = 0 and VSTART[11:0] bits in the DCMIPP_P0SCSTR register from the line number corresponding to the first pixel data line (after first statistics line).
  - Configure HSIZE [11:0] (horizontal screen resolution in number of data 32-bit equivalent to the horizontal resolution of the screen in pixels) and VSIZE [11:0] to the value corresponding to the offset line number from the first pixel data area. These bits are in the DCMIPP_P0SCSZR register.
  - Set bit POSNEG of the DCMIPP_P0SCSZR register to reject data belonging to the rectangle defined, to keep the outside area of the rectangle, where the statistics are taken in this use case.
- Pipe1: Select the area to extract the statistics into DCMIPP_P1SRCR register, by configuring bit FIRSTLINE[11:0] and LASTLINE[11:0] (it avoids to start the image processing on statistics data). Only the pixel data are forwarded, if needed, to the image processing blocks (for example demoisaicing, auto exposure, contrast enhancement) for further processing.

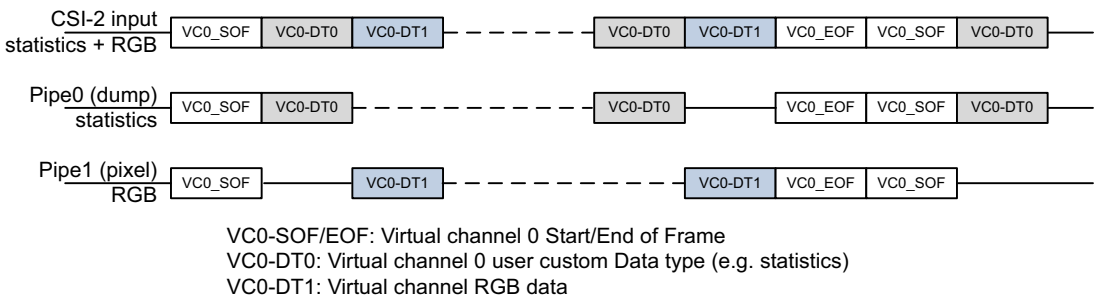
39.9.2 CSI2 camera sensor module

The CSI2 protocol allows, thanks to Datatypes, to make distinction between different data categories. The application may request to handle interlaced video as well as interleaved data flow like described below.

Single virtual channel involving two pipes (for example Pipe0 and Pipe1)

- Use case: the CSI provides two data flows in parallel, typically RGB (or raw Bayer) with its sideband statistics.
- Handling: the statistics are dumped by the dump pipe, while the pixels are sent to the pixel pipes.

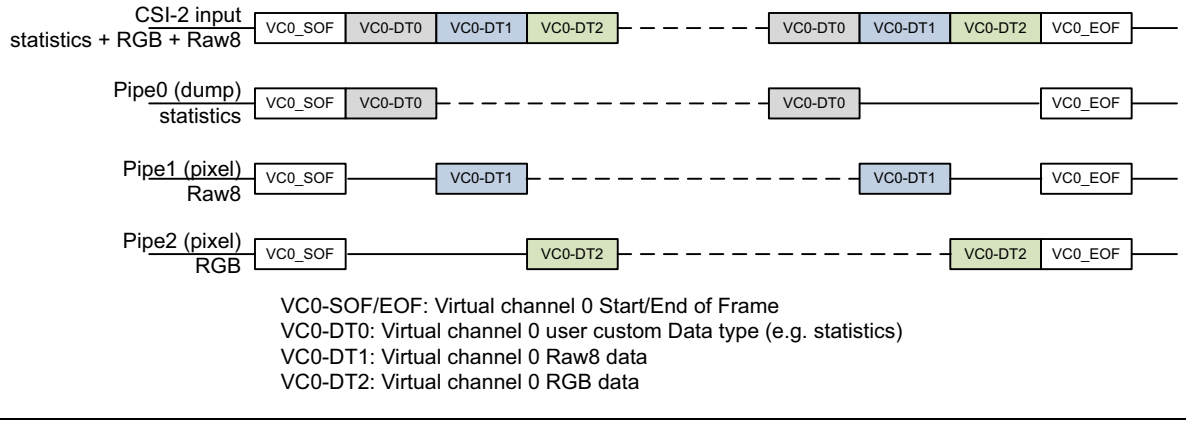
Figure 408. Statistics and RGB data for single virtual channel data flow



Single virtual channel involving three pipes (for example Pipe0, Pipe1 and Pipe2)

Another use case (*Figure 409*) employs different Datatypes in addition to the statistics within the CSI-2 flow based on a single virtual channel.

Figure 409. Three pipes within a single virtual channel in CSI2 mode



Interleaved packets (based on multiple virtual channels)

- Use case: the CSI provides two pixel flows in parallel, typically a JPG-compressed flow and an RGB888 or raw Bayer flow.
- Handling: the JPG is dumped by the dump pipe, while the pixels are sent to the pixel pipes.

Both Pipe1 and Pipe2 can process these pixels. The shared demosaicing mode can be used, hence both Pipe1 and Pipe2 benefit of the potential demosaicing conversion.

Figure 410. Handling interleaved packet

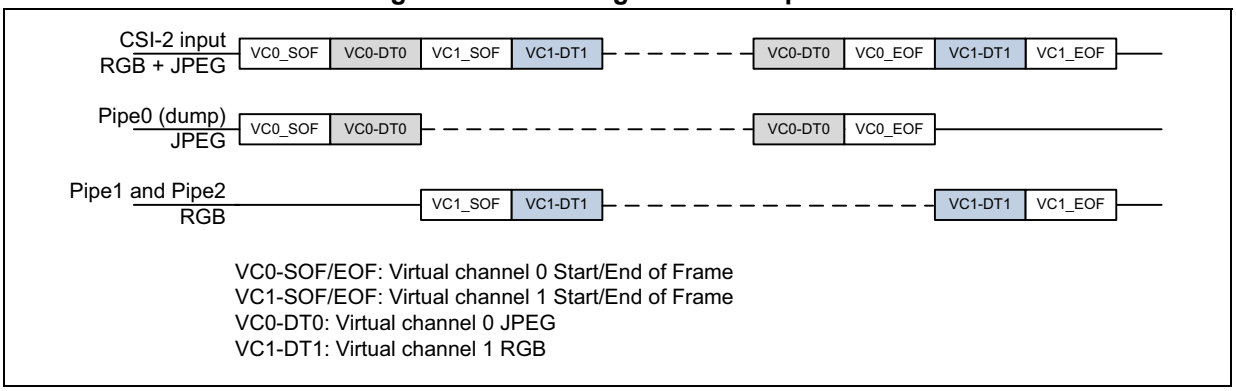


Figure 411. Handling interleaved packets across two pixel pipes

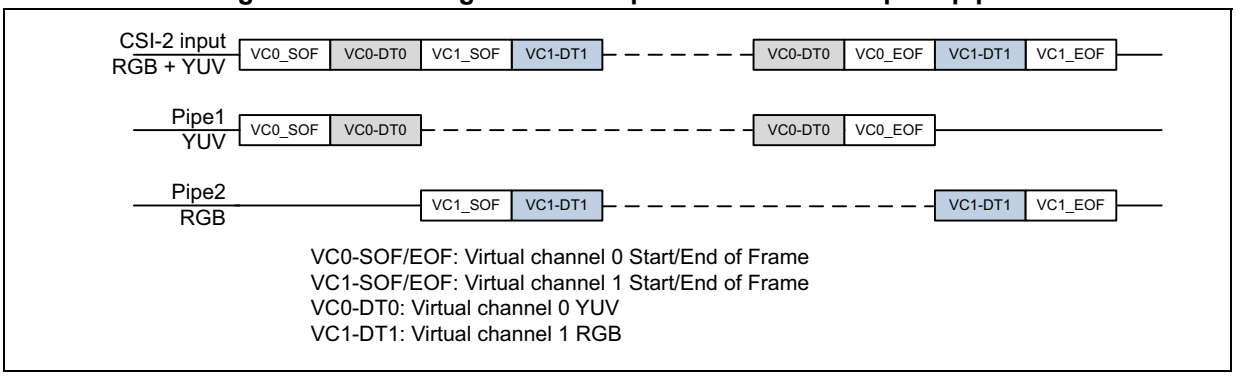

Interlaced video

- Use case: the CSI provides the odd and even frames of an interlaced video onto two different virtual channels (usually with a same data type).
- Handling: the flows of both the virtual channel of the odd field and the virtual channel of the even field are sent to the pixel pipes.
- Single pixel pipe may be configured if the image processing function is required by the application to handle both interlaced frame (refer to *Figure 412*). In such case, a pipe reconfiguration is needed frame by frame to change the virtual channel number and the address memory for the output buffer if the software distinctly keeps the odd and even frame buffers in their respective memory locations.
- Pipe1 and Pipe2 may be used if the application software does not need image processing functions (refer to *Figure 413*). Each pipe is configured with its own virtual channel and its own output buffer address in memory. The split of the odd and even frames is explicitly defined in a static way, avoiding any pipe reconfiguration between two frames.
- Interlaced video can be managed with a single virtual channel identifier, using a different data type to identify odd and even frames. In such case, the CSI2 bridge uses user Datatypes to distinguish between them.
- Limitation: the frames of the two virtual channels must be time-exclusive, by default the case for usual interlaced video sensors.

Figure 412. Interlaced video (based on single pixel pipe)

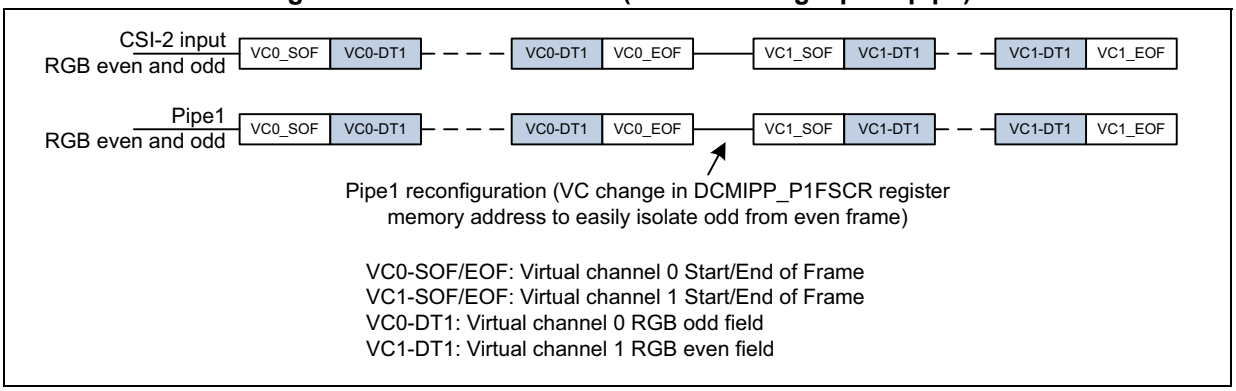

Figure 413. Interlaced video (based on two pixel pipes)

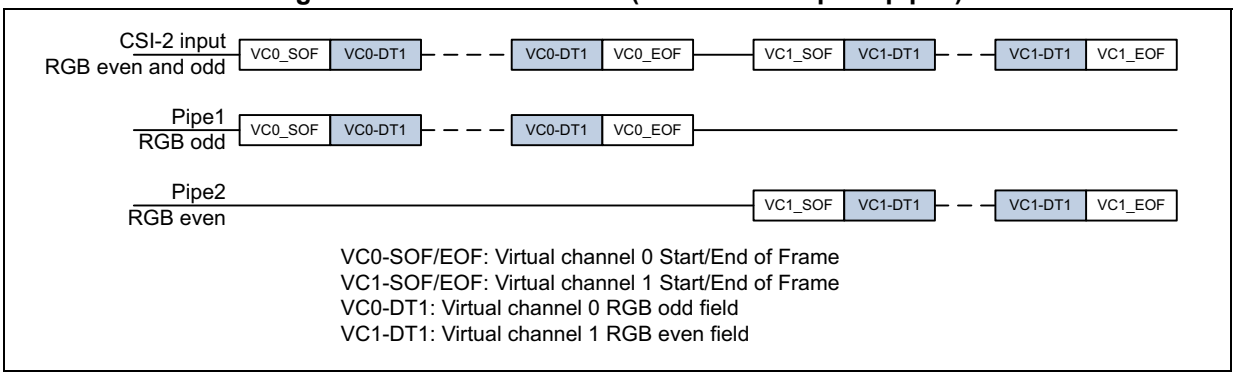


Software configuration

The following configuration must be set first into the static DCMIPP_PxFSCR and DCMIPP_CMCR registers:

- INSEL: Selects the input flow (parallel vs. CSI) in the DCMIPP_CMCR register
- DTMODE[1:0]: mode for CSI flow selection into that pipe:
  - 0: only flow VC/DTIDA is forwarded in the corresponding pipe.
  - 1: flows VC/DTIDA and/or VC/DTIDB are forwarded for Pipe0, and VC/DTIDA and VC/DTIDB for Pipe1.
  - 2: all flows, except the VCDTIDA or VCDTIDB, are forwarded in the pipe (this last setting, 3, is available only for Pipe0).
  - 3: all Datatypes from the selected virtual channel are forwarded in Pipe0. It is valid only for Pipe0 (the pixel formats that are not supported by Pixel pipes are suppressed).

  This bit field is not valid for Pipe2.
- DTIDA/DTIDB: Data type selection ID-A and ID-B for Pipe0 and Pipe1.
- DTIDA: Data type selection for the pixel Pipe2 when PIPEDIFF = 1.
- FDTFEN: Forces the value of the data type (value defined in FDTF[5:0]) to be processed by the pixel Pipe1 and Pipe2, based on the DTIDA/DTIDB detection in the flow selection block of the pipe. Not available for Pipe0.
- FDTF[5:0]: Data type value overwritten the one received by the CSI-2 physical node when equal to DTIDA/DTIDB. Not available for Pipe0.
- PIPEDIFF: Pipe2 to take same input as Pipe1 or differentiated:
  - 0: Pipe2 takes the same VC/DTIDx as well as the same FDTFEN and FDTF[5:0] configured into the DCMIPP_P1FSCR register.
  - 1: Pipe1 and Pipe2 take their own VC/DTID, FDTFEN and FDTF[5:0] values in the data flow.

After all the pipes have been configured, the processing can be activated:

- PIPEN: Set to 1 to start the frame control logic of the pipe. When reset at 0, it immediately resets the frame control logic, which results in immediately stopping an ongoing dump (CPTREQ = 0, CPTACT = 0), see *Figure 397*, *Figure 398*, *Figure 399*.
- CPTREQ: Set to 1 to activate the capture at the next start-of-frame in the DCMIPP_PxFCTCR register.

Note: To be cleanly sampled for the next frame, the VCIDA, VCIDB, DTIDA, and DTIDB fields must be updated after a VSync and after the first HSync.

Configuration example

The following list details five possible use cases, among others interlaced video and interleaved frames, and a 3D sensor (left + right eye):

- Default, with a parallel dump of statistics and processing of an image on both Pipe1 and Pipe2:
  - Image forwarded to the pixel Pipe1 and Pipe2, and processed, with the following settings:
    - Pipe1 / DTMODE = 0, to extract a single flow.
    - Pipe1 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching the image flow
    - Pipe1 / PIPEDIFF = 0, to send the flow to both Pipe1 and Pipe2
  - Statistics are extracted and dumped on Pipe0 with the following config:
    - Pipe0 / DTMODE = 0, to extract a single flow.
    - Pipe0 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching the statistics flow.
- Interlaced video, with the consecutive but exclusive odd and even (requiring the use of the image processing functions):
  - Interlaced video, if having differentiated VC and DT, is forwarded to the pixel Pipe1 and Pipe2, and processed, with the following settings:
    - Pipe1 / DTMODE = 0, to extract the VC /DTIDA flow
    - Pipe1 / VC/DTIDA = vv_dddddd, with VC and DTIDA matching the odd or the even field by reprogramming between two frames
    - Pipe1 / PIPEDIFF = 0, to send the flow to both Pipe1 and Pipe2
    - Pipe1 / Pipe2 / CPTMODE = 1, Snapshot mode
    - Pipe1 / Pipe2 / CPTREQ = 1 alternatively for Pipe1 and Pipe2, frame by frame
  - Any other (different) data can be potentially dumped with the following settings:
    - Pipe0 / DTMODE = 2, to extract all but flows A and B
    - Pipe0 / VCDTIDA = Pipe1 / VC / DTIDA corresponding to the odd field
    - Pipe0 / VCDTIDB = Pipe1 / VC / DTIDB corresponding to the even field

The software needs to reprogram frame to frame the DTIDx fields of the DCMIPP_P1FSCR register to select the data to process into Pipe1 or Pipe2. The software sets CPTMODE bit to work in Snapshot mode for Pipe1 and Pipe2 in the DCMIPP_P1FCTCR and DCMIPP_P2FCTCR registers. Alternatively, bit CPTREQ is set frame by frame in one pipe then in the other one to allow the acquisition of data on the allocated pipe. The data type identifying the odd or even fields needs to by updated into the DCMIPP_P1FSCR register only, as Pipe2 shares the image processing block of Pipe1.

- Interlaced video, with consecutive but exclusive odd and even (bypassing the image processing functions):
  - Interlaced video, if having differentiated VC and/or DT, is forwarded to pixel Pipe1 and Pipe2, and processed, with the following settings:
    - Pipe1 / DTMODE = 0, to extract the VC /DTIDA flow
    - Pipe1 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching (for instance) the odd field data type
    - Pipe2 / DTMODE = 0, to extract the VC /DTIDA flow

> Pipe2 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching (for instance) the even field data type
> Pipe1 / PIPEDIFF = 1, to consider Pipe1 and Pipe2 as totally independent
> Pipe1 / Pipe2 / CPTMODE = 0, Continuous grab mode
> Pipe1 / Pipe2 / CPTREQ = 1 to capture data corresponding to the VCDTIDA attached to the corresponding pipe

– Any other different data can be potentially dumped with the following settings:
> Pipe0 / DTMODE = 2, to extract all but flows A and B
> Pipe0 / VCDTIDA = Pipe0 / VC / DTIDA corresponding to the odd field
> Pipe0 / VCDTIDB = Pipe0 / VC / DTIDB corresponding to the even field

In this case the interlaced video must be differentiated with the data type and not with the virtual channel (since there is a single VC by pipe), if the application wants to dump data other than the odd and even frames on Pipe0.

- Interleaved flows, with a parallel dump of an RGB picture and a JPEG-encoded flow:
  – The RGB picture is extracted and forwarded to pixel Pipe1 to be processed, with the following settings:
  > Pipe1 / DTMODE = 0, to extract one flow, the RGB picture
  > Pipe1 / VC /DTIDA = vv_dddddd, with VC and DTIDA matching the RGB picture data type
  > Pipe1 / PIPEDIFF = 1, to send the RGB on Pipe1 and use Pipe2 for other purposes

  – The JPEG-encoded stream is transmitted under the CSI user-defined format, is extracted and sent to the pipe to be dumped, thanks to the following:
  > Pipe0 / DTMODE = 0, to extract one flow, the JPEG-encoded flow
  > Pipe0 / VCDTIDA = vv_dddddd, with VC and DTIDA matching the JPEG stream data type
  > Pipe0 / VCDTIDB = not used

  – Another pixel picture, like YUV, can be dumped using Pipe2, by overwriting fields:
  > Pipe2 / DTMODE = 0, to extract a second flow for the YUV picture
  > Pipe2 / VCDTIDA = vv_dddddd, with VC and DTIDA matching the YUV picture data type

- 3D sensor, with a parallel transmission of two RGB or YUV pictures: one with data type DT1 for the left eye, and one with data type DT2 for the right eye: the DCMIPP can process each eye on a different pipe (for example left eye on Pipe1 and right eye on Pipe2). Note that, as Pipe1 and Pipe2 are differentiated, the demosaicing is assigned to Pipe1 only and is not available for Pipe2. The left and right eye flows are similar (raw Bayer or RGB), hence they both need to be RGB and not raw Bayer:
  – The left eye RGB picture is extracted and forwarded to the pixel Pipe1:
  > Pipe1 / DTMODE = 0, to extract one flow, the RGB picture
  > Pipe1 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching the left eye data type (DT1)
  > Pipe1 / PIPEDIFF = 1, to split and differentiate the flow between Pipe1 and Pipe2

  – The right eye RGB picture is extracted and forwarded to the pixel Pipe2:
  > Pipe2 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching the right eye

data type (DT2)

  - Another flow can be dumped onto the dump pipe:
    - > Pipe0 / DTMODE = 0, to extract one flow
    - > Pipe0 / VCDTIDA = vv_dddddd, with VC and DTIDA matching the flow to dump for instance
- Sensors in 3D, with left and right image inside a unique global image:
  - If the left and right images are differentiated with a left and right part of a single image, that double image can be extracted and duplicated to both the pixel pipes, and there, cropped differently at input of Pipe1 and Pipe2 respectively
- Sensors with multiple DT:
  - The sensor is supported by sending all (or most) of the flows to the dump pipe, and dumped consecutively, inserting ahead of each dumped packet an header containing the VC, DT, and packet length. See *Section 39.7.9* for more details on the header format. One or two pixel flows can still be extracted and processed by Pipe1 and Pipe2, and potentially suppressed from the extraction of the data dump, thanks to DCMIPP_PxFSCR.DTMODE.

39.9.3 Force data type format from CSI-2 data flow (pixel pipes only)

Application may require to use a user data type in the CSI-2 data flow without specifying the format used for the pixel transfer from a camera bridge to the DCMIPP, thanks to CSI-2 interface physical link.

However, the pixel pipes need to know the data format to process them in a proper way along the pipeline. It is possible to force a data type by software thanks to bits FDTF[5:0] and FDTFEN[5:0]. Only the pixel pipes (Pipe1 and Pipe2) can benefit of this capability. Indeed, Pipe0 manages the data and not the pixel itself.

If FDTFEN bit is set in the DCMIPP_PxFSCR register, the data type set into DTIDA/DTIDB (coupled with DTMODE) is used to detect the data type to be overwritten by FDTF[5:0] value. The value used to force the data type must follow CSI-2 data type format specification to identify the CSI-2 normalized data format.

Note: The forced data type value is unique. This means that, if two data types have been selected to be propagated into Pipe1 (DTMODE = 1), both DTIDA and DTIDB detected in input of the pipe are considered by Pipe1 with the forced value FDTF[5:0] if bit FDTFEN is set.

If the virtual channel and data type values are identical between Pipe1 and Pipe2, the force value FDTF[5:0] needs to be aligned within these two pipes if the respective FDTFEN bits are set, otherwise the behavior is not guaranteed.

If PIPEDIFF = 1, any data type format linked to a raw format can be forced on Pipe2 since it is not sharing the demoisaicing block of Pipe1.

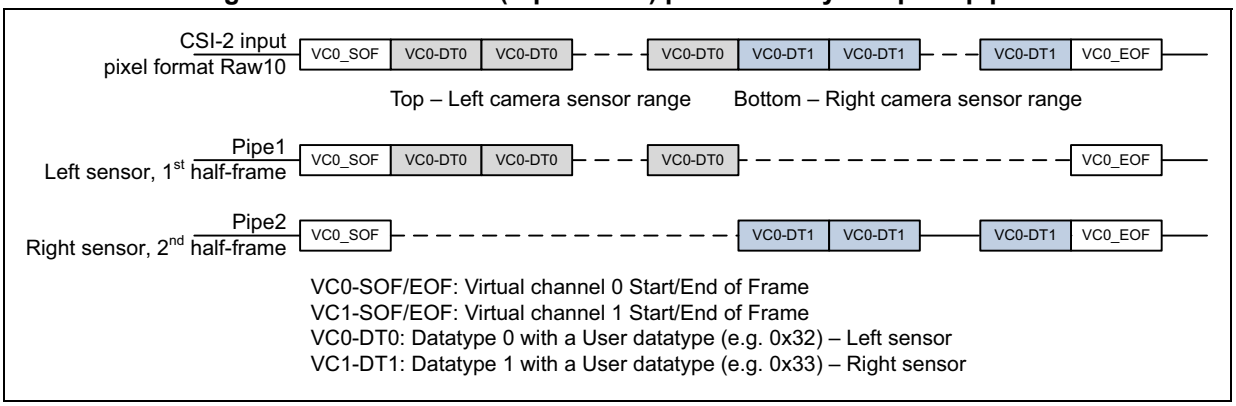
Typical application example: 3D sensors camera (top-bottom)

Some CSI-2 bridges concatenate data from left and right camera in a top-bottom approach. It means that within a frame, first half of the lines are the ones generated by the left camera, whereas the half last lines of a frame are attached to the right camera sensor. The bridge may typically make a distinction between lines coming from left camera and right camera by identifying the data type with a user data type value linked to a camera.

The user data type does not identify a pixel format, but rather a data linked to a camera. To help the pipeline process in a correct way the pixel, the software must inform the pipeline about the pixel format in input attached to the user Datatypes.

Let us imagine that the application has to separate pixels from the left camera from those of the right camera. Two pixel pipes can be configured for that, with, for instance, Pipe1 for left camera and Pipe2 dedicated to extract pixels from the right camera, as shown in *Figure 414*.

Figure 414. 3D sensors (top-bottom) processed by two pixel pipes



DCMIPP_P1FSCR configuration

- PIPEDIFF = 0, Pipe1 shares the demosaicing block with Pipe2 to transform, for instance, Raw10 in RGB888 for the output pixel format.
- VC = Virtual channel number
- DTMODE = 1, both Datatypes (0x32 and 0x33) selected to be propagated into Pipe1 through the demoisaicing, shared with Pipe2.
- DTIDA = 0x32, to let pixel data from the left camera sensor (identified by the user data type 0x32) to be processed by the demosaicing block, and further Pipe1 post processing stages (crop, downsize).
- DTIDB = 0x33, to let pixel data from the right camera sensor (identified by the user data type 0x33) to be processed by the demosaicing block, and further Pipe2 post processing stages (crop, downsize).
- FDTF[5:0] = 0x2B, to inform about the Raw10 data type normalized value in CSI-2 specification as input pixel format of the pipes.
- FDTFEN = 1, to force the user Datatypes DTIDA and DTIDB to be decoded as FDTF[5:0] input pixel format value.
- PIPEN = 1, to activate Pipe1.

Pipe1 crop registers (DCMIPP_P1CRSTR and DCMIPP_P1CRSZR) must be configured to crop only the first half lines of the frame corresponding to the pixels coming from the left camera sensor.

DCMIPP_P2FSCR configuration:

- VC / DTIDA / DTIDB / FDTF[5:0] / FDTFEN = don’t care since it is the same as the one defined in DCMIPP_P1FSCR (as PIPEDIFF = 0).
- PIPEN = 1 to activate Pipe2.

Pipe2 crop registers (DCMIPP_P2CRSTR and DCMIPP_P2CRSZR registers) must be configured to crop only the second half lines of the frame corresponding to the pixels coming from the right camera sensor.

39.10 Pixel format description

This section describes the pixel formats used in the parallel interface and in the pixel pipes and dump pipe. The CSI-2 pixel format is described in the CSI-2 v1.3 Standard.

The support for the pixel formats, per interface (parallel, CSI-2, pixel output, dump output) are summarized in *Table 356*, *Table 335*.

Note: In the following tables the components are represented with their symbolic color: red and Cr (= V) in red, blue and Cb (= U) in blue, green in green, and Y, monochrome, and all raw Bayer components in gray.

39.10.1 Parallel interface formats

This paragraph describes the input pixel format as supported by the parallel interface of the DCMIPP and the possible swap combinations.

Note: The parallel interface does not input specifically RGB444/RGB555 (and RGB666). However, a sensor with these output can connect them onto the DCMIPP, by selecting RGB565 (and RGB888), and by either connecting the missing bits with the MSB of the sensor output or by strapping them.

To adapt to non-standard sensors, the parallel interface is flexible and allows to swap bits, cycles, components, namely:

- Bits: LSB-vs.-MSB bits are swapped, across the whole 16-bit IO pins.
- Cycles: cycle 1/2 and cycle 2/2 are swapped. No impact for 1 or 3 cycles.
- Components: R-vs-B components are swapped (or V-vs-U if YUV).

Table 358 shows these permutations, based on the RGB565 format. It lists the sampled bits of cycles 1 and 2, on pins 0 to 7, and for each of them returns the assignation of the RGB output components.

Table 358. Parallel interface input pixel formats

1. Format identifies the value set in bitfield FORMAT[3:0] of DCMIPP_PxPPCR registers (x = 1 to 2).

39.10.3 Dump pipe formats

The dump pipe, thanks to its capability to dump, supports more formats than the pixel pipe, namely:

- CSI-2 packet headers and data
- CSI-2 raw Bayer pixels on 6/7bits (that can be dumped as-is but are not supported by the pixel pipe and hence cannot be processed as pixels).
- Monochrome and raw Bayer pixels on 10/12/14 bits, padded on 16 bpp.

Table 360 details the support for these additional pixel formats. Other formats are assumed to be pixels with the same width. The other pixel formats used by the dump pipe are similar to the pixel formats used by the pixel pipe.

1. PN indicates Pixel N.

39.10.4 AXI IP-Plug

The AXI IP-Plug dumps the data of the pipes (via the AXI) to the memory. It is unique, shared by all the pipes.

Features

- Pipe ID: AXI IP-Plug differentiates, via its ID, the source of the pipe. It allows to differentiate the QoS depending upon the clients.
- FIFOs: sized to handle up to 2 µs latencies (1 µs average round-trip + 1 µs memory slowdown), with, by default, at reset:
  a) Pipe0: 5 Gbps, thus 1.2 Kbytes
  b) Pipe1-Y/RGB: 200 Mpixel/s peak x 8 bpp, thus 384 bytes
  c) Pipe1-U: 200 Mpixel/s peak x 32 bpp, thus 1.5 Kbytes
  d) Pipe1-V: 200 Mpixel/s peak x 4 bpp, thus 192 bytes
  e) Pipe2: 200 Mpixel/s peak x 32 bpp, thus 1.5 Kbytes
- Burst length: 64 and 128 bytes for all the pipes.
- Outstanding capability: 16 outstandings, to cope with 2 GB/s maximum bandwidth on 128 bytes bursts.
- Bandwidth limiter (via an outstanding limitation per pipe): avoids a last-line dump that would uselessly overload the memory bandwidth.
- Unique AXI-QOS: unique QOS for the DCMIPP (without differentiation between pipes that must all work correctly with their real-time constraint).

Common software configuration

The AXI IP-Plug has a common configuration in the DCMIPP_IPGR1/2/3/8 registers.

The common registers are writable only when the IP-Plug is in Idle mode (see PSTART below to lock it, or below for an example).

- MEMORYPAGE: for efficient handling of DRAM: bursts do not cross this module.
- PSTART: request to freeze the plug, to reconfigure it safely.
- IDLE: status to mention the plug is frozen, to reconfigure it safely.
- IPPID[7:0], ARCHIID[4:0], REVID[4:0], DID[5:0]: version IDs of the IP-Plug.

Per-client software configuration

The AXI IP-Plug has a per-client configuration in the registers DCMIPP_IPCxR1/2/3.

The client registers are writable only when the IP-Plug is in Idle mode (see PSTART in common registers above to lock it, or below for an example).

The clients (1..n) are numbered following the sequence Pipe0..m. Inside each pipe, there are several potential clients when the planar feature is needed.

For instance, the DCMIPP with its three pipes (Pipe0, Pipe1, Pipe2) and with Pipe1 allowing a full planar capability (three buffers: Y, U, V), has the IP-Plug clients, numbered as follows:

- Client1 = Pipe0
- Client2 = Pipe1Y/RGB
- Client3 = Pipe1U
- Client4 = Pipe1V
- Client5 = Pipe2

The configurable per-client features are the following:

- OTR: outstanding transactions per client (Outstanding = OTR + 1)
- TRAFFIC[2:0]: burst size: best select 128 bytes, thus TRAFFIC = 4
- WLRU[3:0]: proportion of total bandwidth: WLRU = BWi / sum (all BW)
- SVC: system virtual channel, keep SVC = 0
- DPREGSTART: local base-address of start of FIFO for this client
- DPREGEND: local base-address of end of FIFO (included word) for this client

Configuration computations

IP-Plug common configuration:

- PSTART: set to 1, to put IP-Plug idle and configure its registers G1/3, R1/3
- IDLE: read and wait till 1, to get it idle
- MEMORYPAGE: 4, to optimize for memory pages of 256 bytes

IP-Plug per-client configuration:

- OTR (client): outstanding requests per client, among a total of 16 requests.
  - The provided value (OTR), is the outstanding amount minus 1.
- DPREG size (client): RAM shared among client, among a total of 640 x 64-bit words
  - DPREGSTART = 0 (or after another client location).
  - DPREGEND = 127 for ((127 - 0) + 1) x 8 B = 1 KB, as example if 1 KB is assigned to this client. The value to program is 127, as the word is included. DPREGEND is defined to include the last given word of memory, so that a FIFO of 128 words (starting at 0) has DPREGEND = 127.

Each client is provided a proportion of the total FIFO size and of the total outstanding available transactions, in function of the local peak bandwidth. Indeed, the DCMIPP implements buffers to smooth the bandwidth, but they are not large enough to buffer full lines. The proportion of the peak bandwidth of each pipe is estimated as:

- PeakBandwidthProportion (= PBP) = OutputWidth (= OW) * PixelFormatSize (= PFS)
- OTR(client) = Total_OTR * PBP(client) / SumAll(PBP) - 1
- DPREG_Size(client) = Total_DPREG_Size * PBP(client) / SumAll(PBP)

As an example, an xRGB 720p display output, a VGA 422 video output (for software), and no statistics, results in:

- PBP(Display) = 1280 * 4 = 5260
- PBP(Video) = 640 * 2B = 1280
- OTR(Display) = 16 * 5260 / (5260 + 1280) - 1 = 11
- OTR(Video) = 16 * 1280 / (5260 + 1280) - 1 = 3
- DPREG_Size(Display) = 640 * 5260 / (5260 + 1280) = 512
- DPREG_Size(Video) = 640 * 1280 / (5260 + 1280) = 128

Video is assigned to Pipe1 (= Client2) and display to Pipe2 (Client5):

- IP-Plug common registers:
  - DCMIPP_IPGR1.MEMORYPAGE = 2 (default, 256 bytes)
  - DCMIPP_IPGR2.PSTART = 1 (locks IP-Plug for reconfiguration)
  - DCMIPP_IPGR3.IDLE to wait until = 1 (to wait before continuing)
- Video as Pipe1, statically mapped onto IP-Plug Client2:
  - DCMIPP_IPC2R1.OTR = 3
  - DCMIPP_IPC2R1.TRAFFIC = 4 (default)
  - DCMIPP_IPC2R3.DPREGSTART = 512
  - DCMIPP_IPC2R3.DPREGEND = 639
- Display as Pipe2, statically mapped onto IP-Plug Client5:
  - DCMIPP_IPC5R1.OTR = 11
  - DCMIPP_IPC5R1.TRAFFIC = 4 (default)
  - DCMIPP_IPC5R3.DPREGSTART = 0
  - DCMIPP_IPC5R3.DPREGEND = 511
- IP-Plug common registers:
  - DCMIPP_IPGR2.PSTART = 1 (unlocks IP-Plug after configuration)

Configuration example 1: Single RGB dump

It is the simplest but most usual configuration, with the DCMIPP dumping to a single xRGB buffer. It has thus a single pipe active, the dump is coplanar (no side U or V planes), and to emphasize, it does not dump separate statistics (with Pipe0), nor does use the second pixel pipe (Pipe2).

All the AXI capabilities are focused on the single active pipe, which gets all the FIFO space and outstanding capability of the DCMIPP. With this setting, a camera dump of 200 Mpixel/s peak on 32 bpp (800 MB/s bandwidth) benefits of:

- 5 Kbytes FIFO, allowing a memory peak slowdown 6 µs (a very high value).
- 16 outstandings of 128 bytes, allowing thus an average memory latency of 2.5 µs (a high value).
- IP-Plug common registers:
  - DCMIPP_IPGR1.MEMORYPAGE = 2 (default, 256 bytes)
  - DCMIPP_IPGR2.PSTART = 1 (locks IP-Plug for reconfig)
  - DCMIPP_IPGR3.IDLE to wait until = 1 (to wait before continuing)
- Single dump on Pipe1 (main pipe), statically mapped onto IP-Plug Client2:
  - DCMIPP_IPC2R1.OTR = 15 (maximum assigned here)
  - DCMIPP_IPC2R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC2R2.WLRU = 0 (not used as single client)
  - DCMIPP_IPC2R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC2R3.DPREGSTART = 0 (single FIFO, start at lowest)
  - DCMIPP_IPC2R3.DPREGEND = 639 (single FIFO, end at highest)
- IP-Plug common registers:
  - DCMIPP_IPGR2.PSTART = 1 (unlocks IP-Plug after configuration)

Configuration example 2: All pipes active

This is the most flexible configuration of the DCMIPP: the five clients of the IP-Plug are configured to dump the maximum bandwidth they can receive).

Note that, as the bus capabilities are shared among the clients, that configuration is less resistant to memory latencies than the above configuration with only a single RGB dump.

The capabilities of the DCMIPP are shared among the clients with the following assumptions:

- Client1 for Pipe0: dump of raw Bayer pixels, padded to 16 bpp, BW = 2 / 12
- Client2 for Pipe1-Y: dump of ARGB pixels, on 32 bpp, BW = 4 / 12
- Client3 for Pipe1-UV: dump of UV components, on 8 bpp, BW = 1 / 12
- Client4 for Pipe1-V: dump of V component, on 4 bpp, BW = 1 / 12
- Client5 for Pipe2: dump of ARGB pixels, on 32 bpp, BW = 4 / 12

The total bandwidth proportion, when all pipes are used, is 12. As some configurations (like the outstanding capability) are divided in other granularities, Pipe1-Y/RGB has some advantages, sometimes is used alone (as in the above simpler use case).

With these settings, a camera dump of 200 Mpixel/s peak on 32 bpp (800 MB/s bandwidth) benefits, for an average pipe like Pipe2, of:

- 1.5 Kbytes FIFO, allowing a memory peak slowdown of ~2 µs
- Four outstandings of 128 bytes, allowing thus an average memory latency of 0.65 µs, (acceptable but not so large): the DCMIPP must get priority to access the memory.

It results in the following register configuration:

- IP-Plug common registers:
  - DCMIPP_IPGR1.MEMORYPAGE = 2 (default, 256 bytes)
  - DCMIPP_IPGR2.PSTART = 1 (locks IP-Plug for reconfiguration)
  - DCMIPP_IPGR3.IDLE to wait until = 1 (to wait before continuing)
- Client1 for Pipe0: (raw Bayer, 16 bpp) with 2 / 12 of the BW:
  - DCMIPP_IPC1R1.OTR = 1 (2 outstandings, among 16)
  - DCMIPP_IPC1R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC1R2.WLRU = 2 (2 parts of BW, among 12)
  - DCMIPP_IPC1R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC1R3.DPREGSTART = 0 (96 parts of FIFO, among 640)
  - DCMIPP_IPC1R3.DPREGEND = 95 (96 parts of FIFO, among 640)
- Client2 for Pipe1-Y/RGB: (ARGB, 32 bpp) with 4 / 12 of the BW:
  - DCMIPP_IPC2R1.OTR = 5 (6 outstandings, among 16)
  - DCMIPP_IPC2R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC2R2.WLRU = 4 (4 parts of BW, among 12)
  - DCMIPP_IPC2R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC2R3.DPREGSTART = 96 (224 parts of FIFO, among 640)
  - DCMIPP_IPC2R3.DPREGEND = 319 (224 parts of FIFO, among 640)
- Client3 for Pipe1-UV: (UV, 16 bpp) with 2 / 12 of the BW:
  - DCMIPP_IPC3R1.OTR = 1 (2 outstandings, among 16)
  - DCMIPP_IPC3R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC3R2.WLRU = 2 (2 parts of BW, among 12)
  - DCMIPP_IPC3R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC3R3.DPREGSTART = 320 (64 parts of FIFO, among 640)
  - DCMIPP_IPC3R3.DPREGEND = 383 (64 parts of FIFO, among 640)
- Client4 for Pipe1-V: (V, 8 bpp) with 1 / 12 of the BW:
  - DCMIPP_IPC4R1.OTR = 1 (2 outstandings, among 16)
  - DCMIPP_IPC4R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC4R2.WLRU = 1 (1 part of BW, among 12)
  - DCMIPP_IPC4R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC4R3.DPREGSTART = 384 (32 parts of FIFO, among 640)
  - DCMIPP_IPC4R3.DPREGEND = 415 (32 parts of FIFO, among 640)
- Client5 for Pipe2: (ARGB, 32 bpp) with 4 / 12 of the BW:
  - DCMIPP_IPC5R1.OTR = 3 (4 outstandings, among 16)
  - DCMIPP_IPC5R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC5R2.WLRU = 4 (4 parts of BW, among 12)

  - DCMIPP_IPC5R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC5R3.DPREGSTART = 416 (224 parts of FIFO, among 640)
  - DCMIPP_IPC5R3.DPREGEND = 639 (224 parts of FIFO, among 640)
- IP-Plug common registers:
  - DCMIPP_IPGR2.PSTART = 1 (unlocks IP-Plug after configuration)

39.11 Shadow registers

A dump and/or pixel pipe must have the capability to be reconfigured without stopping it. Some registers can be written in the middle of a frame without impacting the actual frame acquisition. The values are stored into some shadow registers before being written in their corresponding physical registers, based on a trigger event like described in *Table 361*.

Each physical register in the register map has its address increased by 0x200 respect to its own shadow register address.

Table 361. Shadow and physical registers

Shadow register	Physical register	Trigger event
DCMIPP_P0FSCR(1)	DCMIPP_P0CFSCR	Vsync boundaries
DCMIPP_P0FCTCR	DCMIPP_P0CFCTCR	Vsync boundaries
DCMIPP_P0SCSTR	DCMIPP_P0CSCSTR	Vsync boundaries
DCMIPP_P0SCSZR	DCMIPP_P0CSCSZR	Vsync boundaries
DCMIPP_P0PPCR	DCMIPP_P0CPPCR	Vsync boundaries

DCMIPP_P2PPM0PR	DCMIPP_P2CPPM0PR	Vsync boundaries

1. Bit PIPEN of this register is not shadowed.

It is mandatory to refresh the shadow registers within a frame to prepare the context to be ready for the next start of frame, to avoid any unpredictable behavior during the acquisition. The software must then react to the following interrupt sources to launch the shadow registers accesses:

- At VSYNC interrupt (FrameStart at start of pipe) an interrupt is generated, and the software can update the shadow registers loaded into the physical registers at the end of the current frame (so active for the next frame). The software has an entire frame period to complete the update.
- At LINE interrupt line selection can be used also to trigger the software to update the physical registers with the new frame context to consider. The application code must ensure that the update takes place before the end of frame event (current frame). If not, the context can be partially considered from the next frame, dealing with inconsistent settings.

In any case, the software must ensure that the shadow registers are updated before the end of the current frame, to be active from the next frame. Updates started and not completed before the end of current frame result in inconsistent frame acquisition for the next frame (mixing old and new configurations).

It is recommended to change non-shadowed registers when the corresponding pipe is disabled and in an idle state (refer to *Section 39.4.7: Pipe deactivation*).

39.12 DCMIPP low power modes

This section describes the behavior of the DCMIPP versus the modes listed in *Table 362*.

Table 362. DCMIPP low power modes

Mode	Description
Stop	Peripheral content is kept. It is recommended to follow the pipe(s) disabling procedure before entering it.
Standby	Powered-down. The peripherals must be reinitialized after exiting this mode.
Sleep	No effect. DCMIPP is still working in this mode, peripheral interrupts cause the device to exit it.

39.13 DCMIPP interrupts

This section describes the DCMIPP interrupts, and more globally, the features that are related to real-time, namely:

- Free-running: DCMIPP can run without CPU involvement
- Shadow registers: relieve timing constrains from the software
- Interrupts: source of interrupt
- Event pins: to drive external IPs, like a DMA

39.13.1 Free-running DCMIPP

After a camera flow has been configured and established, it is able to run permanently, without any software involvement. The following features are available:

- Permanent pipe activation, for Pipe0, 1, 2: when set, the respective pipe dumps frame data, for an unlimited amount of frames.
  - DCMIPP_PxFCTCR.CPTMODE = 0
  - DCMIPP_PxSR.CPTACT = 1
  - DCMIPP_PxFCTCR.FRATE = xx (depending on desired frame subsampling rate)
- Double buffered frames: the DCMIPP can be defined with two BaseAddress pointers for the output buffers:
  - Software can set up the two BaseAddress pointers to let the hardware reacting to the VSYNC event to change from one buffer BaseAddress to the other one, and this alternatively.

39.13.2 Interrupts

The DCMIPP handles five interrupts pins, the fifth being the OR of the first four.

A register set is associated to each interrupt to provide the following functionality:

- Unmasked events: reports an event that occurred and has not yet been cleared
- Masks: to mask unwanted events
- Masked events: not readable, any active unmasked bit triggers the interrupt pin
- Clear register: write to clear any active event

The interrupt pins are active when high: they go high when triggered by an unmasked event, and remain high until all the masked events of that interrupt are cleared.

The interrupts lines and registers are:

1. Parallel interface, with the next interrupt events handled:
   - ERR: bad embedded synchronization detected.
     - > Unexpected behavior in the parallel interface, usually not triggered if no issues.
     - > It is due to an unexpected sensor behavior, or to a transmission error.
2. Pipe0 (dump), with the next interrupt events handled:
   - OVR: data overflow: the memory was too slow vs. received pixels.
     - > Unexpected behavior in Pipe0, usually not triggered if no issues.
     - > Same recommendation as for above OVR: skip the impacted frame.
   - LIMIT: received volume is larger than the maximum allowed dump volume.
     - > Unexpected behavior in Pipe0, usually not triggered if no issues.
     - > The transmitted flow is too long. More space must be allocated in memory to store the transmission of a next frame.
   - VSYNC: main interrupt, where most software can sit.
     - > Trigger: at VSync (mid blanking), permanent (even if no dump active).
     - > Typically to reconfigure slowly the pipes (at least shadow registers) for next frame
     - > Typically to trigger usage of the previously captured frame.
   - FRAME: secondary interrupt, as backup for fast-software
     - > Trigger: after last data dump of this pipe, inactive if no capture has occurred.
     - > Typically to quickly reconfigure non-shadow registers (during only vertical blanking)
     - > Typically to trigger usage of the previously captured frame.
   - LINE: interruption for stripe-based operators trigger: after every 1/2/4/8/16/32/64/128 dumped lines and last line. It is measured and extracted at end of pipe, close to output to memory.
     - > Typically to trigger fast/reactive software or hardware stripe-based operators.

Note: The LINE flag (LINEF bit) is set at the end of frame, to trigger out software event when the frame height is not a multiple of the selected number of lines for which the LINEF event is triggered. The last part of the frame can, in such case, have a lower number of lines than the selection. The event/interrupt is generated even if the number of lines is incomplete. The software must consider that this last event has a lower than expected number of lines when reaching the end of frame (FRAME event).

3. Pipe1 (main pipe)
   - Same events handled as Pipe0: OVR, VSYNC, FRAME, LINE, but no LIMIT as only pixels are captured after a potential crop.
4. Pipe2 (ancillary pipe)
   - Same events handled as Pipe1: OVR, VSYNC, FRAME, LINE.
5. Common interrupt: groups the events of the above interrupts in a single register set and drives its own interrupt line.
   - The fifth interrupt is designed for systems where a single driver handles the whole DCMIPP: a single access to this interrupt status allows to retrieve the status of the whole DCMIPP.
   - The first four interrupts are designed for systems where a driver handles a pipe

and (potentially) another one drives the parallel interface. In that case, each driver handles its own individual interrupt register set, without need for semaphores to arbitrate conflicting accesses.

There is also a common interrupt that can be generated if enabled, when a transfer error is detected during an AXI transfer from the IP-Plug to memories. Error flag ATXERR in the DCMIPP_CMSR2 register is set and an interrupt can be generated to inform the software about this error status. There is no specific hardware action linked to this error, it is up to software to handle the transfer error situation.

On multiple-pipe architecture, the error informs that at least one AXI client has a transfer error, but does not identify from which client.

The DCMIPP interrupts are summarized in *Table 363*. An event that generates an interrupt does it at two locations:

– once in the common interrupt register set (when driven by a single CPU)

– once in the local interrupt register set (when driven by multiple CPUs).

Table 363 provides the local (register and bit) and global (bit only, as all bits are in the same DCMIPP_CMSR2 register) locations.

Table 363. DCMIPP interrupts

Interrupt event	Local register	Local bit	Common bit in DCMIPP_CMSR2	Event flag/interrupt clearing method	Interrupt enable control bit local/common register
Synchronization error in parallel interface	DCMIPP_PRSR	ERRF	PRERRF	Write CERRF = 1 / CPRERRF = 1	ERRIE/PRERRFIE
AXI transfer error	-	-	ATXERR	Write CATXERRF = 1	ATXERRIE
Overflow in Pipe0	DCMIPP_P0SR	OVRF	P0OVRF	Write COVRF = 1 / CP0OVRF = 1	OVRIE/P0OVRIE
Limit violation in Pipe0		LIMITF	P0LIMITF	Write CLIMITF = 1 / CP0LIMITF = 1	LIMITIE/P0LIMITIE
Frame start (VSYNC) in Pipe0		VSYNC	P0VSYNC	Write CVSYNCF = 1 / CP0VCSYNCF = 1	VSYNCIE/P0VSYNCIE
Frame end (FRAME) in Pipe0		FRAMEF	P0FRAMEF	Write CFRAMEF = 1 / CP0FRAMEF = 1	FRAMEIE/P0FRAMIE
Multi-line (LINE) in Pipe0		LINEF	P0LINEF	Write CLINEF = 1 / CP0LINEF = 1	LINEFIE/P0LINEFIE
Overflow in Pipe1	DCMIPP_P1SR	OVRF	P1OVRF	Write COVRF = 1 / CP1OVRF = 1	OVRIE/P1OVRIE
Frame start (VSYNC) in Pipe1		VSYNC	P1VSYNC	Write CLIMITF = 1 / CP1LIMITF = 1	LIMITIE/P1LIMITIE
Frame end (FRAME) in Pipe1		FRAMEF	P1FRAMEF	Write CVSYNCF = 1 / CP1VCSYNCF = 1	VSYNCIE/P1VSYNCIE
Multi-line (LINE) in Pipe1		LINEF	P1LINEF	Write CFRAMEF = 1 / CP1FRAMEF = 1	FRAMEIE/P1FRAMIE

Table 363. DCMIPP interrupts (continued)

Interrupt event	Local register	Local bit	Common bit in DCMIPP _CMSR2	Event flag/interrupt clearing method	Interrupt enable control bit local/common register
Overflow in Pipe2	DCMIPP _P2SR	OVRF	P2OVRF	Write COVRF = 1 / CP2OVRF = 1	OVRIE/P2OVRIE
Frame start (VSYNC) in Pipe2		VSYNC	P2VSYNC	Write CLIMITF = 1 / CP2LIMITF = 1	LIMITIE/P2LIMITIE
Frame end (FRAME) in Pipe2		FRAMEF	P2FRAMEF	Write CVSYNCF = 1 / CP2VCSYNCF = 1	VSYNCIE/P2VSYNCIE
Multi-line (LINE) in Pipe2		LINEF	P2LINEF	Write CFRAMEF = 1 / CP2FRAMEF = 1	FRAMEIE/P2FRAMIE

39.13.3 Event pins

Event pins are exposed to let an ancillary HW IP, like a central DMA, to synchronize with them. The event pins are the unmasked synchronization events (VSYNC, FRAME, LINE, HSYNC) of the pipes.

An internal events generates a pulse (15 APB cycles long) on its pin.

Table 364. Event connection

Pipe	Event name	Internal signal
Pipe0	HSYNC	dcmipp_p0_hsync_evt
	VSYNC	dcmipp_p0_vsync_evt
	Frame	dcmipp_p0_frameend_evt
	Line	dcmipp_p0_lineend_evt
Pipe1	HSYNC	dcmipp_p1_hsync_evt
	VSYNC	dcmipp_p1_vsync_evt
	Frame	dcmipp_p1_frameend_evt
	Line	dcmipp_p1_lineend_evt
Pipe2	HSYNC	dcmipp_p2_hsync_evt
	VSYNC	dcmipp_p2_vsync_evt
	Frame	dcmipp_p2_frameend_evt
	Line	dcmipp_p2_lineend_evt

39.14 DCMIPP registers

The registers are split into groups with a same prefix, as shown in *Table 365*.

Table 365. DCMIPP registers organization

Register name	Offset	Function
DCMIPP_IP	0x000	IP-Plug registers
DCMIPP_PR	0x100	Parallel interface
DCMIPP_CM	0x200	Common registers
DCMIPP_P0	0x500	Pipe0 (dump pipe) with shadow registers
	0x700	Pipe0 (dump pipe) with physical registers
DCMIPP_P1	0x800	Pipe1 image processing with shadow registers
	0x900	Pipe1 post-processing with shadow registers
	0xA00	Pipe1 image processing with physical registers
	0xB00	Pipe1 post-processing with physical registers
DCMIPP_P2	0xC00	Pipe2 image processing with shadow registers
	0xD00	Pipe2 post-processing with shadow registers
	0xE00	Pipe2 image processing with physical registers
	0xF00	Pipe2 post-processing with physical registers
DCMIPP_	0xFF0	IP version and configuration (without prefix)

39.14.1 DCMIPP IP-Plug global register 1 (DCMIPP_IPGR1)

Address offset: 0x000

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	QOS_MODE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MEMORYPAGE[2:0]		
													rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **QOS_MODE:** Quality of service
Set of functions enabling to build and configure an architecture meeting bandwidth and latency requirements.

Bits 23:3 Reserved, must be kept at reset value.

Bits 2:0 **MEMORYPAGE[2:0]:** Memory page size, as power of 2 of 64-byte units:
0x0: 64 bytes
0x1: 128 bytes
0x2: 256 bytes
0x3: 512 bytes
0x4: 1K bytes
0x5: 2K bytes
0x6: 4K bytes
0x7: 8K bytes

39.14.2 DCMIPP IP-Plug global register 2 (DCMIPP_IPGR2)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PSTART
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **PSTART:** Request to lock the IP-Plug, to allow reconfiguration.
0: No lock requested, IP-Plug runs on demand by background HW.
1: Lock requested: IP-Plug freezes shortly (see IDLE bit when lock is active).
PSTART must be reset to 0 after configuration is completed, to restart the IP-Plug.

39.14.3 DCMIPP IP-Plug global register 3 (DCMIPP_IPGR3)

Address offset: 0x008

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDLE
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **IDLE:** Status of IP-Plug
0: IP-Plug is running (on demand by background HW)
1: IP-Plug is currently locked and can be reconfigured
IDLE is set after a request by setting PSTART at 1, and reset by resetting PSTART at 0.

39.14.4 DCMIPP IP-Plug identification register (DCMIPP_IPGR8)

Address offset: 0x01C

Reset value: 0xAA04 0314

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	DPREGSTART[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **DPREGEND[9:0]:** End word (AXI width = 64 bits) of the FIFO of Clientx.
The addressed word is included in the FIFO, so that next DPREGSTART is DPREGEND + 1.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **DPREGSTART[9:0]:** Start word (AXI width = 64 bits) of the FIFO of Clientx.

39.14.8 DCMIPP parallel interface control register (DCMIPP_PRCR)

Address offset: 0x104

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	SWAP BITS	SWAP CYCLES	Res.	FORMAT[7:0]							
					rw	rw		rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ENABLE	Res.	EDM[2:0]			Res.	Res.	VSPOL	HSPOL	PCKPOL	ESS	Res.	Res.	Res.	Res.
	rw		rw	rw	rw			rw	rw	rw	rw				

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **SWAPBITS**: Swap LSB vs. MSB within each received component
0: As received
1: Swapped MSB vs. LSB

Bit 25 **SWAPCYCLES**: Swap data (cycle 0 vs. cycle 1) for pixels received on two cycles
0: Default
1: Swap active: the data of cycle 1 is used before the data of cycle 0.
The swap must not be activated by software for pixels received in one or three cycles.

Bit 24 Reserved, must be kept at reset value.

Bits 23:16 **FORMAT[7:0]**:
0x1E: YUV422
0x22: RGB565
0x24: RGB888 (= YUV444)
0x2A: RAW8
0x2B: RAW10
0x2C: RAW12
0x2D: RAW14
0x4A: monochrome 8-bit
0x4B: monochrome 10-bit
0x4C: monochrome 12-bit
0x4D: monochrome 14-bit
0x5A: byte stream (JPEG, compressed video)
Other values: data are captured and output as-is only through the data/dump pipeline (for example JPEG or byte input format).
The monochrome Y input is inserted in the pipe as YUV pixels, with the U and V components set to neutral, to represent a gray color.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE:** Parallel interface enable
0: Parallel interface disabled to lower power consumption
1: Parallel interface enabled
The parallel interface configuration registers must be correctly programmed before enabling this bit.

Bit 13 Reserved, must be kept at reset value.

Bits 12:10 **EDM[2:0]:** Extended data mode
0x0: Interface captures 8-bit data on every pixel clock
0x1: Interface captures 10-bit data on every pixel clock
0x2: Interface captures 12-bit data on every pixel clock
0x3: Interface captures 14-bit data on every pixel clock
0x4: Interface captures 16-bit data on every pixel clock
Other values: Reserved

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **VSPOL:** Vertical synchronization polarity
This bit indicates the level on the VSYNC pin when the data are not valid on the parallel interface.
0: VSYNC active low
1: VSYNC active high

Bit 6 **HSPOL:** Horizontal synchronization polarity
This bit indicates the level on the HSYNC pin when the data are not valid on the parallel interface.
0: HSYNC active low
1: HSYNC active high

Bit 5 **PCKPOL:** Pixel clock polarity
This bit configures the capture edge of the pixel clock
0: Falling edge active
1: Rising edge active

Bit 4 **ESS:** Embedded synchronization select
0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the HSYNC/VSYNC signals.
1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.
Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when this bit is set.

Bits 3:0 Reserved, must be kept at reset value.

39.14.9 DCMIPP parallel interface embedded synchronization code register (DCMIPP_PRESCR)

Address offset: 0x108

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEC[7:0]								LEC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSC[7:0]								FSC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEC[7:0]:** Frame end delimiter code

This byte specifies the code of the frame end delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, FEC.

If FEC is programmed to 0xFF, all the unused codes (0xFF00 00XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]:** Line end delimiter code

This byte specifies the code of the line end delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]:** Line start delimiter code

This byte specifies the code of the line start delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]:** Frame start delimiter code

This byte specifies the code of the frame start delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, FSC.

If FSC is programmed to 0xFF, no frame start delimiter is detected, but the first occurrence of LSC after an FEC code is interpreted as the start of frame delimiter.

39.14.10 DCMIPP parallel interface embedded synchronization unmask register (DCMIPP_PRESUR)

Address offset: 0x10C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEU[7:0]								LEU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSU[7:0]								FSU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEU[7:0]:** Frame end delimiter unmask

This byte specifies the mask to be applied to the code of the frame end delimiter.

0: The corresponding bit in the FEC byte in DCMIPP_ESCR is masked while comparing the frame end delimiter with the received data.

1: The corresponding bit in the FEC byte in DCMIPP_ESCR is compared while comparing the frame end delimiter with the received data

Bits 23:16 **LEU[7:0]:** Line end delimiter unmask

This byte specifies the mask to be applied to the code of the line end delimiter.

0: The corresponding bit in the LEC byte in DCMIPP_ESCR is masked while comparing the line end delimiter with the received data

1: The corresponding bit in the LEC byte in DCMIPP_ESCR is compared while comparing the line end delimiter with the received data

Bits 15:8 **LSU[7:0]:** Line start delimiter unmask

This byte specifies the mask to be applied to the code of the line start delimiter.

0: The corresponding bit in the LSC byte in DCMIPP_ESCR is masked while comparing the line start delimiter with the received data

1: The corresponding bit in the LSC byte in DCMIPP_ESCR is compared while comparing the line start delimiter with the received data

Bits 7:0 **FSU[7:0]:** Frame start delimiter unmask

This byte specifies the mask to be applied to the code of the frame start delimiter.

0: The corresponding bit in the FSC byte in DCMIPP_ESCR is masked while comparing the frame start delimiter with the received data

1: The corresponding bit in the FSC byte in DCMIPP_ESCR is compared while comparing the frame start delimiter with the received data

39.14.11 DCMIPP parallel interface interrupt enable register (DCMIPP_PRIER)

Address offset: 0x1F4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRIE	Res.	Res.	Res.	Res.	Res.	Res.
									rw						

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **ERRIE:** Synchronization error interrupt enable

0: No interrupt generation

1: An interrupt is generated if the embedded synchronization codes are not received in the correct order.

This bit is available only in embedded synchronization mode.

Bits 5:0 Reserved, must be kept at reset value.

39.14.12 DCMIPP parallel interface status register (DCMIPP_PRSR)

Address offset: 0x1F8

Reset value: 0x0003 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VSYNC	HSYNC
														r	r

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRF	Res.	Res.	Res.	Res.	Res.	Res.
									r						

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **VSYNC:**

This bit gives the state of the VSYNC pin with the correct programmed polarity if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in VPOL bit, and cleared otherwise.

When embedded synchronization codes are used:

0: Active frame

1: Synchronization between frames

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMIPP_CR is set.

Bit 16 **HSYNC:**

This bit gives the state of the HSYNC pin with the correct programmed polarity if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in HPOL bit, and cleared otherwise.

When embedded synchronization codes are used:

0: Active line

1: Synchronization between lines

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMIPP_CR is set.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **ERRF:** Synchronization error raw interrupt status

0: No synchronization error detected

1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by writing 1 to the CERRF bit in DCMIPP_PRFCR.

This bit is available only in embedded synchronization mode.

Bits 5:0 Reserved, must be kept at reset value.

39.14.13 DCMIPP parallel interface interrupt clear register (DCMIPP_PRFCR)

Address offset: 0x1FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CERRF	Res.	Res.	Res.	Res.	Res.	Res.
									w						

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CERRF:** Synchronization error interrupt status clear

Writing a 1 into this bit clears the ERRF bit in DCMIPP_PRSR.

This bit is available only in embedded synchronization mode.

Bits 5:0 Reserved, must be kept at reset value.

39.14.14 DCMIPP common configuration register (DCMIPP_CMCR)

Address offset: 0x204

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	Res.	Res.	CFC	Res.	PSFC[1:0]		INSEL
								rw			w		rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **SWAPRB**: Swap R/U and B/V
0: RGB/VYU
1: BGR/UYV
These bits are not valid for Pipe0

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **CFC**: Clear frame counter
When this bit is set, the frame counter associated to a pipe is cleared. It resets DCMIPP_CMFRCR register. This bit is always read at 0.

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **PSFC[1:0]**: Pipe selection for the frame counter
These bits (set and cleared by software) select on which pipe the frame counter is mapped.
00: Frame counter mapped to Pipe0
01: Frame counter mapped to Pipe1
10: Frame counter mapped to Pipe2
Other values: Reserved

Bit 0 **INSEL**: input selection
0: DCMI
1: CSI-2
This selection is common for all the pipes, meaning that the input source (DCMI or CSI) is exclusive. This bit must not be changed if one or more pipes are enabled or still in processing state after a disabling operation (corresponding CPTACT bit set into the DCMIPP_CMSR1 register).

39.14.15 DCMIPP common frame counter register (DCMIPP_CMFRCR)

Address offset: 0x208

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FRMCNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FRMCNT[31:0]**: Frame counter, read-only, loops around.
Incremented following VSYNC detection mapped to the pipe configured into bits PSFC[1:0] of the DCMIPP_CMCR register. The counter is cleared using the CRC bit of that register.

39.14.16 DCMIPP common interrupt enable register (DCMIPP_CMIER)

Address offset: 0x3F0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw				rw	rw	rw		rw	rw					

Bit 31 **P2OVRIE:** Overrun interrupt status enable for Pipe2
0: No interrupt generation
1: An interrupt is generated

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **P2VSYNCIE:** Vertical sync interrupt enable for Pipe2
0: No interrupt generation
1: An interrupt is generated

Bit 25 **P2FRAMEIE:** Frame capture complete interrupt enable for Pipe2
0: No interrupt generation
1: An interrupt is generated

Bit 24 **P2LINEIE:** Multi-line capture complete interrupt enable for Pipe2
0: No interrupt generation
1: An interrupt is generated

Bit 23 **P1OVRIE:** Overrun interrupt enable for Pipe1

Bits 22:20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **P1VSYNCIE:** Vertical sync interrupt enable for Pipe1
0: No interrupt generation
1: An interrupt is generated

Bit 17 **P1FRAMEIE:** Frame capture complete interrupt enable for Pipe1
0: No interrupt generation
1: An interrupt is generated

Bit 16 **P1LINEIE:** Multi-line capture complete interrupt status clear for Pipe1
0: No interrupt generation
1: An interrupt is generated

Bit 15 **P0OVRIE:** Overrun interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bit 14 **P0LIMITIE:** Limit interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **P0VSYNCIE:** Vertical sync interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bit 9 **P0FRAMEIE:** Frame capture complete interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bit 8 **P0LINEIE:** Multi-line capture complete interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PRERRIE:** Limit interrupt enable for the parallel Interface
0: No interrupt generation
1: An interrupt is generated

Bit 5 **ATXERRIE:** AXI transfer error interrupt enable for IP-Plug
0: No interrupt generation
1: An interrupt is generated

Bits 4:0 Reserved, must be kept at reset value.

39.14.17 DCMIPP common status register 1 (DCMIPP_CMSR1)

Address offset: 0x3F4

Reset value: 0x0000 0003

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						r	r							r	r

Bit 31 **P2CPTACT**: Active frame capture (active from start-of-frame to frame complete) for Pipe2
0: No capture currently active
1: Capture currently active

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **P2LSTFRM**: Last frame LSB bit, sampled at frame capture complete event for Pipe2
The information is extracted from the frame data number that can be delivered by the camera through the CSI2 interface.

Bit 24 **P2LSTLINE**: Last line LSB bit, sampled at frame capture complete event for Pipe2
The first line of a frame is counted as 0.

Bit 23 **P1CPTACT**: Active frame capture (active from start-of-frame to frame complete) for Pipe1
0: No capture currently active
1: Capture currently active

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **P1LSTFRM**: Last frame LSB bit, sampled at frame capture complete event for Pipe1
The information is extracted from the frame data number, which can be delivered by the camera through the CSI2 interface.

Bit 16 **P1LSTLINE**: Last line LSB bit, sampled at Frame capture complete event for Pipe1

Bit 15 **P0CPTACT**: Active frame capture (active from start-of-frame to frame complete) for Pipe0
0: No capture currently active
1: Capture currently active

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **P0LSTFRM**: Last frame LSB bit, sampled at Frame capture complete event for Pipe0
The information is extracted from the frame data number that can be delivered by the camera through the CSI2 interface.

Bit 8 **P0LSTLINE**: Last line LSB bit, sampled at Frame capture complete event for Pipe0

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **PRVSYNC:**

This bit gives the state of the VSYNC pin with the correct programmed polarity on the parallel interface if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in VPOL bit of the DCMIPP_PRCR register, and cleared otherwise.

When embedded synchronization codes are used, the meaning of this bit is the following:

0: Active frame

1: Synchronization between frames

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in the DCMIPP_PRCR register is set.

Bit 0 **PRHSYNC:**

This bit gives the state of the HSYNC pin with the correct programmed polarity on the parallel interface if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in HPOL bit of the DCMIPP_PRCR register, and cleared otherwise.

When embedded synchronization codes are used the meaning of this bit is the following:

0: Active line

1: Synchronization between lines

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in the DCMIPP_PRCR register is set.

39.14.18 DCMIPP common status register 2 (DCMIPP_CMSR2)

Address offset: 0x3F8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
P2 OVRF	Res.	Res.	Res.	Res.	P2 VSYNCF	P2 FRAMEF	P2 LINEF	P1 OVRF	Res.	Res.	Res.	Res.	P1 VSYNCF	P1 FRAMEF	P1LINEF
r					r	r	r	r					r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
P0 OVRF	P0 LIMITF	Res.	Res.	Res.	P0 VSYNCF	P0 FRAMEF	P0 LINEF	Res.	PR ERRF	ATX ERRF	Res.	Res.	Res.	Res.	Res.
r	r				r	r	r		r	r					

Bit 31 **P2OVRF:** Overrun raw interrupt status for Pipe2

0: No data buffer overrun occurred

1: A data buffer overrun occurred, and this frame data are corrupted

This bit is cleared by writing 1 to the CP2OVRF bit in DCMIPP_CMFCR.

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **P2VSYNCF:** VSYNC raw interrupt status for Pipe2

This bit is set when the VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in the DCMIPP_CR register. It is cleared by writing 1 to the CP2VSYNCF bit in the DCMIPP_CMFCR register.

Bit 25 **P2FRAMEF:** Frame capture completed raw interrupt status for Pipe2

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).

This bit is cleared by writing 1 to the CP2FRAMEF bit in the DCMIPP_CMFCR.

Bit 24 **P2LINEF:** Multi-line capture completed raw interrupt status for Pipe2

This bit is set when at least a line has been completed, and cleared by writing 1 to the CP2LINEF bit in the DCMIPP_CMFCR register.

The periodicity of LINEF event is configured by LINEMULT bits of the DCMIPP_P2PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame. For embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set.

Bit 23 **P1OVRF:** Overrun raw interrupt status for Pipe1

0: No data buffer overrun occurred

1: A data buffer overrun occurred and this frame data are corrupted

This bit is cleared by writing 1 to the CP1OVRF bit in the DCMIPP_CMFCR register.

Bits 22:20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **P1VSYNCF:** VSYNC raw interrupt status for Pipe1

This bit is set when the VSYNC signal changes from inactive to active state. In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in the DCMIPP_CR register. It is cleared by writing 1 to the CP1VSYNCF bit in the DCMIPP_CMFCR register.

Bit 17 **P1FRAMEF:** Frame capture completed raw interrupt status for Pipe1

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured. In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame). This bit is cleared by writing 1 to the CP1FRAMEF bit in the DCMIPP_CMFCR register.

Bit 16 **P1LINEF:** Multi-line capture completed raw interrupt status for Pipe1

This bit is set when one/more lines have been completed. The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P1PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame. In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMIPP_CR is set. It is cleared by writing 1 to the CP1LINEF bit in the DCMIPP_CMFCR register.

Bit 15 **P0OVRF:** Overrun raw interrupt status for Pipe0

0: No data buffer overrun occurred

1: A data buffer overrun occurred and this frame data are corrupted

This bit is cleared by writing 1 to the CP0OVRF bit in the DCMIPP_CMFCR register.

Bit 14 **P0LIMITF:** Limit raw interrupt status for Pipe0

This bit is set when the data counter DCMIPP_P0DCCNT reaches its maximum value DCMIPP_P0DCLIMIT. It is cleared by writing 1 to the CP0LIMITF bit in the DCMIPP_CMFCR register.

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **P0VSYNCF:** VSYNC raw interrupt status for Pipe0

This bit is set when the VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMIPP_CR. It is cleared by writing 1 to the CP0VSYNCF bit in the DCMIPP_CMFCR register.

Bit 9 **P0FRAMEF:** Frame capture completed raw interrupt status for Pipe0

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop, even if the captured frame is empty (for example window cropped outside the frame).

This bit is cleared by writing 1 to the CP0FRAMEF bit in the DCMIPP_CMFCR register.

Bit 8 **P0LINEF:** Multi-line capture completed raw interrupt status for Pipe0

This bit is set when one/more lines have been completed. The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P0PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set. It is cleared by writing 1 to the CP0LINEF bit in the DCMIPP_CMFCR register.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PRERRF:** Synchronization error raw interrupt status for the parallel interface.

0: No synchronization error detected

1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by writing 1 to the CPRERRF bit in the DCMIPP_CMFCR register.

This bit is available only in embedded synchronization mode.

Bit 5 **ATXERRF:** AXI transfer error interrupt status flag for the IP-Plug.

0: No AXI transfer error detected

1: AXI transfer error occurred on an AXI client. This bit signals an error on a client without any specific hardware action, the software must handle the situation (normally used when debugging software application code).

This bit is cleared by writing 1 to CATXERRF bit in the DCMIPP_CMFCR register.

Bits 4:0 Reserved, must be kept at reset value.

39.14.19 DCMIPP common interrupt clear register (DCMIPP_CMFCR)

Address offset: 0x3FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CP2 OVRF	Res.	Res.	Res.	Res.	CP2 VSYNCF	CP2 FRAMEF	CP2 LINEF	CP1 OVRF	Res.	Res.	Res.	Res.	CP1 VSYNCF	CP1 FRAMEF	CP1 LINEF

w	w				w	w	w		w	w					

Bit 31 **CP2OVRF:** Overrun interrupt status clear
Writing 1 into this bit clears the P2OVRF bit in the DCMIPP_CMSR2 register

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CP2VSYNCF:** Vertical synchronization interrupt status clear
Writing 1 into this bit clears the P2VSYNCF bit in the DCMIPP_CMSR2 register

Bit 25 **CP2FRAMEF:** Frame capture complete interrupt status clear
Writing 1 into this bit clears the P2FRAMEF bit in the DCMIPP_CMSR2 register

Bit 24 **CP2LINEF:** Multi-line capture complete interrupt status clear
Writing 1 into this bit clears P2LINEF in the DCMIPP_CMSR2 register

Bit 23 **CP1OVRF:** Overrun interrupt status clear
Writing 1 into this bit clears the P1OVRF bit in the DCMIPP_CMSR2 register

Bits 22:20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **CP1VSYNCF:** Vertical synchronization interrupt status clear
Writing 1 into this bit clears the P1VSYNCF bit in the DCMIPP_CMSR2 register

Bit 17 **CP1FRAMEF:** Frame capture complete interrupt status clear
Writing 1 into this bit clears the P1FRAMEF bit in the DCMIPP_CMSR2 register

Bit 16 **CP1LINEF:** Multi-line capture complete interrupt status clear
Writing 1 into this bit clears P1LINEF in the DCMIPP_CMSR2 register

Bit 15 **CP0OVRF:** Overrun interrupt status clear
Writing 1 into this bit clears the P0OVRF bit in the DCMIPP_CMSR2 register

Bit 14 **CP0LIMITF:** limit interrupt status clear
Writing 1 into this bit clears P0LIMITF in the DCMIPP_CMSR2 register

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **CP0VSYNCF:** Vertical synchronization interrupt status clear
Writing 1 into this bit clears the P0VSYNCF bit in the DCMIPP_CMSR2 register.

Bit 9 **CP0FRAMEF:** Frame capture complete interrupt status clear
Writing 1 into this bit clears the P0FRAMEF bit in the DCMIPP_CMSR2 register.

Bit 8 **CP0LINEF:** Multi-line capture complete interrupt status clear
Writing 1 into this bit clears P0LINEF in the DCMIPP_CMSR2 register

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CPRERRF:** Synchronization error interrupt status clear
Writing 1 into this bit clears the PRERRF bit in the DCMIPP_CMSR2 register.
This bit is available only in embedded synchronization mode.

Bit 5 **CATXERRF:** AXI transfer error interrupt status clear
Writing 1 into this bit clears the ATXERRF bit in the DCMIPP_CMSR2 register.

Bits 4:0 Reserved, must be kept at reset value.

39.14.20 DCMIPP Pipe0 flow selection configuration register (DCMIPP_P0FSCR)

Address offset: 0x404

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VC[1:0]		Res.	DTMODE[1:0]	
rw											rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	DTIDB[5:0]						Res.	Res.	DTIDA[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 **PIPEN**: Activation of PipeN
0: Pipe disabled
1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK

Note: This bit is not shadowed, differently from all other bits in this register.

Bits 30:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Flow selection mode
Virtual channel ID of the CSI flow to select for further processing on the pipe.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DTMODE[1:0]**: Flow selection mode
00: Only flow DTIDA from the selected virtual channel is forwarded in the pipe
01: Flows DTIDA and/or DTIDB from the selected virtual channel are forwarded in the pipe
10: All data types from the selected virtual channel (except the DTIDA or DTIDB) are forwarded in the pipe
11: All data types of the selected virtual channel VC are forwarded in the pipe

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DTIDB[5:0]**: Data type selection ID B
Data type ID of the CSI flow to select.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Data type selection ID A
Data type ID of the CSI flow to select.

39.14.21 DCMIPP Pipe0 flow control configuration register (DCMIPP_P0FCTCR)

Address offset: 0x500

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPT REQ	CPT MODE	FRATE[1:0]	
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CPTREQ:** Capture requested

0: Capture not requested for next frame

1: Capture requested for next frame

When PIPEN = 1 and CPTREQ = 1. the pipe waits for the first VSync, automatically starts a capture, and sets CPTACT = 1 to mention it.

In Snapshot mode the CPTREQ bit is cleared at the start of the first received frame.

In Continuous grab mode, the capture remains active and CPTREQ = 1 until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.

The DCMI and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 **CPTMODE:** Capture mode

0: Continuous grab mode - The received data are transferred into the destination memory through the AXI master.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame, and then transfers a single frame through the AXI master. At the end of the frame, the CPTACT bit is automatically reset.

Bits 1:0 **FRATE[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.

00: All frames are captured

01: one out of two frames captured (50% bandwidth reduction)

10: one out of four frames captured (75% bandwidth reduction)

11: one out of eight frames captured (87% bandwidth reduction)

39.14.22 DCMIPP Pipe0 statistic/crop start register (DCMIPP_P0SCSTR)

Address offset: 0x504

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	VSTART[11:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSTART[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **VSTART[11:0]**: Vertical start, from 0 to 4094 pixels high

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSTART[11:0]**: Horizontal start, from 0 to 4094 words wide

39.14.23 DCMIPP Pipe0 statistic/crop size register (DCMIPP_P0SCSZR)

Address offset: 0x508

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ENABLE	POSNEG	Res.	Res.	VSIZE[11:0]											
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSIZE[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **ENABLE**:

This bit is set and cleared by software.

0: Bypass. All the data are computed, if the statistic data are sent within the frame, they are sent to the processing pipe as pixels data.

1: Enable. Depending on bit POSNEG value, the rectangle defined by VSIZE, HSIZE, VSTART and HSTART can be used to extract or to remove some data (statistical extraction or removal, or basic 2D crop features).

if POSNEG = 0, the data inside the rectangle area are transmitted (it can correspond to a statistical data removal, or as a crop feature in a data valid image area).

if POSNEG = 1, the data outside of the rectangle area are transmitted (it can correspond to a statistical data extraction, rejecting all data inside the window).

This bit must be kept cleared if the input format is JPEG, to avoid unpredictable behavior of the pipe.

Bit 30 **POSNEG**:

This bit is set and cleared by software. It has a meaning only if ENABLE bit is set.

0: Positive area, the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART

1: Negative area, the area excluding the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Vertical size, from 0 to 4094 pixels high

If the value is maintained at 0 when enabling the crop by means of ENABLE bit, the crop operation is not performed on vertical direction.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Horizontal size, from 0 to 4094 word wide (data 32-bit)

If the value is maintained at 0 when enabling the crop by means of ENABLE bit, the crop operation is not performed on horizontal direction.

39.14.24 DCMIPP Pipe0 dump counter register (DCMIPP_P0DCCNTR)

Address offset: 0x5B0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	CNT[25:16]									
						r	r	r	r	r	r	r	r	r	r

CNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **CNT[25:0]**: Number of data dumped during the frame.

The size of the data is expressed in bytes. It counts only the data selected by means of the CROP 2D function. The counter saturates at 0x3FFFFFF. Granularity is 32-bit for all the formats except for the byte stream formats (for example JPEG) having byte granularity.

39.14.25 DCMIPP Pipe0 dump limit register (DCMIPP_P0DCLMTR)

Address offset: 0x5B4

Reset value: 0x00FF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ENABLE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LIMIT[23:16]							
rw								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LIMIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **ENABLE**:

0: Disabled, no check on the amount of 32-bit words transmitted

1: Enabled, check done versus limit

Bits 30:24 Reserved, must be kept at reset value.

Bits 23:0 **LIMIT[23:0]**: Maximum number of 32-bit data that can be dumped during a frame, after the crop 2D operation.

39.14.26 DCMIPP Pipe0 pixel packer configuration register (DCMIPP_P0PPCR)

Address offset: 0x5C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBM
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw		rw	rw	rw	rw	rw	rw	rw					rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DBM:** Double buffer mode
This bit is set and cleared by software.
0: No double buffer mode activated. Pipe0 always dumps to memory address set by DCMIPP_P0PPM0AR1.
1: Double buffer mode activated. Dump address location switches from DCMIPP_P0PPM0AR1 to DCMIPP_P0PPM0AR2 alternatively on each frame.

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE event and interrupt
0x0: Event after one line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bit 12 Reserved, must be kept at reset value.

Bit 11 **OELS:** Odd/even line select (line select start)
This bit works in conjunction with LSM field (LSM = 1).
0: Interface captures first line after the frame start, second one is dropped
1: Interface captures second line from the frame start, first one is dropped

Bit 10 **LSM:** Line select mode
0: Interface captures all received lines
1: Interface captures one line out of two

Bit 9 **OEBS:** Odd/even byte select (byte select start)
This bit works in conjunction with BSM field (BSM ≠ 00)
0: Interface captures the first data (byte or double byte) from the frame/line start, the second one is dropped
1: Interface captures the second data (byte or double byte) from the frame/line start, the first one is dropped
This bit has a meaning only if INSEL = 0 into the DCMIPP_CMCR register.

Bits 8:7 **BSM[1:0]:** Byte select mode
00: Interface captures all received data
01: Interface captures 1 data out of 2
10: Interface captures one byte out of four
11: Interface captures two bytes out of four
Modes 10 and 11 work only with EDM [2:0] = 000 into the DCMIPP_PRCR register.
This bit has a meaning only if INSEL = 0 into the DCMIPP_CMCR register

Bit 6 **HEADEREN:** CSI header dump enable
0: CSI-2 headers are not dumped
1: CSI-2 headers are dumped as a 32-bit word.
This setting is ignored for parallel interface mode, as there are no headers.

Bit 5 **PAD:** Pad mode for monochrome and raw Bayer 10/12/14 bpp (MSB vs. LSB alignment)
0: Aligns on LSB (and pads null bits on MSB), for backward compatibility with former DCMI.
1: Aligns on MSB (and pads null bits on LSB), for better ease of software or GPU.

Bits 4:1 Reserved, must be kept at reset value.

Bit 0 **SWAPYUV:** *S*waps, within a 32-bit word, byte 0-vs-1 and byte 2-vs-3. It corresponds, for YUV422 pixels formats, to swap between UYVY and YUYV.

0: Outputs the provided words, as described in *Section 39.10: Pixel format description*.

1: Swaps the bytes from provided words, byte 0-vs.-1 and 2-vs.-3

39.14.27 DCMIPP Pipe0 pixel packer Memory0 address register 1 (DCMIPP_P0PPM0AR1)

Address offset: 0x5C4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M0A[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address

Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

39.14.28 DCMIPP Pipe0 pixel packer Memory0 address register 2 (DCMIPP_P0PPM0AR2)

Address offset: 0x5C8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M0A[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address

Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

39.14.29 DCMIPP Pipe0 status Memory0 address register (DCMIPP_P0STM0AR)

Address offset: 0x5D0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M0A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address

Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

The register returns the status of the last captured frame.

39.14.30 DCMIPP Pipe0 interrupt enable register (DCMIPP_P0IER)

Address offset: 0x5F4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR IE	LIMIT IE	Res.	Res.	Res.	VSYNC IE	FRAME IE	LINE IE
								rw	rw				rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OVRIE:** Overrun interrupt enable

0: No interrupt generation

1: An interrupt is generated if the AXI master is unable to transfer the last data before new data (32-bit) are received.

Bit 6 **LIMITIE:** Limit interrupt enable

0: No interrupt generation when the limit is reached

1: An interrupt is generated when the limit is reached

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCIE:** VSYNC interrupt enable

0: No interrupt generation

1: An interrupt is generated on each VSYNC (captured or not)

Bit 1 **FRAMEIE:** Frame capture completed interrupt enable

0: No interrupt generation

1: An interrupt is generated after the full capture of a cropped frame

Bit 0 **LINEIE:** Multi-line capture completed interrupt enable

0: No interrupt generation when the line is received

1: An interrupt is generated after the full capture of a group of lines (or last line reached)

39.14.31 DCMIPP Pipe0 status register (DCMIPP_P0SR)

Address offset: 0x5F8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPTACT	Res.	Res.	Res.	Res.	Res.	LST FRM	LST LINE
								r						r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR F	LIMIT F	Res.	Res.	Res.	VSYNC F	FRAME F	LINE F
								r	r				r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CPTACT:** Capture immediate status

0: Capture currently inactive

1: Capture currently active

This bit is automatically reset at the end of frame capture complete event (after all the data of that frame have been captured and the IP-Plug has started to emit the last burst on the AXI, usually before the next VSync).

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **LSTFRM**: Last frame LSB bit, sampled at frame capture complete event.

The information is extracted from the frame data number that can be delivered by the camera through the CSI2 interface.

Bit 16 **LSTLINE**: Last line LSB bit, sampled at frame capture complete event.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **OVRF:** Overrun raw interrupt status

0: No data buffer overrun occurred

1: A data buffer overrun occurred and this frame data are corrupted

This bit is cleared by writing 1 to the COVRF bit in the DCMIPP_P0FCR register.

Bit 6 **LIMITF:** Limit raw interrupt status

This bit is set when the data counter DCMIPP_PxDCCNTR reaches its maximum value DCMIPP_PxDCLIMITR.

It is cleared by writing 1 to the CLIMITF bit in the DCMIPP_P0FCR register.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCF:** VSYNC raw interrupt status

This bit is set when the VSYNC signal changes from the inactive state to the active state. In case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMIPP_CR.

It is cleared by writing 1 to the CVSYNCF bit in the DCMIPP_P0FCR register.

Bit 1 **FRAMEF:** Frame capture completed raw interrupt status

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured. In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).

This bit is cleared by writing 1 to the CFRAMEF bit in DCMIPP_P0FCR.

Bit 0 **LINEF:** Multi-line capture completed raw interrupt status

This bit is set when one/more lines have been completed. For the JPEG mode, this bit is raised at the end of the frame.

The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P0PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame.

In case of embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set. It is cleared by writing 1 to the CLINEF bit in the DCMIPP_P0FCR register.

39.14.32 DCMIPP Pipe0 interrupt clear register (DCMIPP_P0FCR)

Address offset: 0x5FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								w	w				w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COVRF:** Overrun interrupt status clear

Writing 1 into this bit clears the OVRF bit in the DCMIPP_P0SR register.

Bit 6 **CLIMITF:** limit interrupt status clear

Writing 1 into this bit clears LIMITF in the DCMIPP_P0SR register.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CVSYNCF:** Vertical synchronization interrupt status clear

Writing 1 into this bit clears the VSYNCF bit in the DCMIPP_P0SR register.

Bit 1 **CFRAMEF:** Frame capture complete interrupt status clear

Writing 1 into this bit clears the FRAMEF bit in the DCMIPP_P0SR register.

Bit 0 **CLINEF:** Multi-line capture complete interrupt status clear

Writing 1 into this bit clears LINEF in the DCMIPP_P0SR register.

39.14.33 DCMIPP Pipe0 current flow selection configuration register (DCMIPP_P0CFSCR)

Address offset: 0x604

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VC[1:0]		Res.	DTMODE[1:0]

Res.	Res.	DTIDB[5:0]						Res.	Res.	DTIDA[5:0]					
		r	r	r	r	r	r			r	r	r	r	r	r

Bit 31 **PIPEN**: Current activation of PipeN
0: Pipe disabled
1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK.

Bits 30:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Current flow selection mode
Virtual channel ID of the CSI flow to select for further processing on the pipe.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DTMODE[1:0]**: Flow selection mode
00: Only flow DTIDA from the selected virtual channel is forwarded in the pipe.
01: Flows DTIDA and/or DTIDB from the selected virtual channel are forwarded in the pipe.
10: All Datatypes from the selected virtual channel, except the DTIDA or DTIDB are forwarded into the pipe.
11: All Datatypes of the selected virtual channel VC are forwarded in the pipe.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DTIDB[5:0]**: Current data type selection ID B
Data type ID of the CSI flow to select.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Current data type selection ID A
Data type ID of the CSI flow to select.

39.14.34 DCMIPP Pipe0 current flow control configuration register (DCMIPP_P0CFCTCR)

Address offset: 0x700

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPT REQ	CPT MODE	FRATE[1:0]	
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CPTREQ:** Capture requested

0: Capture not requested for next frame.

1: Capture requested for next frame.

When PIPEN = 1, and when the CPTREQ is set to 1 the pipe waits for the first VSync, and automatically starts a capture and sets CPTACT = 1 to mention it.

In Snapshot mode the CPTREQ bit is automatically cleared at the start of the first frame received.

In continuous grab mode the capture remains active and CPTREQ = 1, until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.

The DCMI and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 **CPTMODE:** Capture mode

0: Continuous grab mode - The received data are transferred into the destination memory through the AXI master.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame, and then transfers a single frame through the AXI master. At the end of the frame the CPTACT bit is automatically reset.

Bits 1:0 **FRATE[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.

00: all frames are captured

01: one out of two frames captured (50% bandwidth reduction)

10: one out of four frames captured (75% bandwidth reduction)

11: one out of eight frames captured (87% bandwidth reduction)

39.14.35 DCMIPP Pipe0 current statistic/crop start register (DCMIPP_P0CSCSTR)

Address offset: 0x704

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	VSTART[11:0]

Res.	Res.	Res.	Res.	HSTART[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **VSTART[11:0]**: Current vertical start, from 0 to 4094 pixels high

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSTART[11:0]**: Current horizontal start, from 0 to 4094 words wide

39.14.36 DCMIPP Pipe0 current statistic/crop size register (DCMIPP_P0CSCSZR)

Address offset: 0x708

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ENABLE	POSNEG	Res.	Res.	VSIZE[11:0]											
r	r			r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSIZE[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ENABLE**: Current value of the ENABLE bit

0: Bypass. All data are computed, if the statistics data are sent within the frame, they are sent to the processing pipe as pixels data.

1: Enable: Depending on bit POSNEG value, the rectangle defined by the VSIZE, HSIZE, VSTART, HSTART can be used to extract or to remove certain amount of data (statistical extraction or removal, or basic 2D crop features)

if POSNEG = 0, the data inside the rectangle area are transmitted (can correspond to a statistical data removal, or as a crop feature in a data valid image area).

if POSNEG = 1, the data outside of the rectangle area are transmitted (can correspond to a statistical data extraction, rejecting all data inside the window)

Bit 30 **POSNEG**: Current value of the POSNEG bit

This bit has a meaning only if ENABLE bit is set.

0: Positive area. The rectangle defined by VSIZE,HSIZE, and VSTART, HSTART is the active area.

1: Negative area. The active area is the area excluding the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART.

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Current vertical size, from 0 to 4094 pixels high.

If the value is maintained at 0 when enabling the crop by means of the ENABLE bit, the value is forced internally at 0xFFE which is the maximum value.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Current horizontal size, from 0 to 4094 word wide (data 32-bit).

If the value is maintained at 0 when enabling the crop by means of the ENABLE bit, the value is forced internally at 0xFFE, which is the maximum value.

39.14.37 DCMIPP Pipe0 current pixel packer configuration register (DCMIPP_P0CPPCR)

Address offset: 0x7C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LMAWE	LMAWM[2:0]			DBM
											r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	r	r		r	r	r	r	r	r	r					r

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **LMAWE**: Line multi address wrapping enable bit

Enables the wrapping of the address every power-of-2 of written lines.
0: Line multi address wrapping disabled.
1: Line multi address wrapping enabled.

Bits 19:17 **LMAWM[2:0]**: Line multi address wrapping modulo

Amount of captured lines after which the write address is wrapped back to the BaseAddress. It is used to write a full frame onto a circular (ping-pong) buffer.
000: Wraps address after every line
001: Wraps address after two lines
010: Wraps address after four lines
011: Wraps address after eight lines
100: Wraps address after sixteen lines
101: Wraps address after 32 lines
110: Wraps address after 64 lines
111: Wraps address after 128 lines

Bit 16 **DBM:** Double buffer mode

0: No double buffer mode activated. Pipe0 is always dump to memory address set by DCMIPP_P0PPM0AR1 register
1: Double buffer mode activated. Dump address location switches from DCMIPP_P0PPM0AR1 register to DCMIPP_P0PPM0AR2 register alternatively on each frame.

Bits 15:13 **LINEMULT[2:0]**: Current amount of capture completed lines for LINE event and interrupt

0x0: Event after every line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bit 12 Reserved, must be kept at reset value.

Bit 11 **OELS:** Current odd/even line select (ine select start)

This bit works in conjunction with LSM field (LSM = 1)
0: Interface captures the first line after the frame start, the second one is dropped
1: Interface captures the second line from the frame start, the first one is dropped
This bit has a meaning only if INSEL = 0 in the DCMIPP_CMCR register.

Bit 10 **LSM:** Current Line select mode

0: Interface captures all received lines
1: Interface captures one line out of two
This bit has a meaning only if INSEL = 0 in the DCMIPP_CMCR register.

Bit 9 **OEBS:** Current odd/even byte select (byte select start)

This bit works in conjunction with BSM field (BSM ≠ 00)
0: Interface captures the first data (byte or double byte) from the frame/line start, the second one is dropped
1: Interface captures the second data (byte or double byte) from the frame/line start, the first one is dropped
This bit has a meaning only if INSEL = 0 in the DCMIPP_CMCR register.

Bits 8:7 **BSM[1:0]:** Current Byte select mode
00: Interface captures all received data
01: Interface captures one data out of two
10: Interface captures one byte out of four
11: Interface captures two bytes out of four
Modes 10 and 11 work only with EDM [2:0] = 000 into the DCMIPP_PRCR register.
This bit has a meaning only if INSEL = 0 into the DCMIPP_CMCR register

Bit 6 **HEADEREN:** Current CSI header dump enable
0: CSI-2 headers are not dumped.
1: CSI-2 headers are dumped as 32-bit words.
This setting is ignored for Parallel interface mode, as there are no headers.

Bit 5 **PAD:** Current Pad mode for monochrome and raw Bayer 10/12/14 bpp (MSB vs. LSB alignment)
0: Aligns on LSB (and pads null bits on MSB), for backward compatibility with former DCMI
1: Aligns on MSB (and pads null bits on LSB), for better ease of software or GPU

Bits 4:1 Reserved, must be kept at reset value.

Bit 0 **SWAPYUV:** Swaps, within a 32-bit word, byte 0 vs. 1 and byte 2 vs. 3. It corresponds, for YUV422 pixels formats, to swap between UYVY and YUYV.
0: Outputs the provided words, as described in *Section 39.10: Pixel format description*.
1: Swaps the bytes from provided words, byte 0 vs. 1 and 2 vs. 3.

39.14.38 DCMIPP Pipe0 current pixel packer Memory0 address register 1 (DCMIPP_P0CPPM0AR1)

Address offset: 0x7C4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M0A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address
Base address of the current memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

39.14.39 DCMIPP Pipe0 current pixel packer Memory0 address register 2 (DCMIPP_P0CPPM0AR2)

Address offset: 0x7C8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
M0A[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M0A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address

Base address of the current memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

39.14.40 DCMIPP Pipe1 flow selection configuration register (DCMIPP_P1FSCR)

Address offset: 0x804

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	FDTFEN	FDTF[5:0]						Res.	Res.	Res.	VC[1:0]		PIPEDIFF	DTMODE[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	DTIDB[5:0]						Res.	Res.	DTIDA[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 **PIPEN**: Activation of PipeN

0: Pipe disabled

1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK

Bit 30 **FDTFEN**: Force Datatype format enable

0: Disable force Datatype format. The Datatype format used by the pipe is the one defined into DTIDx1: Enable force Datatype format. When the Datatype DTIDx is detected by the pipe, the real pixel format considered by the pipe is the one set into the FDTF[5:0] bit field instead of the physical one received by the CSI2 Host. It allows to handle, for instance, 3D sensors camera using user data type in bottom-up approach, and to explicitly define the pixel format to be handled by the pipe. Note that the flow is first selected using the DTMODE and DTIDA/B, and then, if selected, its data type may be forced with the to FDTC using FDTFEN = 1.

Bits 29:24 **FDTF[5:0]**: Force Datatype format

Forcing the Datatype format. This Datatype overwrites the one received by the CSI2-HOST by specifying the pixel format to consider. The value must follow the CSI2 Datatype format definition in the CSI2 standard. This bit field has no meaning if the FDTFEN bit is cleared.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Flow selection mode

Virtual channel ID of the CSI flow to select for further processing on the pipe.

Bit 18 **PIPEDIFF:** Differentiates Pipe2 from Pipe1

0: Pipe2 receives the same data as Pipe1 (data filtered by Pipe1 configuration for VC and DTIDA/DTIDB and DTMODE mode, as well as FDTF and FDTFEN bit).

1: Pipe1 gets pixels only from VC and DT configured in Pipe1, processed by all blocks belonging to the image processing functional block (demosaicing, auto exposure, statistics, contrast enhancement). Pipe2 gets pixels only from VC/DTID and FDTFEN/FDTF bits configured in Pipe2, processed from Crop. There are no shared functions with Pipe1, fully independent.

This bit must be kept cleared when INSEL = 0 into the DCMIPP_CMCR register.

Bits 17:16 **DTMODE[1:0]**: Flow selection mode

00: Only flow DTIDA from the selected virtual channel is forwarded in the pipe

01: Flows DTIDA and/or DTIDB from the selected virtual channel are forwarded in the pipe

Other values: Reserved.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DTIDB[5:0]**: Data type selection ID B

Data type ID of the CSI flow to select.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Data type selection ID A

Data type ID of the CSI flow to select.

39.14.41 DCMIPP Pipe1 stat removal configuration register (DCMIPP_P1SRCR)

Address offset: 0x820

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CROP EN	FIRSTLINEDEL[2:0]			LASTLINE[11:0]											
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **CROPEN**: Crop line enable

0: No crop (all pixels are fed through)

1: Crop

Bits 14:12 **FIRSTLINEDEL[2:0]**: Amount of first lines to delete when CROPEN = 1

Bits 11:0 **LASTLINE[11:0]**: Amount of following lines to keep when CROPEN = 1.

If LASTLINE = 0 all pixels after FIRSTLINEDEL are fed through.

39.14.42 DCMIPP Pipe1 bad pixel removal control register (DCMIPP_P1BPRCR)

Address offset: 0x824

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STRENGTH[2:0]			ENABLE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:1 **STRENGTH[2:0]**: Strength (aggressiveness) of the bad pixel detection

0x0: The filter is fairly tolerant: only a few pixels are declared bad, due to their high noise

...

0x7: The filter is very aggressive: many pixels are declared bad, even if only slightly noisy.

Bit 0 **ENABLE**:

0: Bypass: bad pixel removal is not active, all pixels are transmitted through

1: Enable: if bad pixel are detected, they are replaced by corrected pixels

Bad pixel detection must be enabled only for raw Bayer flows, as it corrupts RGB flows.

39.14.43 DCMIPP Pipe1 bad pixel removal status register (DCMIPP_P1BPRSR)

Address offset: 0x828

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	BADCNT[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **BADCNT[11:0]**: Amount of detected bad pixels

Counts the amount of bad pixels detected in each frame, and if too many, saturates at its maximum value (4095). It is reclocked at the frame end, to remain stable for reading during the next frame.

39.14.44 DCMIPP Pipe1 decimation register (DCMIPP_P1DECR)

This register controls the input decimation.

Address offset: 0x830

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VDEC[1:0]		HDEC[1:0]		ENABLE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **VDEC[1:0]**: Vertical decimation ratio

0x0: All pixels are transmitted, no vertical decimation

0x1: one line out of two transmitted (for raw Bayer data, two lines of components every four)

0x2: one line out of four transmitted (for raw Bayer data, two lines of components every eight)

0x3: one line out of eight transmitted (for raw Bayer data, two lines of components every 16)

Bits 2:1 **HDEC[1:0]**: Horizontal decimation ratio

0x0: All pixels are transmitted, no horizontal decimation

0x1: one line out of two transmitted (for raw Bayer data, two lines of components every four)

0x2: one line out of four transmitted (for raw Bayer data, two lines of components every eight)

0x3: one line out of eight transmitted (for raw Bayer data, two lines of components every 16)

Bit 0 **ENABLE**:

0: Bypass: decimation is not active, all pixels are transmitted

1: Enable: one pixel every 1, 2, 4, or 8, in H and V is transmitted, following HDEC and VDEC

39.14.45 DCMIPP Pipe1 black level calibration control register (DCMIPP_P1BLCCR)

Address offset: 0x840

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BLCR[7:0]								BLCG[7:0]

BLCB[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLE
rw	rw	rw	rw	rw	rw	rw	rw								rw

Bits 31:24 **BLCR[7:0]**: Black level calibration - Red

Value subtracted from the red input MSB component, whether it is on 8, 10, 12, 14 bits.

Bits 23:16 **BLCG[7:0]**: Black level calibration - Green

Value subtracted from the green input MSB component, whether it is on 8, 10, 12, 14 bits.

Bits 15:8 **BLCB[7:0]**: Black level calibration - Blue
Value subtracted from the blue input MSB component, whether it is on 8, 10, 12, 14 bits.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: Black level calibration
0: Bypass: black level calibration is not active, all pixels are transmitted non-modified.
1: Enable: the BLC R, G, B are subtracted.

39.14.46 DCMIPP Pipe1 exposure control register 1 (DCMIPP_P1EXCR1)

Address offset: 0x844

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SHFR[2:0]			MULTR[7:0]								Res.	Res.	Res.	Res.
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLE
															rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SHFR[2:0]**: Exposure shift - Red
0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of reds is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 27:20 **MULTR[7:0]**: Exposure multiplier - Red
Value that is multiplied for the red input components, whether it is on 8, 10, 12, 14 bits.
Multiplying by 64 reduces the exposure (darkens the reds) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the reds as-is).
Multiplying by 255 increase the exposure (lightens the reds) by a factor ~2x.

Bits 19:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: Exposure control (multiplication and shift) of all red, green and blue
0: Bypass: exposure multiplier and shift are not applied
1: Enable: the exposure multiplication and shift is applied

39.14.47 DCMIPP Pipe1 exposure control register 2 (DCMIPP_P1EXCR2)

Address offset: 0x848

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SHFG[2:0]			MULTG[7:0]								Res.	Res.	Res.	Res.
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SHFB[2:0]			MULTB[7:0]								Res.	Res.	Res.	Res.
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SHFG[2:0]**: Exposure shift - Green

0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: Exposure of greens is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 27:20 **MULTG[7:0]**: Exposure multiplier - Green

Value that is multiplied for the green input components, whether it is on 8, 10, 12, 14 bits.
Multiplying by 64 reduces the exposure (darkens the greens) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the greens as-is).
Multiplying by 255 increases the exposure (lightens the greens) by a factor ~2x.

Bits 19:15 Reserved, must be kept at reset value.

Bits 14:12 **SHFB[2:0]**: Exposure shift - Blue

0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of blues is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 11:4 **MULTB[7:0]**: Exposure multiplier - Blue

Value that is multiplied for the blue input components, whether it is on 8, 10, 12, 14 bits.
Multiplying by 64 reduces the exposure (darkens the blues) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the blues as-is).
Multiplying by 255 increases the exposure (lightens the blues) by a factor ~2x.

Bits 3:0 Reserved, must be kept at reset value.

39.14.48 DCMIPP Pipe1 statistics1 control register (DCMIPP_P1ST1CR)

Address offset: 0x850

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODE	SRC[2:0]			BINS[1:0]		Res.	ENABLE
								rw	rw	rw	rw	rw	rw		rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **MODE**: Statistics mode

0: Average: accumulates the 8-bit component value of the considered pixel components.
Typically used to extract the average value of R, G, B, or luminance across the picture, and to drive the exposure control and the white balance.
1: Bins: accumulates 256 for each considered pixel component fitting a bin dynamic.
Typically used to extract how many pixel components fall into the various dynamic bins, and to drive the contrast enhancement.

Bits 6:4 **SRC[2:0]**: Statistics source

0x0, 0x1, 0x2, 0x3: components are sampled after decimation, and sample, respectively, red, green, blue, and luminance. For raw Bayer formats, only one component is available by pixel.
0x4, 0x5, 0x6, 0x7: components are sampled after demosaicing, and sample, respectively, red, green, blue, and luminance.

Bits 3:2 **BINS[1:0]**: Current bin definition
Condition: MODE = Bins
0x0: LowerBins: Accu0 (1, 2) is incremented of 256 if Component <4 (<8, <16)
0x1: LowMid Bins: Accu0 (1, 2) is incremented of 256 if Component <32 (<64, <128)
0x2: UpMid Bins: Accu0 (1, 2) is incremented of 256 if Component >127 (>191, >224)
0x3: UpBins: Accu0 (1, 2) is incremented of 256 if Component >239 (>247, >251)
Condition: MODE = Average
0x0: All Pixels: Accu is incremented of Component, if 0 ≤ Component < 256.
0x1: NoExt16: Accu is incremented of Component, if 16 ≤ Component < 240
0x2: NoExt32: Accu is incremented of Component, if 32 ≤ Component < 224
0x3: NoExt64: Accu is incremented of Component, if 64 ≤ Component < 192

Bit 1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**:
0: Disabled: statistics are not accumulated
1: Enable: statistics are accumulated

39.14.49 DCMIPP Pipe1 statistics 2 control register (DCMIPP_P1ST2CR)

Address offset: 0x854

Reset value: 0x0000 0000

Bits 24:23 Reserved, must be kept at reset value.

Bits 22:17 **LUM6[5:0]**: Luminance increase for input luminance of 192 (increase is idle with LUMx = 16)

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:9 **LUM7[5:0]**: Luminance increase for input luminance of 224 (increase is idle with LUMx = 16)

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:1 **LUM8[5:0]**: Luminance increase for input luminance of 256 (increase is idle with LUMx = 16)

Bit 0 Reserved, must be kept at reset value.

39.14.67 DCMIPP Pipex flow control configuration register (DCMIPP_PxFCTCR)

Address offset: 0x900 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPT REQ	CPT MODE	FRATE[1:0]	
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CPTREQ:** Capture requested

0: Capture not requested for next frame

1: Capture requested for next frame

When PIPEN = 1, and when the CPTREQ is set to 1, the pipe waits for the first VSync, then automatically starts a capture and sets CPTACT = 1 to mention it.

In Snapshot mode, the CPTREQ bit is automatically cleared at the start of the first frame received.

In continuous grab mode, the capture remains active and CPTREQ = 1, until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.

The DCMI and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 **CPTMODE:** Capture mode

0: Continuous grab mode. The received data are transferred into the destination memory through the AXI master.

1: Snapshot mode (single frame). Once activated, the interface waits for the start of frame, and then transfers a single frame through the AXI master. At the end of the frame, the CPTACT bit is automatically reset.

Bits 1:0 **FRATE[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.

00: All frames are captured

01: one out of two frames captured (50% bandwidth reduction)

10: one out of four frames captured (75% bandwidth reduction)

11: one out of eight frames captured (87% bandwidth reduction)

39.14.68 DCMIPP Pipex crop window start register (DCMIPP_PxCRSTR)

Address offset: 0x904 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	HSIZE[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **ENABLE**:
0: Bypass, all pixels are transmitted through (no need to set any start and size values)
1: Enable, only the rectangle defined by VSIZE, HSIZE, VSTART, HSTART is transmitted.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Vertical size, from 0 to 4094 pixels high. If the value is maintained at 0 when enabling the crop thanks to the ENABLE bit, the value is forced internally at 0xFFE, which is the maximum value.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Horizontal size, from 0 to 4094 pixels wide. If the value is maintained at 0 when enabling the crop by means of the ENABLE bit, the value is forced internally at 0xFFE, which is the maximum value.

39.14.70 DCMIPP Pipex decimation register (DCMIPP_PxDCCR)

This register controls decimation, prior to downsize (to complement it).

Address offset: 0x90C + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VDEC[1:0]		HDEC[1:0]		ENABLE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **VDEC[1:0]**: Vertical decimation ratio
0x0: all pixels are transmitted, no vertical decimation
0x1: one line out of two transmitted
0x2: one line out of four transmitted
0x3: one line out of eight transmitted

Bits 2:1 **HDEC[1:0]**: Horizontal decimation ratio
0x0: all pixels are transmitted, no horizontal decimation
0x1: one line out of two transmitted
0x2: one line out of four transmitted
0x3: one line out of eight transmitted

Bit 0 **ENABLE**:
0: Bypass: decimation is not active, all pixels are transmitted
1: Enable: one pixel every 1, 2, 4 or 8, in H and V is transmitted, following HDEC and VDEC

39.14.71 DCMIPP Pipex downsize configuration register (DCMIPP_PxDSCR)

Address offset: 0x910 + 0x400 * (x - 1) (x = 1 to 2)

Reset value: 0x0000 0000

The division factor is an unsigned integer based on the source/destination ratio:

div = max(int(1024 / (source/destination)), 1023)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LINEMULT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	FORMAT[3:0]			
rw	rw	rw									rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **LMAWE**: Line multi address wrapping enable bit.
Enables the wrapping of the address every power-of-2 of written lines.
0: Line multi address wrapping disabled.
1: Line multi address wrapping enabled.

Bits 19:17 **LMAWM[2:0]**: Line multi address wrapping modulo.
Amount of captured lines after which write address is wrapped back to the BaseAddress. It is used to write a full frame onto a circular (ping-pong) buffer.
000: Wraps address after every line
001: Wraps address after two lines
010: Wraps address after four lines
011: Wraps address after eight lines
100: Wraps address after sixteen lines
101: Wraps address after 32 lines
110: Wraps address after 64 lines
111: Wraps address after 128 lines

Bit 16 **DBM:** Double buffer mode
This bit is set and cleared by software.
0: No double buffer mode activated. Pipe1 always drains out the pixels to memory address set by DCMIPP_P1PPM0AR1, and DCMIPP_P1PPM1AR1 as well as DCMIPP_P1PPM2AR1 in case of semi-planar or multi-planar buffer configuration
1: Double buffer mode activated. Output pixels address location switches from DCMIPP_P1PPM0AR1 to DCMIPP_P1PPM0AR2 alternatively on each frame. For the semi- and multi-planar operations, the output pixels switches from/to DCMIPP_P1PPM1AR1 to/from DCMIPP_P1PPM1AR2. Memory buffer switches from/to DCMIPP_P1PPM2AR1 to/from DCMIPP_P1PPM2AR2 for multi-planar operations.

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE Event and Interrupt
0x0: Event after one line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **SWAPRB**: Swaps R-vs-B components if RGB, and U-vs-V components if YUV
0: No swap of R-vs-B (U-vs-V)
1: Swap active

Bits 3:0 **FORMAT[3:0]**: Memory format
0x0: RGB888 or YUV444 1-buffer
0x1: RGB565 1-buffer
0x2: ARGB8888 (with A = 0xFF)
0x3: RGBA8888 (with A = 0xFF)
0x4: monochrome Y8 or G8 1-buffer
0x5: YUV444 1-buffer (32 bpp, FOURCC = AYUV, with A = 0xFF)
0x6: YUV422 1-buffer (16 bpp, FOURCC = YUYV)
0x7: YUV422 2-buffer (16 bpp, FOURCC = none)
0x8: YUV420 2-buffer (12 bpp, FOURCC = NV21), NV12 available with SWAPRB = 1
0x9: YUV420 3-buffer (12 bpp, FOURCC = YV12)
0xA: YUV422 1-buffer (16 bpp, FOURCC = UYVY)
Other formats are reserved and not supported.

39.14.86 DCMIPP Pipe1 pixel packer Memory0 address register 1 (DCMIPP_P1PPM0AR1)

Address offset: 0x9C4

Reset value: 0x0000 0000

Res.	PITCH[14:0]														
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **PITCH[14:0]**: Number of bytes between the address of two consecutive lines.

It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0. It ranges to 32 Kbytes, to allow a double-width buffer, containing a 4-kpixel wide 32 bpp picture.

39.14.89 DCMIPP Pipex status Memory0 address register (DCMIPP_PxSTM0AR)

Address offset: 0x9D0 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVRIE	Res.	Res.	Res.	Res.	VSYNCIE	FRAMEIE	LINEIE
								rw					rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OVRIE:** Overrun interrupt enable

0: No interrupt generation

1: An interrupt is generated if the AXI master is unable to transfer the last data before new data (32-bit) are received.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **VSYNCIE:** VSYNC interrupt enable

0: No interrupt generation

1: An interrupt is generated on each VSYNC (captured or not)

Bit 1 **FRAMEIE:** Frame capture completed interrupt enable

0: No interrupt generation

1: An interrupt is generated after the full capture of a cropped frame

Bit 0 **LINEIE:** Multi-line capture completed interrupt enable

0: No interrupt generation when the line is received

1: An interrupt is generated after the full capture of a group of lines (or last line reached)

39.14.98 DCMIPP Pipe1 status register (DCMIPP_P1SR)

Address offset: 0x9F8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPTACT	Res.	Res.	Res.	Res.	Res.	LSTFRM	LSTLINE
								r						r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVRF	Res.	Res.	Res.	Res.	VSYNCF	FRAMEF	LINEF
								r					r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CPTACT:** Capture immediate status
0: Capture currently inactive
1: Capture currently active
This bit is automatically reset at the end of Frame capture complete event (after all the data of that frame have been captured, usually before the next VSync).

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **LSTFRM**: Last frame LSB bit, sampled at frame capture complete event. The information is extracted from the frame data number, which can be delivered by the camera through the CSI2 interface.

Bit 16 **LSTLINE**: Last line LSB bit, sampled at frame capture complete event.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **OVRF:** Overrun raw interrupt status
0: No data buffer overrun occurred
1: A data buffer overrun occurred and this frame data are corrupted.
This bit is cleared by writing 1 to the COVRF bit in DCMIPP_P1FCR.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **VSYNCF:** VSYNC raw interrupt status
This bit is set when the VSYNC signal changes from the inactive state to the active state.
In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMIPP_CR.
It is cleared by writing 1 to the CVSYNCF bit in DCMIPP_P1FCR.

Bit 1 **FRAMEF:** Frame capture completed raw interrupt status
0: no capture or ongoing capture
1: all data of a frame have been captured
This bit is set when all data of a frame or window have been captured.
In case of a cropped window, this bit is set at the end of line of the last line in the crop, even if the captured frame is empty (for example window cropped outside the frame).
This bit is cleared by writing 1 to the CFRAMEF bit in DCMIPP_P1FCR.

Bit 0 **LINEF:** Multi-line capture completed raw interrupt status

This bit is set when one/more lines have been completed. The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P1PPCR. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMIPP_CR is set. It is cleared by writing 1 to the CLINEF bit in DCMIPP_P1FCR.

39.14.99 DCMIPP Pipe1 interrupt clear register (DCMIPP_P1FCR)

Address offset: 0x9FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COVRF	Res.	Res.	Res.	Res.	CVSYNCF	CFRAMEF	CLINEF
								w					w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COVRF:** Overrun interrupt status clear

Writing 1 into this bit clears the OVRF bit in the DCMIPP_P1SR register.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CVSYNCF:** Vertical synchronization interrupt status clear

Writing 1 into this bit clears the VSYNCF bit in the DCMIPP_P1SR register.

Bit 1 **CFRAMEF:** Frame capture complete interrupt status clear

Writing 1 into this bit clears the FRAMEF bit in the DCMIPP_P1SR register.

Bit 0 **CLINEF:** Multi-line capture complete interrupt status clear

Writing 1 into this bit clears LINEF in the DCMIPP_P1SR register.

39.14.100 DCMIPP Pipe1 current flow selection configuration register (DCMIPP_P1CFSCR)

Address offset: 0xA04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	FDTFEN	FDTF[5:0]						Res.	Res.	Res.	VC[1:0]		PIPEDIFF	DTMODE[1:0]	
r	r	r	r	r	r	r	r				r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	DTIDB[5:0]						Res.	Res.	DTIDA[5:0]					
		r	r	r	r	r	r			r	r	r	r	r	r

Bit 31 **PIPEN**: Current activation of PipeN

0: Pipe disabled

1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK.

Bit 30 **FDTFEN**: Current force data type format enable

0: Disable force data type format. The data type format used by the pipe is the one defined into DTIDx

1: Enable force data type format. When the data type DTIDx is detected by the pipe, the real pixel format considering by the pipe is the one set into the FDTF[5:0] bit field instead of the physical one received by the CSI2 host. It allows to handle, for instance, 3D sensors camera with user data type in bottom-up approach, and to explicitly define the pixel format to be handled by the pipe.

Bits 29:24 **FDTF[5:0]**: Current force data type format

Forcing the data type format. This data type overwrites the one received by the CSI2-HOST by specifying the pixel format to consider. The value must follow the CSI2 data type format definition in the CSI2 standard. This bit field has no meaning if the FDTFEN bit is cleared.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Current flow selection mode

Virtual channel ID of the CSI flow to select for further processing on the pipe.

Bit 18 **PIPEDIFF:** Current differentiates Pipe2 vs. Pipe1

0: Pipe2 gets Pipe1 pixels after their processing in shared Gamma, StatRemoval, Demosaicing. Pipe2 shares the same VC DTID of Pipe1 when a CSI2 camera sensor is plugged.

1: Pipe1 gets pixels from only VC/DTID configured in Pipe1, processed by all including Gamma, StatRemoval, Demosaicing. Pipe2 gets pixels from only VC/DTID configured in Pipe2, processed from Crop only (Gamma common with Pipe1, no StatRem, no demosaicing)

Bits 17:16 **DTMODE[1:0]**: Flow selection mode

00: Only flow DTID A from the selected virtual channel is forwarded in the pipe.

01: Flows DTIDA and DTIDB from the selected virtual channel are forwarded in the pipe. This combination is valid only if the FDTFEN bit is set.

Other values: Reserved.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DTIDB[5:0]**: Current data type ID B

Data type ID of the CSI flow to select.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Current data type ID A

Data type ID of the CSI flow to select.

39.14.101 DCMIPP Pipe1 current bad pixel removal register (DCMIPP_P1CBPRCR)

Address offset: 0xA24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STRENGTH[2:0]			ENABLE
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:1 **STRENGTH[2:0]**: Current strength (aggressiveness) of the bad pixel detection:
0x0: the filter is fairly tolerant: only a few pixels are declared bad, due to their high noise.
0x7: the filter is very aggressive: many pixels are declared bad, even if only slightly noisy.

Bit 0 **ENABLE**: Current status of enable bit
0: Bypass: bad pixel removal is not active, all pixels are transmitted through
1: Enable: if bad pixel are detected, they are replaced by corrected pixels.
(bad pixel detection must be enabled only for raw Bayer flows, as it would corrupt RGB flows)

39.14.102 DCMIPP Pipe1 current black level calibration control register (DCMIPP_P1CBLCCR)

Address offset: 0xA40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BLCR[7:0]								BLCG[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BLCB[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLE
r	r	r	r	r	r	r	r								r

Bits 31:24 **BLCR[7:0]**: Current black level calibration - Red
Value that is subtracted from the red input components, whether it is on 8,10,12,14 bits.

Bits 23:16 **BLCG[7:0]**: Current black level calibration - Green
Value that is subtracted from the green input components, whether it is on 8,10,12,14 bits.

Bits 15:8 **BLCB[7:0]**: Current black level calibration - Blue
Value that is subtracted from the blue input components, whether it is on 8,10,12,14 bits.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: For current black level calibration
0: Bypass: black level calibration is not active, all pixels are transmitted non-modified.
1: Enable: the BLCR, G, B are subtracted.

39.14.103 DCMIPP Pipe1 current exposure control register 1 (DCMIPP_P1CEXCR1)

Address offset: 0xA44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SHFR[2:0]			MULTR[7:0]								Res.	Res.	Res.	Res.
	r	r	r	r	r	r	r	r	r	r	r				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLE
															r

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SHFR[2:0]**: Current exposure shift - Red
0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of reds is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 27:20 **MULTR[7:0]**: Current exposure multiplier - Red
Value that is multiplied for the red input components, whether it is on 8,10,12,14 bits.
Multiplying by 64 reduces the exposure (darkens the reds) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the reds as-is).
Multiplying by 255 increases the exposure (lightens the reds) by a factor ~2x.

Bits 19:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: for exposure control (multiplication and shift)
0: Bypass: exposure multiplier and shift are not applied.
1: Enable: the exposure multiplication and shift is applied.

39.14.104 DCMIPP Pipe1 current exposure control register 2 (DCMIPP_P1CEXCR2)

Address offset: 0xA48

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SHFG[2:0]			MULTG[7:0]								Res.	Res.	Res.	Res.
	r	r	r	r	r	r	r	r	r	r	r				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SHFB[2:0]			MULTB[7:0]								Res.	Res.	Res.	Res.
	r	r	r	r	r	r	r	r	r	r	r				

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SHFG[2:0]**: Current exposure shift - Green
0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of greens is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 27:20 **MULTG[7:0]**: Current exposure multiplier - Green
Value that is multiplied for the green input components, whether it is on 8,10,12,14 bits.
Multiplying by 64 reduces the exposure (darkens the greens) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the greens as-is).
Multiplying by 255 increases the exposure (lightens the greens) by a factor ~2x.

Bits 19:15 Reserved, must be kept at reset value.

Bits 14:12 **SHFB[2:0]**: Current exposure shift - Blue
0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of blues is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 11:4 **MULTB[7:0]**: Current exposure multiplier - Blue
Value that is multiplied for the blue input components, whether it is on 8,10,12,14 bits.
Multiplying by 64 reduces the exposure (darkens the blues) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the blues as-is).
Multiplying by 255 increases the exposure (lightens the blues) by a factor ~2x.

Bits 3:0 Reserved, must be kept at reset value.

39.14.105 DCMIPP Pipe1 current statistics 1 control register (DCMIPP_P1CST1CR)

Address offset: 0xA50

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ACCU[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACCU[7:0]								MODE	SRC[2:0]			BINS[1:0]		Res.	ENABLE
r	r	r	r	r	r	r	r	r	r	r	r	r	r		r

Bits 31:8 **ACCU[23:0]**: Current accumulation result, divided by 256.

Bit 7 **MODE**: Current statistics mode
0: Average: accumulates the 8-bit component value of the considered pixel components.
It is typically used to extract the average value of R, G, B, or luminance across the picture, and to drive the exposure control and the white balance.
1: Bins: accumulates 256 for each considered pixel component fitting a bin dynamic.
It is typically used to extract how many pixel components fall into the various dynamic bins.
It is usually used to drive the contrast enhancement.

Bits 6:4 **SRC[2:0]**: Current source of statistics
0x0, 0x1, 0x2, 0x3: components are sampled before the black level calibration and exposure, and sample, respectively, the red, green, blue components, and luminance (computed as R / 4 + G / 2 + B / 4).
0x4, 0x5, 0x6, 0x7: components are sampled after the black level calibration and exposure, and sample, respectively, red, green, blue and luminance.

Bits 3:2 **BINS[1:0]**: Current bin definition
Condition: MODE = Bins
0x0: LowerBins: Accu0 (1, 2) is incremented of 256 if Component <4 (<8, <16)
0x1: LowMid Bins: Accu0 (1, 2) is incremented of 256 if Component <32 (<64, <128)
0x2: UpMid Bins: Accu0 (1, 2) is incremented of 256 if Component >127 (>191, >224)
0x3: UpBins: Accu0 (1, 2) is incremented of 256 if Component >239 (>247, >251)
Condition: MODE = Average
0x0: AllPixels: Accu is incremented of Component, if 0 ≤ Component < 256
0x1: NoExt16: Accu is incremented of Component, if 16 ≤ Component < 240
0x2: NoExt32: Accu is incremented of Component, if 32 ≤ Component < 224
0x3: NoExt64: Accu is incremented of Component, if 64 ≤ Component < 192

Bit 1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: Current enable bit value

0: Disabled: statistics are not accumulated

1: Enable: statistics are accumulated

39.14.106 DCMIPP Pipe1 current statistics 2 control register (DCMIPP_P1CST2CR)

Address offset: 0xA54

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	HSIZE[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **CROPEN**: Current CROPEN bit value

0: Bypass, all pixels are used to compute the statistics.

1: Enable, only the rectangle defined by VSTART, HSTART, VSIZE, HSIZE, are used for statistics.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Current vertical size, from 0 to 4094 pixels high

If the value is maintained at 0 when enabling the crop by means of the CROPEN bit, the value is forced internally at 0xFFE, which is the maximum value.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Current horizontal size, from 0 to 4094 pixels wide

If the value is maintained at 0 when enabling the crop by means of the CROPEN bit, the value is forced internally at 0xFFE, which is the maximum value.

39.14.110 DCMIPP Pipe1 current ColorConv configuration register (DCMIPP_P1CCCCR)

Address offset: 0xA80

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLAMP	TYPE	ENABLE
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CLAMP**: Clamp the output samples
This bit indicates the current value applied.
0: Not activated (clamped to [0;255] by default)
1: Activated, depending on TYPE

Bit 1 **TYPE**: Output samples type used while CLAMP is activated
This bit indicates the current value applied
0: clamped to [16;235] for Y and to [16;240] for U and V
1: clamped to [16;235] for R, G and B

Bit 0 **ENABLE**: Current value applied
0: ColorConv is bypassed
1: ColorConv is enabled

39.14.111 DCMIPP Pipe1 current ColorConv red coefficient register 1 (DCMIPP_P1CCCRR1)

Address offset: 0xA84

Reset value: 0x0000 0000

Coefficients of the ColorConv, in signed 2.8 format (1.0 is coded by 0x100):

int_value = int(float_value * (1 « 8) + 0.5**)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 24:23 Reserved, must be kept at reset value.

Bits 22:17 **LUM6[5:0]**: Luminance increase for input luminance of 192 (increase is idle with LUMx = 16)

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:9 **LUM7[5:0]**: Luminance increase for input luminance of 224 (increase is idle with LUMx = 16)

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:1 **LUM8[5:0]**: Luminance increase for input luminance of 256 (increase is idle with LUMx = 16)

Bit 0 Reserved, must be kept at reset value.

39.14.120 DCMIPP Pipex current flow control configuration register (DCMIPP_PxCFCTCR)

Address offset: 0xB00 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPT REQ	CPT MODE	FRATE[1:0]	
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CPTREQ:** Capture requested

0: Capture not requested for next frame.

1: Capture requested for next frame.

When PIPEN = 1, and when the CPTREQ is set to 1 the pipe waits for the first VSync, and automatically starts a capture and sets CPTACT= 1 to mention it.

In Snapshot mode, the CPTREQ bit is automatically cleared at the start of the first frame received.

In continuous grab mode, the capture remains active and CPTREQ = 1, until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.

The DCMIPP and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 **CPTMODE:** Capture mode

0: Continuous grab mode - Received data are transferred into the destination memory through the AXI master.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the AXI master. At the end of the frame, the CPTACT bit is automatically reset.

Bits 1:0 **FRATE[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.

00: all frames are captured

01: one out of two frames captured (50% bandwidth reduction)

10: one out of four frames captured (75% bandwidth reduction)

11: one out of eight frames captured (87% bandwidth reduction)

39.14.121 DCMIPP Pipex current crop window start register (DCMIPP_PxCCRSTR)

Address offset: 0xB04 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VDEC[1:0]		HDEC[1:0]		ENABLE
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **VDEC[1:0]**: Vertical decimation ratio
- 0x0: All pixels are transmitted, no vertical decimation
- 0x1: one line out of two transmitted
- 0x2: one line out of four transmitted
- 0x3: one line out of eight transmitted

Bits 2:1 **HDEC[1:0]**: Horizontal decimation ratio
- 0x0: All pixels are transmitted, no horizontal decimation
- 0x1: one line out of two transmitted
- 0x2: one line out of four transmitted
- 0x3: one line out of eight transmitted

Bit 0 **ENABLE**:
- 0: Bypass: decimation is not active, all pixels are transmitted
- 1: Enable: one pixel every 1, 2, 4 or 8, in H and V is transmitted, following HDEC and VDEC

39.14.124 DCMIPP Pipex current downsize configuration register (DCMIPP_PxCDSCR)

Address offset: 0xB10 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

The division factor is an unsigned integer based on the source/destination ratio:

div = max(int(024 / (source/destination)), 1023)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LINEMULT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	FORMAT[3:0]			
r	r	r									r	r	r	r	r

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **LMAWE**: Line multi address wrapping enable bit

Enables the wrapping of the address every power-of-2 of written lines.

0: Line multi address wrapping disabled.

1: Line multi address wrapping enabled.

Bits 19:17 **LMAWM[2:0]**: Line multi address wrapping modulo

Amount of captured lines after which the write address is wrapped back to the BaseAddress. It is used to write a full frame onto a circular (ping-pong) buffer.

000: Wraps address after every line

001: Wraps address after two lines

010: Wraps address after four lines

011: Wraps address after eight lines

100: Wraps address after sixteen lines

101: Wraps address after 32 lines

110: Wraps address after 64 lines

111: Wraps address after 128 lines

Bit 16 **DBM:** Double buffer mode

This bit is set and cleared by software.

0: No double buffer mode activated. Pipe1 always drains out the pixels to memory address set by DCMIPP_P1PPM0AR1, and DCMIPP_P1PPM1AR1 as well as DCMIPP_P1PPM2AR1 in case of semi-planar or multi-planar buffer configuration

1: Double buffer mode activated. Output pixels address location switches from DCMIPP_P1PPM0AR1 to DCMIPP_P1PPM0AR2 alternatively on each frame. For the semi- and multi-planar operations, the output pixels switches from/to DCMIPP_P1PPM1AR1 to/from DCMIPP_P1PPM1AR2. Memory buffer switches from/to DCMIPP_P1PPM2AR1 to/from DCMIPP_P1PPM2AR2 for multi-planar operations.

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE Event and Interrupt
0x0: Event after one line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **SWAPRB**: Swaps R-vs-B components if RGB, and U-vs-V components if YUV
0: No swap of R-vs-B (U-vs-V)
1: Swap active

Bits 3:0 **FORMAT[3:0]**: Memory format
0x0: RGB888 or YUV444 1-buffer
0x1: RGB565 1-buffer
0x2: ARGB8888 (with A = 0xFF)
0x3: RGBA8888 (with A = 0xFF)
0x4: monochrome Y8 or G8 1-buffer
0x5: YUV444 1-buffer (32 bpp, FOURCC = AYUV, with A = 0xFF)
0x6: YUV422 1-buffer (16 bpp, FOURCC = YUYV)
0x7: YUV422 2-buffer (16 bpp, FOURCC = none)
0x8: YUV420 2-buffer (12 bpp, FOURCC = NV21), NV12 available with SWAPRB = 1
0x9: YUV420 3-buffer (12 bpp, FOURCC = YV12)
0xA: YUV422 1-buffer (16 bpp, FOURCC = UYVY)
Other formats are reserved and not supported.

39.14.131 DCMIPP Pipe1 current pixel packer Memory0 address register 1 (DCMIPP_P1CPPM0AR1)

Address offset: 0xBC4

Reset value: 0x0000 0000

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M2A[31:0]**: Memory 2 address

Base address of current memory area 2 where data are written. It is assumed to be a multiple of 16, hence its bits [3:0] are always at 0x0.

39.14.139 DCMIPP Pipe2 flow selection configuration register (DCMIPP_P2FSCR)

Address offset: 0xC04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	FDTFEN	FDTF[5:0]						Res.	Res.	Res.	VC[1:0]		Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw				rw	rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTIDA[5:0]					
										rw	rw	rw	rw	rw	rw

Bit 31 **PIPEN**: Activation of PipeN

0: PipeN disabled

1: PipeN enabled, can start capturing with CPTMODE, CPTREQ, CPTACK

Bit 30 **FDTFEN**: Force data type format enable

0: Disable force data type format. The data type format used by the pipe is the one defined into DTIDx

1: Enable force data type format. When the data type DTIDA is detected by the pipe, the real pixel format considered by the pipe is the one set into the FDTF[5:0] bit field instead of the physical one received by the CSI2 host.

This bit has no meaning if PIPEDIFF = 0 in the DCMIPP_P1FSCR register.

Bits 29:24 **FDTF[5:0]**: Force data type format

This data type overwrites the one received by the CSI2 Host by specifying the pixel format to consider. The value must follow the CSI2 data type format definition in the CSI2 standard. This bit field has no meaning if the FDTFEN bit is cleared.

These bits have no meaning if PIPEDIFF = 0 in the DCMIPP_P1FSCR register.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Flow selection mode

Virtual channel ID of the CSI flow to select for further processing on the pipe.

These bits have no meaning if PIPEDIFF = 0 into DCMIPP_P1FSCR, hence the pipe takes the value VC[1:0] configured into the DMCIPP_P1FSCR register.

Bits 18:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Data type ID

Data type ID of the CSI flow to select.

These bits have no meaning if PIPEDIFF = 0 into DCMIPP_P1FSCR, hence the pipe takes the value of VC and DTIDA[5:0] / DTIDB[5:0] configured into the DMCIPP_P1FSCR register.

39.14.140 DCMIPP Pipe2 ROIx configuration register 1 (DCMIPP_P2RIxCR1)

Address offset: 0xD24 + 0x8 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

CLG[1:0]		CLB[1:0]		HSTART[11:0]											
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **CLR[1:0]:** Color line red

These bits are written and cleared by software or hardware. The two bits coding the red value are duplicated over 8 bits as 0bCLR1 CLR0 CLR1 CLR0 CLR1 CLR0 CLR1 CLR0.

Bits 27:16 **VSTART**[11:0]: Vertical start, from 0 to 4094 pixels high

Bits 15:14 **CLG[1:0]:** Color line green

These bits are written and cleared by software or hardware. The two bits coding the green value are duplicated over 8 bits as 0bCLG1 CLG0 CLG1 CLG0 CLG1 CLG0 CLG1 CLG0.

Bits 13:12 **CLB[1:0]:** Color line blue

These bits are written and cleared by software or hardware. The two bits coding the red value are duplicated over 8 bits as 0bCLB1 CLB0 CLB1 CLB0 CLB1 CLB0 CLB1 CLB0.

Bits 11:0 **HSTART**[11:0]: Horizontal start, from 0 to 4094 pixels wide

39.14.141 DCMIPP Pipe2 ROIx configuration register 2 (DCMIPP_P2RIxCR2)

Address offset: 0xD28 + 0x8 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

Bit 20 **LMAWE**: Line multi address wrapping enable bit

Enables the wrapping of the address every power-of-2 of written lines.

0: Line multi address wrapping disabled.

1: Line multi address wrapping enabled.

Bits 19:17 **LMAWM[2:0]**: Line multi address wrapping modulo
Amount of captured lines after which the write address is wrapped back to the BaseAddress. It is used to write a full frame onto a circular (ping-pong) buffer.
000: Wraps address after every line
001: Wraps address after two lines
010: Wraps address after four lines
011: Wraps address after eight lines
100: Wraps address after sixteen lines
101: Wraps address after 32 lines
110: Wraps address after 64 lines
111: Wraps address after 128 lines

Bit 16 **DBM:** Double buffer mode
This bit is set and cleared by software.
0: No double buffer mode activated. Pipe2 is always dump to memory address set by DCMIPP_P2PPM0AR1
1: Double buffer mode activated. Dump address location switches from DCMIPP_P2PPM0AR1 register to DCMIPP_P2PPM0AR2 register alternatively on each frame

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE event and interrupt
0x0: Event after every line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **SWAPRB**: Swaps R-vs-B components if RGB, and if YUV, swaps U-vs-V components
0: No swap of R-vs-B (U-vs-V)
1: Swap active.

Bits 3:0 **FORMAT[3:0]**: Memory format (only coplanar formats are supported in Pipe2)
0x0: RG/B888 or YUV444 1-buffer
0x1: RGB565 1-buffer
0x2: ARGB8888
0x3: RGBA8888
0x4: monochrome Y8 or G8 1-buffer
0x5: YUV444 1-buffer (FOURCC = AYUV)
0x6: YUV422 1-buffer (FOURCC = YUYV)
Other formats are reserved and not supported.

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OVRIE:** Overrun interrupt enable
0: No interrupt generation
1: An interrupt is generated if the AXI master is unable to transfer the last data before new data (32-bit) are received

Bits 6:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCIE:** VSYNC interrupt enable
0: No interrupt generation
1: An interrupt is generated on each VSYNC (captured or not)

Bit 1 **FRAMEIE:** Frame capture completed interrupt enable
0: No interrupt generation
1: An interrupt is generated after the full capture of a cropped frame

Bit 0 **LINEIE:** Multi-line capture completed interrupt enable
0: No interrupt generation when the line is received
1: An interrupt is generated after the full capture of a group of lines (or last line reached)

39.14.146 DCMIPP Pipe2 status register (DCMIPP_P2SR)

Address offset: 0xDF8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVRF	Res.	Res.	Res.	Res.	VSYNCF	FRAMEF	LINEF
								r					r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CPTACT:** Capture immediate status
0: Capture currently inactive
1: Capture currently active
This bit is automatically reset at the end of frame capture complete event (after all the data of that frame have been captured, usually before the next VSync).

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **LSTFRM**: Last frame LSB bit, sampled at frame capture complete event.
The information is extracted from the frame data number which can be delivered by the camera through the CSI2 interface.

Bit 16 **LSTLINE**: Last line LSB bit, sampled at frame capture complete event.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **OVRF:** Overrun raw interrupt status
0: No data buffer overrun occurred
1: A data buffer overrun occurred and data of this frame are corrupted
This bit is cleared by writing 1 to the COVRF bit in the DCMIPP_P2FCR register.

Bits 6:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCF:** VSYNC raw interrupt status
This bit is set when the VSYNC signal changes from the inactive state to the active state. In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in the DCMIPP_CR register. It is cleared by writing 1 to the CVSYNCF bit in the DCMIPP_P2FCR register.

Bit 1 **FRAMEF:** Frame capture completed raw interrupt status
0: No capture or ongoing capture
1: All data of a frame have been captured
This bit is set when all data of a frame or window have been captured.
In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).
This bit is cleared by writing 1 to the CFRAMEF bit in DCMIPP_P2FCR.

Bit 0 **LINEF:** Multi-line capture completed raw interrupt status
This bit is set when one/more lines have been completed.
The periodicity of LINEF event is configured bu LINEMULT bits into DCMIPP_P1PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame.
In the case of embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set.
It is cleared by writing 1 to the CLINEF bit in the DCMIPP_P2FCR register.

39.14.147 DCMIPP Pipe2 interrupt clear register (DCMIPP_P2FCR)

Address offset: 0xDFC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	C OVRF	Res.	Res.	Res.	Res.	C VSYNCF	C FRAMEF	C LINEF
								w					w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COVRF:** Overrun interrupt status clear
Writing 1 into this bit clears the OVRF bit in the DCMIPP_P2SR register.

Bits 6:3 Reserved, must be kept at reset value.

Bit 2 **CVSYNCF:** Vertical synchronization interrupt status clear
Writing 1 into this bit clears the VSYNCF bit in the DCMIPP_P2SR register.

Bit 1 **CFRAMEF:** Frame capture complete interrupt status clear
Writing 1 into this bit clears the FRAMEF bit in the DCMIPP_P2SR register.

Bit 0 **CLINEF:** Multi-line capture complete interrupt status clear
Writing 1 into this bit clears LINEF in the DCMIPP_P2SR register.

39.14.148 DCMIPP Pipe2 current flow selection configuration register (DCMIPP_P2CFSCR)

Address offset: 0xE04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	FDTFEN	FDTF[5:0]						Res.	Res.	Res.	VC[1:0]		Res.	Res.	Res.
r	r	r	r	r	r	r	r				r	r			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTIDA[5:0]					
										r	r	r	r	r	r

Bit 31 **PIPEN**: Current activation of PipeN
0: Pipe disabled
1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK.

Bit 30 **FDTFEN**: Current force data type format enable
0: Disable force data type format. The data type format used by the pipe is the one defined into DTIDx
1: Enable force data type format. When data type DTIDA is detected by the pipe, the real pixel format considering by the pipe is the one set into the FDTF[5:0] bit field instead of the physical one received by the CSI2 host.
This bit has no meaning if PIPEDIFF = 0 in the DCMIPP_P1FSCR register.

Bits 29:24 **FDTF[5:0]**: Current force data type format
Forcing the data type format. This data type overwrites the one received by the CSI2-HOST by specifying the pixel format to consider. The value must follow the CSI2 data type format definition in the CSI2 standard. This bit field has no meaning if the FDTFEN bit is cleared, or if PIPEDIFF = 0 in the DCMIPP_P1FSCR register.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Current flow selection mode
Virtual channel ID of the CSI flow to select for further processing on the pipe. These bits have no meaning if PIPEDIFF = 0 into DCMIPP_P1FSCR. For this configuration the pipe takes the value VC[1:0] configured in the DMCIPP_P1FSCR register.

Bits 18:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Current data type ID
Data type ID of the CSI flow to select. For this configuration the pipe takes the value DTIDA[5:0] configured in the DMCIPP_P1FSCR register.

39.14.149 DCMIPP Pipe2 current ROIx configuration register 1 (DCMIPP_P2CRIxCR1)

Address offset: 0xF24 + 0x8 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CLG[1:0]		CLB[1:0]		HSTART[11:0]											
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **CLR[1:0]:** Current color line red

The two bits coding the red value are duplicated over 8 bits as 0bCLR1 CLR0 CLR1 CLR0 CLR1 CLR0 CLR1 CLR0.

Bits 27:16 **VSTART**[11:0]: Current vertical start, from 0 to 4094 pixels high

Bits 15:14 **CLG[1:0]:** Current color line green

The two bits coding the red value are duplicated over 8 bits as 0bCLG1 CLG0 CLG1 CLG0 CLG1 CLG0 CLG1 CLG0.

Bits 13:12 **CLB[1:0]:** Current color line blue

The two bits coding the red value are duplicated over 8 bits as 0bCLB1 CLB0 CLB1 CLB0 CLB1 CLB0 CLB1 CLB0.

Bits 11:0 **HSTART**[11:0]: Current horizontal start, from 0 to 4094 pixels wide

39.14.150 DCMIPP Pipe2 current ROIx configuration register 2 (DCMIPP_P2CRIxCR2)

Address offset: 0xF28 + 0x8 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LINEMULT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	FORMAT[3:0]			
r	r	r									r	r	r	r	r

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **LMAWE**: Line multi address wrapping enable bit

Enables the wrapping of the address every power-of-2 of written lines.

0: Line multi address wrapping disabled.

1: Line multi address wrapping enabled.

Bits 19:17 **LMAWM[2:0]**: Line multi address wrapping modulo

Amount of captured lines after which the write address is wrapped back to the BaseAddress. It is used to write a full frame onto a circular (ping-pong) buffer.

000: Wraps address after every line

001: Wraps address after two lines

010: Wraps address after four lines

011: Wraps address after eight lines

100: Wraps address after sixteen lines

101: Wraps address after 32 lines

110: Wraps address after 64 lines

111: Wraps address after 128 lines

Bit 16 **DBM:** Double buffer mode

This bit is set and cleared by software.

0: No double buffer mode activated. Pipe2 is always dump to memory address set by DCMIPP_P2PPM0AR1

1: Double buffer mode activated. Dump address location switches from DCMIPP_P2PPM0AR1 register to DCMIPP_P2PPM0AR2 register alternatively on each frame

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE event and interrupt

0x0: Event after every line

0x1: Event after two lines

0x2: Event after four lines

0x3: Event after eight lines

0x4: Event after sixteen lines

0x5: Event after 32 lines

0x6: Event after 64 lines

0x7: Event after 128 lines

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **SWAPRB**: Swaps R-vs-B components if RGB, and if YUV, swaps U-vs-V components
0: No swap of R-vs-B (U-vs-V)
1: Swap active.

Bits 3:0 **FORMAT[3:0]**: Memory format (only coplanar formats are supported in Pipe2)
0x0: RG/B888 or YUV444 1-buffer
0x1: RGB565 1-buffer
0x2: ARGB8888
0x3: RGBA8888
0x4: monochrome Y8 or G8 1-buffer
0x5: YUV444 1-buffer (FOURCC = AYUV)
0x6: YUV422 1-buffer (FOURCC = YUYV)
Other formats are reserved and not supported.

39.14.152 DCMIPP Pipe2 current pixel packer Memory0 address register 1 (DCMIPP_P2CPPM0AR1)

Address offset: 0xFC4

Reset value: 0x0000 0000

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

40 CSI-2 Host (CSI)

40.1 Introduction

The camera serial interface 2 (CSI-2) is a part of a group of communication protocols defined by the MIPI® Alliance. The MIPI® CSI-2 Host controller is a digital core that implements all protocol functions defined in the MIPI® CSI-2 specification.

It provides an interface between the system and the MIPI® D-PHY, allowing communication with a CSI-2 compliant camera.

40.2 Standard and references

- MIPI Alliance Specification for Camera Serial Interface 2 (CSI-2) v1.3 - 29 May 2014
- MIPI Alliance Specification for D-PHY v1.2 - 01 August 2014

40.3 Glossary

Table 367. Glossary of terms

Term	Definition
D-PHY_RX	D-PHY physical layer receiver
EOF	End of frame
EOT	End of transmission
ESC	Escape mode for the D-PHY_RX
HS	High speed
ISB	Imaging system bus
LLP	Low-level protocol
LP	Low power
PHY	Physical layer
PPI	Phy protocol interface
RX	Receiver
SOF	Start of frame
SOT	Start of transmission

40.4 CSI-2 Host main features

- Compliant with MIPI Alliance standard (see *Section 40.2*)
- Interface with MIPI D-PHY (see *Section 40.2*)
- Up to two D-PHY data lanes supported (up to 2.5 Gbit/s per lane in high-speed (HS) mode and 10 Mbit/s in low-power (LP) mode)
- Data transmission in HS and LP modes supported by the D-PHY
- Escape mode (ESC) and ultra-low-power state mode (ULPS) supported
- CSI-2 lane management layer connected to the D-PHY_RX to merge 1 or 2 data lanes in a single 32-bit ISB-Byte bus
- ECC and error correction capabilities
- CRC check capability
- CSI-2 virtual channel and data type filtering supporting interleaved data
  - Up to 4 virtual channels
  - Support the data formats specified into the MIPI Alliance standard for CSI-2 v1.3 (18 data formats, plus the user defined ones)
- Up to 7 independent data types
- Programmable interrupts:
  - 4 timer interrupts mapped on a selected virtual channel with starting point from SOF (start of frame) or EOF (end of frame)
  - 4 line/byte counter interrupts mapped on a selected virtual channel to trigger an event
- ISB-Byte header generation for internal connection with the DCMIPP peripheral

40.5 CSI-2 Host functional description

40.5.1 General description

The MIPI CSI-2 Host controller offers a means to connect cameras to capture and dispatch a robust header with ECC correction and data payload with checksum.
A D-PHY_RX receiver fills out the role of interfacing the external serial camera devices with the embedded CSI-2 Host controller:

- D-PHY receiver:

  This is a D-PHY_RX receiver composed of two unidirectional data lanes, and one clock lane. It operates in slave mode with HS and LP mode capabilities. The D-PHY drives a PPI interface to communicate with the CSI-2 Host.
- CSI-2 lane merger:

  Up to two data lane inputs to increase data rate while avoiding high clock rates

  The lane manager function collects incoming bytes from N (N = 1 to 2) lanes.
  It consolidates them by merging operations into a complete packet provided to the CSI-2 low-level protocol decoder (LLP), to decompose the meaning of each data packet thanks to the CSI-2 protocol specification.
- CSI-2 clock changer:

  The clock changer moves the data transfer from an input clock domain from D-PHY_RX to a clock_proc domain before being processed by the LLP.

- CSI-2 low-level protocol decoder (LLP)

  The low-level protocol is a byte-orientated packet-based protocol that supports the transport of arbitrary data using short and long packet formats.

  It generates an ISB-byte header data for further processing, with data integrity check or miscellaneous integrity checks.

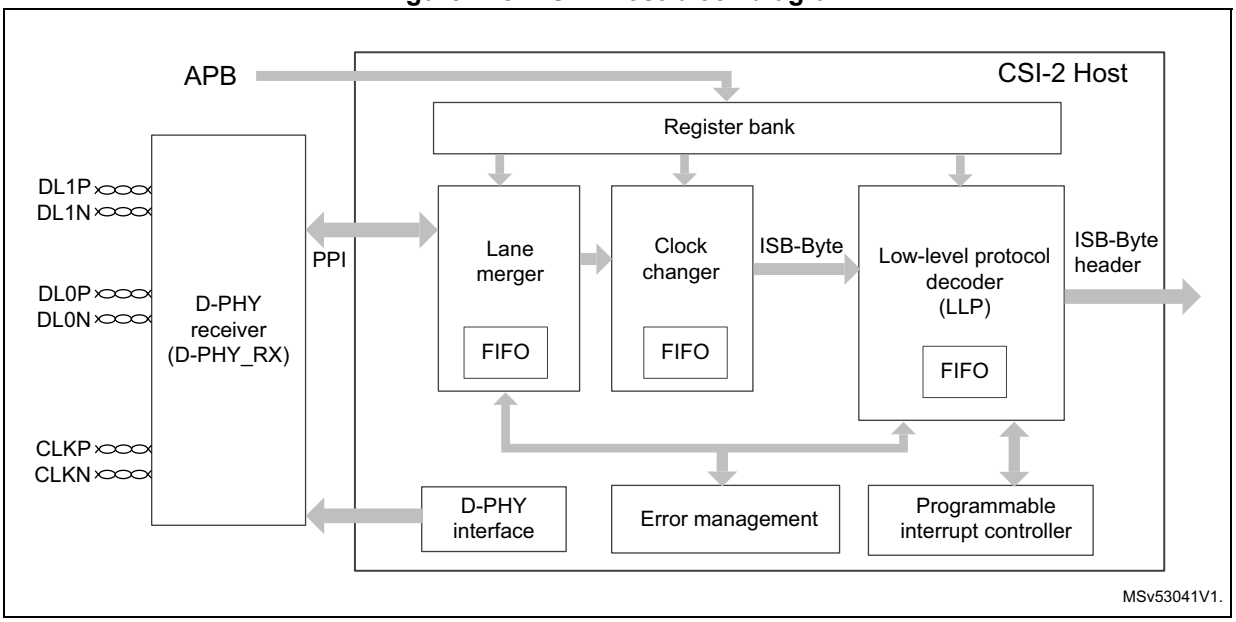
  It supports data interleaving through the support of up to four virtual channels and many data type formats.

  The LLP offers interrupt generation capability, depending on specific events such as line/byte detection within a frame, or a time-base event selected from a SOF or an EOF.

The CSI-2 Host-controller register bank is configured and accessed by the APB bus interface.

A block diagram of the CSI-2 Host is shown in the figure below.

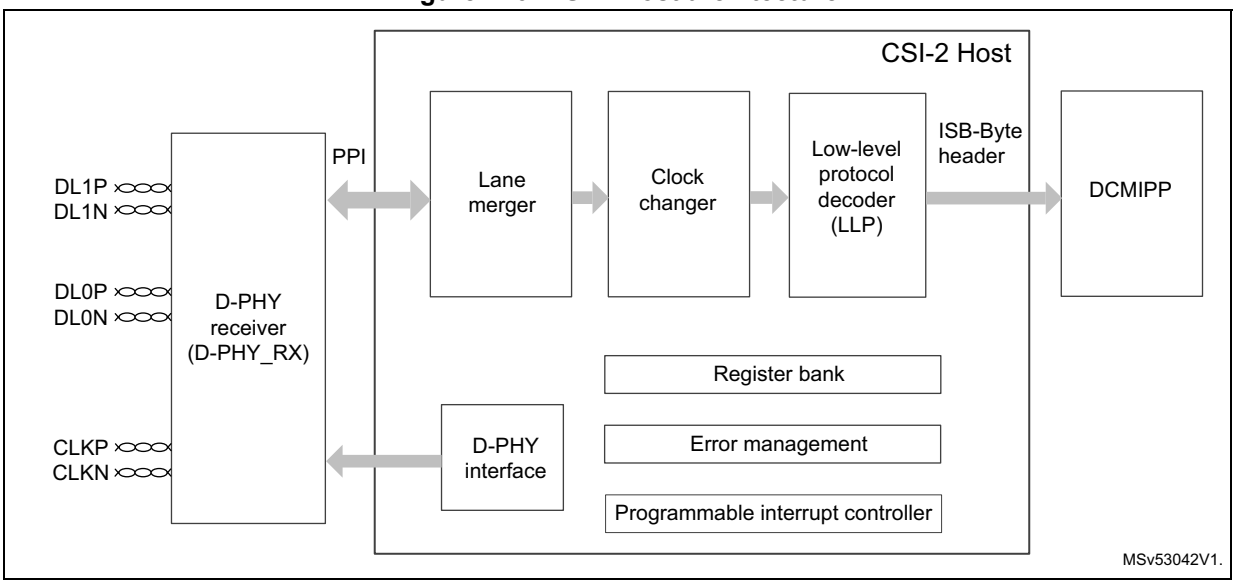
Figure 415. CSI-2 Host block diagram



40.5.2 System level architecture

The figure below shows the CSI-2 Host architecture.

Figure 416. CSI-2 Host architecture



The blocks shown have the following functions:

- D-PHY_RX is a slave receiver device that connects external serial cameras to the CSI-2 Host controller. It is based on unidirectional slave data lanes and clock lanes to handle data transmission from the CSI-2 protocol-based camera devices to subsystems for data processing (handled by the DCMIPP).
- The D-PHY interface manages D-PHY_RX register accesses. It also allows the block to be configured to raise interrupts on the detection of some errors during reception. It highlights the status of the physical lines up to the software layers.
- The lane merger module packs the data coming from the two D-PHY_RX data lanes, if required to do so for increased data rates. It generates a data flow based on an ISB-Byte protocol, which is not linked to any protocol at this point. The data is only identified as a control or a data packet for the clock changer module.
- The clock changer module manages data crossing from the D-PHY_RX clock domain to the clk_proc clock domain.
- The LLP handles data filtering to serve the data-interleaving capability of the DCMIPP. It can filter data from external devices depending on virtual channel identifiers, or on data-type format selection. It also executes, depending on the input pixel format, data reordering in order to optimize the data storage, for instance in memories.
- The CSI-2 Host manages also various errors coming (not exclusively) from the D-PHY_RX physical layer. It can detect error conditions in the received header or a short packet in a frame. ECC is implemented to correct one bit error in the header. A CRC checksum is also implemented to detect any data corruption during the data payload reception. The 16-bit CRC value is located into the packet footer.
  The CSI-2 Host also ensures that specific timings within the data reception are properly in line with the CSI-2 specification. All error conditions and associated interrupts are detailed in *Section 40.8*.

- A specific module generates interrupts following the detection of selected events in a frame. For a given virtual channel, these events may be triggers based on line- and byte-number detection within the frame, or counters from dedicated timers reaching a number of cycles (clk_proc) from an SOF or an EOF.
- Data is filtered out by the LLP, and sent to the DCMIPP in a format that is quite similar to the CSI-2 protocol, but without CRC (packet footer) and ECC information inside the packet header. The data type and the virtual channel are also sent to the DCMIPP to handle the interleaved transmission of different image data formats within the same video data stream.

40.5.3 CSI-2 Host reset and clocks

There are two reset sources:

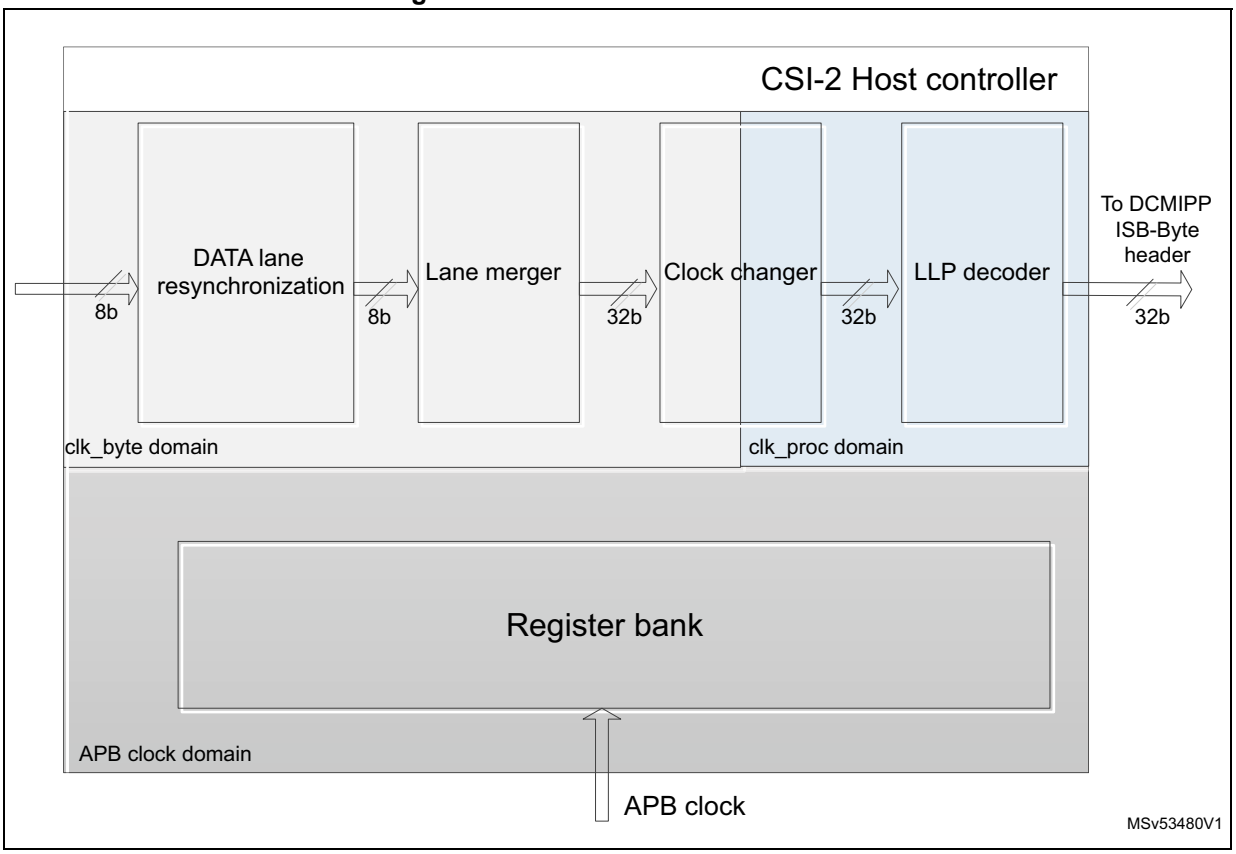
- hardware asynchronous reset which is resynchronized on clk_byte and clk_proc clock domain (processing clock) to reset the flops connected to these clock domains
- APB reset from the reset and clock controller unit to reset mainly all the registers

There are three clocks to serve the CSI-2 Host controller (see *Figure 417*):

- clk_byte: derived from the D-PHY_RX clock lane, and used by the lane merger module and the clock changer module
- clk_proc: used by the kernel of the LLP

  Resynchronization between the clk_byte domain and the clk_proc domain is handled by the clock changer module.
- PCLK clock: APB clock used to access to the register bank

Figure 417. CSI-2 Host clock domain



The D-PHY_RX supports up to 2.5 Gbit/s per data lane: the maximum frequency on the D-PHY_RX clock is 2.5 Gbits / 8 to output a byte = 312 MHz.

40.5.4 Lane merger

Applications requiring more bandwidth than the one provided by a single data lane may expand the data path to more lanes in order to increase the attainable data rate. The lane merger supports then up to two data lanes.

The lane merger module converts the D-PHY_RX PPI protocol into a byte-oriented bus to be sent to the LLP.

The lane merger parallelizes the bytes to 32 bits in parallel to build a 32-bit output as shown in the figures below. The cycle number does not account for module internal latency.

Figure 418. Lane merger input and output (one data lane)

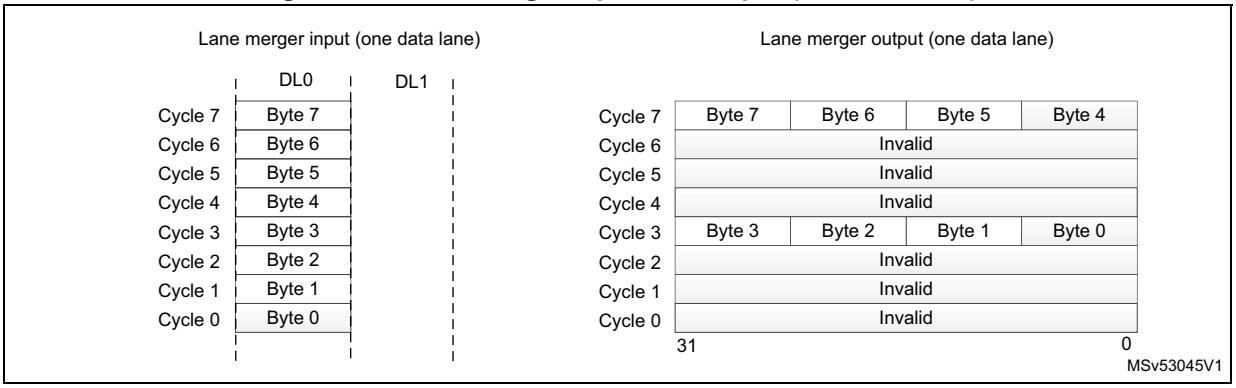


Figure 419. Lane merger input and output (two data lanes)

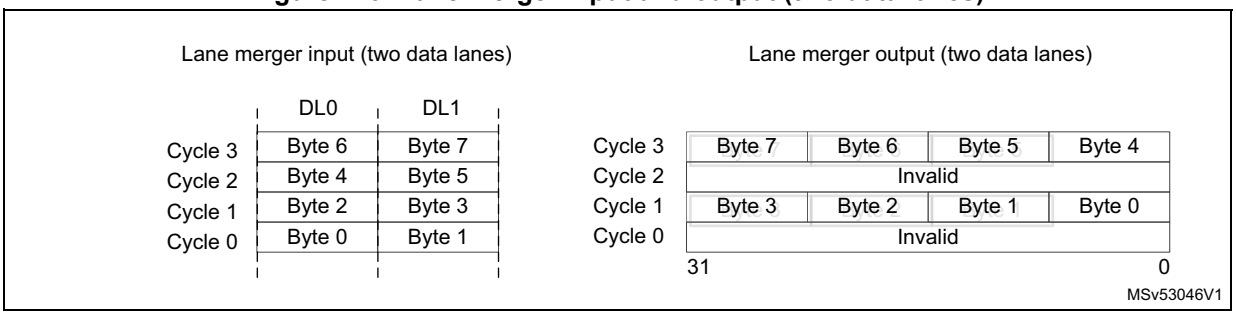
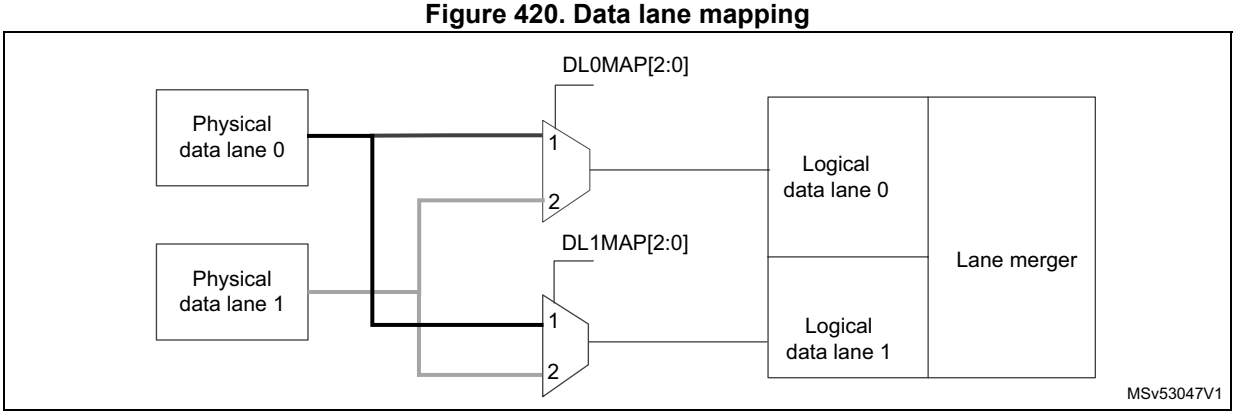


LANENB[2:0] in CSI_LMCFGR configures the number of data lanes used in the application. The software needs to map the physical data lanes input to the lane merger logical data lanes, using DL0MAP[2:0] and DL1MAP[2:0] as shown in the figure below.

Figure 420. Data lane mapping



40.5.5 Clock changer

The clock changer module changes the clock frequency from the input clock domain linked to the D-PHY_RX PPI protocol, to the output clock domain based on clk_proc clock domain (reference clock for the LLP).

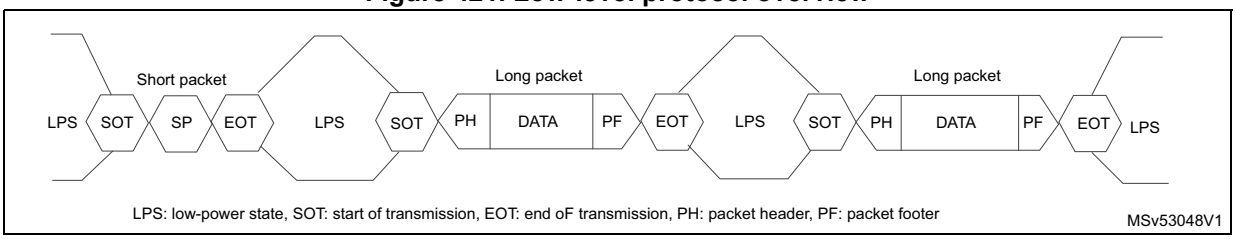
An integrated FIFO receives data from the input clock domain and realigns it to the output clock domain.

40.5.6 Low-level protocol (LLP)

The LPP module retrieves the raw data from the lane merger, and decodes the data flow respect to the CSI-2 low-level protocol. The software selects which data in the data interleaving flow need to be sent to the DCMIPP without being filtered out. The LLP is compliant with the MIPI CSI-2 specification as described in *Section 40.2*.

A data integrity check is done thanks to an ECC code for packet header error correction, and a 16-bit CRC checksum code for payload error detection. All these errors are flagged into specific registers, and may trig interruption for specific software action needs (see *Section 40.8* for more details).

Figure 421. Low-level protocol overview



The CSI-2 low-level protocol is mainly composed by short and long packets, each of them having a well identified role.

Long packet

The long packet format is presented in *Figure 422*. It contains a data ID that is composed of a virtual channel number for which the data packets are attached, and the corresponding data type. The LLP module filters data out by configuring CSI_VCxCFGRy registers (x = 0 to 3, y = 1 to 4), and VCxSTART/VCxSTOP bits in CSI_CR register.

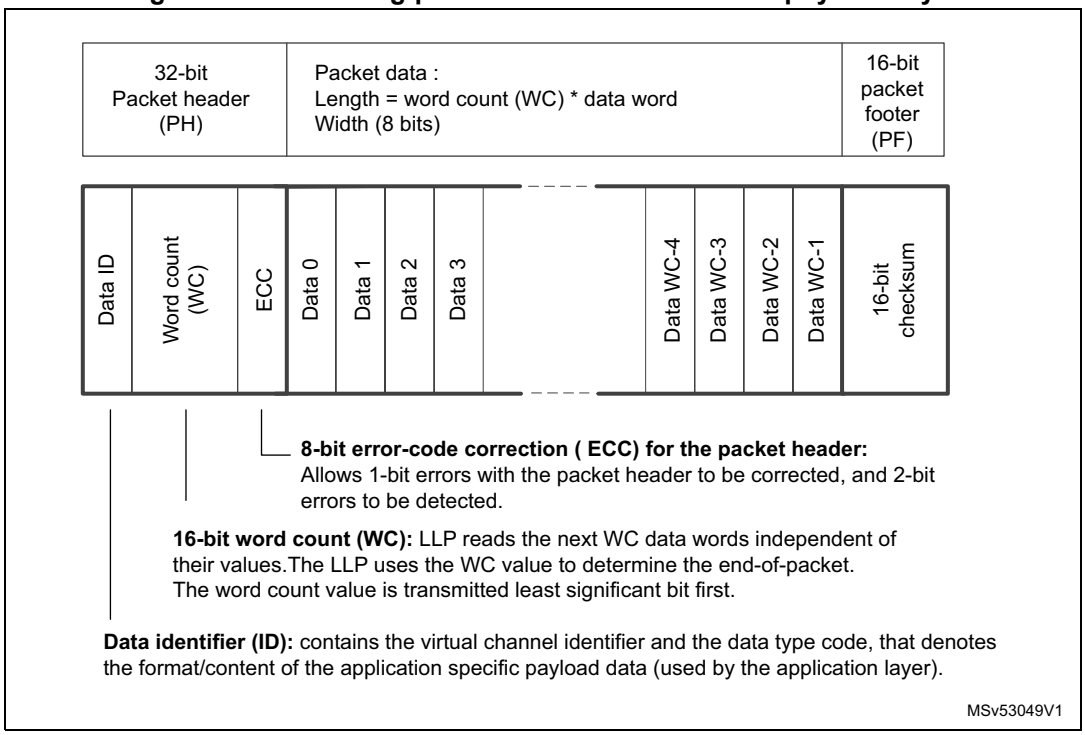
The word-count field allows the LLP to determine the data-payload width before detecting the packet footer and the EOT. This information is used to detect shorter-than-expected packets, and to trigger a corresponding error (refer to *Section 40.8*).

The ECC corrects a single erroneous bit in the packet header in the case of data corruption. An error is raised if there are two errors in total (the LLP decoder immediately stops the current frame), because only one bit can be corrected.

The packet data corresponds to the data payload for a given virtual channel and for an identified data type.

To complete the long-packet reception block, a packet footer that contains a 16-bit CRC checksum is received and compared to that which is internally calculated by the LLP, to check the data integrity of the received data payload.

Figure 422. CSI2- long-packet structure for a D-PHY physical layer

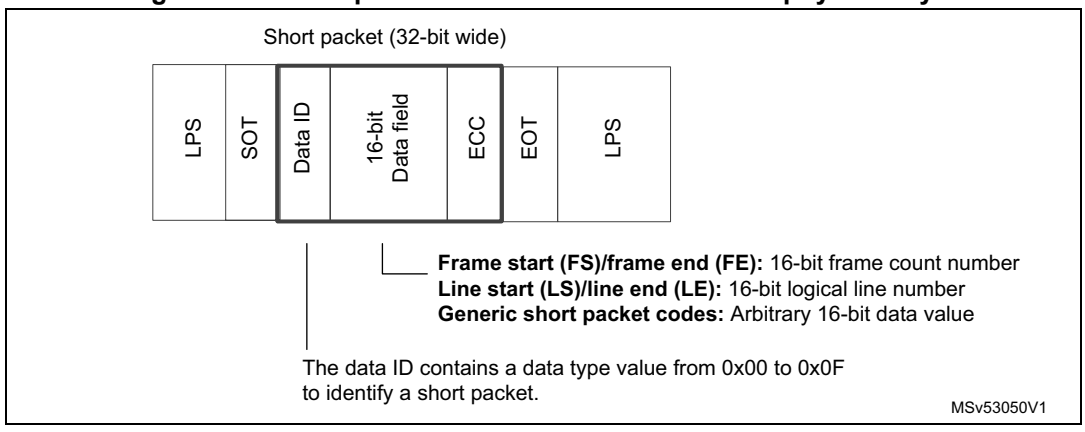


Short packet

The CSI-2 short-packet format for a D-PHY physical layer is shown in *Figure 423*.

It is similar to the long packet header, except that the word count field is replaced by a 16-bit data field. The ECC 8-bit code is present to secure headers having potential bit corruption.

Figure 423. Short-packet structure based on D-PHY physical layer

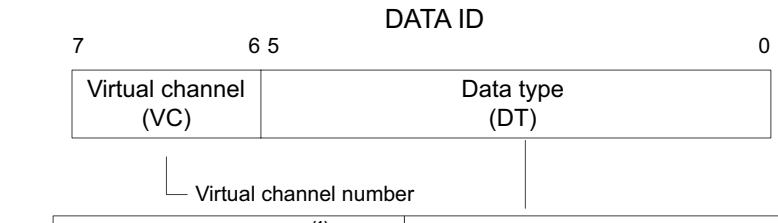


Data ID field

The 8-bit data ID field comprises 2 bits for the virtual channel number coding, and 6 bits to identify the packet data type (short or long packet), and the payload data packet format in the case of long packet reception.

The LLP filters subsequent packets depending on the user configuration indicated in the previously received data ID field (see *Figure 424*).

Figure 424. DATA ID structure in short or long packet format



Data type classes (1)	Description
0x00 to 0x07	Synchronization short packet data types
0x08 to 0x0F	Generic short packet data types
0x10 to 0x17	Generic long packet data types
0x18 to 0x1F	YUV data
0x20 to 0x27	RGB data
0x28 to 0x2F	RAW data
0x30 to 0x37	User defined byte-based data
0x38 to 0x3F	Reserved

(1) Refer to the MIPI Alliance specification for the CSI-2 to have the detail of each intermediate value not described in this table.

MSv53051V1

Data type field

The data type (DT) fields are configured by the application code to determine which data types are processed by the LLP for a given virtual channel. CSI_VCxCFGRy registers are used to configure the data types to be considered by the LLP.

Each virtual channel is managed independently, and up to seven different virtual-channel data types can be declared in parallel. All data type input to the LLP that are not defined for a given virtual channel are filtered out by the LLP module and discarded.

Data types in the video data flow are located:

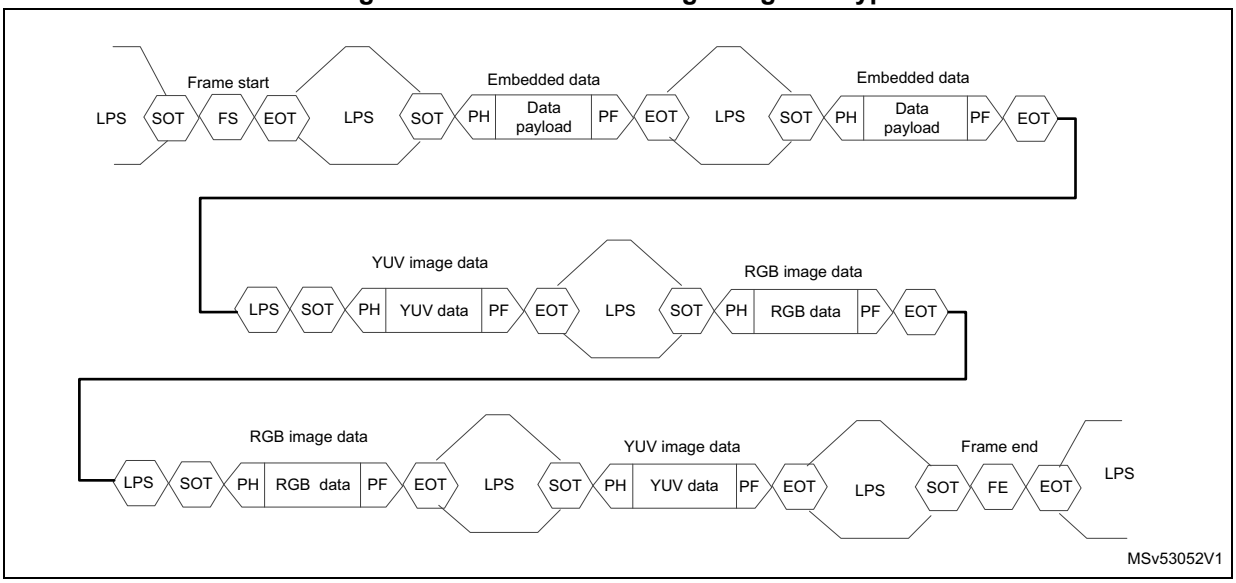
- in the data ID packet for a short packet
- in the packet header (PH) for a long packet format

Data interleaving: data-type based

In the video data flow, the transmitter can merge, on the same physical node, multi-device data transmissions having different data types. The LLP filters out these multi-device flows depending on the application configuration. A typical video data flow interleaving multiple data types is shown in *Figure 425*.

The application software must configure CSI_VCxCFGRy registers to enable data types for a virtual channel, and to set data-type formats to be processed. The LLP reorders the input data in a format that optimizes memory usage (see *Figure 425* to *Figure 433*).

Figure 425. Data interleaving using data type



Data interleaving: virtual channels

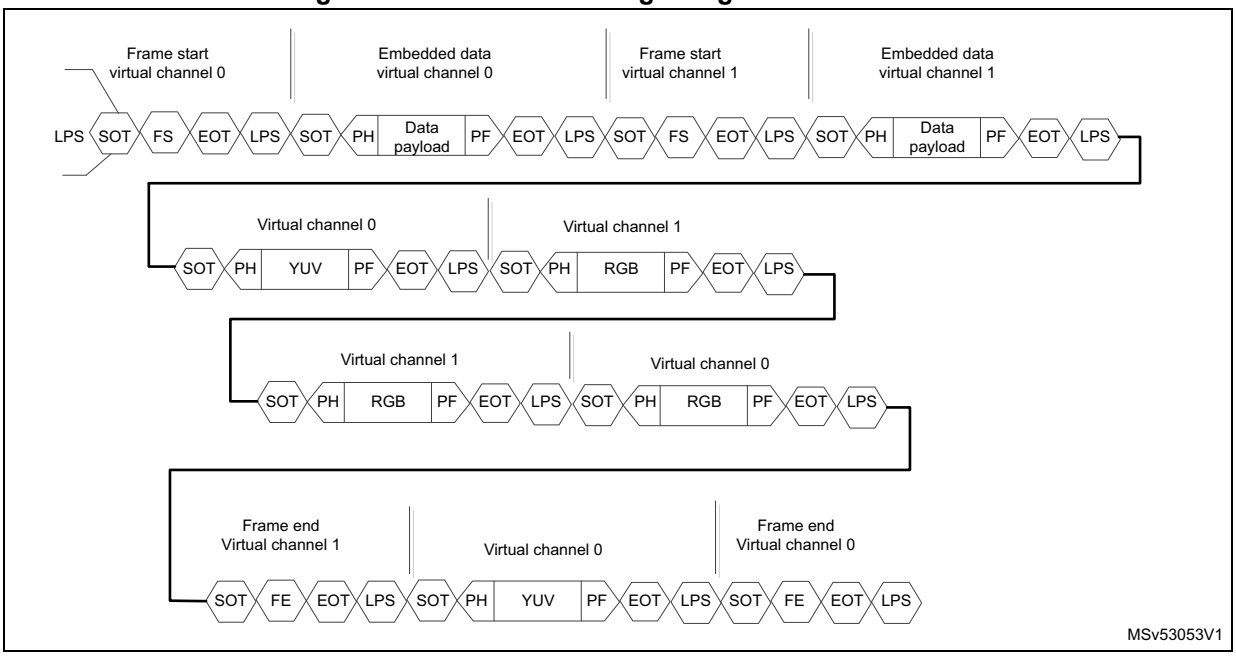
The data interleaving in the video data flow can also be managed by the virtual channel ID. Each external device can have a specific virtual channel identifier in order for the software layer or the DCMIPP to properly handle data packets belonging to a device.

The application code defines which of the virtual channels have to be considered by the LPP without any filtering operation. The CSI_CR register must be configured accordingly by activating the virtual channel (via VCxSTART), or by setting VCxSTOP to deactivate the virtual channel.

The virtual channel number is encapsulated in the data ID packet in short or long packet.

A typical data interleaving case is illustrated in *Figure 426*.

Figure 426. Data interleaving using virtual channels



Data formats

The LLP, in addition to a data-flow filter role, handles data reordering for memory optimization, storage, or post-processing purposes.

The CSI-2 Host controller is compliant with the MIPI Alliance CSI-2 specification. It mainly supports the following data formats:

- BPP6 (for example RAW6, RGB666)
- BPP7 (for example RAW7)
- BPP8 (for example RAW8, YUV 8-bits, RGB444, RGB555, RGB565, RGB888, JPEG)
- BPP10 (for example RAW10, YUV 10-bits)
- BPP12 (for example RAW12)
- BPP14 (for example RAW14)
- BPP16 (for example RAW16)

Figure 427. RAW6 (BPP6) input and output format

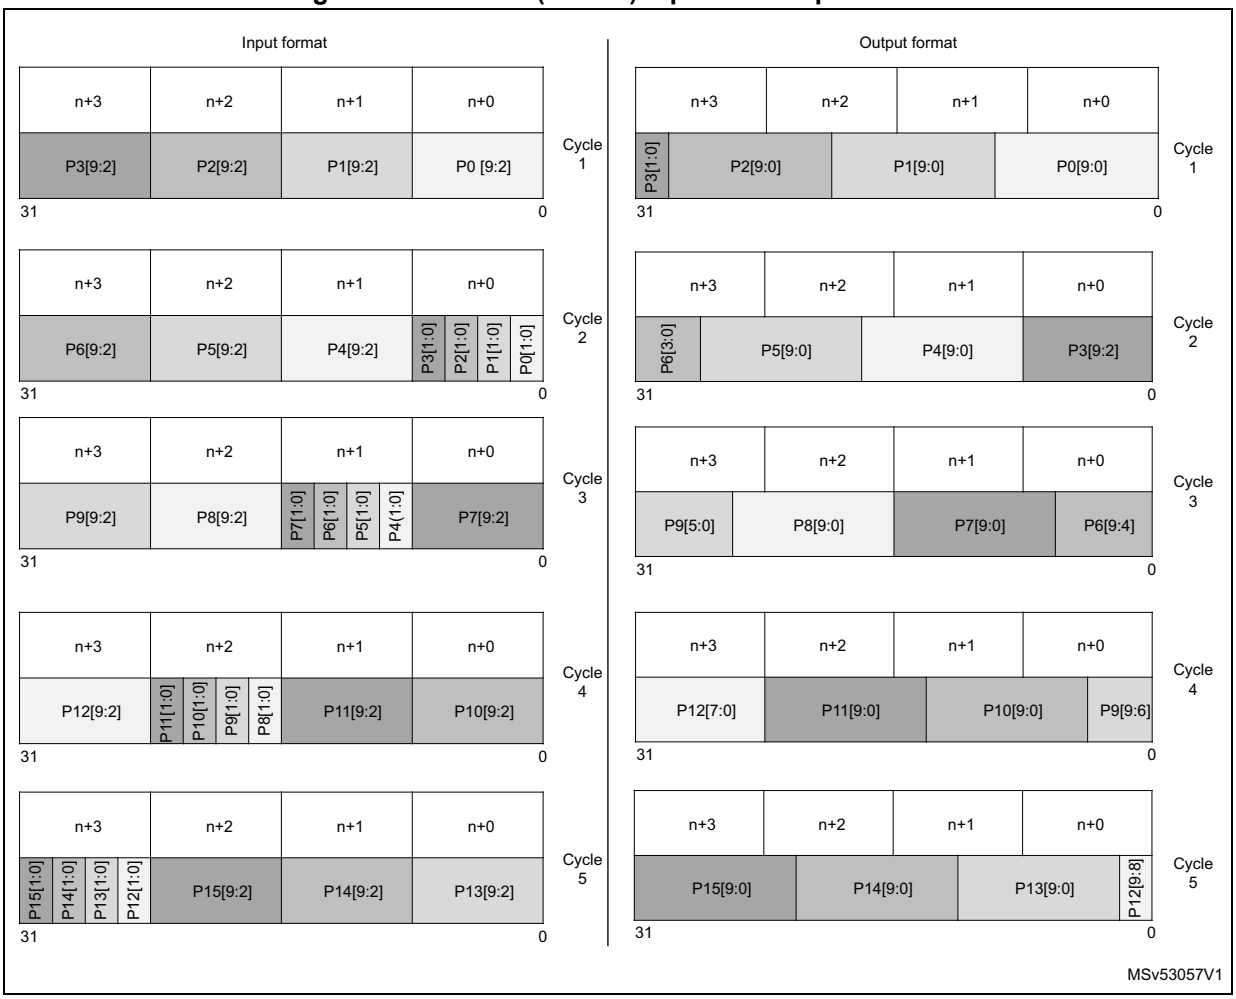

Figure 431. Raw12 (BPP12) input/output format

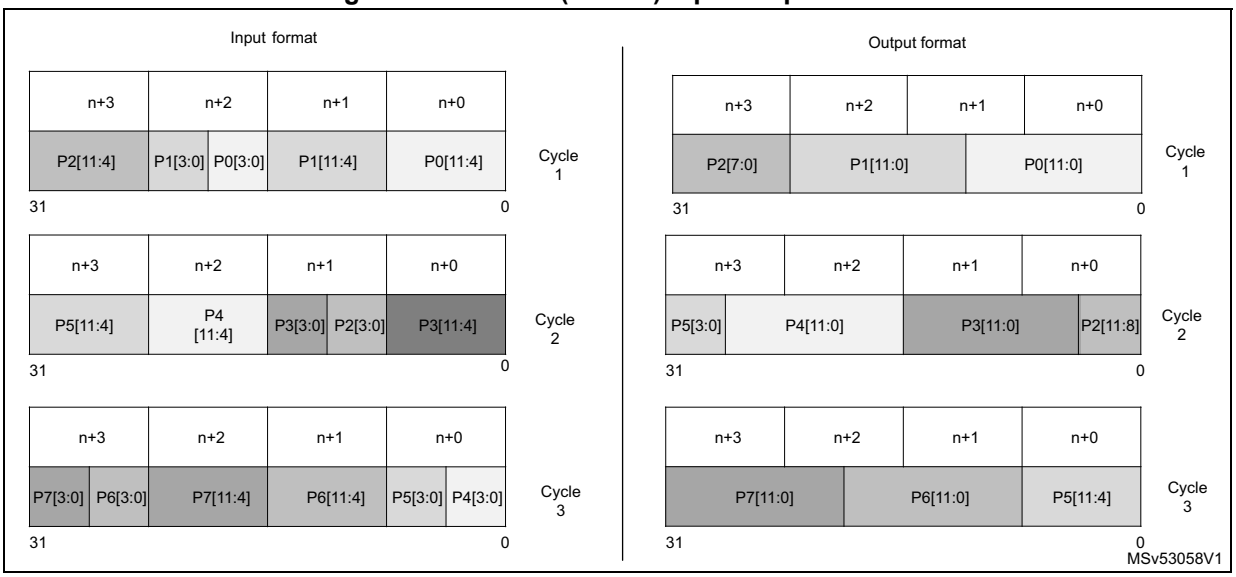

Figure 432. Raw14 (BPP14) input format

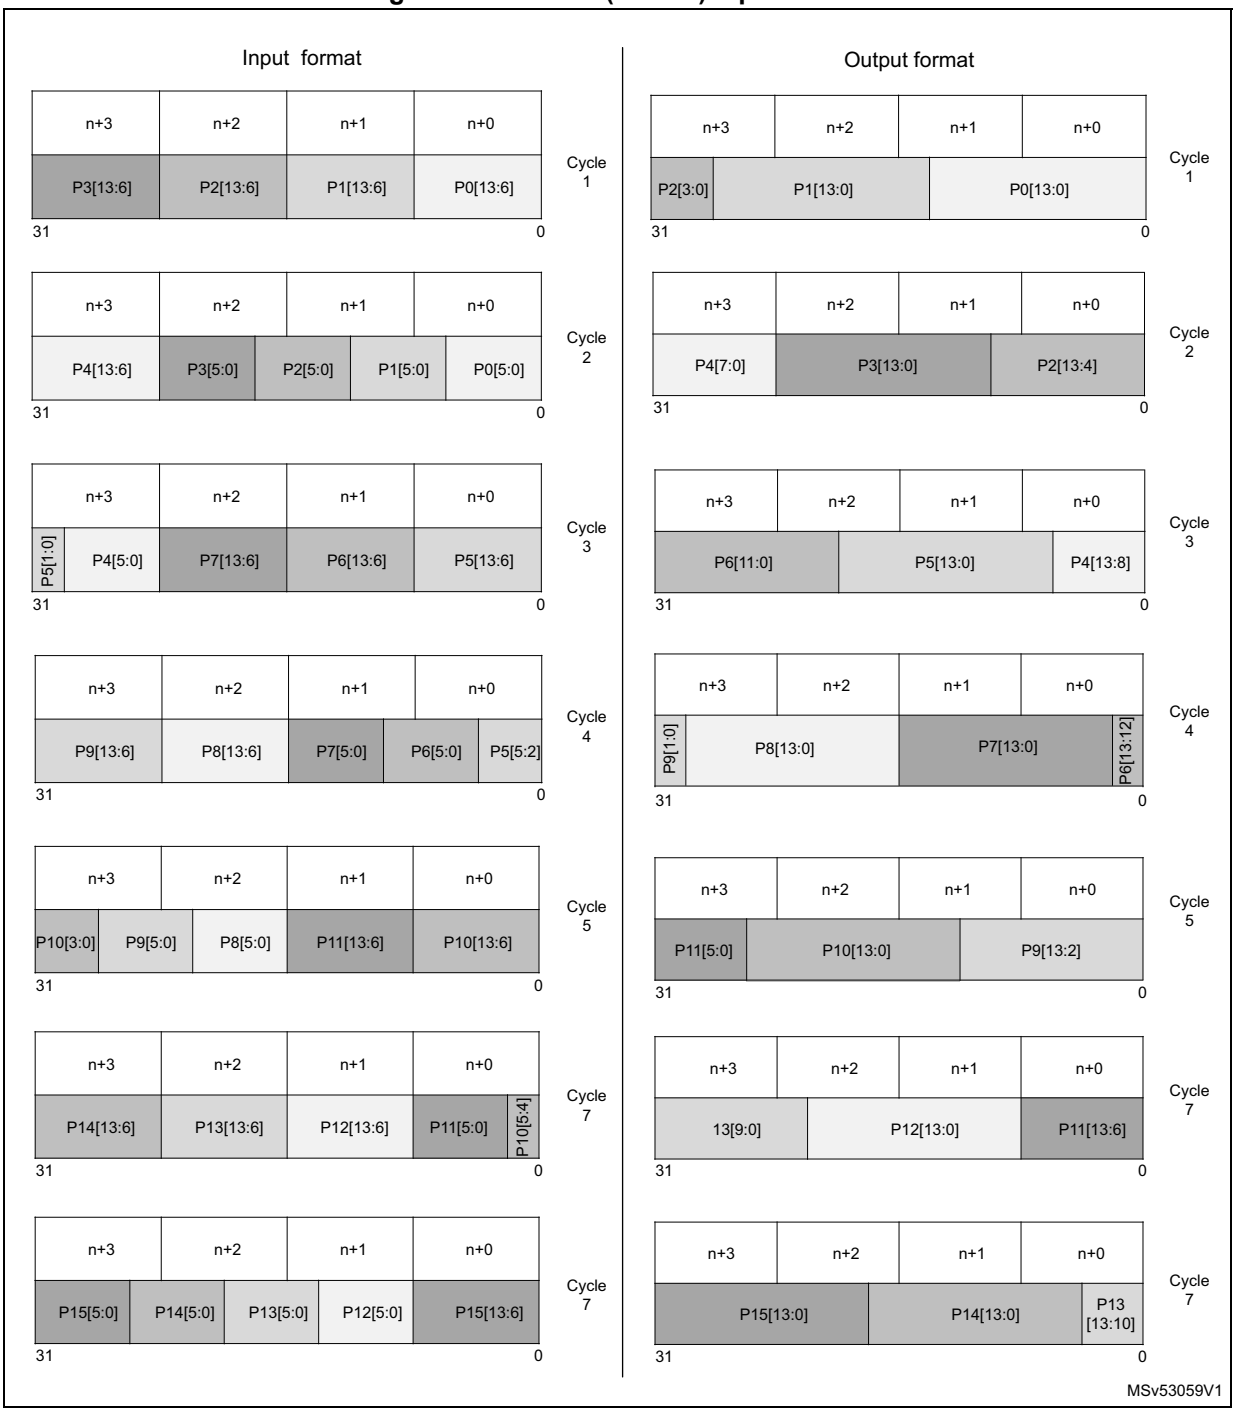

Figure 433. Raw16 (BPP16) input/output format

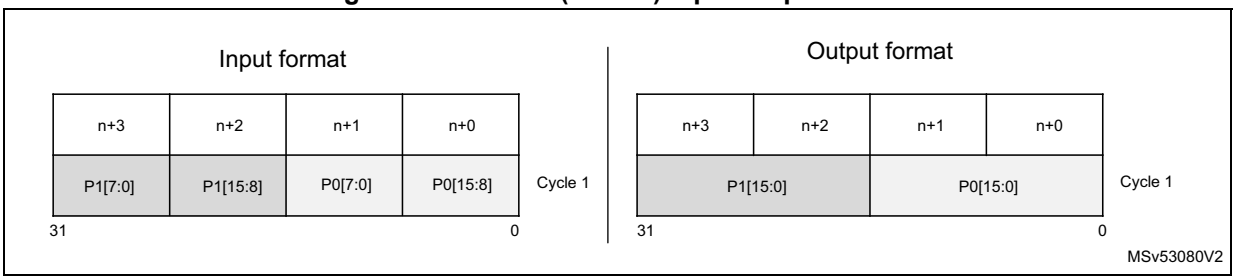

40.5.7 CSI-2 Host protocol output

The CSI-2 Host controller generates ISB-Byte header data according to CSI_VCxCFGRy. The ISB-Byte header generation respects the following rules:

- ISB-Byte header channel number is identical to the CSI-2 virtual channel and data type (LSB aligned).
- ISB-Byte header data type is identical to CSI-2 data type (LSB aligned).
- ISB-Byte header frame number is identical to the CSI-2 frame number.
- ISB-Byte header count is identical to CSI-2 word count.
- The format is updated according to CSI_VCxCFGRy configuration.

The only differences between the ISB-Byte data flow in input to the LLP and the ISB-Byte header bus at the output are listed below:

- There is no ECC information in the data corresponding to the short packet information.
- The packet footer (containing the CRC-16 value) is not transmitted, or forwarded on the output since the decoder already checked it from the input, and raised an error if the data payload is corrupted.
- The data payload output format is reordered and compared to the input data format of the LLP in order to ease pixels storage in memory for further hardware/software post-processing.
- Only identified virtual channels and their selected data types are generated on the output.

The ISB-Byte header is used by the DCMIPP peripheral to handle post-processing data from the external devices.

40.6 CSI-2 Host programming guide

40.6.1 CSI-2 PHY setup

The following actions are required to setup the CSI-2 PHY:

1. Quit the hardware reset state with PEN = 0x01 in CSI_PRCR.
2. Configure frequency settings with:
   – DLD = 0x00 in CSI_PFCR (to remain in Rx)
   – HSFR in CSI_PFCR that depends on the bit-rate expected on the data lanes
   – CCFR = RoundUp((F - 17) × 4) in CSI_PFCR (F = configuration clock frequency)
3. Configure internal registers via the test interface, with TRSEN = TCKEN = 0x0 in CSI_PTCR0.

40.6.2 CSI-2 Host controller setup and data reception start

The D-PHY RX software initialization is required to set up the CSI-2 Host controller.

Lane-merger configuration (static configuration)

The lane merger must be configured while CSIEN = 0 in CSI_CR, and when the D-PHY_RX is not streaming (when it is not providing a clock).

To map the physical data lane to the logical data lane, the lane merger needs to be configured through DL0MAP and DL1MAP in CSI_LMCFGR. In addition, the number of valid data lanes must be configured through LANENB in the same register.

LLP configuration

1. Configure the watchdog value in CSI_WDR. This corresponds to the maximum number of clock cycles between two packets before an input frame is considered erroneous and the transmission failed. It can be left at 0x0 to disable the watchdog feature.
2. Enable the CSI-2 Host controller with CSIEN = 1 in CSI_CR.
3. Configure the selected virtual channels in CSI_VCxCFGRy.

   If all data types must be captured with the same format, in CSI_VCxCFGR1:
   - Set ALLDT = 0x011.
   - Select the format with CDTFT[4:0].

   If only a few data types are to be captured, or if the format is not identical for all data types, then up to seven data types can be selected:
   - Set ALLDT = 0x0 in CSI_VCxCFGR1.
   - Set DTyEN = 0x1 (y = 0 to 6) in CSI_VCxCFGR1 for the data types used.
   - Set DTy[5:0] in CSI_VCxCFGRy to the selected data type.
   - Set DTyFT[4:0] in CSI_VCxCFGRy to the selected format.
4. Depending on application requirements, specific software actions may detect particular events in a frame, and trigger a corresponding interrupt, with the following:
   - Set LINECNT[15:0] and BYTECNT[15:0] in CSI_LBxCFGR to trigger an event when the data corresponding to a specific byte within a specific line is detected by the LLP. Up to four independent triggers can be programmed and linked to a selected virtual channel through LBxVC[1:0] in CSI_PRGITR. The selected trigger can be enabled by setting LBxEN in the same register.
   - Set COUNT[24:0] in CSI_TIMxCFGR to trigger an event after a specified number of clock cycles (clk_proc) from an SOF or an EO, depending on TIMxEOF and TIMxEN in CSI_PRGITR. Up to four independent timer triggers can be programmed and linked to a selected virtual channel through TIMxVC[1:0] in CSI_PRGITR.
5. Enable interrupt sources for which the code needs to make specific actions, by configuring CSI_IER0 and CSI_IER1 registers.
6. D-PHY_RX lanes can be enabled by setting DL0EN and/or DL1EN, and CLEN in CSI_PCR.
7. Start the virtual channel by setting VCxSTART = 0x1 in CSI_CR.

40.6.3 Data reception stop

To stop data reception, set VCxSTOP = 1 in CSI_CR. The data reception stops at the end of the current frame. The virtual channel status can be retrieved from VCxSTATEF in CSI_SR0.

Note: A virtual channel cannot start before it has been completely stopped (VCxSTATEF = 0 in CSI_SR0).

40.7 CSI-2 Host low-power modes

Table 368. Effect of low-power modes on CSI-2 Host controller

Mode	Description
Sleep	No effect. The CSI-2 host interrupts cause the device to exit the Sleep mode.
Stop	The CSI-2 host is in power-down, and must be reinitialized after exiting Stop mode.
Standby	The CSI-2 host is in power-down, and must be reinitialized after exiting Standby mode.

40.8 CSI-2 Host interrupts and errors

Few events can generate an error flag or an interrupt from the CSI-2 Host controller interrupt handler.

The table below defines the error sources flagged by the CSI-2 HOST controller.
The content of CSI_ERR1 and CSI_ERR2 registers can be used to know exactly from which virtual number and data types a particular error appeared and has been detected. It can be used as debug purpose too.

Table 369. List of errors detected by the CSI-2 Host controller

Error description	Bit name	Register
Virtual channel number on which a data ID information error is detected	IDVCERR[1:0]	CSI_ERR1
Data type for which a data ID information error is detected	IDDTERR[5:0]	
Virtual channel number for which the ECC has corrected one bit in error	CECCVCERR[1:0]	
Data type for which the ECC has corrected one bit in error	CECCDTERR[5:0]	
Virtual channel number for which a CRC error is detected	CRCVCERR[1:0]	
Data type for which a CRC error is detected	CRCDTERR[5:0]	
Virtual channel number on which the invalid synchronization has been detected	SYNCVCERR[1:0]	CSI_ERR2
Virtual channel number on which a watchdog error has been detected	WDVCERR[1:0]	
Virtual channel number on which a shorter packet than expected has been detected	SPKTVCERR[1:0]	
Data type for which the shorter packet than expected error has been detected	SPKTDTERR[5:0]	

The table below shows the interrupt sources that are triggered by the CSI-2 Host controller if the corresponding bit is enabled.

Table 370. List of events that trigger an interrupt

Interrupt flag	Register	Interrupt sources
SYNCERRF	CSI_SR0	Synchronization error. The interrupt is enabled if SYNCERRIE is set in CSI_IER0(1).
WDERRF		Watchdog error. The interrupt is enabled if WDERRIE is set in CSI_IER0(1).
SPKTERRF		Shorter packet than expected error. The interrupt is enabled if SPKTERRIE is set in CSI_IER0 register(1).
IDERRF		Data ID information error. The interrupt is enabled if IDERRIE is set in CSI_IER0(1).
CECCERRF		Corrected ECC error. The interrupt is enabled if CECCERRIE is set in CSI_IER0(1).
ECCERRF		ECC error. The interrupt is enabled if ECCERRIE is set in CSI_IER0(1).
CRCERRF		CRC error. The interrupt is enabled if CRCERRIE is set in CSI_IER0(1).
CCFIFOFF		Clock changer FIFO full event. The interrupt is enabled if CCFIFOFFIE is set in CSI_IER0(2).
SPKTF		Short packet detection. The interrupt is enabled if SPKTIE is set in CSI_IER0(2).
EOF3F		EOF on virtual channel 3. The interrupt is enabled if EOF3IE is set in CSI_IER0(2).
EOF2F		EOF on virtual channel 2. The interrupt is enabled if EOF2IE is set in CSI_IER0(2).
EOF1F		EOF on virtual channel 1. The interrupt is enabled if EOF1IE is set in CSI_IER0(2).
EOF0F		EOF on virtual channel 0. The interrupt is enabled if EOF0IE is set in CSI_IER0(2).
SOF3F		SOF on virtual channel 3. The interrupt is enabled if SOF3IE is set in CSI_IER0(2).
SOF2F		SOF on virtual channel 2. The interrupt is enabled if SOF2IE is set in CSI_IER0(2).
SOF1F		SOF on virtual channel 1. The interrupt is enabled if SOF1IE is set in CSI_IER0(2).
SOF0F		SOF on virtual channel 0. The interrupt is enabled if SOF0IE is set in CSI_IER0(2).
TIM3F		Timer 3 counter value reached. The interrupt is enabled if TIM3IE is set in CSI_IER0(2).
TIM2F		Timer 2 counter value reached. The interrupt is enabled if TIM2IE is set in CSI_IER0(2).
TIM1F		Timer 1 counter value reached. The interrupt is enabled if TIM1IE is set in CSI_IER0(2).
TIM0F		Timer 0 counter value reached. The interrupt is enabled if TIM0IE is set in CSI_IER0(2).
LB3F		Line/byte event 3 reached. The interrupt is enabled if LB3IE is set in CSI_IER0(2).
LB2F		Line/byte event 2 reached. The interrupt is enabled if LB2IE is set in CSI_IER0(2).
LB1F		Line/byte event 1 reached. The interrupt is enabled if LB1IE is set in CSI_IER0(2).
LB0F		Line/byte event 0 reached. The interrupt is enabled if LB0IE is set in CSI_IER0(2).

Table 370. List of events that trigger an interrupt (continued)

Interrupt flag	Register	Interrupt sources
ECTRLDL1F	CSI_SR1	Error control on data line 1. The interrupt is enabled if ECTRLDL1IE is set in CSI_IER1.
ESYNCESCDL1F		Low-power data transmission synchronization error on data line 1. The interrupt is enabled if ESYNCESCDL1IE is set in CSI_IER1.
EESCDL1F		Escape entry error on data line 1. The interrupt is enabled if EESCDL1IE is set in CSI_IER1.
ESOTSYNCDL1F		SOT synchronization error on data line 1. The interrupt is enabled if ESOTSYNCDL1IE is set inCSI_IER1.
ESOTDL1F		SOT error on data line 1. The interrupt is enabled if the bit ESOTDL1IE is set into CSI_IER1.
ECTRLDL0F		Error control on data line 0. The interrupt is enabled if the bit ECTRLDL0IE is set into CSI_IER1.
ESYNCESCDL0F		Low-power data transmission synchronization error on data line 0. The interrupt is enabled if the bit ESYNCESCDL0IE is set into CSI_IER1.
EESCDL0F		Escape entry error on data line 0. The interrupt is enabled if EESCDL0IE is set in CSI_IER1.
ESOTSYNCDL0F		SOT synchronization error on data line 0. The interrupt is enabled if ESOTSYNCDL0IE is set in CSI_IER1.
ESOTDL0F		SOT error on data line 0. The interrupt is enabled if ESOTDL0IE is set in CSI_IER1.

1. Refer to *Section 40.8.1: Error handling*.
2. Refer to *Section 40.8.2: Interrupt handling*.

40.8.1 Error handling

Details of the errors are given in CSI_ERR1 and CSI_ERR2.

Note: Except for data ID information, all other errors can occur during the product life, and must be handled by the software.

Corrected ECC error

When this error is detected, the CECCERR interrupt is triggered if CECCERRIE = 1 in CSI_IER0. This is an information event rather than a real error, as the CSI-2 Host controller successfully recovered the ECC error, so the frame is processed properly. Some details of the error are located in CECCVCERR and CECCDTERR in CSI_ERR1:

ECC error

When a multi-bit ECC error is detected, the ECCERR interrupt is triggered if ECCERRIE = 1 in CSI_IER0. As all virtual channels are potentially corrupted, the LPP immediately stops the current frames.

The CSI-2 Host controller restarts each enabled virtual channel on the next SOF packet of each channel. The software must perform the necessary error management (such as resetting some peripherals after this error detection). No details are available for the error as the relevant information is corrupted.

CRC error

When a CRC error is detected, the CRCERR interrupt is triggered if CRCERRIE = 1 in CSI_IER0. As the frame envelope is not corrupted, the CSI-2 Host controller does not stop the frame processing. The software must perform the necessary error management (such as reseting some peripherals, possibly including the CSI-2 Host controller). Details are available for this error in CRCVCERR and CRCDTERR in CSI_ERR1.

Data ID information

When a reserved data type is detected, the IDERR interrupt is triggered if IDERRIE = 1 in CSI_IER0. This is an information event rather than a real error, as the hardware processes this packet as for any non-erroneous packet.Details for the error are available in IDVCERR and IDDTERR in CSI_ERR1.

Invalid synchronization

When an invalid synchronization is detected, the SYNCERR interrupt is triggered if SYNCERRIE = 1 in CSI_IER0. An invalid synchronization is either an SOF short packet during a frame, or an EOF short packet during an inter-frame. It is an information event rather than a real error, as the hardware is able to handle such an error:

- An SOF short packet during a frame is interpreted as back-to-back EOF and SOF. It behaves accordingly (ISB-Byte header EOF, ISB-Byte header SOF, and so on). The SOFx interrupt is generated in addition to the SYNCERR one if SOFxIE = 1 in CSI_IER0.
- An EOF short packet during an inter-frame is ignored (no EOFx interrupt is generated whatever the state of EOFx in CSI_IER0). Details for the error are available in SYNCVCERR in CSI_ERR2.

Shorter than expected packet

When a shorter-than-expected packet is received, the SPKTERR interrupt is triggered if SPKTERRIE = 1 in CSI_IER0. The packet is padded up to its theoretical size, and the frame is processed as if no error occurred. The software must perform the necessary error management (such as reseting some peripherals, possibly including the CSI decoder). Details for the error are available in SPKTVCERR and SPKTDTERR in CSI_ERR2.

Watchdog

When the time between two packets of a given virtual channel is longer than the programmed watchdog (CNT[31:0] in CSI_WDR), the WDERR interrupt is triggered if WDERRIE = 1 in CSI_WDR. As the corresponding virtual channel stream is corrupted, the CSI2 Host controller immediately stops processing this virtual channel. The software must perform the necessary error management (such as reseting some peripherals after this error detection), before restarting the CSI-2 Host. Details for the error are available in WDVCERR in CSI_ERR2.

40.8.2 Interrupt handling

The CSI-2 Host controller offers many interrupt sources that can be activated if the associated enable bit is set. Some interrupt sources are linked to an error detection from the D-PHY physical layer or the CSI-2 Host controller (refer to *Section 40.8.1*).

Short packet interrupt

This interrupt notifies the software that a generic short packet has been received. The software can retrieve the associated data in CSI_SPDFR. This register value is overwritten with each new generic short packet.

SOF and EOF interrupts

The CSI-2 Host controller generates an SOF interrupt for each SOF short packet received. It also generates an EOF interrupt for each EOF short packet, independently for all four virtual channels. These interrupts are generated even if the virtual channel is disabled. The software must mask or ignore these interrupts if they are not needed.

Line/byte programmable interrupts

The CSI-2 Host controller provides four interrupts that can be programmed to be triggered at any point during the active data of a frame. In order to set a programmable line/byte interrupt, the software must follow these steps:

1. Select a virtual channel by setting LBxVC[1:0] in CSI_PRGITR.
2. Select the frame location at which the interrupt is triggered by setting LINECNT and BYTECNT in CSI_LBxCFGRy.
3. Enable the line/byte counting by setting LBxEN in the CSI_PGRITR register. This bit must be set only when the CSI-2 is enabled.
4. Enable the interrupt by setting LBxIE in CSI_IER0.
5. The interrupt is generated starting from the next frame on the selected virtual channel.

In order to stop a programmable interrupt, the software must reset the LBxIE bit in the CSI_IER0 register. It immediately stops the interrupt.

Note: All four line/byte programmable interrupts are independent.

Timer-based programmable interrupts

The CSI-2 Host controller provides four interrupts that can be programmed to be triggered based on a timer. In order to set a programmable timer based interrupt, the software must select a virtual channel by setting TIMxVC[1:0] in CSI_PRGITR. The following steps must be followed, while the CSI-2 is disabled:

1. Select the starting event of the timer with TIMxEOF in CSI_PRGITR.
2. Select the timer duration by setting COUNT[24:0] in CSI_TIMxCFGR.
3. Select and enable counting by setting TIMxEN in CSI_PRGITR.
4. Enable the interrupt by setting TIMxIE in CSI_IER0.
5. The interrupt is generated starting from the next frame on the selected virtual channel.

In order to stop a programmable interrupt, the software must reset the TIMxIE bit in the CSI_IER0 register. It immediately stops the interrupt.

Note: All four timer-based programmable interrupts are independent.

If the timer is set to a value longer than the frame period, the interrupt may not be generated for all frames.

Clock-changer FIFO full interrupt

The clock changer is also built around a FIFO which is never full in normal conditions. If the overall system works very slowly (for example due to the CSI-2 and DCMIPP processing clock frequency being set to an inadequate frequency, system-bus bandwidth availability, and so on), the clock-changer FIFO may become full. In this case, an interrupt is set if CCFIFOFIE = 1 in CSI_IER0.

40.9 CSI-2 Host registers

40.9.1 CSI-2 Host control register (CSI_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w			w	w			w	w			w	w		rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **VC3STOP**: Virtual channel 3 stop

The CSI-2 decoder stops the virtual channel 3.

0: No effect

1: Pulse generation to stop the virtual channel 3 processing

Note: The CSI-2 decoder stops processing the virtual channel 3 after the next EOF event (or immediately if the Stop command is issued during frame blanking).

A write operation into this bit must not be simultaneous with a write into VC3START.

Reading this bit returns 0.

Bit 14 **VC3START**: Virtual channel 3 start

The CSI-2 decoder processes the virtual channel 3 according to CSI_VC3CFGRx (x = 0..3).

0: No effect

1: Pulse generation to start the virtual channel 3 processing

Note: The CSI-2 decoder starts processing the virtual channel 3 after the next SOF event.

A write operation into this bit must not be simultaneous with a write into VC3STOP.

Reading this bit returns 0.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **VC2STOP**: Virtual channel 2 stop
The CSI-2 decoder stops the virtual channel 2.
0: No effect
1: Pulse generation to stop the virtual channel 2 processing
Note: The CSI-2 decoder stops processing the virtual channel 2 after the next EOF event (or immediately if the Stop command is issued during frame blanking).
A write operation into this bit must not be simultaneous with a write into VC2START.
Reading this bit returns 0.

Bit 10 **VC2START**: Virtual channel 2 start
The CSI-2 decoder processes the virtual channel 2 according to CSI_VC2CFGRx (x = 0..3).
0: No effect
1: Pulse generation to start the virtual channel 2 processing
Note: The CSI-2 decoder starts processing the virtual channel 2 after the next SOF event.
A write operation into this bit must not be simultaneous with a write into VC2STOP.
Reading this bit returns 0.

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **VC1STOP**: Virtual channel 1 stop
The CSI-2 decoder stops the virtual channel 1.
0: No effect
1: Pulse generation to stop the virtual channel 1 processing
Note: The CSI-2 decoder stops processing the virtual channel 1 after the next EOF event (or immediately if the Stop command is issued during frame blanking).
A write operation into this bit must not be simultaneous with a write into VC1START.
Reading this bit returns 0.

Bit 6 **VC1START**: Virtual channel 1 start
The CSI-2 decoder processes the virtual channel 1 according to CSI_VC1CFGRx (x = 0..3).
0: No effect
1: Pulse generation to start the virtual channel 1 processing
Note: The CSI-2 decoder starts processing the virtual channel 1 after the next SOF event.
A write operation into this bit must not be simultaneous with a write into VC1STOP.
Reading this bit returns 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **VC0STOP**: Virtual channel 0 stop
The CSI-2 decoder stops the virtual channel 0.
0: No effect
1: Pulse generation to stop the virtual channel 0 processing
Note: The CSI-2 decoder stops processing the virtual channel 0 after the next EOF event (or immediately if the Stop command is issued during frame blanking).
A write operation into this bit must not be simultaneous with a write into VC0START.
Reading this bit returns 0.

Bit 2 **VC0START**: Virtual channel 0 start
he CSI-2 decoder processes the virtual channel 0 according to CSI_VC 0CFGRx (x = 0..3).
0: No effect
1: Pulse generation to start the virtual channel 0 processing
Note: The CSI-2 decoder starts processing the virtual channel 0after the next SOF event.
A write operation into this bit must not be simultaneous with a write into VC0STOP.
Reading this bit returns 0.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CSIEN**: CSI-2 enable

This bit enables the CSI-2 peripheral for processing the data flow coming from the camera through the D-PHY_RX.

0: CSI-2 disabled

1: CSI-2 enabled

40.9.2 CSI-2 Host DPHY_RX control register (CSI_PCR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DL1EN	DL0EN	CLEN	PWR DOWN
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **DL1EN**: D-PHY_RX data lane 1 enable

This bit enables the data lane 1 for the D-PHY_RX.

0: Data lane 1 module is in shutdown mode.

1: Enable the data lane 1 module.

Bit 2 **DL0EN**: D-PHY_RX data lane 0 enable

This bit enables the data lane 0 for the D-PHY_RX.

0: Data lane 0 module is in shutdown mode.

1: Enable the data lane 0 module.

Bit 1 **CLEN**: Clock lane enable

This bit enables the clock lane module of the D-PHY_RX.

0: Clock lanes disabled

1: Clock lanes enabled

Bit 0 **PWRDOWN**: Power down

This bit keeps the D-PHY_RX in power-down state.

0: Active state

1: Power down the D-PHY_RX

40.9.3 CSI-2 Host virtual channel x configuration register 1 (CSI_VCxCFGR1)

Address offset: 0x10 + 0x10 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while the virtual channel x is running is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DT0FT[4:0]					Res.	Res.	DT0[5:0]

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **DT0FT[4:0]**: Data type 0 format

These bits configure the input pixel format for the virtual channel x on data type 0.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: reserved and must not be used

Note: The format selection is valid only if ALLDT = 0 and DT0EN = 1. These bits have no effect if ALLDT = 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **DT0[5:0]**: Data type 0 class selection for virtual channel x

These bits select the data type 0 class and subclass for the virtual channel x according to the MIPI specification for CSI-2.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **CDTFT[4:0]**: Common format for all data types

These bits are configured to select which input pixel format is applied for all the seven data type on virtual channel x.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved

Note: The format selection is valid only if ALLDT = 1. These bits have no effect if ALLDT = 0.

Bit 7 **DT6EN**: Data type 6 enable

This bit enables the data type 6 for the virtual channel x. The data type format is applied with respect to the configuration of DT6[5:0] and DT6FT[4:0] in CSI_VCxCFGR4.

0: Data type 6 for virtual channel x is disabled.

1: Data type 6 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 6 **DT5EN**: Data type 5 enable

This bit enables the data type 5 for the virtual channel x. The data type format is applied with respect to the configuration of DT5[5:0] and DT5FT[4:0] in CSI_VCxCFGR4.

0: Data type 5 for virtual channel x is disabled.

1: Data type 5 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 5 **DT4EN**: Data type 4 enable

This bit enables the data type 4 for the virtual channel x. The data type format is applied with respect to the configuration of DT4[5:0] and DT4FT[4:0] in CSI_VCxCFGR3.

0: Data type 4 for virtual channel x is disabled.

1: Data type 4 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 4 **DT3EN**: Data type 3 enable

This bit enables the data type 3 for the virtual channel x. The data type format is applied with respect to the configuration of DT3[5:0] and DT3FT[4:0] in CSI_VCxCFGR3.

0: Data type 3 for virtual channel x is disabled.

1: Data type 3 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 3 **DT2EN**: Data type 2 enable

This bit enables the data type 2 for the virtual channel x. The data type format is applied with respect to the configuration of DT2[5:0] and DT2FT[4:0] in CSI_VCxCFGR2.

0: Data type 2 for virtual channel x is disabled.

1: Data type 2 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 2 **DT1EN**: Data type 1 enable

This bit enables the data type 1 for the virtual channel x. The data type format is applied with respect to the configuration of DT1[5:0] and DT1FT[4:0] in CSI_VCxCFGR2.

0: Data type 1 for virtual channel x is disabled.

1: Data type 1 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 1 **DT0EN**: Data type 0 enable

This bit enables the data type 0 for the virtual channel x. The data type format is applied with respect to the configuration of DT0[5:0] and DT0FT[4:0] in CSI_VCxCFGR1.

0: Data type 0 for virtual channel x is disabled.

1: Data type 0 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 0 **ALLDT**: All data types enable for the virtual channel x

This bit allows to capture all data types according to CDTFT[4:0] for the virtual channel x.

0: Data type capture managed individually

1: All data types captured for virtual channel x

40.9.4 CSI-2 Host virtual channel x configuration register 2 (CSI_VCxCFGR2)

Address offset: 0x14 + 0x10 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while the virtual channel x is running is ignored.

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **DT2FT[4:0]**: Data type 2 format

These bits configure the input pixel format for the virtual channel x on data type 2.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved and must not be used.

Note: The format selection is valid only if ALLDT = 0 and DT2EN = 1. These bits have no effect if ALLDT = 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **DT2[5:0]**: Data type 2 class selection for virtual channel x

These bits select the data type 2 class and subclass for the virtual channel x according to the MIPI specification for CSI- 2.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DT1FT[4:0]**: Data type 1 format

These bits configure the input pixel format for the virtual channel x on data type 1.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7 -it words (for example RAW7)
00010: (BPP8) 8 -it words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12 -it words (for example RAW12)
00101: (BPP14) 14 -it words (for example RAW14)
00110: (BPP16) 16 -it words (for example RAW16)
Others: Reserved and must not be used.

Note: The format selection is valid only if ALLDT = 0 and DT1EN = 1. These bits have no effect if ALLDT = 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DT1[5:0]**: Data type 1 class selection for virtual channel x

These bits select the data type 1 class and subclass for the virtual channel x according to the MIPI specification for CSI- 2.

40.9.5 CSI-2 Host virtual channel x configuration register 3 (CSI_VCxCFGR3)

Address offset: 0x18 + 0x10 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while the virtual channel x is running is ignored.

00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved and must not be used.

Note: The format selection is valid only if ALLDT = 0 and DT6EN = 1. These bits have no effect if ALLDT = 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **DT6[5:0]**: Data type 6 class selection for virtual channel x

These bits select the data type 6 class and subclass for the virtual channel x according to the MIPI specification for CSI-2.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DT5FT[4:0]**: Data type 5 format

These bits configure the input pixel format for the virtual channel x on data type 5.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved.

Note: The format selection is valid only if ALLDT = 0 and DT5EN = 1. These bits have no effect if ALLDT = 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DT5[5:0]**: Data type 5 class selection for virtual channel x

These bits select the data type 5 class and subclass for the virtual channel x according to the MIPI specification for Camera Serial Interface 2.

40.9.7 CSI-2 Host line byte x configuration register (CSI_LBxCFGR)

Address offset: 0x50 + 0x04 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while LBxEN bit is set into the CSI_PRGITR is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BYTECNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **LINECNT[15:0]**: Line counter

These bits select the line number, associated to LINECNT[15:0], to trigger, if enabled, the corresponding line/byte interruption flag based on the selected virtual channel identified in CSI_PRGITR.

Bits 15:0 **BYTECNT[15:0]**: Byte counter

These bits select the byte number, associated to BYTECNT[15:0], to trigger, if enabled, the corresponding line/byte interruption flag based on the selected virtual channel identified in CSI_PRGITR.

40.9.8 CSI-2 Host timer x configuration register (CSI_TIMxCFGR)

Address offset: 0x60 + 0x04 * x, (x = 0 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

COUNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **COUNT[24:0]**: Clock cycle counter

This register is used to specify how many clock cycles (clk_proc) the timer needs to count from a SOF on the considered virtual channel, before triggering the associated interrupt flag if enabled in CSI_PRGITR. The interruption is generated if TIMxIE is set in CSI_IER0.

40.9.9 CSI-2 Host lane merger configuration register (CSI_LMCFGR)

Address offset: 0x70

Reset value: 0x4321 0200

This register must not be modified while the CSI-2 is enabled.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **DL1MAP[2:0]**: Physical mapping of logical data lane 1

These bits are used to map the physical data lane 1 on the logical data lane.
001: Physical data lane 1 connected to logical data lane 0
010: Physical data lane 1 connected to logical data lane 1
Others: Reserved

Note: This field value must be different from DL0MAP[2:0].

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **DL0MAP[2:0]**: Physical mapping of logical data lane 0

These bits are used to map the physical data lane 0 on the logical data lane.
001: Physical data lane 0 connected to logical data lane 0
010: Physical data lane 0 connected to logical data lane 1
Others: Reserved

Note: This field value must be different from DL1MAP[2:0].

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **LANENB[2:0]**: Number of lanes

These bits are used to specify the number of lanes used for the data reception.
001: 1 lane for the reception
010: 2 lanes for the reception
Others: Reserved

Bits 7:0 Reserved, must be kept at reset value.

40.9.10 CSI-2 Host program interrupt register (CSI_PRGITR)

Address offset: 0x74

Reset value: 0x0000 0000

Bit 31 **TIM3EN**: TIM3 base time enable

This bit is used to enable the mechanism of event generation starting from SOF or EOF depending on TIM3EOF. An interrupt is generated if TIM3IE is set int CSI_IER0.
0: Timer 3 clock cycle counter not active
1: Timer 3 clock cycle counter active

Note: Enabling this bit locks TIM3EOF and TIM3VC[1:0] values.
The counting starts from the next frame after setting this bit.
This bit must be written only when the CSI-2 is disabled.

Bit 30 **TIM3EOF**: TIM3 base time starting from the EOF

This bits is used to select the starting point of the counter on the selected virtual channel.
0: SOF selected as starting point for the counter
1: EOF selected as starting point for the counter

Note: The write access to this bit is ignored if TIM3EN = 1 in CSI_PRGITR.
This bit must be written only when the CSI-2 is disabled.

Bits 29:28 **TIM3VC[1:0]**: TIM3 base time linked to a virtual channel

These bits are used to select from which of the virtual channels the TIM3 counter is linked.
00: Virtual channel 0 used to generate the TIM3 event
01: Virtual channel 1 used to generate the TIM3 event
10: Virtual channel 2 used to generate the TIM3 event
11: Virtual channel 3 used to generate the TIM3 event

Note: The write access to these bits is ignored if TIM3EN = 1 in CSI_PRGITR.
These bits must be written only when the CSI-2 is disabled.

Bit 27 **TIM2EN**: TIM2 base time enable

This bit is used to enable the mechanism of event generation starting from SOF or EOF depending on TIM2EOF. An interrupt is generated if TIM2IE is set in CSI_IER0.

0: Timer 2 clock cycle counter not active.

1: Timer 2 clock cycle counter active

Note: Enabling this bit locks TIM2EOF and TIM2VC[1:0] values.

The counting starts from the next frame after setting this bit.

This bit must be written only when the CSI-2 is disabled.

Bit 26 **TIM2EOF**: TIM2 base time starting from the EOF

This bits is used to select the starting point of the counter on the selected virtual channel.

0: SOF selected as starting point for the counter

1: EOF selected as starting point for the counter

Note: The write access to this bit is ignored if TIM2EN = 1 in CSI_PRGITR.

This bit must be written only when the CSI-2 is disabled.

Bits 25:24 **TIM2VC[1:0]**: TIM2 base time linked to a virtual channel

These bits are used to select from which of the virtual channels the TIM2 counter is linked.

00: Virtual channel 0 used to generate the TIM2 event

01: Virtual channel 1 used to generate the TIM2 event

10: Virtual channel 2 used to generate the TIM2 event

11: Virtual channel 3 used to generate the TIM2 event

Note: The write access to these bits is ignored if TIM2EN = 1 in CSI_PRGITR.

These bits must be written only when the CSI-2 is disabled.

Bit 23 **TIM1EN**: TIM1 base time enable

This bit is used to enable the mechanism of event generation starting from SOF or EOF depending on TIM1EOF. An interrupt is generated if TIM1IE is set in CSI_IER0.

0: Timer 1 clock cycle counter not active.

1: Timer 1 clock cycle counter active

Note: Enabling this bit locks TIM1EOF and TIM1VC[1:0] values.

The counting starts from the next frame after setting this bit.

This bit must be written only when the CSI-2 is disabled.

Bit 22 **TIM1EOF**: TIM1 base time starting from the EOF

This bits is used to select the starting point of the counter on the selected virtual channel.

0: SOF selected as starting point for the counter

1: EOF selected as starting point for the counter

Note: The write access to this bit is ignored if TIM1EN = 1 in CSI_PRGITR.

This bit must be written only when the CSI-2 is disabled.

Bits 21:20 **TIM1VC[1:0]**: TIM1 base time linked to a virtual channel

These bits are used to select from which of the virtual channels the TIM1 counter is linked.

00: Virtual channel 0 used to generate the TIM1 event

01: Virtual channel 1 used to generate the TIM1 event

10: Virtual channel 2 used to generate the TIM1 event

11: Virtual channel 3 used to generate the TIM1 event

Note: The write access to these bits is ignored if TIM1EN = 1 in CSI_PRGITR.

These bits must be written only when the CSI-2 is disabled.

Bit 19 **TIM0EN**: TIM0 base time enable

This bit is used to enable the mechanism of event generation starting from SOF or EOF depending on TIM0EOF. An interrupt is generated if TIM0IE is set in CSI_IER0.

0: Timer 0 clock cycle counter not active

1: Timer 0 clock cycle counter active

Note: Enabling this bit locks TIM0EOF and TIM0VC[1:0] values.

The counting starts from the next frame after setting this bit.

This bit must be written only when the CSI-2 is disabled.

Bit 18 **TIM0EOF**: TIM0 base time starting from the EOF

This bits is used to select the starting point of the counter on the selected virtual channel.

0: SOF selected e as starting point for the counter

1: EOF selected as starting point for the counter

Note: The write access to this bit is ignored if TIM0EN = 1 in CSI_PRGITR.

This bit must be written only when the CSI-2 is disabled.

Bits 17:16 **TIM0VC[1:0]**: TIM0 base time linked to a virtual channel

These bits are used to select from which of the virtual channels the TIM0 counter is linked.

00: Virtual channel 0 used to generate the TIM0 event

01: Virtual channel 1 used to generate the TIM0 event

10: Virtual channel 2 used to generate the TIM0 event

11: Virtual channel 3 used to generate the TIM0 event

Note: The write access to these bits is ignored if TIM0EN = 1 in CSI_PRGITR.

These bits must be written only when the CSI-2 is disabled.

Bit 15 **LB3EN**: Line/byte 3 counter enable

This bit is used to enable the mechanism of event generation at any location in the frame corresponding to the value set in CSI_LB3CFGR. An interrupt is generated if LB3IE is set in CSI_IER0.

0: Line/byte 3 counter stopped

1: Line/byte 3 counter active

Note: Enabling this bit locks LB3VC[1:0] value.

The counter starts from the next frame after setting this bit.

This bit must be set only when the CSI-2 is enabled.

Bit 14 Reserved, must be kept at reset value.

Bits 13:12 **LB3VC[1:0]**: Line/byte counter 3 linked to a virtual channel

These bits are used to select from which of the virtual channels the line/byte counter 3 is linked.

00: Virtual channel 0 used to generate the line/byte counter 3 event

01: Virtual channel 1 used to generate the line/byte counter 3 event

10: Virtual channel 2 used to generate the line/byte counter 3 event

11: Virtual channel 3 used to generate the line/byte counter 3 event

Note: The write access to these bits is ignored if LB3EN = 1 in CSI_PRGITR.

Bit 11 **LB2EN**: Line/byte 2 counter enable

This bit is used to enable the mechanism of event generation at any location in the frame corresponding to the value set in CSI_LB2CFGR. An interrupt is generated if LB2IE is set in CSI_IER0.

0: Line/byte 2 counter stopped

1: Line/byte 2 counter active

Note: Enabling this bit locks LB2VC[1:0] value.

The counter starts from the next frame after setting this bit.

This bit must be set only when the CSI-2 is enabled.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **LB2VC[1:0]**: Line/byte counter 2 linked to a virtual channel

These bits are used to select from which of the virtual channels the line/byte counter 2 is linked.

00: Virtual channel 0 used to generate the line/byte counter 2 event

01: Virtual channel 1 used to generate the line/byte counter 2 event

10: Virtual channel 2 used to generate the line/byte counter 2 event

11: Virtual channel 3 used to generate the line/byte counter 2 event

Note: The write access to these bits is ignored if LB2EN = 1 in CSI_PRGITR.

Bit 7 **LB1EN**: Line/byte 1 counter enable

This bit is used to enable the mechanism of event generation at any location in the frame corresponding to the value set in CSI_LB1CFGR. An interrupt is generated if LB1IE is set in CSI_IER0.

0: Line/byte 1 counter stopped

1: Line/byte 1 counter active

Note: Enabling this bit locks LB1VC[1:0] value.

The counter starts from the next frame after setting this bit.

This bit must be set only when the CSI-2 is enabled.

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **LB1VC[1:0]**: Line/byte counter 1 linked to a virtual channel

These bits are used to select from which of the virtual channels the line/byte counter 1 is linked.

00: Virtual channel 0 used to generate the line/byte counter 1 event

01: Virtual channel 1 used to generate the line/byte counter 1 event

10: Virtual channel 2 used to generate the line/byte counter 1 event

11: Virtual channel 3 used to generate the line/byte counter 1 event

Note: The write access to these bits is ignored if LB1EN = 1 in CSI_PRGITR.

Bit 3 **LB0EN**: Line/byte 0 counter enable

This bit is used to enable the mechanism of event generation at any location in the frame corresponding to the value set in CSI_LB0CFGR. An interrupt is generated if LB0IE is set in CSI_IER0.

0: Line/byte 0 counter stopped

1: Line/byte 0 counter active

Note: Enabling this bit locks LB0VC[1:0] value.

The counter starts from the next frame after setting this bit.

This bit must be set only when the CSI-2 is enabled.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **LB0VC[1:0]**: Line/byte counter 0 linked to a virtual channel

These bits are used to select from which of the virtual channels the line/byte counter 0 is linked.

00: Virtual channel 0 used to generate the line/byte counter 0 event

01: Virtual channel 1 used to generate the line/byte counter 0 event

10: Virtual channel 2 used to generate the line/byte counter 0 event

11: Virtual channel 3 used to generate the line/byte counter 0 event

Note: The write access to these bits is ignored if LB0EN = 1 in CSI_PRGITR.

40.9.11 CSI-2 Host watchdog register (CSI_WDR)

Address offset: 0x78

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CNT[31:0]**: Watchdog counter

These bits contains the maximum number of clock cycles (clk_proc) between an EOF and a SOF for a given channel before triggering an interrupt if WDERRIE = 1 in CSI_IER0.

The value 0x000000 disables the watchdog counter.

40.9.12 CSI-2 Host interrupt enable register 0 (CSI_IER0)

Address offset: 0x80

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SYNCERRIE**: Invalid synchronization error interrupt enable

This bit enables the interrupt generation when an invalid synchronization is detected.

It can be a SOF short packet during a frame, or and EOF short packet during an inter-frame.

0: Interrupt on invalid synchronization error disabled

1: Interrupt on invalid synchronization error enabled

Bit 29 **WDERRIE**: Watchdog error interrupt enable
This bit enables the interrupt generation when the time between two packets for a virtual channel is longer than the programmed watchdog.
0: Interrupt on watchdog error disabled
1: Interrupt on watchdog error enabled

Bit 28 **SPKTERRIE**: Short packet error interrupt enable
This bit enables the interrupt generation based on a reception of a shorter packet than expected.
0: Interrupt on short packet error disabled
1: Interrupt on short packet error enabled

Bit 27 **IDERRIE**: Data type ID error interrupt enable
This bit enables the interrupt generation based on a detection of a reserved data type.
0: Interrupt on reception of reserved data type disabled
1: Interrupt on reception of reserved data type enabled

Bit 26 **CECCERRIE**: Corrected ECC error interrupt enable
This bit enables the interrupt generation based on a corrected ECC error detection.
0: Interrupt on corrected ECC error detection disabled
1: Interrupt on corrected ECC error detection enabled

Bit 25 **ECCERRIE**: ECC error interrupt enable
This bit enables the interrupt generation based on an ECC error detection.
0: Interrupt on ECC error detection disabled
1: Interrupt on ECC error detection enabled

Bit 24 **CRCERRIE**: CRC error interrupt enable
This bit enables the interrupt generation based on CRC error detection on a long packet reception.
0: Interrupt on CRC error detection disabled
1: Interrupt on CRC error detection enabled

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCFIFOFIE**: Clock changer FIFO full interrupt enable
This bit enables the interrupt generation based on clock changer FIFO full detection.
0: Interrupt on clock changer FIFO full detection disabled
1: Interrupt on clock changer FIFO full detection enabled

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 **SPKTIE**: Short packet interrupt enable
This bit generates an interrupt which notifies that a generic short packet has been received by the CSI-2 Host.
0: Short packet detection interrupt disabled
1: Short packet detection interrupt enabled

Bit 15 **EOF3IE**: EOF for virtual channel 3 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding an EOF on the virtual channel 3.
0: EOF on virtual channel 3 interrupt disabled
1: EOF on virtual channel 3 interrupt enabled

Bit 14 **EOF2IE**: EOF for virtual channel 2 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding an EOF on the virtual channel 2.
0: EOF on virtual channel 2 interrupt disabled
1: EOF on virtual channel 2 interrupt enabled

Bit 13 **EOF1IE**: EOF for virtual channel 1 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding an EOF on the virtual channel 1.
0: EOF on virtual channel 1 interrupt disabled
1: EOF on virtual channel 1 interrupt enabled

Bit 12 **EOF0IE**: EOF for virtual channel 0 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding an EOF on the virtual channel 0.
0: EOF on virtual channel 0 interrupt disabled
1: EOF on virtual channel 0 interrupt enabled

Bit 11 **SOF3IE**: SOF for virtual channel 3 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding a SOF on the virtual channel 3.
0: SOF on virtual channel 3 interrupt disabled
1: SOF on virtual channel 3 interrupt enabled

Bit 10 **SOF2IE**: SOF for virtual channel 2 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding a SOF on the virtual channel 2.
0: SOF on virtual channel 2 interrupt disabled
1: SOF on virtual channel 2 interrupt enabled

Bit 9 **SOF1IE**: SOF for virtual channel 1 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding a SOF on the virtual channel 1.
0: SOF on virtual channel 1 interrupt disabled.
1: SOF on virtual channel 1 interrupt enabled.

Bit 8 **SOF0IE**: SOF for virtual channel 0 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding a SOF on the virtual channel 0.
0: SOF on virtual channel 0 interrupt disabled
1: SOF on virtual channel 0 interrupt enabled

Bit 7 **TIM3IE**: Timer 3 interrupt enable
This bit enables the interrupt generation from the timer 3 linked to the virtual channel number configured by TIM3VC in CSI_PRGITR. The interrupt raises when the timer 3 value reaches the value configured in CSI_TIM3CFGR.
0: Timer 3 interrupt disabled
1: Timer 3 interrupt enabled

Bit 6 **TIM2IE**: Timer 2 interrupt enable
This bit enables the interrupt generation from the timer 2 linked to the virtual channel number configured by TIM2VC in CSI_PRGITR. The interrupt raises when the timer 2 value reaches the value configured in CSI_TIM2CFGR.
0: Timer 2 interrupt disabled
1: Timer 2 interrupt enabled

Bit 5 **TIM1IE**: Timer 1 interrupt enable

This bit enables the interrupt generation from the timer 1 linked to the virtual channel number configured by TIM1VC in CSI_PRGITR. The interrupt raises when the timer 1 value reaches the value configured in CSI_TIM1CFGR.

0: Timer 1 interrupt disabled

1: Timer 1 interrupt enabled

Bit 4 **TIM0IE**: Timer 0 interrupt enable

This bit enables the interrupt generation from the timer 0 linked to the virtual channel number configured by TIM0VC in CSI_PRGITR. The interrupt raises when the timer 0 value reaches the value configured in CSI_TIM0CFGR.

0: Timer 0 interrupt disabled

1: Timer 0 interrupt enabled

Bit 3 **LB3IE**: Line/byte counter 3 interrupt enable

This bit enables the interrupt generation when the active frame of the virtual channel configured by LB3VC in CSI_PRGITR reaches the line/byte number programmed in CSI_LB3CFGR.

Bit 2 **LB2IE**: Line/byte counter 2 interrupt enable

This bit enables the interrupt generation when the active frame of the virtual channel configured by LB2VC in CSI_PRGITR reaches the line/byte number programmed in CSI_LB2CFGR.

Bit 1 **LB1IE**: Line/byte counter 1 interrupt enable

This bit enables the interrupt generation when the active frame of the virtual channel configured by LB1VC in CSI_PRGITR reaches the line/byte number programmed in CSI_LB1CFGR.

Bit 0 **LB0IE**: Line/byte counter 0 interrupt enable

This bit enables the interrupt generation when the active frame of the virtual channel configured by LB0VC in CSI_PRGITR reaches the line/byte number programmed in CSI_LB0CFGR.

40.9.13 CSI-2 Host interrupt enable register 1 (CSI_IER1)

Address offset: 0x84

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **ECTRLDL1IE**: D-PHY_RX lane 1 control error interrupt enable
This bit enables the D-PHY_RX control error interrupt detected on lane 1 consecutive to an incorrect line state sequence.
0: Lane 1 control error interrupt disabled
1: Lane 1 control error interrupt enabled

Bit 11 **ESYNCESCDL1IE**: D-PHY_RX lane 1 low-power data transmission synchronization error interrupt enable
This bit enables the interrupt generation when the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends on lane 1.
0: Lane 1 low-power data transmission interrupt error disabled
1: Lane 1 low-power data transmission Interrupt error enabled

Bit 10 **EESCDL1IE**: D-PHY_RX lane 1 escape entry error interrupt enable
This bit enables the interrupt generation when an unrecognized escape entry command is received on lane 1.
0: Lane 1 unrecognized escape entry command interrupt error disabled
1: Lane 1 unrecognized escape entry command interrupt error enabled

Bit 9 **ESOTSYNCDL1IE**: SOT synchronization interrupt error enable on lane 1
This bit enables the interrupt generation when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization cannot be expected.
0: Lane 1 SOT synchronization interrupt error disabled
1: Lane 1 SOT synchronization interrupt error enabled

Bit 8 **ESOTDL1IE**: SOT error interrupt enable on lane 1
This bit enables the interrupt generation when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization can still be achieved.
0: Lane 1 SOT interrupt error disabled
1: Lane 1 SOT interrupt error enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ECTRLDL0IE**: D-PHY_RX lane 0 control error interrupt enable
This bit enables the D-PHY_RX control error interrupt detected on lane 0 consecutive to an incorrect line state sequence.
0: Lane 0 control error interrupt disabled
1: Lane 0 control error interrupt enabled

Bit 3 **ESYNCESCDL0IE**: D-PHY_RX lane 0 low power data transmission synchronization error interrupt enable
This bit enables the interrupt generation when the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends on lane 1.
0: Lane 0 low-power data transmission interrupt error disabled
1: Lane 0 low-power data transmission Interrupt error enabled

Bit 2 **EESCDL0IE**: D-PHY_RX lane 0 escape entry error interrupt enable
This bit enables the interrupt generation when an unrecognized escape entry command is received on lane 0.
0: Lane 0 unrecognized escape entry command interrupt error disabled
1: Lane 0 unrecognized escape entry command interrupt error enabled

Bit 1 **ESOTSYNCDL0IE**: SOT synchronization interrupt error enable on lane 0
This bit enables the interrupt generation when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization cannot be expected.
0: Lane 0 SOT synchronization interrupt error disabled
1: Lane 0 SOT synchronization interrupt error enabled

Bit 0 **ESOTDL0IE**: SOT error interrupt enable on lane 0
This bit enables the interrupt generation when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization can still be achieved.
0: Lane 0 SOT interrupt error disabled
1: Lane 0 SOT interrupt error enabled

40.9.14 CSI-2 Host status register 0 (CSI_SR0)

Address offset: 0x90

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SYNCERRF**: Invalid synchronization error flag
This bit indicates an invalid synchronization is detected. It can be a SOF short packet during a frame, or and EOF short packet during an inter-frame.

Bit 29 **WDERRF**: Watchdog error flag
This bit indicates that the time between two packets for a virtual channel is longer than the programmed watchdog.

Bit 28 **SPKTERRF**: Short packet error flag
This bit indicates a reception of a shorter packet than expected.

Bit 27 **IDERRF**: Data type ID error flag
This bit indicates a detection of a reserved data type.

Bit 26 **CECCERRF**: Corrected ECC error flag
This bit indicates a corrected ECC error detection took place in the frame.

Bit 25 **ECCERRF**: ECC error flag
This bit indicates that an ECC error has been detected.

Bit 24 **CRCERRF**: CRC error flag
This bit indicates a CRC error detection on a long packet reception.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCFIFOFF**: Clock changer FIFO full flag
This bit indicates a FIFO full detection in the clock changer.

Bit 20 **VC3STATEF**: Virtual channel 3 state flag
This bit indicates the state of the virtual channel 3.
0: Virtual channel inactive
1: Virtual channel active

Bit 19 **VC2STATEF**: Virtual channel 2 state flag
This bit indicates the state of the virtual channel 2.
0: Virtual channel inactive
1: Virtual channel active

Bit 18 **VC1STATEF**: Virtual channel 1 state flag
This bit indicates the state of the virtual channel 1.
0: Virtual channel inactive
1: Virtual channel active

Bit 17 **VC0STATEF**: Virtual channel 0 state flag
This bit indicates the state of the virtual channel 0.
0: Virtual channel inactive
1: Virtual channel active

Bit 16 **SPKTF**: Short packet flag
This bit notifies that a generic short packet has been received by the CSI-2 Host.

Bit 15 **EOF3F**: EOF flag for virtual channel 3
This bit notifies that the CSI-2 Host decodes an EOF on the virtual channel 3.

Bit 14 **EOF2F**: EOF flag for virtual channel 2
This bit notifies that the CSI-2 Host is decoding an EOF on the virtual channel 2.

Bit 13 **EOF1F**:EOF flag for virtual channel 1
This bit notifies that the CSI-2 Host is decoding an EOF on the virtual channel 1.

Bit 12 **EOF0F**: EOF flag for virtual channel 0
This bit notifies that the CSI-2 Host is decoding an EOF on the virtual channel 0.

Bit 11 **SOF3F**: SOF flag for virtual channel 3
This bit notifies that the CSI-2 Host is decoding a SOF on the virtual channel 3.

Bit 10 **SOF2F**: SOF flag for virtual channel 2
This bit notifies that the CSI-2 Host is decoding a SOF on the virtual channel 2.

Bit 9 **SOF1F**: SOF flag for virtual channel 1
This bit notifies that the CSI-2 Host is decoding a sSOF on the virtual channel 1.

Bit 8 **SOF0F**: SOF flag for virtual channel 0
This bit notifies that the CSI-2 Host is decoding a SOF on the virtual channel 0.

Bit 7 **TIM3F**: Timer 3 flag
This bit indicates that the timer 3 linked to the virtual channel configured by TIM3VC in CSI_PRGITR reaches the value programmed in CSI_TIM3CFGR.

Bit 6 **TIM2F**: Timer 2 flag
This bit indicates that the timer 2 linked to the virtual channel configured by TIM2VC in CSI_PRGITR reaches the value programmed in CSI_TIM2CFGR.

Bit 5 **TIM1F**: Timer 1 flag
This bit indicates that the timer 1 linked to the virtual channel configured by TIM1VC in CSI_PRGITR reaches the value programmed in CSI_TIM1CFGR.

Bit 4 **TIM0F**: Timer 0 flag
This bit indicates that the timer 0 linked to the virtual channel configured by TIM0VC in CSI_PRGITR reaches the value programmed in CSI_TIM0CFGR.

Bit 3 **LB3F**: Line/byte counter 3 flag
This bit notifies that the active frame of the virtual channel configured by LB3VC in CSI_PRGITR has reached the line/byte number programmed in th CSI_LB3CFGR.

Bit 2 **LB2F**: Line/byte counter 2 flag
This bit notifies that the active frame of the virtual channel configured by LB2VC in CSI_PRGITR has reached the line/byte number programmed in CSI_LB2CFGR.

Bit 1 **LB1F**: Line/byte counter 1 flag
This bit notifies that the active frame of the virtual channel configured by LB1VC in CSI_PRGITR has reached the line/byte number programmed in CSI_LB1CFGR.

Bit 0 **LB0F**: Line/byte counter 0 flag
This bit notifies that the active frame of the virtual channel configured by LB0VC in CSI_PRGITR has reached the line/byte number programmed in CSI_LB0CFGR.

40.9.15 CSI-2 Host status register 1 (CSI_SR1)

Address offset: 0x94

Reset value: 0x0000 0000

			r	r	r	r	r				r	r	r	r	r

Bit 31 **ACTCLF**: D-PHY_RX receiver clock active flag
This bit indicates the status of RxClkactiveHs D-PHY_RX signal.

Bit 30 **ULPNCLF**: D-PHY_RX receiver Ultra-Low power state (not) on clock lane.
This bit indicates the status of RxUlpsClkNot D-PHY_RX signal.

Bit 29 **ULPNACTF**: D-PHY_RX receiver ULP state (not) active
This bit indicates the status of UlpsactiveNotC D-PHY_RX signal.

Bit 28 **STOPCLF**: D-PHY_RX receiver in stop state for the clock lane
This bit indicates the status of StopStateC D-PHY_RX signal.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **ULPNDL1F**: D-PHY_RX receiver ultra-low-power state (not) active on data lane 1
This bit indicates the status of UlpsActiveNot_D_lane1 D-PHY_RX signal.

Bit 25 **STOPDL1F**: D-PHY_RX receiver data lane 1 in stop state
This bit indicates the status of StopState_D_lane1 D-PHY_RX signal.

Bit 24 **SKCALDL1F**: D-PHY_RX lane 1 high-speed skew calibration
This bit indicates the status of RxSkewCalHS_lane1 D-PHY_RX signal.

Bit 23 **SYNCDL1F**: D-PHY_RX lane 1 receiver synchronization observed
This bit indicates the status of RXSyncHS_lane1 D-PHY_RX signal.

Bit 22 **ACTDL1F**: D-PHY_RX lane 1 high-speed reception active
This bit indicates the status of RxActiveHS_lane1 D-PHY_RX signal.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **ULPNDL0F**: D-PHY_RX receiver ultra-low-power state (not) active on data lane 0
This bit indicates the status of UlpsActiveNot_D_lane0 D-PHY_RX signal.

Bit 19 **STOPDL0F**: D-PHY_RX receiver data lane 0 in stop state
This bit indicates the status of StopState_D_lane0 D-PHY_RX signal.

Bit 18 **SKCALDL0F**: D-PHY_RX lane 0 high-speed skew calibration
This bit indicates the status of RxSkewCalHS_lane0 D-PHY_RX signal.

Bit 17 **SYNCDL0F**: D-PHY_RX lane 0 receiver synchronization observed
This bit indicates the status of RXSyncHS_lane0 D-PHY_RX signal.

Bit 16 **ACTDL0F**: D-PHY_RX lane 0 high-speed reception active
This bit indicates the status of RxActiveHS_lane0 D-PHY_RX signal.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **ECTRLDL1F**: D-PHY_RX lane 1 control error flag
This bit indicates that the D-PHY_RX detected on lane 1 an incorrect line state sequence.

Bit 11 **ESYNCESCDL1F**: D-PHY_RX lane 1 low-power data transmission synchronization error flag
This bit notifies a synchronization error when the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends on lane 1.

Bit 10 **EESCDL1F**: D-PHY_RX lane 1 escape entry error flag
This bit notifies an escape entry error when an unrecognized escape entry command is received on lane 1.

Bit 9 **ESOTSYNCDL1F**: SOT synchronization error flag on lane 1
This bit indicates a SOT synchronization error when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization cannot be expected.

Bit 8 **ESOTDL1F**: SOT error flag on lane 1
This bit notifies a SOT error when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization can still be achieved.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ECTRLDL0F**: D-PHY_RX lane 0 control error flag
This bit indicates that the D-PHY_RX detected on lane 0 an incorrect line state sequence.

Bit 3 **ESYNCESCDL0F**: D-PHY_RX lane 0 low-power data transmission synchronization error flag
This bit notifies a synchronization error when the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends on lane 0.

Bit 2 **EESCDL0F**: D-PHY_RX lane 0 escape entry error flag
This bit notifies an escape entry error when an unrecognized escape entry command is received on lane 0.

Bit 1 **ESOTSYNCDL0F**: SOT synchronization error flag on lane 0
This bit indicates a SOT synchronization error when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization cannot be expected.

Bit 0 **ESOTDL0F**: SOT error flag on lane 0
This bit notifies a SOT error when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization can still be achieved.

40.9.16 CSI-2 Host flag clear register 0 (CSI_FCR0)

Address offset: 0x100

Reset value: 0x0000 0000

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CSYNCERRF**: Clear invalid synchronization error flag
Write 1 clears SYNCERRF flag in CSI_SR0.

Bit 29 **CWDERRF**: Clear watchdog error flag
Write 1 clears WDERRF flag in CSI_SR0.

Bit 28 **CSPKTERRF**: Clear short packet error flag
Write 1 clears SPKTERRF flag in CSI_SR0.

Bit 27 **CIDERRF**: Clear data type ID error flag
Write 1 clears CIDERRF flag in CSI_SR0.

Bit 26 **CCECCERRF**: Clear corrected ECC error flag
Write 1 clears CCECCERRF flag in CSI_SR0.

Bit 25 **CECCERRF**: Clear ECC error flag
Write 1 clears CECCERRF flag in CSI_SR0.

Bit 24 **CCRCERRF**: Clear CRC error flag
Write 1 clears CRCERRF flag in CSI_SR0.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCCFIFOFF**: Clear clock changer FIFO full flag
Write 1 clears CCFIFOFF flag in CSI_SR0.

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 **CSPKTF**: Clear short packet flag
Write 1 clears SPKTF flag in CSI_SR0.

Bit 15 **CEOF3F**: Clear EOF flag for virtual channel 3
Write 1 clears EOF3F flag in CSI_SR0.

Bit 14 **CEOF2F**: Clear EOF flag for virtual channel 2
Write 1 clears EOF2F flag in CSI_SR0.

Bit 13 **CEOF1F**: Clear EOF flag for virtual channel 1
Write 1 clears EOF1F flag in CSI_SR0.

Bit 12 **CEOF0F**: Clear EOF flag for virtual channel 0
Write 1 clears EOF0F flag in CSI_SR0.

Bit 11 **CSOF3F**: Clear SOF flag for virtual channel 3
Write 1 clears SOF3F flag in CSI_SR0.

Bit 10 **CSOF2F**: Clear SOF flag for virtual channel 2
Write 1 clears SOF2F flag in CSI_SR0.

Bit 9 **CSOF1F**: Clear SOF flag for virtual channel 1
Write 1 clears SOF1F flag in CSI_SR0.

Bit 8 **CSOF0F**: Clear SOF flag for virtual channel 0
Write 1 clears SOF0F flag in CSI_SR0.

Bit 7 **CTIM3F**: Clear timer 3 flag
Write 1 clears TIM3F flag in CSI_SR0.

Bit 6 **CTIM2F**: Clear timer 2 flag
Write 1 clears TIM2F flag in CSI_SR0.

Bit 5 **CTIM1F**: Clear timer 1 flag
Write 1 clears TIM1F flag in CSI_SR0.

Bit 4 **CTIM0F**: Clear timer 0 flag
Write 1 clears TIM0F flag in CSI_SR0.

Bit 3 **CLB3F**: Clear line/byte counter 3 flag
Write 1 clears LB3F flag in CSI_SR0.

Bit 2 **CLB2F**: Clear line/byte counter 2 flag
Write 1 clears LB2F flag in CSI_SR0.

Bit 1 **CLB1F**: Clear line/byte counter 1 flag
Write 1 clears LB1F flag in CSI_SR0.

Bit 0 **CLB0F**: Clear line/byte counter 0 flag
Write 1 clears LB0F flag in CSI_SR0.

40.9.17 CSI-2 Host flag clear register 1 (CSI_FCR1)

Address offset: 0x104

Reset value: 0x0000 0000

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **CECTRLDL1F**: Clear D-PHY_RX lane 1 control error flag
Write 1 clears ECTRLDL1F flag in CSI_SR1.

Bit 11 **CESYNCESCDL1F**: Clear D-PHY_RX lane 1 low-power data transmission synchronization error flag
Write 1 clears ESYNCESCDL1F flag in CSI_SR1.

Bit 10 **CEESCDL1F**: Clear D-PHY_RX lane 1 escape entry error flag
Write 1 clears the EESCDL1F flag in the CSI_SR1 register

Bit 9 **CESOTSYNCDL1F**: Clear SOT synchronization error flag on lane 1
Write 1 clears ESOTSYNCDL1F flag in CSI_SR1.

Bit 8 **CESOTDL1F**: Clear SOT error flag on lane 1
Write 1 clears ESOTDL1F flag in CSI_SR1.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CECTRLDL0F**: Clear D-PHY_RX lane 0 control error flag
Write 1 clears ECTRLDL0F in CSI_SR1.

Bit 3 **CESYNCESCDL0F**: Clear D-PHY_RX lane 0 low-power data transmission synchronization error flag
Write 1 clears ESYNCESCDL0F flag in CSI_SR1.

Bit 2 **CEESCDL0F**: Clear D-PHY_RX lane 0 escape entry error flag
Write 1 clears EESCDL0F flag in CSI_SR1.

Bit 1 **CESOTSYNCDL0F**: Clear SOT synchronization error flag on lane 0
Write 1 clears ESOTSYNCDL0F flag in CSI_SR1.

Bit 0 **CESOTDL0F**: Clear SOT error flag on lane 0
Write 1 clears ESOTDL0F flag in CSI_SR1.

40.9.18 CSI-2 Host short packet data field register (CSI_SPDFR)

Address offset: 0x110

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VCHANNEL[1:0]		DATATYPE[5:0]

DATAFIELD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **VCHANNEL[1:0]**: Virtual channel
This bit indicates which is the virtual channel number decoded in the last generic short packet data field reception. Write to this bit has no effect.

Bits 21:16 **DATATYPE[5:0]**: Data type class
This bit indicates which is the data type class and subclass (according to the MIPI specification for CSI-2) decoded in the last generic short packet data field reception. Write to this bit has no effect.

Bits 15:0 **DATAFIELD[15:0]**: Data field
This bit indicates which is the current data field decoded in the last generic short packet data field reception. Write to this bit has no effect.

40.9.19 CSI-2 Host error register 1 (CSI_ERR1)

Address offset: 0x114

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **IDVCERR[1:0]**: Virtual channel having ID error
This bit indicates for which virtual channel an ID error has been detected.
IDERRF is set in CSI_SR0 to highlight the error.

Bits 21:16 **IDDTERR[5:0]**: Data type in error
This bit indicates for which data type an ID error has been detected.
IDERRF is set in CSI_SR0 to highlight the error.

Bits 15:14 **CECCVCERR[1:0]**: Virtual channel having a corrected ECC error
This bit indicates for which virtual channel a corrected ECC error has been detected.
CECCERRF is set in CSI_SR0 to highlight the error.

Bits 13:8 **CECCDTERR[5:0]**: Data type having a corrected ECC error
This bit indicates for which data type a corrected ECC error has been detected.
CECCERRF is set in CSI_SR0 to highlight the error.

Bits 7:6 **CRCVCERR[1:0]**: Virtual channel having a CRC error
This bit indicates for which virtual channel a CRC error has been detected.
CRCERRF is set in CSI_SR0 to highlight the error.

Bits 5:0 **CRCDTERR[5:0]**: Data type having a CRC error
This bit indicates for which data type a CRC error has been detected.
CRCERRF is set in CSI_SR0 to highlight the error.

40.9.20 CSI-2 Host error register 2 (CSI_ERR2)

Address offset: 0x118

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SPKTVCERR [1:0]		SPKTDTERR [5:0]					
								r	r	r	r	r	r	r	r

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 **SYNCVCERR[1:0]**: Virtual channel having synchronization error
This bit indicates for which virtual channel a synchronization error has been detected. SYNCERRF is set in CSI_SR0 to highlight the error.

Bits 17:16 **WDVCERR[1:0]**: Virtual channel having a watchdog error
This bit indicates for which virtual channel a watchdog error has been detected. WDERRF is set in CSI_SR0 to highlight the error.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 **SPKTVCERR[1:0]**: Virtual channel having a short packet error
This bit indicates for which virtual channel a short packet error has been detected. SPKTERRF is set in CSI_SR0 to highlight the error.

Bits 5:0 **SPKTDTERR[5:0]**: Data type having a short packet error
This bit indicates for which data type a shorter packet than expected error has been detected. SPKTERRF is set in CSI_SR0 to highlight the error.

40.10 CSI PHY registers

40.10.1 CSI PHY reset control register (CSI_PRCR)

Address offset: 0x1000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PEN	Res.
														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PEN**:
When set to 0, this bit places the digital section of the D-PHY in the reset state.
0: PHY is disabled (in reset state).
1: PHY is enabled (out of reset state).

Bit 0 Reserved, must be kept at reset value.

40.10.2 CSI PHY mode control register (CSI_PMCR)

Address offset: 0x1004

Reset value: 0x0001 1003

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TUEXDL0
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	TUESDL0	Res.	Res.	Res.	RTDL0	Res.	Res.	Res.	DTDL	Res.	FTXSMDL0	FRXMDL1	FRXMDL0
			rw				rw				rw		rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **TUEXDL0**: Tx ULP exit sequence data lane 0
This bit initiates the transmission of the ULP exit sequence.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **TUESDL0**: Tx ULP escape-mode data lane 0

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **RTDL0**: Turn-around request data lane 0
This bit is used to indicate that the protocol layer needs to turn the lane around, allowing from the other side to start transmitting the data.
0: No request
1: Request for turn-around for DL0

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **DTDL**: Disable turn-around data lane 0
This bit is used to prevent the bi-directional lane from processing a turn-around request in the lane interconnect
0: Disabled
1: Enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTXSMDL0**: Force to Tx Stop mode the data lane 0
0: Disabled
1: Enabled

Bit 1 **FRXMDL1**: Force to Rx mode the data lane 1
Module 0 into receive mode/wait for stop state.
0: Disabled
1: Enabled

Bit 0 **FRXMDL0**: Force to Rx mode the data lane 0
Module 0 into receive mode/wait for stop state.
0: Disabled
1: Enabled

40.10.3 CSI PHY frequency control register (CSI_PFCR)

Address offset: 0x1008

Reset value: 0x0000 0017

Refer to *Section 2.3* for the register boundary addresses.

41 Parallel synchronous slave interface (PSSI)

The PSSI peripheral and the DCMI (digital camera interface) use the same circuitry. As a result, these two peripherals cannot be used at the same time: when using the PSSI, the DCMI registers cannot be accessed, and vice-versa.

In addition, the PSSI and the DCMI share the same alternate functions and interrupt vector (see *Section 41.3.2: PSSI pins and internal signals*).

41.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

41.2 PSSI main features

The PSSI peripheral main features are the following:

- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) and Ready (PSSI_RDY) alternate function

  When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.
- Clock out mode

41.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals.

Figure 434 shows the PSSI block diagram.

41.3.1 PSSI block diagram

Figure 434. PSSI block diagram

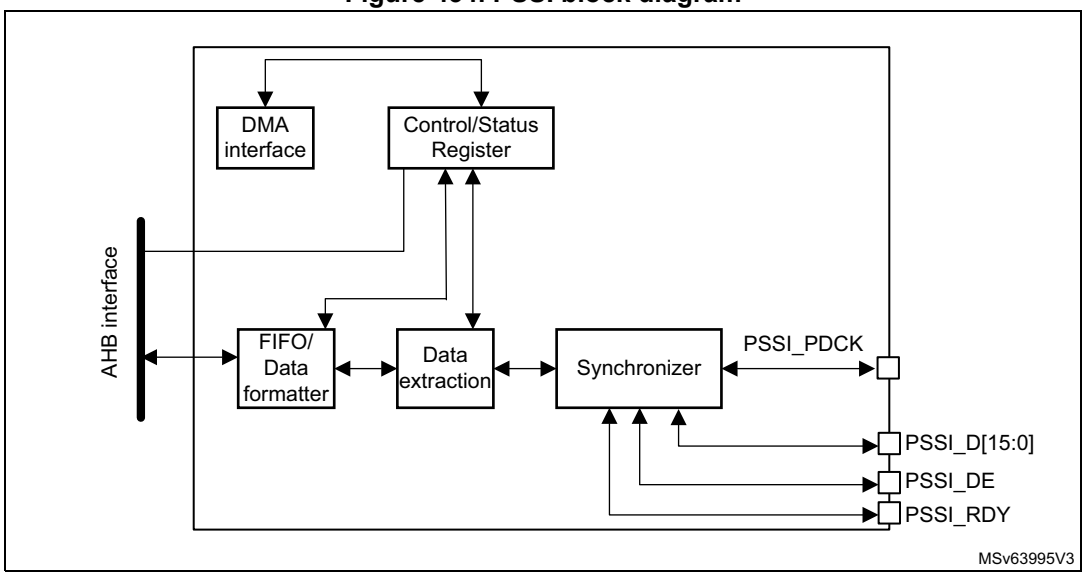

Figure 435. Top-level block diagram

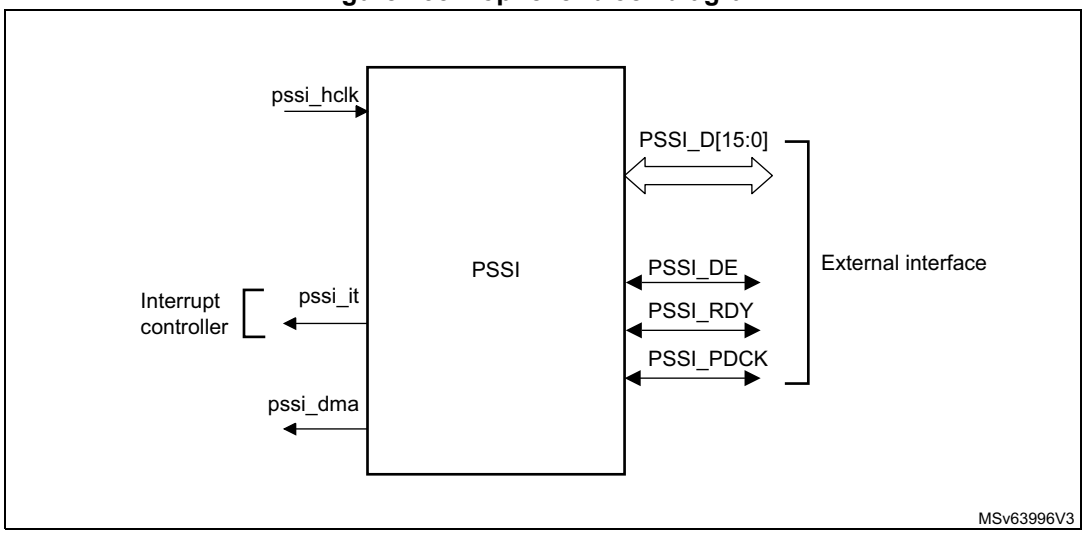


41.3.2 PSSI pins and internal signals

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. *Table 372* shows the PSSI pins.

When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, the alternate functions and the interrupt vector are associated with the PSSI. Otherwise, they are associated with the DCMI. The DCMI ENABLE bit (bit 15 of DCMI_CR) and the PSSI ENABLE bit (bit 14 of PSSI_CR) must not be set to 1 at the same time. As an example, if a GPIO is configured to use the alternate function PSSI_PDCK/DCMI_PIXCK, it is the PSSI_PDCK function which becomes active if PSSI_CR/ENABLE is set to 1.

Table 372. PSSI input/output pins

PSSI signal name	DCMI signal it is shared with	Signal type	Description
PSSI_PDCK	DCMI_PIXCK	Input/output	Parallel data clock input/output
PSSI_D[15:0]	DCMI_D[13:0]	Input/output	Data output when transmitting, data input when receiving
PSSI_DE	DCMI_HSYNC	Input/output	Data enable signal
PSSI_RDY	DCMI_VSYNC	Input/output	Ready signal

Table 373 shows the PSSI internal input/output signals.

Table 373. PSSI internal input/output signals

Internal signal name	Signal type	Description
pssi_it	Output	Interrupt
pssi_dma	Output	DMA request
pssi_hclk	Input	AHB clock

41.3.3 PSSI clock

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

The PSSI_PDCK can be configured in input mode (default) or in output mode. When configured in output mode, the clock is generated by the device RCC.

41.3.4 PSSI data management

Data direction

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.

Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:

- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly perform transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:28) corresponds to the forth byte transferred. *Table 374* illustrates the positioning of the data bytes in two 32-bit words.

Table 374. Positioning of captured data bytes in 32-bit words (8-bit width)

Byte address	31:24	23:16	15:8	7:0
0	D_{n+3}[7:0]	D_{n+2}[7:0]	D_{n+1}[7:0]	D_n[7:0]
4	D_{n+7}[7:0]	D_{n+6}[7:0]	D_{n+5}[7:0]	D_{n+4}[7:0]

16-bit data

When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. *Table 375* illustrates the positioning of the data in two 32-bit words.

Table 375. Positioning of captured data bytes in 32-bit words (16-bit width)

Byte address	31:16	15:0
0	D_{n+1}[15:0]	D_n[15:0]
4	D_{n+3}[15:0]	D_{n+2}[15:0]

FIFO data buffer and error conditions

An eight-word FIFO helps improving performance and avoids overruns and underruns.

If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

41.3.5 PSSI optional control signals

Data Enable (PSSI_DE) alternate function input

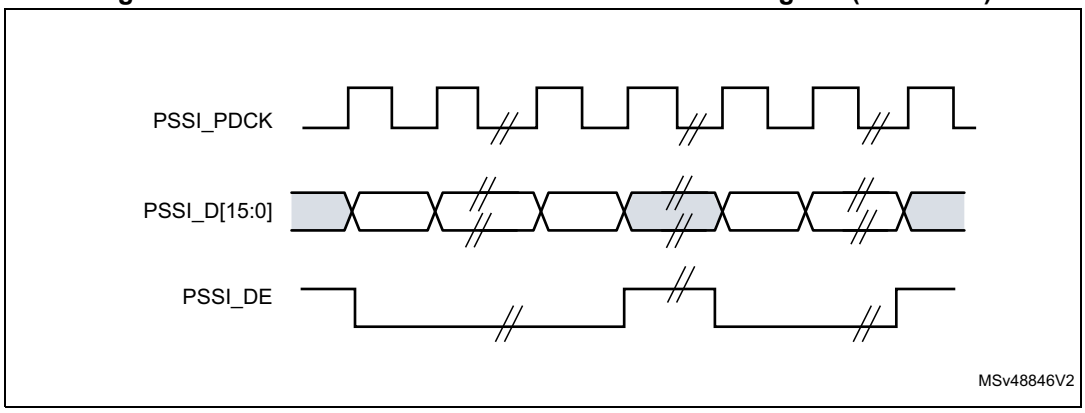
The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is et to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.

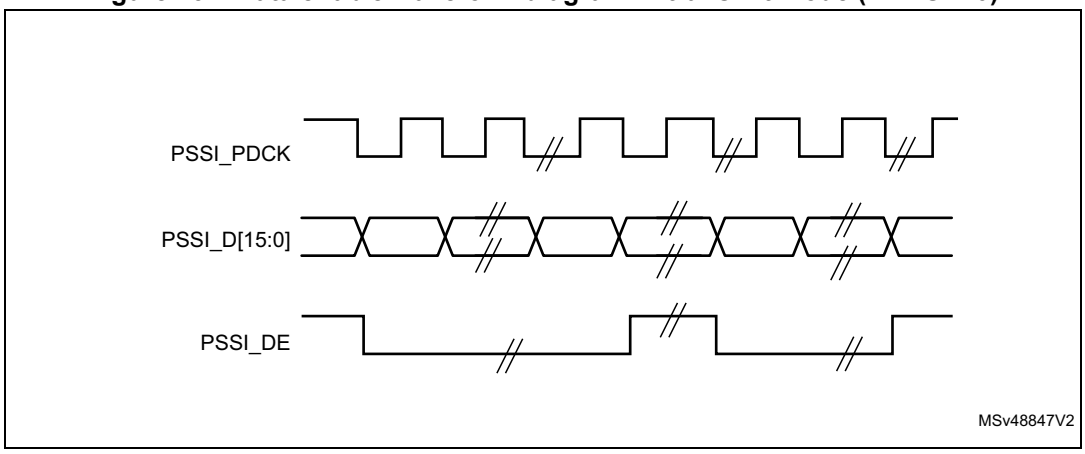
If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.

Figure 436. Data enable in receive mode waveform diagram (CKPOL=0)



If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

Figure 437. Data enable waveform diagram in transmit mode (CKPOL=0)



Ready (PSSI_RDY) alternate function output

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

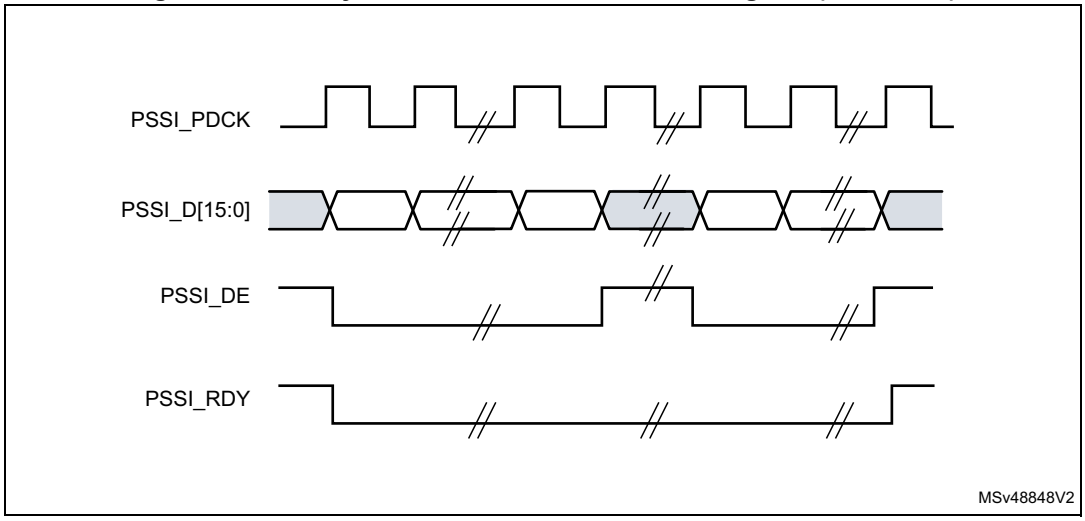
This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples

the data (D[15:0]). If the FIFO has enough free space to receive more data, the PSSI drives the PSSI_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the PSSI drives the PSSI_RDY signal inactive. The transmitting device must repeat the current data in the next cycle when it detects that PSSI_RDY is inactive. This flow control function allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

Figure 438. Ready in receive mode waveform diagram (CKPOL=0)



If the PSSI_RDY alternate input function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI samples the PSSI_RDY signal on the opposite PSSI_PDCK edge to the one at which D[15:0] are driven. If the PSSI_RDY signal is inactive, the PSSI keeps the same data (D[15:0]) and PSSI_DE signals that valid data are available during the next PSSI_PDCK clock cycle. Otherwise, if PSSI_RDY signal is sampled as active, the next data from the TX FIFO (if available) is output on the data outputs (D[15:0]). If no new data are available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI_DE signal as inactive (if enabled).

The receiving device uses the PSSI_RDY to control the data flow and avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

Bidirectional PSSI_DE/PSSI_RDY signal

A single pin can be used for both data enable (PSSI_DE) and ready (PSSI_RDY) functions if DEPOL and RDYPOL are both set to 1 and DERDYCFG is set to 111 or 100 in the PSSI_CR register. In this case, the GPIO corresponding to selected alternate function (PSSI_DE when DERDYCFG=111 or PSSI_RDY when DERDYCFG=100) must be configured as open-drain. The other device must also be configured to drive the line as open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling the current data), then both devices know that the data is not being transferred in the current cycle.

Figure 439. Bidirectional PSSI_DE/PSSI_RDY waveform

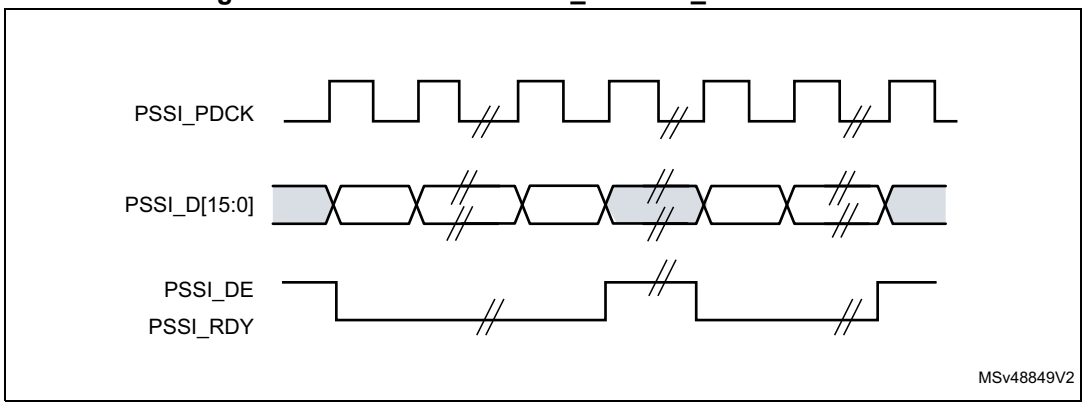


Figure 440. Bidirectional PSSI_DE/PSSI_RDY connection diagram

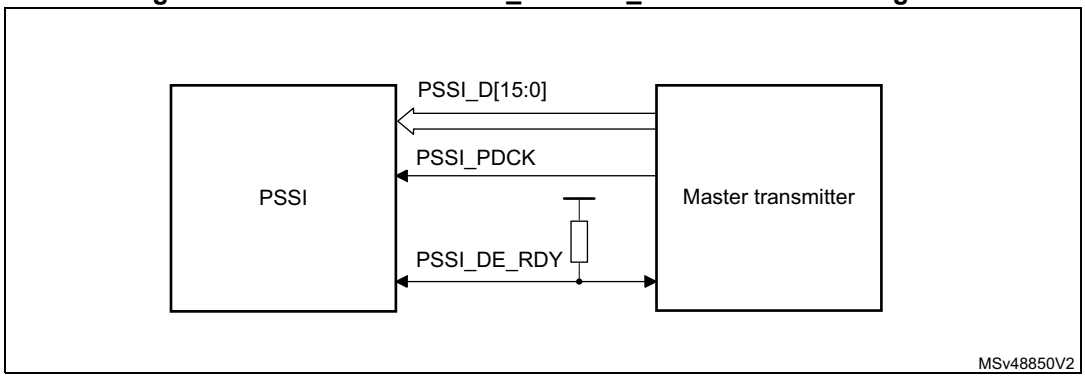

41.4 PSSI interrupts

The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to *Table 376* for the list of interrupts.

The PSSI and the DCMI share the same interrupt vector. When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, these interrupts are triggered by the PSSI. Otherwise, they are controlled by the DCMI.

The DCMI ENABLE bit (bit 14 of DCMI_CR) and PSSI ENABLE bit must not be set to 1 at the same time.

Table 376. PSSI interrupt requests

Interrupt acronym	Shared with DCMI	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from low-power mode
IT_OVR	IT_OVR	indicates overrun in receive mode or underrun in transmit mode	OVR_RIS	OVR_IE	OVR_ISC	NA

41.5 PSSI registers

An 8-bit write or a 16-bit write operation to any PSSI register besides PSSI_DR, results in a bus error. 32-bit read and write operations are permitted.

41.5.1 PSSI control register (PSSI_CR)

Address offset: 0x00

Reset value: 0x4000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OUTEN	DMAEN	CKSRC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DERDYCFG[2:0]			Res.	Res.
rw	rw	rw									rw	rw	rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ENABLE	Res.	Res.	EDM[1:0]		Res.	RDYPOL	Res.	DEPOL	CKPOL	Res.	Res.	Res.	Res.	Res.
	rw			rw	rw		rw		rw	rw					

Bit 31 **OUTEN:** Data direction selection bit

0: Receive mode: data is input synchronously with PSSI_PDCK

1: Transmit mode: data is output synchronously with PSSI_PDCK

Bit 30 **DMAEN:** DMA enable bit

0: DMA transfers are disabled. The user application can directly access the PSSI_DR register when DMA transfers are disabled.

1: DMA transfers are enabled (default configuration). A DMA channel in the general-purpose DMA controller must be configured to perform transfers from/to PSSI_DR.

Bit 29 **CKSRC**: Clock source

This bit configures the clock source of the PSSI_PDCK.

0: External clock (PSSI_PDCK in input)

1: Internal clock (PSSI_PDCK in output)

Bits 28:21 Reserved, must be kept at reset value.

Bits 20:18 **DERDYCFG[2:0]:** Data enable and ready configuration

000: PSSI_DE and PSSI_RDY both disabled

001: Only PSSI_RDY enabled

010: Only PSSI_DE enabled

011: Both PSSI_RDY and PSSI_DE alternate functions enabled

100: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_RDY pin (see *Bidirectional PSSI_DE/PSSI_RDY signal on page 2073*)

101: Only PSSI_RDY function enabled, but mapped to PSSI_DE pin

110: Only PSSI_DE function enabled, but mapped to PSSI_RDY pin

111: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_DE pin (see *Bidirectional PSSI_DE/PSSI_RDY signal on page 2073*)

When the PSSI_RDY function is mapped to the PSSI_DE pin (settings 101 or 111), it is still the RDYPOL bit which determines its polarity. Similarly, when the PSSI_DE function is mapped to the PSSI_RDY pin (settings 110 or 111), it is still the DEPOL bit which determines its polarity.

Bits 17:15 Reserved, must be kept at reset value.

Bit 14 **ENABLE:** PSSI enable

0: PSSI disabled

1: PSSI enabled

The contents of the FIFO are flushed when ENABLE is cleared to 0.

Note: When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.

The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.

The ENABLE bit and the DCMI ENABLE bit (bit 15 of DCMI_CR) must not be set to 1 at the same time.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]:** Extended data mode

00: Interface captures 8-bit data on every parallel data clock

01: Reserved, must not be selected

10: Reserved, must not be selected

11: The interface captures 16-bit data on every parallel data clock

Bit 9 Reserved, must be kept at reset value.

Bit 8 **RDYPOL:** Ready (PSSI_RDY) polarity

This bit indicates the level on the PSSI_RDY pin when the data are not valid on the parallel interface.

0: PSSI_RDY active low (0 indicates that the receiver is ready to receive)

1: PSSI_RDY active high (1 indicates that the receiver is ready to receive)

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DEPOL:** Data enable (PSSI_DE) polarity

This bit indicates the level on the PSSI_DE pin when the data are not valid on the parallel interface.

0: PSSI_DE active low (0 indicates that data is valid)

1: PSSI_DE active high (1 indicates that data is valid)

Bit 5 **CKPOL:** Parallel data clock polarity

This bit configures the capture edge of the parallel clock or the edge used for driving outputs, depending on OUTEN.

0: Falling edge active for inputs or rising edge active for outputs

1: Rising edge active for inputs or falling edge active for outputs.

Bits 4:0 Reserved, must be kept at reset value.

41.5.2 PSSI status register (PSSI_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RTT1B	RTT4B	Res.	Res.
												r	r		

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RTT1B:** FIFO is ready to transfer one byte

1: FIFO is ready for a one byte (32-bit) transfer. In receive mode, this means that at least one valid data byte is in the FIFO. In transmit mode, this means that there is at least one byte free in the FIFO.

0: FIFO is not ready for a 1-byte transfer

Bit 2 **RTT4B:** FIFO is ready to transfer four bytes

1: FIFO is ready for a four-byte (32-bit) transfer. In receive mode, this means that at least four valid data bytes are in the FIFO. In transmit mode, this means that there are at least four bytes free in the FIFO.

0: FIFO is not ready for a four-byte transfer

Bits 1:0 Reserved, must be kept at reset value.

41.5.3 PSSI raw interrupt status register (PSSI_RIS)

Address offset: 0x08

Reset value: 0x0000 0000

PSSI_RIS gives the raw interrupt status. This register is read-only. When read, it returns the status of the corresponding interrupt before masking with the PSSI_IER register value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_RIS	Res.
														r	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_RIS:** Data buffer overrun/underrun raw interrupt status

0: No overrun/underrun occurred

1: An overrun/underrun occurred: overrun in receive mode, underrun in transmit mode. This bit is cleared by writing a 1 to the OVR_ISC bit in PSSI_ICR.

Bit 0 Reserved, must be kept at reset value.

41.5.4 PSSI interrupt enable register (PSSI_IER)

Address offset: 0x0C

Reset value: 0x0000 0000

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_IE	Res.
														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_IE:** Data buffer overrun/underrun interrupt enable
0: No interrupt generation
1: An interrupt is generated if either an overrun or an underrun error occurred.

Bit 0 Reserved, must be kept at reset value.

41.5.5 PSSI masked interrupt status register (PSSI_MIS)

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is set if the corresponding enable bit in PSSI_IER is set and the corresponding bit in PSSI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_MIS	Res.
														r	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_MIS:** Data buffer overrun/underrun masked interrupt status
This bit is set to 1 only when PSSI_IER/OVR_IE and PSSI_RIS/OVR_RIS are both set to 1.
0: No interrupt is generated when an overrun/underrun error occurs
1: An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.

Bit 0 Reserved, must be kept at reset value.

41.5.6 PSSI interrupt clear register (PSSI_ICR)

Address offset: 0x14

Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_ISC	Res.
														w	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_ISC:** Data buffer overrun/underrun interrupt status clear
Writing this bit to 1 clears the OVR_RIS bit in PSSI_RIS.

Bit 0 Reserved, must be kept at reset value.

41.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28

Reset value: 0x0000 0000

In receive mode (OUTEN = 0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN = 1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bits 7 to 0 and 16-bit accesses from bits 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.

Refer to *Section 2.3* for the register boundary addresses.

42 Display subsystem

42.1 Introduction

The display subsystem is targeted to drive up to 1080p60 display panels, through a parallel interface. It supports some on-the-fly compositions to offload the GPU and optimize the use of the system bandwidth: up to two layers, color conversion, blend, mirror, and a final YUV conversion.

The display subsystem can display a secure layer with data that cannot be read by nonsecure application, and with the display guaranteed stable.

42.2 Display subsystem main features

The display subsystem is built around LTDC:

- LTDC: handles display composition
  - Composition: two layers
  - Input pixel format: flexible format, including YUV420 full-planar on layer L1
  - Secure layer: protected access to buffer and configuration registers.
  - Mirror: horizontal and vertical
  - Miscellaneous: color lookup-table, color keying, Gamma
  - 1080p60 max performance
- LTDC parallel interface (integrated inside the LTDC):
  - Standard: 24 bpp + Hs, Vs, De (DataEnable) synchronization signals with ReTime
  - Output rate: 150 Mpixel/s
  - Resolution: 1920x1080 at 60 fps max, with HDMI blankings
  - Pixel formats: RGB888, 666, 565, YUV422-16 bits/BT601/709

42.3 Display subsystem implementation

The implementation is described in *Section 43: LCD-TFT display controller (LTDC)*.

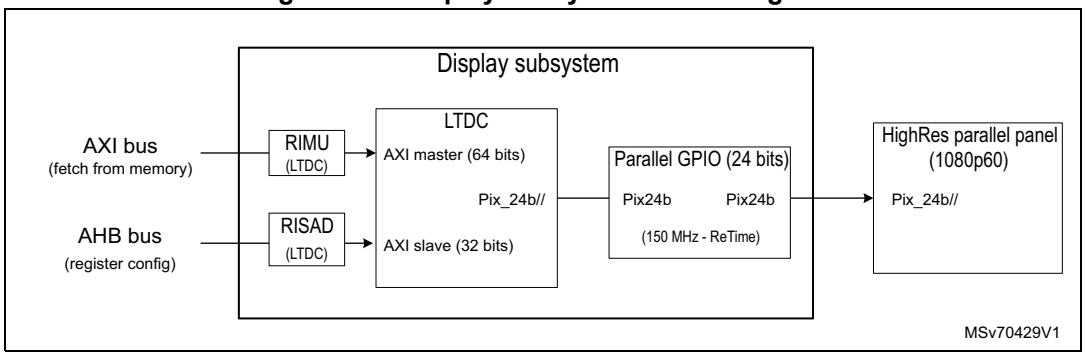
42.4 Display subsystem functional description

42.4.1 Display subsystem block diagram

Figure 441 shows the functional blocks in the display subsystem, with their instance/design names:

- LTDC: composition engine, includes a parallel interface
- Parallel GPIO: Parallel I/O-ring of the device with up to 24 bpp + H/V synchronization
- RIMU/RISAD: RIF security logic, configured for the specific display needs

Figure 441. Display subsystem block diagram

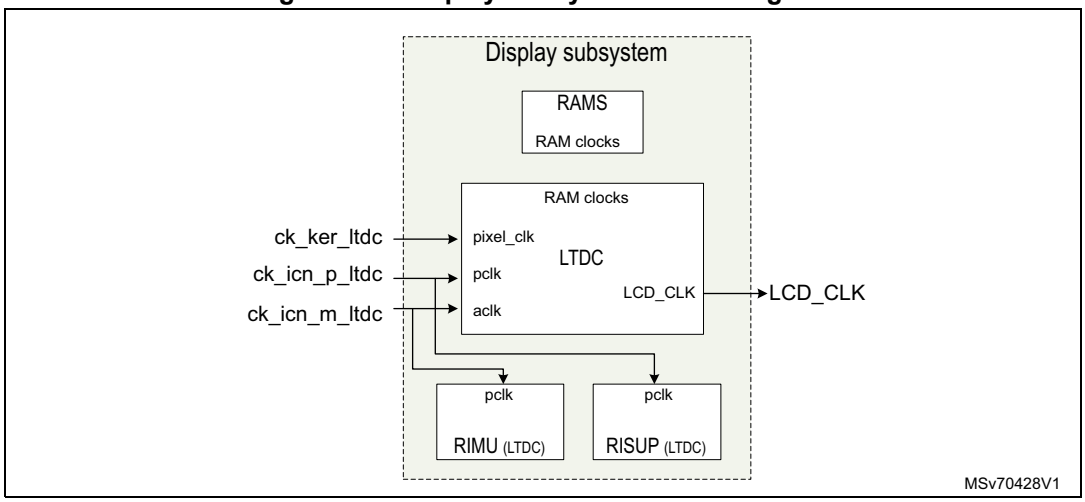


42.4.2 Display subsystem pins and external signal interface

The details of the pins and external signal interface of the display subsystem can be found in the respective functional block sections in this reference manual.

42.4.3 Display subsystem clocks

Figure 442. Display subsystem clock diagram



The display subsystem is implemented with the following clock max frequencies:

- LTDC pixel clock (pixel_clk): 150 MHz
- LTDC parallel interface (lcd_clk): 150 MHz (I/O ReTime mandatory)
- Register clocks (ck_icn_p_*): 200 MHz (all APB/AHB register files)
- AXI-Master clock (ck_icn_m_ltdc): 400 MHz

42.4.4 Display subsystem security

This section is an application of RIF security architecture (see *Section 3.5.3: RIF infrastructure*). The security of the display subsystem is based on the protection of its register map and its master access to the system interconnect, based on default RISUP and RIMU respectively.

The RISUP differentiates the access right of accesses performed toward the following RIF protected peripheral ID (see *Table 20: RISUP indexes*):

- LTDC common: LTDC common registers, about panel info, synchronization, interface
- LTDC_L1 (layer 1): for the window of a default application
- LTDC_L2 (layer 2): LTDC layer 2, for the window of a potentially secure application

The RIMU (RIMU_AXI_LTDC) differentiates the bus transactions emitted by the following AXI masters:

- RIMU_L1: read access only for layer 1, always non-protected
- RIMU_L2: read access only for layer 2, potentially protected

Security configuration of devices with never-secure display content

The security setup of devices that are never required to display any secure content is detailed below (the display subsystem works by default in a non-protected mode):

- The display subsystem configuration space is set as non-protected.

  The default operating system (OS) software has a full access and can configure/handle all peripherals of the display subsystem.
- The layer 2 (which has a hardware secure capability) can be reused as a default layer, like layer 1, and can display the content of any application.

Note: Layer 2 is not fully featured, and lacks the resize and multi-planar capabilities of layer 1.

- The LTDC AXI-master emits by default non-protected accesses.

  The AXI CID = DISP S and P can be associated to the two AXI clients, via the RIMU, to tag that the AXI transaction contains pixels.

Security configuration of devices with a temporary secure content

For devices that temporarily display a secure content, it is expected that the secure content is displayed during short periods.

The working principle of the display subsystem is to segregate configuration spaces:

- The secure layer 2 is always protected.
- Never-secure layer 1 is always non-protected.
- The intermediate common features (such as panel data, synchronization) are usually non-protected and handled by the OS (when no secure content is displayed), but temporarily protected (with no OS access) during the short period when a secure content is displayed via layer 2. Removing the access of the non-protected OS guarantees that a malware does not impact the stability of the displayed protected content.
- A few minor items get specifically protected or open, as detailed below.

The configuration of the display subsystem for a secure content is the following:

- Layer 2 is set permanently protected:
  - RIF LTDC_L2 RISUP peripheral ID must be set as protected (S and/or P flags).
  - RIF LTDC_L2 RIMU AXI-Master emits protected transactions (tagged as S a/o P), which allow it to retrieve the protected layer 2 pixels from their protected memory

buffer. The RIMU must be updated by a trusted domain application using RIFSC_RIMC_ATTR11.

The recommendation is to use a secure, privileged (optional), and CID = 0x4 setup. With this secure setup, the application must make sure that CID4 has access to the secure pixels area.

  - Only a secure software is able to configure the layer 2 parameters (such as width, height, buffer address), so that the characteristics of the layer 2 are guaranteed.
  - The interrupt bank B is associated automatically with the layer 2, and gets permanently protected and devoted to the secure software handling layer 2. The secure software must thus handle and be driven by that interrupt bank B.
  - The LTDC features that must allow data-evasion get also protected (automatically, as associated with the layer 2 rights), with an access allowed only to the secure software. These features are the CRC (which allows the displayed frames to be signed mainly for test purposes), the blend-order (which is used to hide the protected content below some malware layer faking the protected content).
- Layer 1 is set permanently as non-protected:
  - RIF LTDC_L1 RISUP peripheral ID is set as not protected.
  - RIF LTDC_L1 RIMU AXI-master keeps its initial setup in RIFSC_RIMC_ATTR10, and emits only non-protected transactions which is enough to retrieve pixels from any application buffer.
  - The default OS drivers handle the layer 1 parameters (such as width, height, buffer address).
  - The interrupt bank A is associated automatically with layer 1, and keeps an non-protected open access. The OS must then handle and be driven by that Interrupt bank A to globally drive the display.
- Common registers must be set at boot as non-protected, temporarily:
  - RIF LTDC common non-layer peripheral indexes is concerned.
  - This allows the default OS to boot the display subsystem, and to handle it.
- Common registers must be set as protected when displaying a protected content:
  - The RIF LTDC common must be set protected before starting to display a protected content, and be unprotected after the protected content has finished to be updated. The LTDC common configuration spaces keep a permanent read access for nonsecure or unprivileged software.
  - The protection restricts the write accesses only: it removes the access of the non-protected OS, and so guarantees that a malware does not impact the stability of the displayed protected content. The LTDC common configuration spaces keep a permanent read-access for nonsecure or unprivileged software.
  - The protection does not restrict the read accesses: the OS is usually unaware of the status of the protected layer 2 that is handled by a different, secure, software. The read access capability for the OS allow the display drivers to remain. somehow stable, although the write access of the display drivers is not performed.

Table 378 lists vertically all the functional blocks of the display subsystem, and horizontally lists the associated RIF peripheral ID.

Note: Table color legend for recommended settings:

- green for a permanently non-protected setting

- blue for a temporarily protected versus non-protected

- purple for a permanently protected state

42.5 Display subsystem programmable parameters

Steps to configure the various main use cases supported by the display subsystem are detailed below. They provide the global picture and settings of the display subsystem (not repeating information available in the local sections).

The display subsystem drives a display panel or bridge through the parallel interface. It allows panels to be driven up to 1080p60 (150 Mpixel/s), with either RGB888 or YUV422.

The RCC provides a pixel clock that drives both the LTDC and its synchronous parallel interface. Aside, the LTDC needs an AXI-Master clock to fetch pixels, and an APB-Slave clock to get configured.

The steps to follow are detailed below:

1. Setup security settings, with or without a secure layer depending on application needs, as described in *Figure 441*.
2. Clock and reset:
   - ck_ker_ltdc clock, provided by the RCC, as output pixel clock.

     One PLL of the RCC needs to be allocated to the display subsystem to provide the clock that is exactly at the wanted pixel rate for the output display. For instance, a standard 1080p60 requires a 148,50 MHz clock.
   - LTDC_CLK is driven automatically by the LTDC (after some gating) from its above provided pixel_clock (ck_ker_ltdc from the RCC).
   - ck_icn_p_ltdc is provided by the RCC to allow the LTDC configuration (default 200 MHz).
   - ck_icn_m_ltdc is provided by the RCC to allow the LTDC AXI to work (default 400 MHz).

   See *Section 14: Reset and clock control (RCC)*for more details.
3. LTDC configuration:
   - Setup the LTDC (such as input layers, display information, parallel interface, AXI settings) as described in the LTDC section.
4. Signal polarity:

   The polarities of the signals are impacted by the fact that the LTDC parallel interface signals are reclocked in the IO-ReTime logic, downstream of the LTDC. It results the following when configuring the polarities to match the panel on the parallel interface:
   - The clock polarity (rising-vs-falling edge) must be configured in the IO-ReTime only (see *Section 15: General-purpose I/Os (GPIO)*), and not in the LTDC output logic. The clock polarity logic in the LTDC must remain in its default post-reset state.
   - The polarity of the Vs, Hs, and De synchronization signals, unlike for the clock polarity, can be configured directly in the LDTC output stage (see *Section 43: LCD-TFT display controller (LTDC)*).
5. I/O configuration:

   Allocate an alternate GPIO bank to the display subsystem, with usually 28 pins needed: 24 pins for RGB888 and four others for the ancillary: Hs, Vs, De, and clock.

42.6 Display subsystem interrupts

The interrupts are described in sections of peripherals in this reference manual.

42.7 Display subsystem registers

All registers are described in *Section 43: LCD-TFT display controller (LTDC)*.

43 LCD-TFT display controller (LTDC)

43.1 LTDC introduction

The LTDC (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (Red, Green, Blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD-TFT panels.

43.2 LTDC main features

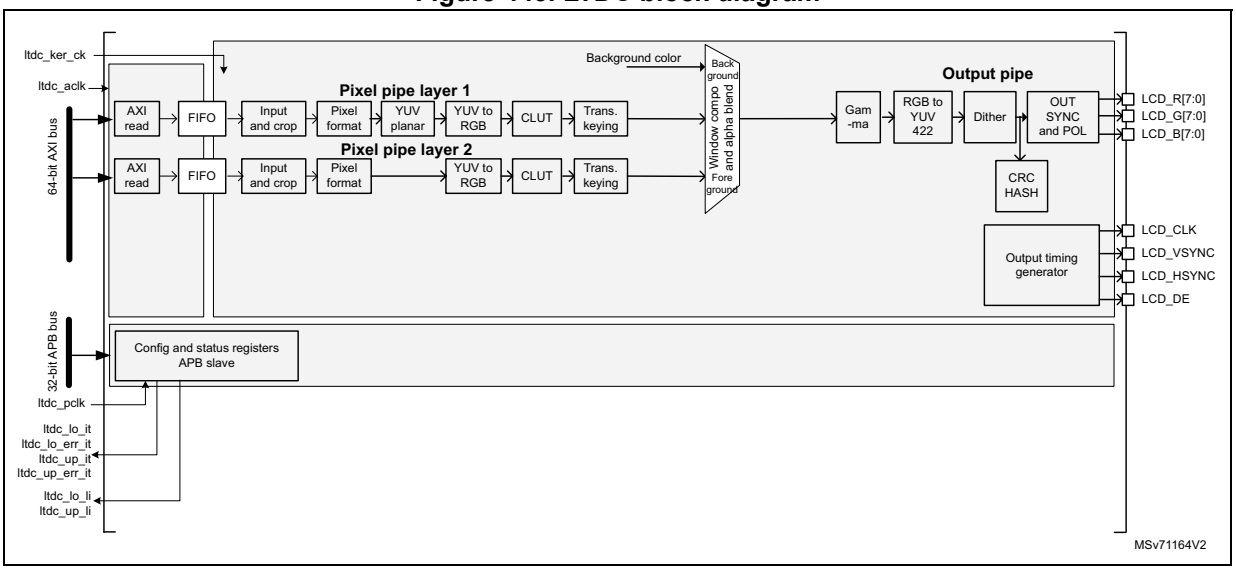
- 2 input layers blended together to compose the display
- Cropping of layers from any input size and location
- Multiple input pixel formats:
  - Predefined ARGB formats: ARGB8888, ABGR8888, RGBA8888, BGRA8888, RGB565, BGR565, and RGB888packed
  - Flexible ARGB, allowing any width and location for A,R,G, and B components
  - Predefined YUV formats: YUV422-1L (FourCC: YUYV, Interleaved), YUV420-2L (FourCC: NV12, semi planar), YUV420-3L (FourCC: Yxx I420, full planar) with some flexibility on the component sequence
- Color look-up table (CLUT) up to 256 colors (256 x 24 bits) per layer
- Color transparency keying
- Composition with flexible window position and size versus output display
- Blending with flexible layer order and alpha value (per pixel or constant)
- Background underlying color
- Gamma with non-linear configurable table
- Dithering for output with less bits per component (pseudo-random on 2 bits)
- Polarity inversion for HSync, VSync, and DataEnable outputs
- Output as RGB888 24 bpp or YUV422 16 bpp
- Secure layer (using layer2) capability, with grouped regs and additional interrupt set
- Interrupts based on 7 different events
- AXI master interface with long efficient bursts (64 or 128 bytes)

Note: The above mentioned FourCC pixel formats are described at www.fourcc.org.

43.3 LTDC functional description

43.3.1 LTDC block diagram

Figure 443. LTDC block diagram



43.3.2 LTDC pins and internal signals

Table 379. LTDC pins

Pin name	Pin type	Description
LCD_CLK	Output	Clock output
LCD_HSYNC		Horizontal synchronization
LCD_VSYNC		Vertical synchronization
LCD_DE		Not data enable
LCD_R[7:0]		8-bit Red data (or U/V component, if output is YUV422)
LCD_G[7:0]		8-bit Green data (or Y component if output is YUV422)
LCD_B[7:0]		8-bit Blue data

The LTDC pins must be configured by the user application. The unused pins can be used for other purposes.

Using less pins than the default 24 bpp

The LTDC outputs the pixels on 24 pins by default (RGB888). The user can however connect the display panel using less wires, for instance 16 wires (if RGB565) or 18 wires (RGB666). If so, R (resp. G, B) wires must be connected to the MSB of the LTDC R (resp. G, B) output pins (see *Section 43.3.2*).

Example: LTDC interfacing with a RGB565 16-bit display panel. Display panel R[4:0], G[5:0] and B[4:0] wires and input pins must be connected to LTDC_R[7:3], LCD_G[7:2], and LCD_B[7:3] output pins.

The following table shows how the LTDC is connected.

Table 380. LTDC trigger interconnections

Trigger name	Direction	Trigger source/destination
ltdc_lo_li	Output	hpdma1_trigsel[20] gpdma1_trigsel[20]
ltdc_up_li	Output	hpdma1_trigsel[110] gpdma1_trigsel[110]

43.3.3 LTDC reset and clocks

The LTDC uses the following clock domains:

- **AXI clock domain**

  This domain contains the LTDC AXI master interface for data transfer from the memories to the layer FIFO and the frame buffer configuration register.
- **APB clock domain**

  This domain contains the global configuration registers and the interrupt register.
- **Pixel clock domain**

  This domain contains the pixel data generation, the layer configuration register as well as the LTDC interface signal generator. The LCD_CLK output must be configured following the panel requirements.

Note: For normal operation, all clocks must be provided to allow clock domain crossing for read and write operations.

The following table lists the clock domains used to store the register values.

Table 381. Clock domain for each register

LTDC register	Clock domain
LTDC_SSCR	Pixel clock
LTDC_BPCR	AXI + pixel clock
LTDC_AWCR	
LTDC_TWCR	
LTDC_GCR	
LTDC_SRCR	APB clock
LTDC_GCCR	Pixel clock
LTDC_BCCR	
LTDC_IER	APB clock
LTDC_ISR	
LTDC_ICR	

Table 381. Clock domain for each register (continued)

LTDC register	Clock domain
LTDC_LIPCR	Pixel clock
LTDC_CPSR	
LTDC_CDSR	
LTDC_EDCR	
LTDC_IER2	APB clock
LTDC_ISR2	
LTDC_ICR2	
LTDC_LIPCR2	Pixel clock
LTDC_ECRCR	
LTDC_CCRCR	
LTDC_FUTR	Pixel clock
LTDC_LxC0R	APB clock
LTDC_LxC1R	
LTDC_LxRCR	
LTDC_LxCR	AXI + pixel clock
LTDC_LxWHPCR	Pixel clock
LTDC_LxWVPCR

Table 381. Clock domain for each register (continued)

LTDC register	Clock domain
LTDC_LxCLUTWR	Pixel clock
LTDC_LxCYR0R	
LTDC_LxCYR1R	
LTDC_LxFPF0R	
LTDC_LxFPR1R	

While accessing LTDC registers, the APB bus is stalled during the access for a given time period detailed in the following table.

Table 382. LTDC register access and updated durations

Access type	AXI register clock domain	APB register clock domain	Pixel register clock domain
Read	7 x ltdc_pclk + 5 x ltdc_aclk	7 x ltdc_pclk	7 x ltdc_pclk + 5 x ltdc_ker_clk
Write	6 x ltdc_pclk + 5 x ltdc_aclk	6 x ltdc_pclk	6 x ltdc_pclk + 5 x ltdc_ker_clk

The LTDC can be reset by setting the corresponding bit in the RCC, that resets the three clock domains.

43.4 LTDC configuration parameters

The LTDC configuration parameters are sequenced following the pixel flow as shown in *Figure 443*, starting at the input (AXI master that reads pixels) and ending at the pixel output.

Common controls (such as interrupts) are listed at the end.

43.4.1 AXI master

The AXI master busses perform the accesses to the memory and are driven by the internal logic. The LTDC internal per-layer FIFOs are fairly large to cope with reasonably long external memory latencies.

The LDTC generates long burst (128-byte) for higher external memory efficiency.
For more granularity, it is possible to decrease the max burst size to 64 bytes, but it is not recommended.

Parameter in LTDC_LxBLCR

BL: burst length, in 64-bit words, with a default 0 for max size

Default configuration

The default AXI burst length is set at its maximum value after reset, with BL = 0.

43.4.2 Input layer definition and cropping

The LTDC supports two layers. Each layer is defined by:

- Its base-address in the memory

  If the buffer is YUV semi-planar or full-planar, there are respectively two and three base-addresses. The first buffer is called main and stores the luminance data, while the other buffers are called auxiliary and store the chrominance data.
- A dimension in the memory
  - Width defined as its pitch (or address jump or stride): amount of bytes between the start of one line and the start of the next line
  - Height that does not need to be defined
- A dimension of the pixel rectangle that is cropped and read from the memory
  - Top-left start position: set by the base-address at exactly the byte where the top-left pixel is located
  - Width, number of bytes per line to read

    - If too few bytes versus required, a FIFO underrun interrupt is generated(FUWIF).

    - If too many bytes versus required, the useless data are discarded.
  - Height, number of lines per frame to read

Note: The pitch and number of bytes per line can be different if a sub-part of a frame is cropped to be displayed. If the full frame is displayed, the pitch and number of lines are the same.

Parameters

- LEN in LTDC_LxCR: activates this layer.
- CFBADD in LTDC_LxCFBAR: main base address, for ARGB or Y buffer
- CFBLL in LTDC_LxCFBLR: main number of bytes per line
- CFBP in LTDC_LxCFBLR: pitch between two consecutive lines of the main buffer
- CFBLNBR in LTDC_LxCFBLNR: main number of lines per frame

Specifically for multi-planar layers, the following additional registers have to be configured (only required for YUV420 semi-planar and full-planar pixel formats):

- AFBADD0 in LTDC_L1AFBA0R: auxiliary address 0, for UV if semi-planar or for V if full-planar
- AFBADD1 in LTDC_L1AFBA1R: auxiliary address 1, for U if full-planar
- AFBLL in LTDC_L1AFBLR: auxiliary 0 and 1, number of bytes per line
- AFBP in LTDC_L1AFBLR: pitch for the auxiliary 0 and 1 buffers
- AFBLNBR in LTDC_L1AFBLNR: auxiliary 0 and 1 number of lines per frame

Configuration examples

- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000207 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 3 = 960), where pitch = line length requires a value of 0x03C003C7 to be written into this register.

- A frame buffer having the format CbCr (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000207 to be written into this register.
- A frame buffer having the format Cb (1 byte per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 1 = 320), where pitch = line length requires a value of 0x01400147 to be written into this register.

43.4.3 Input pixel format

The LTDC reads the pixel data from memory buffers and maps it onto the internal LTDC format that is based on the definition of the input pixel format, defined per layer.

The pixel formats are grouped as follows:

- **Predefined ARGB formats:**

  ARGB8888, ABGR8888, RGBA8888, BGRA8888, RGB565, BGR565, and RGB888pack
- **Flexible ARGB format:**

  Allows a configurable width and location of each A,R,G, and B component and is used to extend the above list to any multi-component pixel format except to coplanar ARGB.
- **YUV formats:**

  Used to read YUV with a 422 coplanar, 420 semi-planar, or 420 full-planar format, and to convert the YUV color into RGB.

  While the layer 1 supports all YUV formats, the layer 2 only supports the 422 coplanar format.

Note: The LTDC hardware pipeline uses 8 bits per component: when reading and mapping a pixel format, with less than 8 bits per component. That component is extended to 8 bits by stuffing the LSB, that are recopied from its MSB. This applies mostly on RGB565.

For instance, a component on 5 bits (named: 43210) results in the following 8 bits mapped into the pipe: 43210432. A 3-bit input (named 210) results in 21021021.

Parameter when using the predefined ARGB formats

- PF in LTDC_LxPFCR: 0 to 6 to select one of the seven predefined pixel formats

Parameters when using the flexible ARGB formats

- PR in LTDC_LxPFCR: seven to activate the flexible pixel format type
- PSIZE in LTDC_LxFPF1R: defines the amount of bytes per pixel (typically 1,2,3, or 4)
- APOS/RPOS in LTDC_LxFPF0R: defines the Alpha/Red location inside a 32-bit word
- BPOS/GPOS in LTDC_LxFPF1R: defines the Blue/Green location inside a 32-bit word
- ALEN/RLEN in LTDC_LxFPF0R: defines the amount of bits for Alpha/Red components
- BLEN/GLEN in LTDC_LxFPF1R: defines the amount of bits for Blue/Green components

Examples:

An RGB565 pixel format is defined as follows:

– Alpha: APOS = 0, ALEN = 0
– Red: RPOS= 11, RLEN = 5
– Green: GPOS = 5, GLEN = 6
– Blue: BPOS = 0, BLEN = 5

The BGRA8888 32 bpp pixel format is set as follows (default reset values of LTDC_LxFPF0R and LTDC_LxFPF1R):

– Alpha: APOS = 0, ALEN = 8
– Red: RPOS= 8, RLEN = 8
– Green: GPOS = 16, GLEN = 8
– Blue: BPOS = 24, BLEN = 8

Parameters when using the YUV formats

The YUV pixel format is defined and detailed in *Section 43.4.4: YUV planar* and supersedes any setting here.

The following table describes the memory mapping of the predefined ARGB pixel format.

Table 383. Pixel data mapping versus color format

ARGB8888 (PF = 000)			
@+3 A_x[7:0]	@+2 R_x[7:0]	@+1 G_x[7:0]	@ B_x[7:0]
@+7 A_{x+1}[7:0]	@+6 R_{x+1}[7:0]	@+5 G_{x+1}[7:0]	@+4 B_{x+1}[7:0]
ABGR8888 (PF = 001)			
@+3 A_x[7:0]	@+2 B_x[7:0]	@+1 G_x[7:0]	@ R_x[7:0]
@+7 A_{x+1}[7:0]	@+6 B_{x+1}[7:0]	@+5 G_{x+1}[7:0]	@+4 R_{x+1}[7:0]
RGBA8888 (PF = 010)			
@+3 R_x[7:0]	@+2 G_x[7:0]	@+1 B_x[7:0]	@ A_x[7:0]
@+7 R_{x+1}[7:0]	@+6 G_{x+1}[7:0]	@+5 B_{x+1}[7:0]	@+4 A_{x+1}[7:0]
BGRA8888 (PF = 011)			
@+3 B_x[7:0]	@+2 G_x[7:0]	@+1 R_x[7:0]	@ A_x[7:0]
@+7 B_{x+1}[7:0]	@+6 G_{x+1}[7:0]	@+5 R_{x+1}[7:0]	@+4 A_{x+1}[7:0]
RGB565 (PF = 100)			
@+3 R_{x+1}[4:0] G_{x+1}[5:3]	@+2 G_{x+1}[2:0] B_{x+1}[4:0]	@+1 R_x[4:0] G_x[5:3]	@ G_x[2:0] B_x[4:0]

Table 383. Pixel data mapping versus color format (continued)

@+7 R_{x+3}[4:0] G_{x+3}[5:3]	@+6 G_{x+3}[2:0] B_{x+3}[4:0]	@+5 R_{x+2}[4:0] G_{x+2}[5:3]	@+4 G_{x+2}[2:0] B_{x+2}[4:0]
BGR565 (PF = 101)			
@+3 B_{x+1}[4:0] G_{x+1}[5:3]	@+2 G_{x+1}[2:0] R_{x+1}[4:0]	@+1 B_x[4:0] G_x[5:3]	@ G_x[2:0] R_x[4:0]
@+7 B_{x+3}[4:0] G_{x+3}[5:3]	@+6 G_{x+3}[2:0] R_{x+3}[4:0]	@+5 B_{x+2}[4:0] G_{x+2}[5:3]	@+4 G_{x+2}[2:0] R_{x+2}[4:0]
RGB888 (PF = 110)			
@+3 B_{x+1}[7:0]	@+2 R_x[7:0]	@+1 G_x[7:0]	@ B_x[7:0]
@+7 G_{x+2}[7:0]	@+6 B_{x+2}[7:0]	@+5 R_{x+1}[7:0]	@+4 G_{x+1}[7:0]
The flexible format (PF = 111), not represented here, allows any above mapping.			

43.4.4 YUV planar

This operator handles the YUV planar formats, reading data from potentially several distinct buffers (Y versus Cb versus Cr) into a single pixel information. The feature is available for layer 1 and layer 2 (coplanar only for the layer 2).

The LTDC supports the following planar formats:

- YUV422 coplanar (one buffer)
- YUV420 semi-planar (two buffers)
- YUV420 full-planar (three buffers)

Following its configuration, the LTDC reads the relevant luminance and chrominance buffers, upscales the chrominance components required to reach YUV444 pixels, and converts the color from YUV to RGB as described in *Section 43.4.5*.

The LTDC allows swapping the memory locations of the Y and Cb/Cr data and of the Cb and Cr data. It also allows inverting the endianness of the Y data. This extends the amount of supported pixel format variants.

Parameters

Pixel format parameters are stored in LTDC_LxPCR:

- YCEN: activates the YUV mode (both the planar extraction and color conversion).
- YCM: selects the input scheme (422 for coplanar, 420 for semi-planar, 420 for full-planar).
- YF: defines if either Y or Cb/Cr is provided first (from LSB).
- CBF: defines if either Cb or Cr is provided first (from LSB).
- OF: defines if either odd or even Y is provided first (from LSB).

When using a semi-planar or full-planar buffer, some additional base-address must be configured for auxiliary (chrominance) buffers, as well as the pitch of these buffers (see *Section 43.4.2*).

Configuration examples

Settings of OF, CBF, YF bits for a YCbCr 422 pixel format:

- OF = 0, CBF = 0, YF = 0 define the buffer word to containWord[31:0] = Y1-Cb-Y0-Cr.
- OF = 1, CBF = 0, YF = 0 define the buffer word to contain Word[31:0] = Y0-Cb-Y1-Cr.
- OF = 0, CBF = 1, YF = 0 define the buffer word to contain Word[31:0] = Y0-Cr-Y1-Cb.
- OF = 0, CBF = 0, YF = 1 define the buffer word to contain Word[31:0] = Cb-Y1-Cr-Y0.
- OF = 1, CBF = 1, YF = 1 define the buffer word to contain Word[31:0] = Cr-Y0-Cb-Y1.

  These settings are also valid for YCbCr 420 pixel formats.

43.4.5 YUV-to-RGB color conversion

This operator handles the YUV-to-RGB color conversion of the YUV planar pixels. The color conversion is activated automatically, simultaneously with the YUV planar handling.

The color conversion is based on a semi-flexible 3x3 matrix multiplication:

- It is restricted to YUV-to-RGB conversion due to some frozen coefficients (see next).
- It handles the most used YUV references (ITU-R BT.601 and ITU-R BT.709) thanks to some configurable coefficients.
- It supports the full versus reduced dynamic of the input pixel (luminance defined either in 0 to 255, or in 16 to 235), by extending a potential reduced-range input to a full range.

Parameters

- YCEN in LTDC_LxPCR: activates the color conversion, same bit as for planar.
- YREN in LTDC_LxPCR: if active, extends a reduced range to a full range.
- CR2R in LTDC_LxCYR0R: matrix coefficient from Cr to Red
- CB2B in LTDC_LxCYR0R: matrix coefficient from Cb to Blue
- CR2G in LTDC_LxCYR0R: matrix coefficient from Cr to Green
- CB2G in LTDC_LxCYR0R: matrix coefficient from Cb to Green

The full matrix computation, to convert from YCbCr to RGB, is defined as the following:

$$\begin{pmatrix} R \\ G \\ B \end{pmatrix} = \begin{pmatrix} CR2R & 256 & 0 \\ -CR2G & 256 & -CB2G \\ 0 & 256 & CB2B \end{pmatrix} \times \begin{pmatrix} Cr - 128 \\ Y \\ Cb - 128 \end{pmatrix}$$

The CR2R, CB2B, CR2G, and CB2G coefficients are defined on 10 bits unsigned: as the operator works with 8-bit components, the coefficients are thus equivalent, in fixed-point, to 2-bit integer and 8-bit decimals.

The CR2G and CB2G coefficients are configured as unsigned positive, but are set negative in the hardware computation, as shown in the above matrix where a “-” is mentioned.

When the luminance scaling is active (YREN = 1, thus where the YCbCr input is assumed in the range of 16 to 235/240, and RGB in 0 to 255), then the Y input value is first scaled in hardware to Y’ = 255/219 * (Y - 16). That first result is then inserted as input to the above matrix multiplication.

Configuration examples

To read an ITU-R BT.601 layer and to convert its YCbCr (assuming a default reduced dynamic in 16 to 235/240) to RGB (with full dynamic in 0 to 255), the recommended coefficients are:

- YCEN = 1: to activate the conversion
- YREN = 1: to select the reduced dynamic range
- CR2R = 409: specific coefficient set for ITU-R BT.601
- CR2G = 208
- CB2G = 100
- CB2B = 516

To read an ITU-R BT.709 layer and to convert its YCbCr (assuming a default reduced dynamic in 16 to 235/240) to RGB (with full dynamic in 0 to 255), the recommended values to configure coefficients are:

- YCEN = 1: to activate the conversion
- YREN = 1: to select the reduced dynamic range
- CR2R = 459: specific following coefficient set is for ITU-R BT.709
- CR2G = 136
- CB2G = 55
- CB2B = 541

43.4.6 Horizontal or vertical mirroring

The LTDC can mirror horizontally or vertically its input layers, thus to read them from right to left, and/or from bottom to top.

It applies on both coplanar (ARGB, YUV422) and multi-planar (YUV420) pixel formats.

Parameters for horizontal mirroring

To mirror a layer horizontally, the LTDC must be configured to extract the pixels from right to left (backward), and to set the layer base-address at the right-end of the line.

The configuration bitfields are the following:

- HMEN in LTDC_LxCR: activates the horizontal mirroring.
- CFBADD in LTDC_LxCFBAR: base + (width - 1) (increase for horizontal mirror)
- AFBADD0 in LTDC_L1AFBA0R: base + (width - 1)
- AFBADD1 in LTDC_L1AFBA1R: base + (width - 1)

Parameters for vertical mirroring

To mirror a layer vertically, the LTDC must be configured to start reading this layer from the bottom, and line per line, to come upward. The layer base-address must be set to the start of the bottom line, and a negative line-per-line pitch must be provided.

The configuration bitfields for the base-address are (all to be set at bottom line start):

- CFBADD in LTDC_LxCFBAR: main base-address
- AFBADD0 in LTDC_L1AFBA0R: auxiliary address 0
- AFBADD1 in LTDC_L1AFBA1R: auxiliary address 1
- CFBADD in LTDC_LxCFBAR: base + (lines - 1) * pitch (increase for vertical mirror)

- AFBADD0 in LTDC_L1AFBA0R: base + (lines - 1) * pitch
- AFBADD1 in LTDC_L1AFBA1R: base + (lines - 1) * pitch

The configuration bitfields for the pitch are (all to be set with a negative pitch):

- CFBP in LTDC_LxCFBLR: -pitch (negative line pitch for vertical mirror)
- AFBP in LTDC_L1AFBLR: -pitch

43.4.7 Default layer color

Every layer has a default color in the format ARGB8888, that is used outside the defined layer window or when a layer is disabled. This default color can be configured as active or absent.

Parameters

The default layer color parameters are:

- DCBEN in LTDC_LxCR: default color activation
- DCALPHA in LTDC_LxDCCR: default Alpha transparency setting
- DCRED in LTDC_LxDCCR: default Red component
- DCGREEN in LTDC_LxDCCR: default Green component
- DCBLUE in LTDC_LxDCCR: default Blue component

Default configuration

By default, and after reset, the default layer color is inactive (DCBEN = 0 and DCALPHA = 0.

Note: The blending of a layer is always performed even when a layer is disabled. To avoid displaying the default color when a layer is disabled, the default Alpha must be set to null (DCALPHA = 0), or the whole default color must be disabled (with DCBEN).

43.4.8 Color look-up table (CLUT)

The LTDC supports frame buffers with each pixel defined as an index to a color table, allowing a display with a set of 256 colors, but stored in memory with only 8 bpp.

The CLUT defines 256 colors and must be indexed with a maximum 8-bit pixel format (typically L8 or AL44). Such format can be extracted using the flexible RGB approach described in *Section 43.4.3*.

The CLUT table is differentiated for each layer. It must be initialized with one RGB888 value per color index, with the color index corresponding to the CLUT address:

- For L8, the CLUT must be loaded with 256 colors.
- For AL44, the CLUT must be only loaded with 16 colors. Each color address is defined by replicating the 4-bit L channel to 8 bits as follows:
  - Color L4 = 0: looks out its RGB888 from index = 0x00.
  - Color L4 = 1: looks out its RGB888 from index = 0x11.
  - Color L4 = 2: looks out its RGB888 from index = 0x22.
  - ...
  - Color L4 = 15: looks out its RGB888 from index = 0xFF.
- For ARGB, the Blue component is used as the CLUT index.

Parameters

The RGB888 values and color indices are configured through the following bitfields in LTDC_LxCLUTWR:

- CLUTADD defines the color index to update.
- RED defines the 8-bit Red component of that color index.
- GREEN defines the 8-bit Green component of that color index.
- BLUE defines the 8-bit Blue component of that color index.

43.4.9 Transparency color keying

Pixels can be defined as transparent using a color key. If the pixel RGB components equals the defined RGB color key, that pixel is considered transparent and its Alpha channel is forced null.

A pixel forced to transparent is transparent when proceeding to the later blending phase, and shows the pixel of the underlying layer.

The color key is defined as an RGB888 value, that is compared with the flowing pixel after some processing in the input format operator (where LSBs are stuffed by replication) and CLUT processing. The constant color keying parameters must take these previous processing into account.

Parameters

The color keying parameters are the following:

- CKEN in LTDC_LxCR enables the color keying.
- CKRED in LTDC_LxCKCR defines the 8-bit Red color key.
- CKGREEN in LTDC_LxCKCR defines the 8-bit Green color key.
- CKBLUE in LTDC_LxCKCR defines the 8-bit Blue color key.

Configuration example

A mid-yellow color (50 % Red + 50 % Green) is used as the transparent color key. The color keying parameters take it into account as follows:

- ARGB8888 input: The mid-yellow input is 0x808000. Set LTDC_LxCKCR = 0x808000.
- RGB565 input: The mid-yellow input is 0x8400. Set LTDC_LxCKCR = 0x848200 (due to the replication of input MSB onto the missing LSB).
- CLUT input for L8, AL88 or AL44: Set one of the palette entry to the mid-yellow color 0x808000 and set LTDC_LxCKCR = 0x808000.

43.4.10 Display composition - windowing

When performing the display composition, every layer can be cropped and positioned into the active display area. The window position and size are configured by defining its top-left and bottom-right corners.

Note: The locations are defined versus the internal timing generator that must take into account the potential synchronization header, the back porch size and the chosen active pixel area (as shown in Figure 444).

The mapping between the input layer and the visible window is performed as follows:

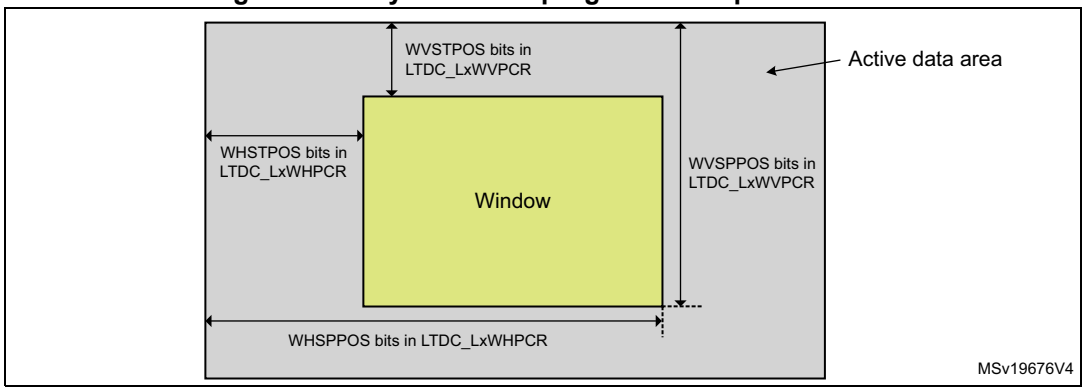
- The most top-left pixels of the input layer are mapped to the top-left of the visible window of this layer.
- If the visible window is smaller (less wide, less high) than the input layer, then the exceeding input pixels are automatically discarded from the pipe.

Parameters:

The following parameters are defined versus the top-left of the synchronization:

- WHSTPOS in LTDC_LxWHPCR: first (left) visible pixel of the layer
- WHSPPOS in LTDC_LxWHPCR: last (right) visible pixel of the layer
- WVSTPOS in LTDC_LxWVPCR: first (top) visible line of the layer
- WVSPPOS in LTDC_LxWVPCR: last (bottom) visible line of the layer

Figure 444. Layer window programmable parameters



Configuration examples

- LTDC_BPCR is configured to 0x000E0005 (AHBP[11:0] is 0xE), and LTDC_AWCR is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the active data area:
  - Layer window first pixel: WHSTPOS[11:0] must be programmed to 0x14 (0xE + 1 + 0x5).
  - Layer window last pixel: WHSPPOS[11:0] must be programmed to 0x28A.
- LTDC_BPCR is configured to 0x000E0005 (AVBP[11:0] is 0x5) and LTDC_AWCR is configured to 0x028E01E5 (AAH[11:0] is 0x1E5). To configure the vertical position of a window size of 630x460, with vertical start offset of eight lines in the active data area:
  - Layer window, first line: WVSTPOS[11:0] must be programmed to 0xE (0x5 + 1 + 0x8).
  - Layer window last line: WVSTPOS[11:0] must be programmed to 0x1DA.

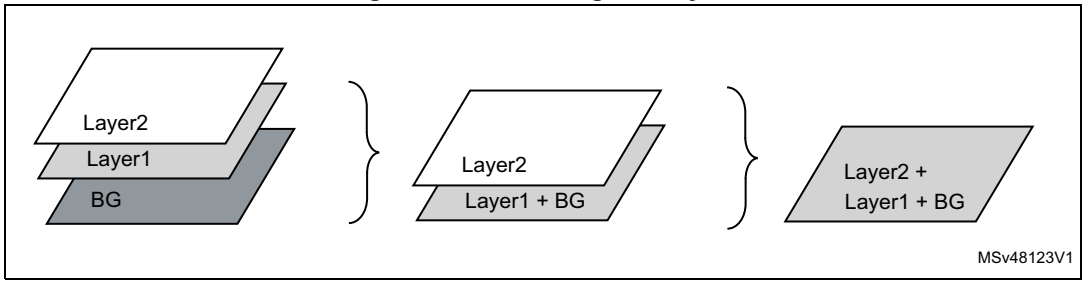
43.4.11 Display composition - blending

The Alpha blending stage is used to blend together the 2 input layers, on top of a background color.

It is possible to select the sequence of the layers (foreground, middle, and background), to apply a global multiplicative Alpha per-layer, and to define an underlying background color.

The blending computation is performed from back to front, sequentially, as shown the following figure.

Figure 445. Blending two layers



The general formula for a 2-to-1 blending is CR = (BF1 x C1) + (BF2 x C2) where:

- CR: resulting blended color
- BF1: blending-factor of current layer
- C1: layer-color of the current layer
- BF2: blend-factor of underlying pixels
- C2: layer-color of the underlying pixels

Both blending factor, BF1 and BF2, can be defined as one of the following:

- Pure per-pixel Alpha value
- Mix of per-pixel Alpha and a global per-layer Alpha (the mix is multiplicative)

Parameters

- CONSTA in LTDC_LxCACR: global multiplicative Alpha value of the current layer
- BOR in LTDC_LxBFCR: blending order of the current layer
- BF1 in LTDC_LxBFCR: blending factor for the current layer
- BF2 in LTDC_LxBFCR: blending factor for the underlying layer

The background color is defined by the following bitfields in LTDC_BCCR:

- BCRED: background Red component
- BCGREEN: background Green component
- BCBLUE: background Blue component

Note: For secure purposes, in case of an inconsistent configuration, the blending order falls back to a fixed order, with the layer 2 on the foreground, and layer 1 in background, followed by the underlying background color.

The inconsistent fallback is setup to protect a potential secure layer: If a secure software configures the secure layer2 to be on the foreground, and a malware tries to place that another layer on the foreground, the inconsistency is detected, and the secure layer is automatically forced on the foreground, guaranteeing that it is visible.

Configuration example

Only layer 1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in LTDC_LxCACR is 240 (0xF0). Thus, the constant alpha value is 240 / 255 = 0.94. C: current layer color is 128. Cs: background color is 48. Layer 1 is blended with the background color.
BC = constant alpha x C + (1 - constant alpha) x Cs = 0.94 x 128 + (1 - 0.94) x 48 = 123.

Default configuration

All active layers can be made visible and blended by keeping the following configuration values after reset:

- CONSTA: keep as reset CONSTA = 255.
- BOR: keep as reset BOR (layer) = LayerID-1.
- BF1: keep as reset BF1 = 6 for default mixed Alpha.
- BF12: keep as reset BF2 = 7 for default mixed 1-Alpha.
- Background color: keep as reset (black), although any color is ok.

43.4.12 Gamma correction

The gamma correction is a non-linear operator that adapts the pixel to the non-linear display, using a compensating pre-distortion. The R, G, B components can be independently adapted, using a configurable non-linear transformation.

The non-linear transformation is implemented in the LTDC as eight independent linearly-interpolated segments: the desired non-linear transformation must thus be mapped onto the eight segments, and the shape of the eight segments configured in LTDC registers.

Parameters

- GAMEN in LTDC_GCR: activation of the gamma operator
- ADDR in LTDC_GCCR: table configuration, index (among 256) to write-in
- COMP in LTDC_GCCR: table configuration, 8-bit component to write-in
- REN in LTDC_GCCR: table configuration, active to write into the Red table
- GEN in LTDC_GCCR: table configuration, active to write into the Green table
- BEN in LTDC_GCCR: table configuration, active to write into the Blue table

Note: As the gamma correction works with eight interpolated segments. The only table indices to write-in are located at index: 0, 32, 64, 96,...,224, 255. The value to provide for index 255 contains the value for the pseudo-index 256.

Example configuration

The gamma correction is recommended to be set to pre-compensate the pixels with a gamma exponent of 2.2: Red, Green, and Blue components are compensated the same way by the Gamma. The configuration of Red, Green, and Blue tables is then usually the same.

Default configuration

The gamma correction is disabled with the default configuration after reset, with GAMEN = 0.

43.4.13 YUV output conversion

The default RGB888 24 bpp output can be converted to a YUV422 16 bpp output (coplanar), in order to reduce the bitrate or the interface width, if necessary.

The operator can convert the RGB to YUV with either ITU-R BT.601 versus BT.709 reference, and filter down the chrominance, to output the pixels as a YUV422 interface.

When the conversion is enabled, the Y is output on the LCD_G (green bits) and the Cb/Cr are output on the LCD_R (red bits).

Parameters in LTDC_EDCR

- OCYEN: activates the output conversion to YUV422.
- OCSEL: selects between a color conversion to ITU-R BT.601 versus to BT.709.
- OCYCO: defines whether Cb or Cr is output first.

The configuration must follow what is expected by the external display panel.

Default configuration

The YUV output conversion is disabled with the default configuration after reset, with OCYEN = 0, allowing a default RGB888 to be output.

43.4.14 Dithering

The dithering operator allows a clean conversion of the RGB888 output into a reduced pixel format, like RGB565 or RGB666, and so avoiding the usual artifact of flat area that occurs when no dithering is available.

The dithering is based on a LFSR (polynomial generating random) and adds pseudo-random noise on the LSB of each of the displayed component (bit 2 in case of an RGB666), and makes that the average of the local pixels represents the information content of the full 8-component value.

Once the LTDC is enabled, the LFSR starts running with the first active pixel and it is kept running even during blanking periods and when dithering is switched off. If the LTDC is disabled, the LFSR is reset.

Parameters in LTDC_GCR

- DEN: dithering enable
- DRW: bit-id of LSB of the displayed Red component (among 8 bits)
- DGW: bit-id of LSB of the displayed Green component (among 8 bits)
- DBW: bit-id of LSB of the displayed Blue component (among 8 bits)

Example

To dither from RGB888 to RGB565 (assuming a RGB565 display panel):

- The LTDC outputs the Red component on pins LCD_R[7:0].
- The display panel probes the five MSB bits LCD_R[7:3].
- The red bit to dither, using its two following LSB as decimals, is the bit 3.
- DRW must be configured to 3.
- DGW = 2 and DBW = 3.

Similarly, a dithering to RGB666 requires DRW = DGW = DBW = 2.

Default configuration

The dithering is disabled with the default configuration after reset, with DEN = 0, allowing a default RGB888 to be output.

43.4.15 CRC hashing

The CRC operator allows a 16-bit signature to be extracted for each frame, by hashing the R,G,B components of all the frame pixels.

The computed CRC can be read in LTDC_CCRCR.

An expected CRC value can be configured: if the computed CRC does not match the expected CRC, the CRC interrupt is triggered. It allows a system test, letting the LTDC run for hours, and be warned only if a failed frame occurs.

Parameters

- CRCEN in LTDC_GCR: activates the CRC computation
- ECRC in LTDC_ECRCR: expected 16-bit CRC value
- CCRC in LTDC_CCRCR: computed 16-bit CRC value

Default configuration

The CRC hashing is disabled with the default configuration after reset, with CRCEN = 0.

43.4.16 Display timing

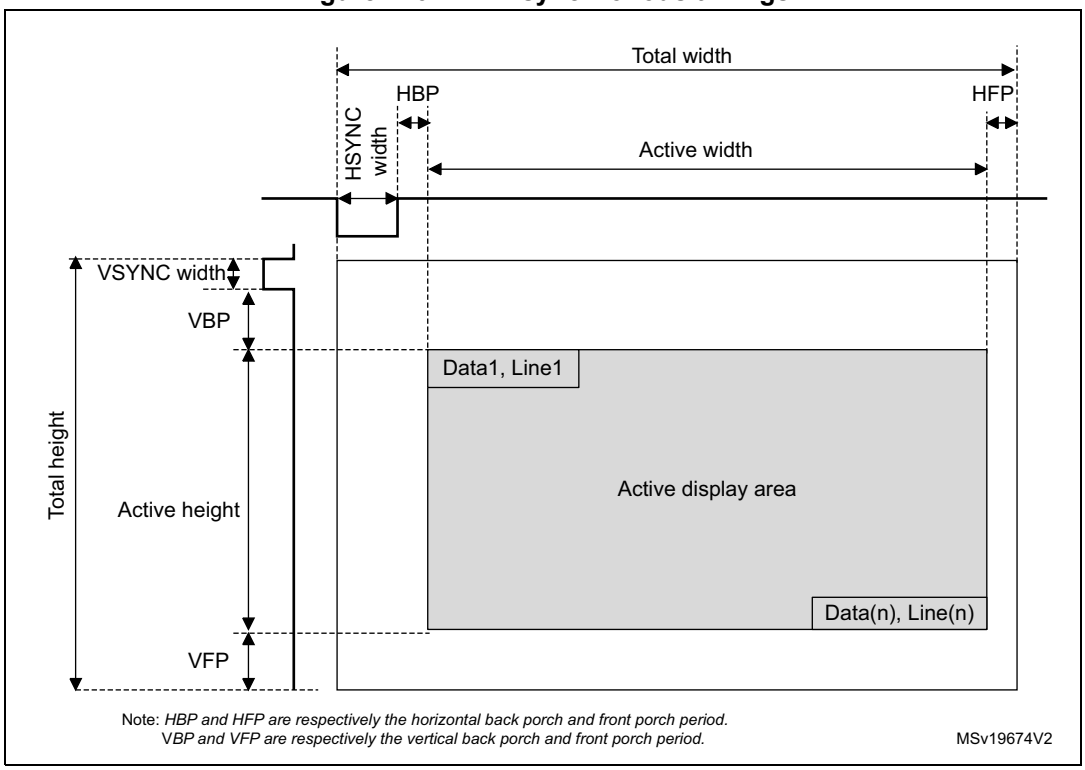
This section describes the configuration of the display timings, so that the LTDC matches what is expected by the external display panel.

The configuration defines the horizontal and vertical duration of each of the following items:

- Synchronization period (HSYNC and VSYNC)
- Back porch (HBP, VBP)
- Active display (pixels that are visible on the screen)
- Front porch (HFP, VFP)

These timings are described in the following figure.

Figure 446. LTDC synchronous timings



As a result of these timings, the LTDC samples in pixels during the active display duration, and generates the output synchronization signals (HSYNC, VSYNC), the pixel data, and the data-enable signal.

Parameters

All the timings configured next are absolute timings, computed from the display start position, and not the relative increment (or width or height) of each area.

All these bitfields indicate the last pixel of each area, and hence are subtracted 1.

- **HSYNC and VSYNC width** (horizontal and vertical synchronization width) in LTDC_SSCR:
  - HSW = HSYNC width - 1
  - VSW = VSYNC width - 1
- **HBP and VBP** (last pixel/line of the horizontal and vertical synchronization back porch) in LTDC_BPCR:
  - AHBP = HSYNC width + HBP - 1
  - AVBP = VSYNC width + VBP - 1
- **Active width and active height** (last pixel/line of the active display area) in LTDC_AWCR:
  - AAW = HSYNC width + HBP + active width - 1
  - AAW = VSYNC width + VBP + active height - 1

- **Total display width** (last pixel/line of the total display timings) in LTDC_TWCR:
  - TOTALW = HSYNC width + HBP + active width + HFP - 1
  - TOTALH = VSYNC height + VBP + active height + VFP - 1

Note: When the LTDC is enabled, timings generated start at the position (X,Y) = (0,0), and generate immediately the first horizontal synchronization pixel in the vertical synchronization, followed by the back porch, then the active display area, and finally the front porch.

When the LTDC is disabled, the timing generator block is reset to X = total width - 1, Y = total height - 1. It holds the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore, only blanking data is output continuously.

Example of synchronous timing configuration

Assume the following display panel timings (to be extracted from panel datasheet):

- Horizontal and vertical synchronization width: 0xA pixels, 0x2 lines
- Horizontal and vertical back porch: 0x14 pixels, 0x2 lines
- Active width and active height (320x240): 0x140 pixels, 0x0F0 lines
- Horizontal and vertical front porch: 0xA pixels 0x4 lines

Bitfield values to configure become:

- HSW[11:0] = 0x9 (horizontal synchro -1) in LTDC_SSCR.
- VSH[11:0] = 0x1 (vertical synchro -1) in LTDC_SSCR.
- AHBP[11:0] = 0x1D (horizontal synchro + back porch -1) in LTDC_BPCR.
- AVBP[11:0] = 0x3 (vertical synchro + back porch -1) in LTDC_BPCR.
- AAW[11:0] = 0x15D (horizontal synchro + back porch + width -1) in LTDC_AWCR.
- AAH[11:0] = 0xF3 (vertical synchro + back porch + height -1) in LTDC_AWCR.
- TOTALW[11:0] = 0x167 (horizontal synchro + back porch + width + front porch -1) in LTDC_TWCR.
- TOTALH[11:0] = 0xF7 (vertical synchro + back porch + width + front porch -1) in LTDC_TWCR.

Default configuration

There is no default configuration to propose. As display timings depend on the specific display panel and its own required timings, all these parameters must be extracted from the display panel specification.

Note: The configuration of all the above is mandatory to have the LTDC driving correctly the external display panel.

43.4.17 Output interface polarity

The polarity of the control signals of the output interface includes the clock polarity, the vertical/horizontal synchronization, and the data-enable signal.

Parameters in LTDC_GCR

- PCPOL: polarity of the output clock
- VSPOL: polarity of the vertical synchronization
- HSPOL: polarity of the vertical synchronization

- DEPOL: polarity of the data enable

Default configuration

There is not default configuration, as the configuration of the polarity depends on the display panel specifications.

The following configuration can be used to have all items working with a positive polarity:

- PCPOL = 1 (rising-edge)
- VSPOL = 1 (active high)
- HSPOL = 1 (active high)
- DEPOL = 1 (active high)

43.4.18 Shadow registers

When activated, the LTDC is expected to display continuously data, frame after frame.

The user may want to modify some settings: for example, add a new layer, modify the layer window location, or update the displayed content by updating the pointer to the buffer that is displayed.
