Reference manual

STM32N647/657xx Arm®-based 32-bit MCUs

Introduction

This document is addressed to application developers. It provides complete information on how to use the STM32N647xx and STM32N657xx (referred to as STM32N6x7xx) microcontrollers memory and peripherals.

For ordering information, mechanical and electrical device characteristics, refer to the datasheet.

For information on the Arm® Cortex®-M55 core, refer to the corresponding Arm® Technical Reference Manual available on http://infocenter.arm.com.

STM32N6x7xx microcontrollers include ST state-of-the-art patented technology.

6 Resource isolation framework security controller (RIFSC) 246

6.1 Introduction 246
6.2 RIFSC main features 246
6.3 RIFSC functional description 246
6.3.1 RIFSC reset and clocks 246
6.3.2 RISUP 246
6.3.3 RCC security settings for RIF-aware peripherals and RAMs 247
6.3.4 RIMU 248

6.4 RIFSC registers 249
6.4.1 RIFSC RISC slave configuration register x (RIFSC_RISC_CR) 249
6.4.2 RIFSC RISC slave security configuration register x (RIFSC_RISC_SECCFGRx) 250
6.4.3 RIFSC RISFC slave privileged register x (RIFSC_RISC_PRIVCFGRx) 250
6.4.4 RIFSC RISC slave resource configuration lock register x (RIFSC_RISC_RCFGLOCKRx) 251
6.4.5 RIFSC RIMC master configuration register (RIFSC_RIMC_CR) 251
6.4.6 RIFSC RIMC master attribute register x (RIFSC_RIMC_ATTRx) 252
6.4.7 RIFSC peripheral protection status register 0 (RIFSC_PPSR0) 252
6.4.8 RIFSC peripheral protection status register 1 (RIFSC_PPSR1) 253
6.4.9 RIFSC peripheral protection status register 2 (RIFSC_PPSR2) 253
6.4.10 RIFSC peripheral protection status register 3 (RIFSC_PPSR3) 253
6.4.11 RIFSC peripheral protection status register 4 (RIFSC_PPSR4) 254
6.4.12 RIFSC peripheral protection status register 5 (RIFSC_PPSR5) 254
6.4.13 RIFSC register map 255

7 Resource isolation slave unit for address space protection (full version) (RISAF) 256

7.1 RISAF introduction 256
7.2 RISAF main features 256
7.3 RISAF implementation 257
7.4 RISAF functional description 258
7.4.1 RISAF block diagram 258
7.4.2 RISAF internal signals 258
7.4.3 RISAF reset and clocks 259
7.4.4 RISAF address space management 259
7.4.5 RISAF programming 260
7.4.6 RISAF runtime modification of region or subregion configuration 261
7.4.7 Managing illegal accesses 262
7.5 RISAF registers 263
7.5.1 RISAF configuration register (RISAF_CR) 263
7.5.2 RISAF illegal access status register (RISAF_IASR) 263
7.5.3 RISAF illegal access clear register (RISAF_IACR) 264
7.5.4 RISAF illegal access error status register (RISAF_IAESR) 264
7.5.5 RISAF illegal address register (RISAF_IADDR) 265
7.5.6 RISAF region x configuration register (RISAF_REGx_CFGR) 265

7.5.7 RISAF region x start-address register (RISAF_REGx_STARTR) 266
7.5.8 RISAF region x end-address register (RISAF_REGx_ENDR) 267
7.5.9 RISAF region x CID configuration register (RISAF_REGx_CIDCFGR) 267
7.5.10 RISAF region x subregion A configuration register (RISAF_REGx_ACFGR) 268
7.5.11 RISAF region x subregion A start-address register (RISAF_REGx_ASTARTR) 269
7.5.12 RISAF region x subregion A end-address register (RISAF_REGx_AENDR) 270
7.5.13 RISAF region x subregion A nested mode register (RISAF_REGx_ANESTR) 271
7.5.14 RISAF region x subregion B configuration register (RISAF_REGx_BCFGR) 272
7.5.15 RISAF region x subregion B start-address register (RISAF_REGx_BSTARTR) 273
7.5.16 RISAF region x subregion B end-address register (RISAF_REGx_BENDR) 274
7.5.17 RISAF region x subregion B nested mode register (RISAF_REGx_BNESTR) 275
7.5.18 RISAF register map 275

8 Illegal access controller (IAC) 278

8.1 IAC introduction 278
8.2 IAC main features 278
8.3 IAC implementation 278
8.4 IAC functional description 279
8.4.1 IAC block diagram 279
8.4.2 IAC internal signals 280
8.4.3 IAC reset and clocks 280
8.4.4 IAC use in RIF 280
8.4.5 IAC management by trusted application 280
8.5 IAC interrupts 281
8.6 IAC registers 281
8.6.1 IAC interrupt enable register x (IAC_IERx) 281
8.6.2 IAC interrupt status register x (IAC_ISRx) 281
8.6.3 IAC interrupt clear register x (IAC_ICRx) 282
8.6.4 IAC ILAC input status register x (IAC_IISRx) 282
8.6.5 IAC register map 283

9 Boot modes 284
9.1 Boot after system reset 284
9.1.1 Flash boot 284
9.1.2 Serial boot 284
9.1.3 Development boot 284
9.2 Boot from a low-power mode 285

10 SRAM configuration controller (RAMCFG) 286
10.1 RAMCFG introduction 286
10.2 RAMCFG main features 286
10.3 RAMCFG functional description 286
10.3.1 Internal SRAM features 286
10.3.2 FLEXRAM control 287
10.3.3 ECC (BKPSRAM) 290
10.4 RAMCFG low-power modes 291
10.5 RAMCFG interrupts 292
10.6 RAMCFG registers 293
10.6.1 RAMCFG AXISRAM1 control register (RAMCFG_AXISRAM1CR) . . . 293
10.6.2 RAMCFG AXISRAMx interrupt status register (RAMCFG_AXISRAMxISR) 293
10.6.3 RAMCFG AXISRAMx erase key register (RAMCFG_AXISRAMxERKEYR) 294
10.6.4 RAMCFG AXISRAMx control register (RAMCFG_AXISRAMxCR) . . . 294
10.6.5 RAMCFG AHBSRAMx control register (RAMCFG_AHBSRAMxCR) . 295
10.6.6 RAMCFG AHBSRAMx interrupt status register (RAMCFG_AHBSRAMxISR) 295
10.6.7 RAMCFG AHBSRAMx erase key register (RAMCFG_AHBSRAMxERKEYR) 296
10.6.8 RAMCFG VENCRAM control register (RAMCFG_VENCRAMCR) . . . 296
10.6.9 RAMCFG VENCRAM interrupt status register (RAMCFG_VENCRAMISR) 297
10.6.10 RAMCFG VENCRAM erase key register (RAMCFG_VENCRAMERKEYR) 297
10.6.11 RAMCFG BKPSRAM control register (RAMCFG_BKPSRAMCR) . . . 298
10.6.12 RAMCFG BKPSRAM interrupt enable register (RAMCFG_BKPSRAMIER) 299
10.6.13 RAMCFG BKPSRAM interrupt status register (RAMCFG_BKPSRAMISR) 299

10.6.14 RAMCFG BKPSRAM single error address register (RAMCFG_BKPSRAMESEAR) . . . 300
10.6.15 RAMCFG BKPSRAM double error address register (RAMCFG_BKPSRAMEDEAR) . . . 300
10.6.16 RAMCFG BKPSRAM interrupt clear register (RAMCFG_BKPSRAMICR) . . . 301
10.6.17 RAMCFG BKPSRAM ECC key register (RAMCFG_BKPSRAMECCKEYR) . . . 301
10.6.18 RAMCFG BKPSRAM erase key register (RAMCFG_BKPSRAMERKEYR) . . . 302
10.6.19 RAMCFG FLEXRAM control register (RAMCFG_FLEXRAMCR) . . . 302
10.6.20 RAMCFG FLEXRAM interrupt status register (RAMCFG_FLEXRAMISR) . . . 303
10.6.21 RAMCFG FLEXRAM erase key register (RAMCFG_FLEXRAMERKEYR) . . . 303
10.6.22 RAMCFG register map . . . 304

11 Texture cache (ICACHE) . . . 306
11.1 ICACHE introduction . . . 306
11.2 ICACHE main features . . . 306
11.3 ICACHE implementation . . . 307
11.4 ICACHE functional description . . . 307
11.4.1 ICACHE block diagram . . . 308
11.4.2 ICACHE reset and clocks . . . 308
11.4.3 ICACHE TAG memory . . . 309
11.4.4 Direct-mapped ICACHE (1-way cache) . . . 310
11.4.5 ICACHE enable . . . 311
11.4.6 Cacheable and noncacheable traffic . . . 311
11.4.7 Cacheable accesses . . . 312
11.4.8 ICACHE maintenance . . . 312
11.4.9 ICACHE performance monitoring . . . 313
11.4.10 ICACHE boot . . . 313
11.5 ICACHE low-power modes . . . 313
11.6 ICACHE error management and interrupts . . . 314
11.7 ICACHE registers . . . 314
11.7.1 ICACHE control register (ICACHE_CR) . . . 314
11.7.2 ICACHE status register (ICACHE_SR) . . . 315
11.7.3 ICACHE interrupt enable register (ICACHE_IER) . . . 316

11.7.4 ICACHE flag clear register (ICACHE_FCR) 316
11.7.5 ICACHE hit monitor register (ICACHE_HMONR) 317
11.7.6 ICACHE miss monitor register (ICACHE_MMONR) 317
11.7.7 ICACHE register map 318

12 AXI cache (CACHEAXI) 319

12.1 CACHEAXI introduction 319
12.2 CACHEAXI main features 320
12.3 CACHEAXI implementation 321
12.4 CACHEAXI functional description 322
12.4.1 CACHEAXI block diagram 323
12.4.2 CACHEAXI reset and clocks 323
12.4.3 CACHEAXI TAG memory 324
12.4.4 CACHEAXI enable 327
12.4.5 Cacheable and noncacheable AXI traffic to slave cache port 327
12.4.6 Cacheable accesses 328
12.4.7 AXI traffic to master port 329
12.4.8 AXI traffic to slave SRAM port 330
12.4.9 CACHEAXI security 330
12.4.10 CACHEAXI maintenance 330
12.4.11 CACHEAXI performance monitoring 332
12.4.12 CACHEAXI boot 333
12.5 CACHEAXI low-power modes 333
12.6 CACHEAXI error management and interrupts 333
12.7 CACHEAXI registers 335
12.7.1 CACHEAXI control register 1 (CACHEAXI_CR1) 335
12.7.2 CACHEAXI status register (CACHEAXI_SR) 336
12.7.3 CACHEAXI interrupt enable register (CACHEAXI_IER) 337
12.7.4 CACHEAXI flag clear register (CACHEAXI_FCR) 338
12.7.5 CACHEAXI read-hit monitor register (CACHEAXI_RHMONR) 339
12.7.6 CACHEAXI read-miss monitor register (CACHEAXI_RMMONR) 339
12.7.7 CACHEAXI read-allocate miss monitor register (CACHEAXI_RAMMONR) 339
12.7.8 CACHEAXI eviction monitor register (CACHEAXI_EVIMONR) 340
12.7.9 CACHEAXI write-hit monitor register (CACHEAXI_WHMONR) 340
12.7.10 CACHEAXI write-miss monitor register (CACHEAXI_WMMONR) . . . 340

12.7.11 CACHEAXI write-allocate miss monitor register (CACHEAXI_WAMMONR) . . . 341
12.7.12 CACHEAXI write-through monitor register (CACHEAXI_WTMONR) . 341
12.7.13 CACHEAXI control register 2 (CACHEAXI_CR2) . . . 341
12.7.14 CACHEAXI command range start address register (CACHEAXI_CMDRSADDRR) . . . 342
12.7.15 CACHEAXI command range end address register (CACHEAXI_CMDREADDRR) . . . 343
12.7.16 CACHEAXI register map . . . 343

13.5.7 Peripheral voltage monitoring (PVM) . . . 363
13.5.8 Battery voltage thresholds . . . 364
13.5.9 Temperature thresholds . . . 365
13.6 Power management . . . 366
13.6.1 Operating modes . . . 366
13.6.2 Voltage scaling . . . 371
13.6.3 Power management examples . . . 372
13.7 Low-power modes . . . 374

13.7.1 Slowing down system clocks . . . 375
13.7.2 Controlling peripheral clocks . . . 375
13.7.3 Entering low-power modes . . . 375
13.7.4 Exiting low-power modes . . . 375
13.7.5 Sleep mode . . . 376
13.7.6 Stop mode . . . 377
13.7.7 Standby mode . . . 379
13.7.8 Power mode output pins . . . 381
13.8 PWR security and privileged protection . . . 381
13.8.1 Secure/nonsecure access filtering . . . 382
13.8.2 Privileged/unprivileged access filtering . . . 383
13.9 PWR registers . . . 383
13.9.1 PWR control register 1 (PWR_CR1) . . . 383
13.9.2 PWR control register 2 (PWR_CR2) . . . 384
13.9.3 PWR control register 3 (PWR_CR3) . . . 385
13.9.4 PWR control register 4 (PWR_CR4) . . . 385
13.9.5 PWR voltage scaling control register (PWR_VOSCR) . . . 386
13.9.6 PWR backup domain control register 1 (PWR_BDCR1) . . . 387
13.9.7 PWR backup domain control register 2 (PWR_BDCR2) . . . 388
13.9.8 PWR disable backup protection control register (PWR_DBPCR) . . . 389
13.9.9 PWR CPU control register (PWR_CPUCR) . . . 389
13.9.10 PWR supply voltage monitoring control register 1 (PWR_SVMCR1) . 390
13.9.11 PWR supply voltage monitoring control register 2 (PWR_SVMCR2) . 392
13.9.12 PWR supply voltage monitoring control register 3 (PWR_SVMCR3) . 393
13.9.13 PWR wake-up clear register (PWR_WKUPCR) . . . 395
13.9.14 PWR wake-up status register (PWR_WKUPSR) . . . 396
13.9.15 PWR wake-up enable and polarity register (PWR_WKUPEPR) . . . 397
13.9.16 PWR security configuration register (PWR_SECCFGR) . . . 399
13.9.17 PWR privilege configuration register (PWR_PRIVCFGR) . . . 400
13.9.18 PWR debug control register 1 (PWR_CRCFG1) . . . 403
13.9.19 PWR debug control register 2 (PWR_CRCFG2) . . . 404
13.9.20 PWR Debug control register 3 (PWR_CRCFG3) . . . 404
13.9.21 PWR register map . . . 406

14 Reset and clock control (RCC) . . . 409
14.1 RCC main features . . . 409
14.2 RCC power domains . . . 409

14.3 RCC block diagram . . . 410
14.4 RCC pins and internal signals . . . 410
14.5 Functional description of RCC reset . . . 412
14.5.1 Reset from the PWR . . . 412
14.5.2 System and application resets (sys_rst, nreset_rstn) . . . 413
14.5.3 NRST reset . . . 414
14.5.4 Low-power mode security reset (lpwr_rst) . . . 414
14.5.5 Backup domain reset . . . 415
14.5.6 CoreSight debug reset . . . 415
14.5.7 Option-byte loading . . . 415
14.5.8 Reset of peripherals . . . 416
14.5.9 Reset pulse control (RPCTL) . . . 416
14.5.10 Reset coverage summary . . . 417
14.5.11 Reset source identification . . . 418
14.5.12 Power-on and wake-up sequences . . . 418
14.6 Functional description of RCC clocks . . . 419
14.6.1 Clock naming convention . . . 422
14.6.2 Oscillator description . . . 422
14.6.3 Clock security system (CSS) . . . 430
14.6.4 Clock output generation (MCO1/MCO2) . . . 433
14.6.5 PLL description . . . 433
14.6.6 System clocks . . . 438
14.6.7 Clock generation in Stop and Standby modes . . . 440
14.6.8 Peripheral clock distribution . . . 441
14.6.9 General clock concept overview . . . 465
14.6.10 Peripheral allocation . . . 466
14.6.11 Peripheral clock-gating control . . . 467
14.6.12 CPU and bus matrix clock-gating control . . . 469
14.6.13 Low-power emulation modes . . . 470
14.7 RCC interrupts . . . 471
14.8 RCC application information . . . 471
14.8.1 HSE crystal auto-detection . . . 471
14.8.2 Calibration and clock frequency measurement using TIMx . . . 472
14.8.3 Clock monitoring . . . 473
14.8.4 Clock frequency limits . . . 473
14.9 RCC security . . . 474

14.9.1 Internal register protection 475
14.9.2 Internal register write-protection 476
14.10 RCC registers 476
14.10.1 RCC control register (RCC_CR) 476
14.10.2 RCC status register (RCC_SR) 478
14.10.3 RCC Stop mode control register (RCC_STOPCR) 479
14.10.4 RCC configuration register 1 (RCC_CFGR1) 480
14.10.5 RCC configuration register 2 (RCC_CFGR2) 481

18 High-performance direct memory access controller (HPDMA) 827
18.1 HPDMA introduction 827
18.2 HPDMA main features 827
18.3 HPDMA implementation 828

18.3.1 HPDMA channels . . . 828
18.3.2 HPDMA allowed AXI maximum burst length . . . 829
18.3.3 HPDMA in low-power modes . . . 829
18.3.4 HPDMA requests . . . 829
18.3.5 HPDMA block requests . . . 834
18.3.6 HPDMA channels with peripheral early termination . . . 834
18.3.7 HPDMA triggers . . . 835
18.4 HPDMA functional description . . . 839
18.4.1 HPDMA block diagram . . . 839
18.4.2 HPDMA channel state and direct programming without any linked-list . . . 839
18.4.3 HPDMA channel suspend and resume . . . 840
18.4.4 HPDMA channel abort and restart . . . 841
18.4.5 HPDMA linked-list data structure . . . 842
18.4.6 Linked-list item transfer execution . . . 845
18.4.7 HPDMA channel state and linked-list programming in run-to-completion mode . . . 846
18.4.8 HPDMA channel state and linked-list programming in link step mode . . . 850
18.4.9 HPDMA channel state and linked-list programming . . . 857
18.4.10 HPDMA FIFO-based transfers . . . 859
18.4.11 HPDMA transfer request and arbitration . . . 875
18.4.12 HPDMA triggered transfer . . . 879
18.4.13 HPDMA circular buffering with linked-list programming . . . 880
18.4.14 HPDMA transfer in peripheral flow-control mode . . . 882
18.4.15 HPDMA secure/nonsecure channel . . . 883
18.4.16 HPDMA privileged/unprivileged channel . . . 884
18.4.17 HPDMA error management . . . 884
18.5 HPDMA in debug mode . . . 886
18.6 HPDMA in low-power modes . . . 886
18.7 HPDMA interrupts . . . 887
18.8 HPDMA registers . . . 888
18.8.1 HPDMA secure configuration register (HPDMA_SECCFGR) . . . 888
18.8.2 HPDMA privileged configuration register (HPDMA_PRIVCFGR) . . . 889
18.8.3 HPDMA configuration lock register (HPDMA_RCFGLOCKR) . . . 890
18.8.4 HPDMA nonsecure masked interrupt status register (HPDMA_MISR) . . . 890
18.8.5 HPDMA secure masked interrupt status register (HPDMA_SMISR) . . 891

18.8.6 HPDMA channel x linked-list base address register (HPDMA_CxLBAR) . . . 892
18.8.7 HPDMA channel x CID register (HPDMA_CxCIDCFGR) . . . 892
18.8.8 HPDMA channel x semaphore control register (HPDMA_CxSEMCR) . . . 894
18.8.9 HPDMA channel x flag clear register (HPDMA_CxFCR) . . . 896
18.8.10 HPDMA channel x status register (HPDMA_CxSR) . . . 897
18.8.11 HPDMA channel x control register (HPDMA_CxCR) . . . 898
18.8.12 HPDMA channel x transfer register 1 (HPDMA_CxTR1) . . . 901
18.8.13 HPDMA channel x transfer register 2 (HPDMA_CxTR2) . . . 905
18.8.14 HPDMA channel x block register 1 (HPDMA_CxBR1) . . . 909
18.8.15 HPDMA channel x alternate block register 1 (HPDMA_CxBR1) . . . 910
18.8.16 HPDMA channel x source address register (HPDMA_CxSAR) . . . 913
18.8.17 HPDMA channel x destination address register (HPDMA_CxDAR) . . 915
18.8.18 HPDMA channel x transfer register 3 (HPDMA_CxTR3) . . . 917
18.8.19 HPDMA channel x block register 2 (HPDMA_CxBR2) . . . 918
18.8.20 HPDMA channel x linked-list address register (HPDMA_CxLLR) . . . 919
18.8.21 HPDMA channel x alternate linked-list address register (HPDMA_CxLLR) . . . 921

23 Graphic timer (GFXTIM) 1075

23.1 Introduction 1075

23.2 GFXTIM main features 1075
23.3 GFXTIM functional description 1075
23.3.1 Block diagram 1075
23.3.2 GFXTIM pins and internal signals 1076
23.3.3 Clock generator 1077
23.3.4 Example of clock generator configuration 1079
23.3.5 Absolute timers 1083
23.3.6 Relative timers 1084
23.3.7 Tearing-effect detection 1085
23.3.8 Event generator 1085
23.3.9 Watchdog timer 1086
23.4 GFXTIM interrupts 1087
23.5 GFXTIM registers 1088
23.5.1 GFXTIM configuration register (GFXTIM_CR) 1088
23.5.2 GFXTIM clock generator configuration register (GFXTIM_CGCR) . . 1089
23.5.3 GFXTIM timers configuration register (GFXTIM_TCR) 1091
23.5.4 GFXTIM timers disable register (GFXTIM_TDR) 1092
23.5.5 GFXTIM events control register (GFXTIM_EVCR) 1093
23.5.6 GFXTIM events selection register (GFXTIM_EVSR) 1093
23.5.7 GFXTIM watchdog timer configuration register (GFXTIM_WDGTCR) 1095
23.5.8 GFXTIM interrupt status register (GFXTIM_ISR) 1097
23.5.9 GFXTIM interrupt clear register (GFXTIM_ICR) 1098
23.5.10 GFXTIM interrupt enable register (GFXTIM_IER) 1100
23.5.11 GFXTIM timers status register (GFXTIM_TSR) 1102
23.5.12 GFXTIM line clock counter reload register (GFXTIM_LCCRR) 1103
23.5.13 GFXTIM frame clock counter reload register (GFXTIM_FCCRR) . . . 1103
23.5.14 GFXTIM absolute time register (GFXTIM_ATR) 1103
23.5.15 GFXTIM absolute frame counter register (GFXTIM_AFCR) 1104
23.5.16 GFXTIM absolute line counter register (GFXTIM_ALCR) 1104
23.5.17 GFXTIM absolute frame counter compare 1 register (GFXTIM_AFCC1R) 1105
23.5.18 GFXTIM absolute line counter compare 1 register (GFXTIM_ALCC1R) 1105
23.5.19 GFXTIM absolute line counter compare 2 register (GFXTIM_ALCC2R) 1105
23.5.20 GFXTIM relative frame counter 1 register (GFXTIM_RFC1R) 1106

23.5.21 GFXTIM relative frame counter 1 reload register (GFXTIM_RFC1RR) 1106
23.5.22 GFXTIM relative frame counter 2 register (GFXTIM_RFC2R) 1107
23.5.23 GFXTIM relative frame counter 2 reload register (GFXTIM_RFC2RR) 1107
23.5.24 GFXTIM watchdog counter register (GFXTIM_WDGCR) 1107
23.5.25 GFXTIM watchdog reload register (GFXTIM_WDGRR) 1108
23.5.26 GFXTIM watchdog pre-alarm register (GFXTIM_WDGPAR) 1108
23.5.27 GFXTIM register map 1108

24 Nested vectored interrupt controller (NVIC) 1111

24.1 NVIC features 1111
24.1.1 SysTick calibration value register 1111
24.1.2 Interrupt and exception vectors 1111

25 Extended interrupts and event controller (EXTI) 1119

25.1 EXTI main features 1119
25.2 EXTI implementation 1120
25.3 EXTI block diagram 1120
25.3.1 EXTI connections between peripherals and CPU 1121
25.3.2 EXTI wake-up interrupt list 1122
25.4 EXTI functional description 1124
25.4.1 EXTI configurable event input wake-up 1124
25.4.2 EXTI direct event input wake-up 1125
25.4.3 EXTI multiplexer selection 1125
25.5 EXTI functional behavior 1126
25.6 EXTI event protection 1127
25.6.1 EXTI register security protection 1127
25.6.2 EXTI register privilege protection 1128
25.7 EXTI registers 1128
25.7.1 EXTI rising trigger selection register (EXTI_RTSR1) 1128
25.7.2 EXTI falling trigger selection register (EXTI_FTSR1) 1129
25.7.3 EXTI software interrupt event register (EXTI_SWIER1) 1130
25.7.4 EXTI rising edge pending register (EXTI_RPR1) 1131
25.7.5 EXTI falling edge pending register (EXTI_FPR1) 1131
25.7.6 EXTI security configuration register (EXTI_SECCFGR1) 1132
25.7.7 EXTI privilege configuration register (EXTI_PRIVCFGR1) 1132

25.7.8 EXTI rising trigger selection register (EXTI_RTSR2) 1133
25.7.9 EXTI falling trigger selection register (EXTI_FTSR2) 1134
25.7.10 EXTI software interrupt event register (EXTI_SWIER2) 1135
25.7.11 EXTI rising edge pending register (EXTI_RPR2) 1136
25.7.12 EXTI falling edge pending register (EXTI_FPR2) 1137
25.7.13 EXTI security enable register (EXTI_SECCFGR2) 1138
25.7.14 EXTI privilege enable register (EXTI_PRIVCFGR2) 1139
25.7.15 EXTI rising trigger selection register (EXTI_RTSR3) 1139
25.7.16 EXTI falling trigger selection register (EXTI_FTSR3) 1140
25.7.17 EXTI software interrupt event register (EXTI_SWIER3) 1141
25.7.18 EXTI rising edge pending register (EXTI_RPR3) 1142
25.7.19 EXTI falling edge pending register (EXTI_FPR3) 1142
25.7.20 EXTI security enable register (EXTI_SECCFGR3) 1143
25.7.21 EXTI privilege enable register (EXTI_PRIVCFGR3) 1144
25.7.22 EXTI external interrupt selection register 1 (EXTI_EXTICR1) 1144
25.7.23 EXTI external interrupt selection register 2 (EXTI_EXTICR2) 1147
25.7.24 EXTI external interrupt selection register 3 (EXTI_EXTICR3) 1150
25.7.25 EXTI external interrupt selection register 4 (EXTI_EXTICR4) 1152
25.7.26 EXTI lock register (EXTI_LOCKR) 1155
25.7.27 EXTI CPU wake-up with interrupt mask register 1 (EXTI_IMR1) . . . 1155
25.7.28 EXTI CPU wake-up with event mask register 1 (EXTI_EMR1) 1156
25.7.29 EXTI CPU wake-up with interrupt mask register 2 (EXTI_IMR2) . . . 1156
25.7.30 EXTI CPU wake-up with event mask register 2 (EXTI_EMR2) 1157
25.7.31 EXTI CPU wake-up with interrupt mask register 3 (EXTI_IMR3) . . . 1157
25.7.32 EXTI CPU wake-up with event mask register 3 (EXTI_EMR3) 1158
25.7.33 EXTI register map 1160

26 Cyclic redundancy check calculation unit (CRC) 1163

26.1 Introduction 1163
26.2 CRC main features 1163
26.3 CRC functional description 1164
26.3.1 CRC block diagram 1164
26.3.2 CRC internal signals 1164
26.3.3 CRC operation 1164
26.4 CRC registers 1166
26.4.1 CRC data register (CRC_DR) 1166
26.4.2 CRC independent data register (CRC_IDR) 1166

26.4.3 CRC control register (CRC_CR) 1167
26.4.4 CRC initial value (CRC_INIT) 1168
26.4.5 CRC polynomial (CRC_POL) 1168
26.4.6 CRC register map 1169

27 Flexible memory controller (FMC) 1170

27.1 FMC main features 1170
27.2 FMC implementation 1171
27.3 FMC block diagram 1172
27.4 FMC internal signals 1173
27.5 AHB interface 1173
27.6 AXI interface 1173
27.6.1 Supported memories and transactions 1174
27.7 External device address mapping 1175
27.7.1 NOR/PSRAM address mapping 1176
27.7.2 NAND flash memory address mapping 1176
27.7.3 SDRAM address mapping 1177
27.8 NOR flash/PSRAM controller 1180
27.8.1 External memory interface signals 1182
27.8.2 Supported memories and transactions 1184
27.8.3 General timing rules 1186
27.8.4 NOR flash/PSRAM controller asynchronous transactions 1186
27.8.5 Synchronous transactions 1205
27.8.6 NOR/PSRAM controller registers 1210
27.9 NAND flash controller 1219
27.9.1 External memory interface signals 1220
27.9.2 NAND flash supported memories and transactions 1221
27.9.3 Timing diagrams for NAND flash memory 1222
27.9.4 NAND flash operations 1223
27.9.5 NAND flash prewait function 1224
27.9.6 NAND ECC controller 1225
27.9.7 FMC command sequencer 1228
27.9.8 NAND flash controller interrupt 1235
27.9.9 NAND flash controller registers 1236
27.10 SDRAM controller 1260
27.10.1 SDRAM controller main features 1260

27.10.2 SDRAM External memory interface signals 1260
27.10.3 SDRAM controller functional description 1261
27.10.4 Low-power modes 1267
27.10.5 SDRAM controller registers 1269
27.11 FMC register map 1277

28 Extended-SPI interface (XSPI) 1282
28.1 Introduction 1282
28.2 XSPI main features 1282
28.3 XSPI implementation 1283
28.4 XSPI functional description 1284
28.4.1 XSPI block diagram 1284
28.4.2 XSPI pins and internal signals 1288
28.4.3 Clock constraints 1289
28.4.4 XSPI interface to memory modes 1289
28.4.5 XSPI regular-command protocol 1289
28.4.6 XSPI regular-command protocol signal interface 1293
28.4.7 HyperBus protocol 1298
28.4.8 Specific features 1303
28.4.9 XSPI operating modes introduction 1305
28.4.10 XSPI indirect mode 1305
28.4.11 XSPI automatic status-polling mode 1307
28.4.12 XSPI memory-mapped mode 1307
28.4.13 XSPI configuration introduction 1308
28.4.14 XSPI system configuration 1308
28.4.15 XSPI device configuration 1309
28.4.16 XSPI regular-command mode configuration 1311
28.4.17 XSPI HyperBus protocol configuration 1314
28.4.18 XSPI error management 1314
28.4.19 XSPI high-speed interface and calibration 1315
28.4.20 XSPI BUSY and ABORT 1316
28.4.21 XSPI reconfiguration or deactivation 1316
28.4.22 NCS behavior 1317
28.4.23 Software control of two external memories 1317
28.4.24 Hardware-controlled extended memory support 1318
28.5 Address alignment and data number 1319

28.6 XSPI interrupts 1321
28.7 XSPI registers 1321
28.7.1 XSPI control register (XSPI_CR) 1321
28.7.2 XSPI device configuration register 1 (XSPI_DCR1) 1325
28.7.3 XSPI device configuration register 2 (XSPI_DCR2) 1326
28.7.4 XSPI device configuration register 3 (XSPI_DCR3) 1327
28.7.5 XSPI device configuration register 4 (XSPI_DCR4) 1328
28.7.6 XSPI status register (XSPI_SR) 1328
28.7.7 XSPI flag clear register (XSPI_FCR) 1329
28.7.8 XSPI data length register (XSPI_DLR) 1330
28.7.9 XSPI address register (XSPI_AR) 1330
28.7.10 XSPI data register (XSPI_DR) 1331
28.7.11 XSPI polling status mask register (XSPI_PSMKR) 1332
28.7.12 XSPI polling status match register (XSPI_PSMAR) 1332
28.7.13 XSPI polling interval register (XSPI_PIR) 1333
28.7.14 XSPI communication configuration register (XSPI_CCR) 1333
28.7.15 XSPI timing configuration register (XSPI_TCR) 1335
28.7.16 XSPI instruction register (XSPI_IR) 1336
28.7.17 XSPI alternate bytes register (XSPI_ABR) 1336
28.7.18 XSPI low-power timeout register (XSPI_LPTR) 1336
28.7.19 XSPI wrap communication configuration register (XSPI_WPCCR) 1337
28.7.20 XSPI wrap timing configuration register (XSPI_WPTCR) 1339
28.7.21 XSPI wrap instruction register (XSPI_WPIR) 1340
28.7.22 XSPI wrap alternate byte register (XSPI_WPABR) 1340
28.7.23 XSPI write communication configuration register (XSPI_WCCR) 1340
28.7.24 XSPI write timing configuration register (XSPI_WTCR) 1342
28.7.25 XSPI write instruction register (XSPI_WIR) 1343
28.7.26 XSPI write alternate byte register (XSPI_WABR) 1343
28.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR) 1344
28.7.28 XSPI full-cycle calibration configuration (XSPI_CALFCR) 1344
28.7.29 XSPI DLL master calibration configuration (XSPI_CALMR) 1345
28.7.30 XSPI DLL slave output calibration configuration (XSPI_CALSOR) 1346
28.7.31 XSPI DLL slave input calibration configuration (XSPI_CALSIR) 1347
28.7.32 XSPI register map 1347

29 XSPI I/O manager (XSPIM) 1351

29.1 Introduction 1351

29.2 XSPIM main features 1351

29.3 XSPIM implementation 1351

29.4 XSPIM functional description 1351

29.4.1 XSPIM block diagram 1351

29.4.2 XSPIM input/output pins 1352

29.4.3 XSPIM matrix 1353

29.4.4 XSPIM multiplexed mode 1353

29.5 Use cases description 1354

29.5.1 XSPIs direct octal mode 1354

29.5.2 XSPI direct 16-bit mode 1355

29.5.3 XSPI dual-octal mode 1356

29.5.4 XSPI swapped mode 1357

29.5.5 Two XSPIs multiplexed mode to Port 1 accessing two external memories, and the third XSPI accessing Port 2 1358

29.5.6 Two XSPIs multiplexed mode to Port 2 accessing two external memories and the third XSPI accessing Port 1 1359

29.5.7 XSPI1 and XSPI2 drive a single external memory 1360

29.5.8 A single XSPI drives two external memories 1361

29.6 XSPIM registers 1363

29.6.1 XSPIM control register (XSPIM_CR) 1363

29.6.2 XSPIM register map 1364

30 Secure digital input/output MultiMediaCard interface (SDMMC) . . 1365

30.1 SDMMC main features 1365

30.2 SDMMC implementation 1365

30.3 SDMMC bus topology 1366

30.4 SDMMC operation modes 1368

30.5 SDMMC functional description 1369

30.5.1 SDMMC block diagram 1369

30.5.2 SDMMC pins and internal signals 1369

30.5.3 General description 1370

30.5.4 SDMMC adapter 1372

30.5.5 SDMMC AHB slave interface 1394

30.5.6 SDMMC AHB master interface 1395

30.5.7 AHB and SDMMC_CK clock relation 1398
30.6 Card functional description 1399
30.6.1 SD I/O mode 1399
30.6.2 CMD12 send timing 1407
30.6.3 Sleep (CMD5) 1411
30.6.4 Interrupt mode (Wait-IRQ) 1412
30.6.5 Boot operation 1413
30.6.6 Response R1b handling 1416
30.6.7 Reset and card cycle power 1417
30.7 Hardware flow control 1418
30.7.1 Hardware flow control during data transfer 1418
30.7.2 Block gap hardware flow control 1419
30.8 Ultra-high-speed phase I (UHS-I) voltage switch 1420
30.9 SDMMC interrupts 1423
30.10 SDMMC registers 1425
30.10.1 SDMMC power control register (SDMMC_POWER) 1425
30.10.2 SDMMC clock control register (SDMMC_CLKCR) 1426
30.10.3 SDMMC argument register (SDMMC_ARGR) 1428
30.10.4 SDMMC command register (SDMMC_CMDR) 1428
30.10.5 SDMMC command response register (SDMMC_RESPCMDR) 1430
30.10.6 SDMMC response x register (SDMMC_RESPxR) 1431
30.10.7 SDMMC data timer register (SDMMC_DTIMER) 1431
30.10.8 SDMMC data length register (SDMMC_DLENR) 1432
30.10.9 SDMMC data control register (SDMMC_DCTRL) 1433
30.10.10 SDMMC data counter register (SDMMC_DCNTR) 1434
30.10.11 SDMMC status register (SDMMC_STAR) 1435
30.10.12 SDMMC interrupt clear register (SDMMC_ICR) 1438
30.10.13 SDMMC mask register (SDMMC_MASKR) 1440
30.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER) . . . 1443
30.10.15 SDMMC data FIFO threshold register (SDMMC_FIFOTHRR) 1443
30.10.16 SDMMC DMA control register (SDMMC_IDMACTRLR) 1444
30.10.17 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER) 1444
30.10.18 SDMMC IDMA buffer base address register (SDMMC_IDMABASER) 1445
30.10.19 SDMMC IDMA linked list address register (SDMMC_IDMALAR) . . . 1445
30.10.20 SDMMC IDMA linked list memory base register (SDMMC_IDMABAR) 1446

30.10.21 SDMMC data FIFO registers x (SDMMC_FIFORx) 1447
30.10.22 SDMMC register map 1447

31 Delay block (DLYB) 1450
31.1 Introduction 1450
31.2 DLYB main features 1450
31.3 DLYB implementation 1450
31.4 DLYB functional description 1450
31.4.1 DLYB diagram 1450
31.4.2 DLYB internal signals 1452
31.4.3 General description 1454
31.4.4 Lock mode procedure 1455
31.4.5 Bypass mode procedure 1455
31.5 DLYB SDMMC registers description 1456
31.5.1 Delay block SDMMC DLL configuration (DLYBSD_CFG) 1456
31.5.2 Delay block SDMMC DLL status (DLYBSD_STATUS) 1457
31.5.3 DLYB register map 1457

32 Analog-to-digital converters (ADC) 1459
32.1 Introduction 1459
32.2 ADC main features 1459
32.3 ADC implementation 1461
32.4 ADC functional description 1462
32.4.1 ADC block diagram 1462
32.4.2 ADC pins and internal signals 1463
32.4.3 ADC clocks 1466
32.4.4 ADC connectivity 1467
32.4.5 Slave AHB interface 1469
32.4.6 ADC Deep-power-down mode (DEEPPWD) 1469
32.4.7 Single-ended and differential input channels 1469
32.4.8 Calibration (ADCAL, CALADDOS, ADC_CALFACT) 1470
32.4.9 ADC on-off control (ADEN, ADDIS, ADRDY) 1472
32.4.10 Constraints when writing the ADC control bits 1473
32.4.11 Channel selection (SQRx, JSQRx) 1474
32.4.12 Channel preselection register (ADC_PCSEL) 1474
32.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2) 1475

32.4.14 Single conversion mode 1477
32.4.15 Continuous conversion mode (CONT = 1) 1477
32.4.16 Starting conversions (ADSTART, JADSTART) 1478
32.4.17 Timing 1479
32.4.18 Stopping an ongoing conversion (ADSTP, JADSTP) 1480
32.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN) 1481
32.4.20 Injected channel management 1483
32.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN) 1484
32.4.22 Programmable resolution (RES) - fast conversion mode 1486
32.4.23 End of conversion and end of sampling phase (EOC, JEOC, EOSMP) 1486
32.4.24 End of conversion sequence (EOS, JEOS) 1486
32.4.25 Timing diagram examples (single/continuous modes, hardware/software triggers) 1487
32.4.26 Data management 1489
32.4.27 Managing conversions using the MDF 1497
32.4.28 Dynamic low-power features 1498
32.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT) 1502
32.4.30 Oversampler 1507
32.4.31 Dual ADC modes 1513
32.4.32 VBAT supply monitoring 1529
32.4.33 Monitoring the internal voltage reference 1529
32.4.34 Monitoring the supply voltage 1531
32.5 ADC interrupts 1531
32.6 ADC registers (for each ADC) 1532
32.6.1 ADC interrupt and status register (ADC_ISR) 1532
32.6.2 ADC interrupt enable register (ADC_IER) 1535
32.6.3 ADC control register (ADC_CR) 1537
32.6.4 ADC configuration register (ADC_CFGR1) 1540
32.6.5 ADC configuration register 2 (ADC_CFGR2) 1543
32.6.6 ADC sample time register 1 (ADC_SMPR1) 1546
32.6.7 ADC sample time register 2 (ADC_SMPR2) 1547
32.6.8 ADC channel preselection register (ADC_PCSEL) 1547
32.6.9 ADC regular sequence register 1 (ADC_SQR1) 1548
32.6.10 ADC regular sequence register 2 (ADC_SQR2) 1549

32.6.11 ADC regular sequence register 3 (ADC_SQR3) 1550
32.6.12 ADC regular sequence register 4 (ADC_SQR4) 1551
32.6.13 ADC regular data register (ADC_DR) 1551
32.6.14 ADC injected sequence register (ADC_JSQR) 1552
32.6.15 ADC offset y configuration register (ADC_OFCFGRy) 1553
32.6.16 ADC offset y register (ADC_OFRy) 1554
32.6.17 ADC gain compensation register (ADC_GCOMP) 1555
32.6.18 ADC injected channel y data register (ADC_JDRy) 1556
32.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR) 1556
32.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR) . . . 1557
32.6.21 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR) 1557
32.6.22 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR) 1558
32.6.23 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR) 1558
32.6.24 ADC analog watchdog 2 higher threshold register (ADC_AWD2HTR) 1559
32.6.25 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR) 1559
32.6.26 ADC analog watchdog 3 higher threshold register (ADC_AWD3HTR) 1560
32.6.27 ADC differential mode selection register (ADC_DIFSEL) 1560
32.6.28 ADC calibration factors (ADC_CALFACT) 1560
32.6.29 ADC option register (ADC_OR) 1562
32.7 ADC common registers 1563
32.7.1 ADC common status register (ADCC_CSR) 1563
32.7.2 ADC common control register (ADCC_CCR) 1564
32.7.3 ADC common regular data register for dual mode (ADCC_CDR) 1566
32.7.4 ADC common regular data register for dual mode (ADCC_CDR2) 1566
32.8 ADC register map 1567

33 Digital temperature sensor (DTS) 1571

33.1 Introduction 1571
33.2 DTS main features 1571
33.3 DTS functional description 1572
33.3.1 DTS block diagram 1572
33.3.2 DTS pins and internal signals 1572

33.3.3 DTS reset and clocks . . . 1573
33.3.4 DTS serial data adapter (SDA) . . . 1575
33.3.5 Alarms . . . 1581
33.3.6 Main APB programming routines . . . 1582
33.3.7 Temperature sensor configuration . . . 1585
33.4 DTS interrupts . . . 1587
33.5 DTS registers . . . 1588
33.5.1 DTS PVT common registers . . . 1588
33.5.2 PVT IRQ registers . . . 1590
33.5.3 TS common registers . . . 1594
33.5.4 TS individual registers . . . 1601
33.5.5 DTS register map . . . 1608

34 Voltage reference buffer (VREFBUF) . . . 1613
34.1 Introduction . . . 1613
34.2 VREFBUF implementation . . . 1613
34.3 VREFBUF functional description . . . 1613
34.4 VREFBUF trimming . . . 1614
34.5 VREFBUF power sequence . . . 1615
34.6 VREFBUF registers . . . 1616
34.6.1 VREFBUF control and status register (VREFBUF_CSR) . . . 1616
34.6.2 VREFBUF calibration control register (VREFBUF_CCR) . . . 1617
34.6.3 VREFBUF register map . . . 1617

35 Multi-function digital filter (MDF) . . . 1618
35.1 MDF introduction . . . 1618
35.2 MDF main features . . . 1619
35.3 MDF implementation . . . 1619
35.4 MDF functional description . . . 1621
35.4.1 MDF block diagram . . . 1621
35.4.2 MDF pins and internal signals . . . 1622
35.4.3 Serial input interfaces (SITF) . . . 1623
35.4.4 ADC slave interface (ADCITF) . . . 1628
35.4.5 Clock generator (CKGEN) . . . 1629
35.4.6 Bitstream matrix (BSMX) . . . 1631
35.4.7 Short-circuit detectors (SCD) . . . 1632

35.4.8 Digital filter processing (DFLT) . . . 1634
35.4.9 Out-of-limit detector (OLD) . . . 1644
35.4.10 Digital filter acquisition modes . . . 1647
35.4.11 Start-up sequence examples . . . 1657
35.4.12 Break interface . . . 1658
35.4.13 Data transfer to memory . . . 1659
35.4.14 Autonomous mode . . . 1664
35.4.15 Register protection . . . 1665
35.5 MDF low-power modes . . . 1666
35.6 MDF interrupts . . . 1666
35.7 MDF application informations . . . 1668
35.7.1 MDF configuration examples for audio capture . . . 1668
35.7.2 Programming examples . . . 1669
35.7.3 Connection examples . . . 1671
35.7.4 Global frequency response . . . 1672
35.7.5 Total MDF gain . . . 1673
35.8 MDF registers . . . 1677
35.8.1 MDF global control register (MDF_GCR) . . . 1678
35.8.2 MDF clock generator control register (MDF_CKGCR) . . . 1678
35.8.3 MDF serial interface control register x (MDF_SITFxCR) . . . 1681
35.8.4 MDF bitstream matrix control register x (MDF_BSMXxCR) . . . 1682
35.8.5 MDF digital filter control register x (MDF_DFLTxCR) . . . 1683
35.8.6 MDF digital filter configuration register x (MDF_DFLTxCICR) . . . 1685
35.8.7 MDF reshape filter configuration register x (MDF_DFLTxRSFR) . . . 1686
35.8.8 MDF integrator configuration register x (MDF_DFLTxINTR) . . . 1687
35.8.9 MDF out-of limit detector control register x (MDF_OLDxCR) . . . 1688
35.8.10 MDF OLDx low threshold register x (MDF_OLDxTHLR) . . . 1690
35.8.11 MDF OLDx high threshold register x (MDF_OLDxTHHR) . . . 1690
35.8.12 MDF delay control register x (MDF_DLYxCR) . . . 1691
35.8.13 MDF short circuit detector control register x (MDF_SCDxCR) . . . 1691
35.8.14 MDF DFLT0 interrupt enable register 0 (MDF_DFLT0IER) . . . 1692
35.8.15 MDF DFLTx interrupt enable register x (MDF_DFLTxIER) . . . 1694
35.8.16 MDF DFLT0 interrupt status register 0 (MDF_DFLT0ISR) . . . 1695
35.8.17 MDF DFLTx interrupt status register x (MDF_DFLTxISR) . . . 1697
35.8.18 MDF offset error compensation control register x (MDF_OECxCR) . 1698
35.8.19 MDF snapshot data register x (MDF_SNPSxDR) . . . 1699
35.8.20 MDF digital filter data register x (MDF_DFLTxDR) . . . 1699

37 Camera subsystem 1777

37.1 Introduction 1777
37.2 Camera path main features 1777
37.2.1 DCMI path main features 1777
37.2.2 DCMIPP path main features 1778
37.3 Camera subsystem implementation 1779
37.3.1 Hardware settings 1779
37.4 Camera subsystem functional description 1780
37.4.1 Camera subsystem block diagram 1780
37.4.2 Camera subsystem pins and external signal interface 1780
37.4.3 Camera subsystem reset and clocks 1781
37.4.4 Streaming from the camera subsystem to slave peripherals 1781
37.4.5 Camera subsystem security 1782
37.5 Camera subsystem programmable parameters 1783
37.5.1 Low-resolution parallel camera and DCMI 1784
37.5.2 High-resolution parallel camera and DCMIPP 1784
37.5.3 High-resolution CSI2 camera and DCMIPP 1785
37.5.4 Sensors over target resolution 1786
37.5.5 Sensors over target pixel rate 1786
37.5.6 Double sensors 1786
37.6 Camera subsystem interrupts 1787
37.7 Camera subsystem registers 1787

38 Digital camera interface (DCMI) 1788

38.1 Introduction 1788

38.2 DCMI main features 1788
38.3 DCMI functional description 1788
38.3.1 DCMI block diagram 1789
38.3.2 DCMI pins and internal signals 1789
38.3.3 DCMI clocks 1790
38.3.4 DCMI DMA interface 1790
38.3.5 DCMI physical interface 1790
38.3.6 DCMI synchronization 1792
38.3.7 DCMI capture modes 1794
38.3.8 DCMI crop feature 1795
38.3.9 DCMI JPEG format 1796
38.3.10 DCMI FIFO 1796
38.3.11 DCMI data format description 1797
38.4 DCMI interrupts 1799
38.5 DCMI registers 1799
38.5.1 DCMI control register (DCMI_CR) 1799
38.5.2 DCMI status register (DCMI_SR) 1802
38.5.3 DCMI raw interrupt status register (DCMI_RIS) 1802
38.5.4 DCMI interrupt enable register (DCMI_IER) 1803
38.5.5 DCMI masked interrupt status register (DCMI_MIS) 1804
38.5.6 DCMI interrupt clear register (DCMI_ICR) 1805
38.5.7 DCMI embedded synchronization code register (DCMI_ESCR) 1806
38.5.8 DCMI embedded synchronization unmask register (DCMI_ESUR) . 1806
38.5.9 DCMI crop window start (DCMI_CWSTRT) 1807
38.5.10 DCMI crop window size (DCMI_CWSIZE) 1808
38.5.11 DCMI data register (DCMI_DR) 1808
38.5.12 DCMI register map 1809

39 Digital camera interface pixel pipeline (DCMIPP) 1810
39.1 Introduction 1810
39.2 DCMIPP main features 1813
39.3 DCMIPP functional description 1815
39.3.1 DCMIPP block diagram 1815
39.3.2 DCMIPP pads and internal signals 1816
39.3.3 DCMIPP reset and clocks 1816
39.3.4 DCMIPP maximum resolution 1819

39.3.5 DCMIPP minimum requirements for frame structure 1820
39.3.6 Description of DCMIPP pixel format support 1820
39.4 DCMIPP input and flow control 1821
39.4.1 Parallel input interface 1822
39.4.2 Interface from CSI-2 host 1825
39.4.3 Input selection 1825
39.4.4 Flow selection 1826
39.4.5 Frame counter 1827
39.4.6 Frame control 1828
39.4.7 Pipe deactivation 1833
39.5 Pipe0 (dump pipe) 1834
39.5.1 Overview 1834
39.5.2 Decimation 1835
39.5.3 Crop/statistics selection/suppression 1835
39.5.4 Header insertion 1836
39.5.5 Dump counter 1837
39.5.6 Double buffer mode 1838
39.6 Pipe1 (ISP part) 1839
39.6.1 Overview 1839
39.6.2 Byte-to-pixel conversion 1839
39.6.3 Statistics removal 1840
39.6.4 Bad pixel removal 1841
39.6.5 Input decimation 1842
39.6.6 Black level calibration 1843
39.6.7 Exposure compensation and white-balance calibration 1844
39.6.8 Demosaicing 1845
39.6.9 Color conversion 1847
39.6.10 Contrast enhancement 1850
39.6.11 Statistics extraction 1851
39.7 Pipe1 (post-processing part) 1856
39.7.1 Overview 1856
39.7.2 Pixel 2D cropping 1856
39.7.3 Decimation pre-downsize 1857
39.7.4 Downsize 1858
39.7.5 Regions of interest (ROIs) 1860
39.7.6 Gamma conversion 1861
39.7.7 YUV conversion 1861

39.7.8 Chroma down-sampling . . . 1861
39.7.9 Pixel packing . . . 1862
39.7.10 Overrun detection . . . 1864
39.8 Pipe2 (post-processing) . . . 1865
39.8.1 Overview . . . 1865
39.8.2 Pipe1 and Pipe2 sharing image processing functions . . . 1866
39.9 Application use cases . . . 1866
39.9.1 Parallel interface camera sensor module . . . 1866
39.9.2 CSI2 camera sensor module . . . 1867
39.9.3 Force data type format from CSI-2 data flow (pixel pipes only) . . . 1874
39.10 Pixel format description . . . 1877
39.10.1 Parallel interface formats . . . 1877
39.10.2 Pixel pipe formats . . . 1879
39.10.3 Dump pipe formats . . . 1880
39.10.4 AXI IP-Plug . . . 1882
39.11 Shadow registers . . . 1888
39.12 DCMIPP low power modes . . . 1890
39.13 DCMIPP interrupts . . . 1891
39.13.1 Free-running DCMIPP . . . 1891
39.13.2 Interrupts . . . 1891
39.13.3 Event pins . . . 1894
39.14 DCMIPP registers . . . 1895
39.14.1 DCMIPP IP-Plug global register 1 (DCMIPP_IPGR1) . . . 1895
39.14.2 DCMIPP IP-Plug global register 2 (DCMIPP_IPGR2) . . . 1896
39.14.3 DCMIPP IP-Plug global register 3 (DCMIPP_IPGR3) . . . 1896
39.14.4 DCMIPP IP-Plug identification register (DCMIPP_IPGR8) . . . 1897
39.14.5 DCMIPP IP-Plug Clientx register 1 (DCMIPP_IPCxR1) . . . 1897
39.14.6 DCMIPP IP-Plug Clientx register 2 (DCMIPP_IPCxR2) . . . 1898
39.14.7 DCMIPP IP-Plug Clientx register 3 (DCMIPP_IPCxR3) . . . 1898
39.14.8 DCMIPP parallel interface control register (DCMIPP_PRCR) . . . 1899
39.14.9 DCMIPP parallel interface embedded synchronization code register (DCMIPP_PRESCR) . . . 1900
39.14.10 DCMIPP parallel interface embedded synchronization unmask register (DCMIPP_PRESUR) . . . 1901
39.14.11 DCMIPP parallel interface interrupt enable register (DCMIPP_PRIER) . . . 1902
39.14.12 DCMIPP parallel interface status register (DCMIPP_PRSR) . . . 1902

39.14.13 DCMIPP parallel interface interrupt clear register (DCMIPP_PRFCR) 1903
39.14.14 DCMIPP common configuration register (DCMIPP_CMCR) 1904
39.14.15 DCMIPP common frame counter register (DCMIPP_CMFRCR) 1905
39.14.16 DCMIPP common interrupt enable register (DCMIPP_CMIER) 1905
39.14.17 DCMIPP common status register 1 (DCMIPP_CMSR1) 1906
39.14.18 DCMIPP common status register 2 (DCMIPP_CMSR2) 1908
39.14.19 DCMIPP common interrupt clear register (DCMIPP_CMFCR) 1910
39.14.20 DCMIPP Pipe0 flow selection configuration register (DCMIPP_P0FSCR) 1912
39.14.21 DCMIPP Pipe0 flow control configuration register (DCMIPP_P0FCTCR) 1912
39.14.22 DCMIPP Pipe0 statistic/crop start register (DCMIPP_P0SCSTR) . . . 1913
39.14.23 DCMIPP Pipe0 statistic/crop size register (DCMIPP_P0SCSZR) . . . 1914
39.14.24 DCMIPP Pipe0 dump counter register (DCMIPP_P0DCCNTR) 1914
39.14.25 DCMIPP Pipe0 dump limit register (DCMIPP_P0DCLMTR) 1915
39.14.26 DCMIPP Pipe0 pixel packer configuration register (DCMIPP_P0PPCR) 1915
39.14.27 DCMIPP Pipe0 pixel packer Memory0 address register 1 (DCMIPP_P0PPM0AR1) 1917
39.14.28 DCMIPP Pipe0 pixel packer Memory0 address register 2 (DCMIPP_P0PPM0AR2) 1917
39.14.29 DCMIPP Pipe0 status Memory0 address register (DCMIPP_P0STM0AR) 1917
39.14.30 DCMIPP Pipe0 interrupt enable register (DCMIPP_P0IER) 1918
39.14.31 DCMIPP Pipe0 status register (DCMIPP_P0SR) 1919
39.14.32 DCMIPP Pipe0 interrupt clear register (DCMIPP_P0FCR) 1920
39.14.33 DCMIPP Pipe0 current flow selection configuration register (DCMIPP_P0CFSCR) 1920
39.14.34 DCMIPP Pipe0 current flow control configuration register (DCMIPP_P0CFCTCR) 1921
39.14.35 DCMIPP Pipe0 current statistic/crop start register (DCMIPP_P0CSCSTR) 1922
39.14.36 DCMIPP Pipe0 current statistic/crop size register (DCMIPP_P0CSCSZR) 1922
39.14.37 DCMIPP Pipe0 current pixel packer configuration register (DCMIPP_P0CPPCR) 1923
39.14.38 DCMIPP Pipe0 current pixel packer Memory0 address register 1 (DCMIPP_P0CPPM0AR1) 1925
39.14.39 DCMIPP Pipe0 current pixel packer Memory0 address register 2 (DCMIPP_P0CPPM0AR2) 1925

39.14.40 DCMIPP Pipe1 flow selection configuration register (DCMIPP_P1FSCR) 1926
39.14.41 DCMIPP Pipe1 stat removal configuration register (DCMIPP_P1SRCR) 1927
39.14.42 DCMIPP Pipe1 bad pixel removal control register (DCMIPP_P1BPRCR) 1928
39.14.43 DCMIPP Pipe1 bad pixel removal status register (DCMIPP_P1BPRSR) 1928
39.14.44 DCMIPP Pipe1 decimation register (DCMIPP_P1DECR) 1929
39.14.45 DCMIPP Pipe1 black level calibration control register (DCMIPP_P1BLCCR) 1929
39.14.46 DCMIPP Pipe1 exposure control register 1 (DCMIPP_P1EXCR1) . . 1930
39.14.47 DCMIPP Pipe1 exposure control register 2 (DCMIPP_P1EXCR2) . . 1930
39.14.48 DCMIPP Pipe1 statistics1 control register (DCMIPP_P1ST1CR) . . . 1931
39.14.49 DCMIPP Pipe1 statistics 2 control register (DCMIPP_P1ST2CR) . . . 1932
39.14.50 DCMIPP Pipe1 statistics 3 control register (DCMIPP_P1ST3CR) . . . 1933
39.14.51 DCMIPP Pipe1 statistics window start register (DCMIPP_P1STSTR) 1934
39.14.52 DCMIPP Pipe1 statistics window size register (DCMIPP_P1STSZR) 1934
39.14.53 DCMIPP Pipe1 statistics 1 status register (DCMIPP_P1ST1SR) . . . 1935
39.14.54 DCMIPP Pipe1 statistics 2 status register (DCMIPP_P1ST2SR) . . . 1936
39.14.55 DCMIPP Pipe1 statistics 3 status register (DCMIPP_P1ST3SR) . . . 1936
39.14.56 DCMIPP Pipe1 demosaicing configuration register (DCMIPP_P1DMCR) 1936
39.14.57 DCMIPP Pipe1 ColorConv configuration register (DCMIPP_P1CCCR) 1937
39.14.58 DCMIPP Pipe1 ColorConv red coefficient register 1 (DCMIPP_P1CCRR1) 1938
39.14.59 DCMIPP Pipe1 ColorConv red coefficient register 2 (DCMIPP_P1CCRR2) 1938
39.14.60 DCMIPP Pipe1 ColorConv green coefficient register 1 (DCMIPP_P1CCGR1) 1939
39.14.61 DCMIPP Pipe1 ColorConv green coefficient register 2 (DCMIPP_P1CCGR2) 1939
39.14.62 DCMIPP Pipex ColorConv blue coefficient register 1 (DCMIPP_P1CCBR1) 1940
39.14.63 DCMIPP Pipe1 ColorConv blue coefficient register 2 (DCMIPP_P1CCBR2) 1940
39.14.64 DCMIPP Pipe1 contrast control register 1 (DCMIPP_P1CTCR1) . . . 1941
39.14.65 DCMIPP Pipe1 contrast control register 2 (DCMIPP_P1CTCR2) . . . 1941

39.14.66 DCMIPP Pipe1 contrast control register 3 (DCMIPP_P1CTCR3) . . . 1942
39.14.67 DCMIPP Pipex flow control configuration register (DCMIPP_PxFCTCR) 1942
39.14.68 DCMIPP Pipex crop window start register (DCMIPP_PxCRSTR) . . . 1943
39.14.69 DCMIPP Pipex crop window size register (DCMIPP_PxCRSZR) . . . 1944
39.14.70 DCMIPP Pipex decimation register (DCMIPP_PxDCCR) 1944
39.14.71 DCMIPP Pipex downsize configuration register (DCMIPP_PxDSCR) 1945
39.14.72 DCMIPP Pipex downsize ratio register (DCMIPP_PxDSRTIOR) . . . 1945
39.14.73 DCMIPP Pipex downsize destination size register (DCMIPP_PxDSSZR) 1946
39.14.74 DCMIPP Pipex common ROI configuration register (DCMIPP_PxCMRICR) 1946
39.14.75 DCMIPP Pipe1 ROIx configuration register 1 (DCMIPP_P1RIxCR1) 1948
39.14.76 DCMIPP Pipe1 ROIx configuration register 2 (DCMIPP_P1RIxCR2) 1948
39.14.77 DCMIPP Pipex gamma configuration register (DCMIPP_PxGMCR) . 1949
39.14.78 DCMIPP Pipe1 YUVConv configuration register (DCMIPP_P1YUVCR) 1949
39.14.79 DCMIPP Pipe1 YUVConv red coefficient register 1 (DCMIPP_P1YUVRR1) 1949
39.14.80 DCMIPP Pipe1 YUVConv red coefficient register 2 (DCMIPP_P1YUVRR2) 1950
39.14.81 DCMIPP Pipe1 YUVConv green coefficient register 1 (DCMIPP_P1YUVGR1) 1950
39.14.82 DCMIPP Pipe1 YUVConv green coefficient register 2 (DCMIPP_P1YUVGR2) 1951
39.14.83 DCMIPP Pipe1 YUVConv blue coefficient register 1 (DCMIPP_P1YUVBR1) 1951
39.14.84 DCMIPP Pipe1 YUV blue coefficient register 2 (DCMIPP_P1YUVBR2) 1951
39.14.85 DCMIPP Pipe1 pixel packer configuration register (DCMIPP_P1PPCR) 1952
39.14.86 DCMIPP Pipe1 pixel packer Memory0 address register 1 (DCMIPP_P1PPM0AR1) 1953
39.14.87 DCMIPP Pipe1 pixel packer Memory0 address register 2 (DCMIPP_P1PPM0AR2) 1954
39.14.88 DCMIPP Pipex pixel packer Memory0 pitch register (DCMIPP_PxPPM0PR) 1954
39.14.89 DCMIPP Pipex status Memory0 address register (DCMIPP_PxSTM0AR) 1955
39.14.90 DCMIPP Pipex pixel packer Memory1 address register 1 (DCMIPP_PxPPM1AR1) 1955

39.14.91 DCMIPP Pipex pixel packer Memory1 address register 2 (DCMIPP_PxPPM1AR2) 1955
39.14.92 DCMIPP Pipex pixel packer Memory1 pitch register (DCMIPP_PxPPM1PR) 1956
39.14.93 DCMIPP Pipex status Memory1 address register (DCMIPP_PxSTM1AR) 1956
39.14.94 DCMIPP Pipex pixel packer memory2 address register 1 (DCMIPP_PxPPM2AR1) 1957
39.14.95 DCMIPP Pipex pixel packer memory2 address register 2 (DCMIPP_PxPPM2AR2) 1957
39.14.96 DCMIPP Pipex status Memory2 address register (DCMIPP_PxSTM2AR) 1957
39.14.97 DCMIPP Pipe1 interrupt enable register (DCMIPP_P1IER) 1958
39.14.98 DCMIPP Pipe1 status register (DCMIPP_P1SR) 1959
39.14.99 DCMIPP Pipe1 interrupt clear register (DCMIPP_P1FCR) 1960
39.14.100 DCMIPP Pipe1 current flow selection configuration register (DCMIPP_P1CFSCR) 1960
39.14.101 DCMIPP Pipe1 current bad pixel removal register (DCMIPP_P1CBPRCR) 1961
39.14.102 DCMIPP Pipe1 current black level calibration control register (DCMIPP_P1CBLCCR) 1962
39.14.103 DCMIPP Pipe1 current exposure control register 1 (DCMIPP_P1CEXCR1) 1962
39.14.104 DCMIPP Pipe1 current exposure control register 2 (DCMIPP_P1CEXCR2) 1963
39.14.105 DCMIPP Pipe1 current statistics 1 control register (DCMIPP_P1CST1CR) 1964
39.14.106 DCMIPP Pipe1 current statistics 2 control register (DCMIPP_P1CST2CR) 1965
39.14.107 DCMIPP Pipe1 current statistics 3 control register (DCMIPP_P1CST3CR) 1966
39.14.108 DCMIPP Pipe1 current statistics window start register (DCMIPP_P1CSTSTR) 1967
39.14.109 DCMIPP Pipe1 current statistics window size register (DCMIPP_P1CSTSZR) 1967
39.14.110 DCMIPP Pipe1 current ColorConv configuration register (DCMIPP_P1CCCCR) 1968
39.14.111 DCMIPP Pipe1 current ColorConv red coefficient register 1 (DCMIPP_P1CCCRR1) 1968
39.14.112 DCMIPP Pipe1 current ColorConv red coefficient register 2 (DCMIPP_P1CCCRR2) 1969
39.14.113 DCMIPP Pipe1 current ColorConv green coefficient register 1 (DCMIPP_P1CCCGR1) 1969

39.14.114DCMIPP Pipe1 current ColorConv green coefficient register 2 (DCMIPP_P1CCCGR2) 1970
39.14.115DCMIPP Pipex current ColorConv blue coefficient register 1 (DCMIPP_P1CCCBR1) 1970
39.14.116DCMIPP Pipe1 current ColorConv blue coefficient register 2 (DCMIPP_P1CCCBR2) 1971
39.14.117DCMIPP Pipe1 current contrast control register 1 (DCMIPP_P1CCTCR1) 1971
39.14.118DCMIPP Pipe1 current contrast control register 2 (DCMIPP_P1CCTCR2) 1972
39.14.119DCMIPP Pipe1 current contrast control register 3 (DCMIPP_P1CCTCR3) 1972
39.14.120DCMIPP Pipex current flow control configuration register (DCMIPP_PxCFCTCR) 1973
39.14.121DCMIPP Pipex current crop window start register (DCMIPP_PxCCRSTR) 1974
39.14.122DCMIPP Pipex current crop window size register (DCMIPP_PxCCRSZR) 1974
39.14.123DCMIPP Pipex current decimation register (DCMIPP_PxCDCCR) . 1975
39.14.124DCMIPP Pipex current downsize configuration register (DCMIPP_PxCDSCR) 1975
39.14.125DCMIPP Pipex current downsize ratio register (DCMIPP_PxCDSRTIOR) 1976
39.14.126DCMIPP Pipex current downsize destination size register (DCMIPP_PxCDSSZR) 1976
39.14.127DCMIPP Pipex current common ROI configuration register (DCMIPP_PxCCMRICR) 1977
39.14.128DCMIPP Pipe1 current ROIx configuration register 1 (DCMIPP_P1CRIxCR1) 1978
39.14.129DCMIPP Pipe1 current ROIx configuration register 2 (DCMIPP_P1CRIxCR2) 1978
39.14.130DCMIPP Pipe1 current pixel packer configuration register (DCMIPP_P1CPPCR) 1979

40 CSI-2 Host (CSI) 2009
40.1 Introduction 2009
40.2 Standard and references 2009
40.3 Glossary 2009
40.4 CSI-2 Host main features 2010
40.5 CSI-2 Host functional description 2010
40.5.1 General description 2010

40.5.2 System level architecture . . . 2012
40.5.3 CSI-2 Host reset and clocks . . . 2013
40.5.4 Lane merger . . . 2014
40.5.5 Clock changer . . . 2015
40.5.6 Low-level protocol (LLP) . . . 2016
40.5.7 CSI-2 Host protocol output . . . 2026
40.6 CSI-2 Host programming guide . . . 2026
40.6.1 CSI-2 PHY setup . . . 2026
40.6.2 CSI-2 Host controller setup and data reception start . . . 2027
40.6.3 Data reception stop . . . 2028
40.7 CSI-2 Host low-power modes . . . 2028
40.8 CSI-2 Host interrupts and errors . . . 2028
40.8.1 Error handling . . . 2030
40.8.2 Interrupt handling . . . 2032
40.9 CSI-2 Host registers . . . 2033
40.9.1 CSI-2 Host control register (CSI_CR) . . . 2033
40.9.2 CSI-2 Host DPHY_RX control register (CSI_PCR) . . . 2035
40.9.3 CSI-2 Host virtual channel x configuration register 1 (CSI_VCxCFGR1) . . . 2036
40.9.4 CSI-2 Host virtual channel x configuration register 2 (CSI_VCxCFGR2) . . . 2038
40.9.5 CSI-2 Host virtual channel x configuration register 3 (CSI_VCxCFGR3) . . . 2039
40.9.6 CSI-2 Host virtual channel x configuration register 4 (CSI_VCxCFGR4) . . . 2040
40.9.7 CSI-2 Host line byte x configuration register (CSI_LBxCFGR) . . . 2041
40.9.8 CSI-2 Host timer x configuration register (CSI_TIMxCFGR) . . . 2042
40.9.9 CSI-2 Host lane merger configuration register (CSI_LMCFGR) . . . 2042
40.9.10 CSI-2 Host program interrupt register (CSI_PRGITR) . . . 2043
40.9.11 CSI-2 Host watchdog register (CSI_WDR) . . . 2047
40.9.12 CSI-2 Host interrupt enable register 0 (CSI_IER0) . . . 2047
40.9.13 CSI-2 Host interrupt enable register 1 (CSI_IER1) . . . 2050
40.9.14 CSI-2 Host status register 0 (CSI_SR0) . . . 2052
40.9.15 CSI-2 Host status register 1 (CSI_SR1) . . . 2054
40.9.16 CSI-2 Host flag clear register 0 (CSI_FCR0) . . . 2056
40.9.17 CSI-2 Host flag clear register 1 (CSI_FCR1) . . . 2057
40.9.18 CSI-2 Host short packet data field register (CSI_SPDFR) . . . 2058
40.9.19 CSI-2 Host error register 1 (CSI_ERR1) . . . 2059

40.9.20 CSI-2 Host error register 2 (CSI_ERR2) 2060
40.10 CSI PHY registers 2060
40.10.1 CSI PHY reset control register (CSI_PRCR) 2060
40.10.2 CSI PHY mode control register (CSI_PMCR) 2061
40.10.3 CSI PHY frequency control register (CSI_PFCR) 2062
40.10.4 CSI PHY test control register 0 (CSI_PTCR0) 2062
40.10.5 CSI PHY test control register 1 (CSI_PTCR1) 2063
40.10.6 CSI PHY test status register (CSI_PTSR) 2063
40.11 CSI-2 Host and PHY register map 2063

41 Parallel synchronous slave interface (PSSI) 2067
41.1 Introduction 2067
41.2 PSSI main features 2067
41.3 PSSI functional description 2067
41.3.1 PSSI block diagram 2068
41.3.2 PSSI pins and internal signals 2068
41.3.3 PSSI clock 2069
41.3.4 PSSI data management 2069
41.3.5 PSSI optional control signals 2071
41.4 PSSI interrupts 2074
41.5 PSSI registers 2075
41.5.1 PSSI control register (PSSI_CR) 2075
41.5.2 PSSI status register (PSSI_SR) 2076
41.5.3 PSSI raw interrupt status register (PSSI_RIS) 2077
41.5.4 PSSI interrupt enable register (PSSI_IER) 2078
41.5.5 PSSI masked interrupt status register (PSSI_MIS) 2078
41.5.6 PSSI interrupt clear register (PSSI_ICR) 2079
41.5.7 PSSI data register (PSSI_DR) 2079
41.5.8 PSSI register map 2080

42 Display subsystem 2081
42.1 Introduction 2081
42.2 Display subsystem main features 2081
42.3 Display subsystem implementation 2081
42.4 Display subsystem functional description 2081
42.4.1 Display subsystem block diagram 2081

42.4.2 Display subsystem pins and external signal interface 2082
42.4.3 Display subsystem clocks 2082

43 LCD-TFT display controller (LTDC) 2087
43.1 LTDC introduction 2087
43.2 LTDC main features 2087
43.3 LTDC functional description 2088
43.3.1 LTDC block diagram 2088
43.3.2 LTDC pins and internal signals 2088
43.3.3 LTDC reset and clocks 2089
43.4 LTDC configuration parameters 2091
43.4.1 AXI master 2091
43.4.2 Input layer definition and cropping 2092
43.4.3 Input pixel format 2093
43.4.4 YUV planar 2095
43.4.5 YUV-to-RGB color conversion 2096
43.4.6 Horizontal or vertical mirroring 2097
43.4.7 Default layer color 2098
43.4.8 Color look-up table (CLUT) 2098
43.4.9 Transparency color keying 2099
43.4.10 Display composition - windowing 2099
43.4.11 Display composition - blending 2100
43.4.12 Gamma correction 2102
43.4.13 YUV output conversion 2102
43.4.14 Dithering 2103
43.4.15 CRC hashing 2104
43.4.16 Display timing 2104
43.4.17 Output interface polarity 2106
43.4.18 Shadow registers 2107
43.4.19 General control 2108
43.4.20 Hardware trigger generation 2108
43.4.21 Provision for a secure layer 2109

43.5 LTDC interrupts 2110
43.6 LTDC programming procedure 2111
43.7 LTDC registers 2112
43.7.1 LTDC synchronization size configuration register (LTDC_SSCR) . . . 2112
43.7.2 LTDC back porch configuration register (LTDC_BPCR) 2112
43.7.3 LTDC active width configuration register (LTDC_AWCR) 2113
43.7.4 LTDC total width configuration register (LTDC_TWCR) 2114
43.7.5 LTDC global control register (LTDC_GCR) 2114
43.7.6 LTDC shadow reload configuration register (LTDC_SRCR) 2116
43.7.7 LTDC gamma correction configuration register (LTDC_GCCR) 2116
43.7.8 LTDC background color configuration register (LTDC_BCCR) 2117
43.7.9 LTDC interrupt enable register (LTDC_IER) 2118
43.7.10 LTDC interrupt status register (LTDC_ISR) 2119
43.7.11 LTDC interrupt clear register (LTDC_ICR) 2119
43.7.12 LTDC line interrupt position configuration register (LTDC_LIPCR) . . 2120
43.7.13 LTDC current position status register (LTDC_CPSR) 2121
43.7.14 LTDC current display status register (LTDC_CDSR) 2121
43.7.15 LTDC external display control register (LTDC_EDCR) 2122
43.7.16 LTDC interrupt enable register 2 (LTDC_IER2) 2122
43.7.17 LTDC interrupt status register 2 (LTDC_ISR2) 2123
43.7.18 LTDC interrupt clear register 2 (LTDC_ICR2) 2124
43.7.19 LTDC line interrupt position configuration register 2 (LTDC_LIPCR2) 2125
43.7.20 LTDC expected CRC register (LTDC_ECRCR) 2125
43.7.21 LTDC computed CRC register (LTDC_CCRCR) 2126
43.7.22 LTDC FIFO underrun threshold register (LTDC_FUTR) 2126
43.7.23 LTDC layer x configuration 0 register (LTDC_LxC0R) 2127
43.7.24 LTDC layer x configuration 1 register (LTDC_LxC1R) 2128
43.7.25 LTDC layer x reload control register (LTDC_LxRCR) 2128
43.7.26 LTDC layer x control register (LTDC_LxCR) 2129
43.7.27 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR) 2130
43.7.28 LTDC layer x window vertical position configuration register (LTDC_LxWVPCR) 2131
43.7.29 LTDC layer x color keying configuration register (LTDC_LxCKCR) 2131
43.7.30 LTDC layer x pixel format configuration register (LTDC_LxPFCR) 2132

43.7.31 LTDC layer x constant alpha configuration register (LTDC_LxCACR) 2132
43.7.32 LTDC layer x default color configuration register (LTDC_LxDCCR) 2133
43.7.33 LTDC layer x blending factors configuration register (LTDC_LxBFCR) 2133
43.7.34 LTDC layer x burst length configuration register (LTDC_LxBLCR) 2134
43.7.35 LTDC layer x planar configuration register (LTDC_LxPCR) 2135
43.7.36 LTDC layer x color frame buffer address register (LTDC_LxCFBAR) 2136
43.7.37 LTDC layer x color frame buffer length register (LTDC_LxCFBLR) 2136
43.7.38 LTDC layer x color frame buffer line number register (LTDC_LxCFBLNR) 2137
43.7.39 LTDC layer 1 auxiliary frame buffer address 0 register (LTDC_L1AFBA0R) 2137
43.7.40 LTDC layer 1 auxiliary frame buffer address 1 register (LTDC_L1AFBA1R) 2138
43.7.41 LTDC layer 1 auxiliary frame buffer length register (LTDC_L1AFBLR) 2138
43.7.42 LTDC layer 1 auxiliary frame buffer line number register (LTDC_L1AFBLNR) 2139
43.7.43 LTDC layer x CLUT write register (LTDC_LxCLUTWR) 2139
43.7.44 LTDC layer x conversion YCbCr RGB 0 register (LTDC_LxCYR0R) . 2140
43.7.45 LTDC layer x conversion YCbCr RGB 1 register (LTDC_LxCYR1R) . 2140
43.7.46 LTDC layer x flexible pixel format 0 register (LTDC_LxFPF0R) 2141
43.7.47 LTDC layer x flexible pixel format 1 register (LTDC_LxFPF1R) 2141
43.7.48 LTDC register map 2142

45.7.18 VENC encoder control register 4 (VENC_SWREG18) 2161
45.7.19 VENC encoder control register 5 (VENC_SWREG19) 2161
45.7.20 VENC encoder control register 6 (VENC_SWREG20) 2162
45.7.21 VENC encoder control register 7 (VENC_SWREG21) 2162
45.7.22 VENC stream header remainder MSB bits register (VENC_SWREG22) 2162
45.7.23 VENC stream header remainder LSB bits register (VENC_SWREG23) 2163
45.7.24 VENC stream buffer limit/output stream size register (VENC_SWREG24) 2163
45.7.25 VENC encoder control register 8 (VENC_SWREG25) 2163
45.7.26 VENC intra-slice bitmap register (VENC_SWREG26) 2164
45.7.27 VENC encoder control register 9 (VENC_SWREG27) 2164
45.7.28 VENC encoder control register 10 (VENC_SWREG28) 2164
45.7.29 VENC encoder control register 11 (VENC_SWREG29) 2165
45.7.30 VENC encoder control register 12 (VENC_SWREG30) 2165
45.7.31 VENC encoder control register 13 (VENC_SWREG31) 2165
45.7.32 VENC encoder control register 14 (VENC_SWREG32) 2166
45.7.33 VENC encoder control register 15 (VENC_SWREG33) 2166
45.7.34 VENC encoder control register 16 (VENC_SWREG34) 2166
45.7.35 VENC H.264 checkpoint word error 5-6/encoder control register 17 (VENC_SWREG35) 2167
45.7.36 VENC H.264 checkpoint delta QP 1-8/encoder control register 18 (VENC_SWREG36) 2167
45.7.37 VENC encoder control register 19, stream start offset (VENC_SWREG37) 2167
45.7.38 VENC macroblock count output register (VENC_SWREG38) 2168
45.7.39 VENC base address for next pic luminance register (VENC_SWREG39) 2168
45.7.40 VENC stabilization mode control register (VENC_SWREG40) 2168
45.7.41 VENC stabilization motion sum div8 output register (VENC_SWREG41) 2169
45.7.42 VENC stabilization GMV output, matrix 1, up-left position output register (VENC_SWREG42) 2169
45.7.43 VENC stabilization GMV output, matrix 2, up position output register (VENC_SWREG43) 2169

45.7.44 VENC stabilization matrix 3, up-right position output register (VENC_SWREG44) 2170
45.7.45 VENC stabilization matrix 4, left position output register (VENC_SWREG45) 2170
45.7.46 VENC stabilization matrix 5, GMV position output register (VENC_SWREG46) 2170
45.7.47 VENC stabilization matrix 6, right position output register (VENC_SWREG47) 2171
45.7.48 VENC stabilization matrix 7, down-left position output register (VENC_SWREG48) 2171
45.7.49 VENC stabilization matrix 8, down position output register (VENC_SWREG49) 2171
45.7.50 VENC stabilization matrix 9, down-right position output register (VENC_SWREG50) 2172
45.7.51 VENC base address for cabac context tables H264 register (VENC_SWREG51) 2172
45.7.52 VENC base address for MV output writing register (VENC_SWREG52) 2172
45.7.53 VENC RGB to YUV conversion coefficient A - B register (VENC_SWREG53) 2173
45.7.54 VENC RGB to YUV conversion coefficient C - E register (VENC_SWREG54) 2173
45.7.55 VENC RGB to YUV conversion coefficient F, RGB mask MSB bit position register (VENC_SWREG55) 2173
45.7.56 VENC intra area register (VENC_SWREG56) 2174
45.7.57 VENC CIR intra mb position register (VENC_SWREG57) 2174
45.7.58 VENC intra slice bitmap for slices 0..31/base address for 1st DCT partition register (VENC_SWREG58) 2174
45.7.59 VENC intra slice bitmap for slices 32..63/base address for 2nd DCT partition register (VENC_SWREG59) 2175
45.7.60 VENC 1st ROI area register (VENC_SWREG60) 2175
45.7.61 VENC 2nd ROI area register (VENC_SWREG61) 2175
45.7.62 VENC ROI area delta QP, MV register (VENC_SWREG62) 2176
45.7.63 VENC synthesis configuration register encoder 0 register (VENC_SWREG63) 2176
45.7.64 VENC JPEG luma quantization 1/intra 16x16 mode 0-1 penalty register (VENC_SWREG64) 2176
45.7.65 VENC JPEG luma quantization 2/intra 16x16 mode 2-3 penalty register (VENC_SWREG65) 2177
45.7.66 VENC JPEG luma quantization 3/intra 4x4 mode 0-1 penalty register (VENC_SWREG66) 2177
45.7.67 VENC JPEG luma quantization 4/intra 4x4 mode 2-3 penalty register (VENC_SWREG67) 2177

45.7.68 VENC JPEG luma quantization 5/intra 4x4 mode 4-5 penalty register (VENC_SWREG68) 2178
45.7.69 VENC JPEG luma quantization 6/intra 4x4 mode 6-7 penalty register (VENC_SWREG69) 2178
45.7.70 VENC JPEG luma quantization 7/intra 4x4 mode 8-9 penalty register (VENC_SWREG70) 2178
45.7.71 VENC JPEG luma quantization 8/base address for segmentation map register (VENC_SWREG71) 2179
45.7.72 VENC JPEG luma quantization 9/segment1 parameter register (VENC_SWREG72) 2179
45.7.73 VENC JPEG luma quantization 10/segment1 parameter register (VENC_SWREG73) 2179
45.7.74 VENC JPEG luma quantization 11/segment1 parameter register (VENC_SWREG74) 2180
45.7.75 VENC JPEG luma quantization 12/segment1 parameter register (VENC_SWREG75) 2180
45.7.76 VENC JPEG luma quantization 13/segment1 parameter register (VENC_SWREG76) 2180
45.7.77 VENC JPEG luma quantization 14/segment1 parameter register (VENC_SWREG77) 2181

46.1 Introduction . . . 2258
46.2 JPEG codec main features . . . 2258
46.3 JPEG codec block functional description . . . 2259
46.3.1 General description . . . 2259
46.3.2 JPEG internal signals . . . 2259
46.3.3 JPEG decoding procedure . . . 2260
46.3.4 JPEG encoding procedure . . . 2262
46.4 JPEG codec interrupts . . . 2265
46.5 JPEG codec registers . . . 2265
46.5.1 JPEG codec control register (JPEG_CONFR0) . . . 2265
46.5.2 JPEG codec configuration register 1 (JPEG_CONFR1) . . . 2266
46.5.3 JPEG codec configuration register 2 (JPEG_CONFR2) . . . 2267
46.5.4 JPEG codec configuration register 3 (JPEG_CONFR3) . . . 2267
46.5.5 JPEG codec configuration register x (JPEG_CONFRx) . . . 2268
46.5.6 JPEG control register (JPEG_CR) . . . 2269
46.5.7 JPEG status register (JPEG_SR) . . . 2270
46.5.8 JPEG clear flag register (JPEG_CFR) . . . 2271
46.5.9 JPEG data input register (JPEG_DIR) . . . 2272
46.5.10 JPEG data output register (JPEG_DOR) . . . 2272
46.5.11 JPEG quantization memory x (JPEG_QMEMx_y) . . . 2273
46.5.12 JPEG Huffman min (JPEG_HUFFMINx_y) . . . 2273
46.5.13 JPEG Huffman min x (JPEG_HUFFMINx_y) . . . 2274
46.5.14 JPEG Huffman base (JPEG_HUFFBASEx) . . . 2274
46.5.15 JPEG Huffman symbol (JPEG_HUFFSYMBx) . . . 2275
46.5.16 JPEG DHT memory (JPEG_DHTMEMx) . . . 2276
46.5.17 JPEG Huffman encoder ACx (JPEG_HUFFENC_ACx_y) . . . 2276
46.5.18 JPEG Huffman encoder DCx (JPEG_HUFFENC_DCx_y) . . . 2277
46.5.19 JPEG codec register map . . . 2278

47 True random number generator (RNG) . . . 2280
47.1 Introduction . . . 2280
47.2 RNG main features . . . 2280

47.3 RNG functional description . . . 2281
47.3.1 RNG block diagram . . . 2281
47.3.2 RNG internal signals . . . 2281
47.3.3 Random number generation . . . 2281
47.3.4 RNG initialization . . . 2284
47.3.5 RNG operation . . . 2285
47.3.6 RNG clocking . . . 2287
47.3.7 Error management . . . 2287
47.3.8 RNG low-power use . . . 2288
47.4 RNG interrupts . . . 2289
47.5 RNG processing time . . . 2289
47.6 RNG entropy source validation . . . 2290
47.6.1 Introduction . . . 2290
47.6.2 Validation conditions . . . 2290
47.7 RNG registers . . . 2291
47.7.1 RNG control register (RNG_CR) . . . 2291
47.7.2 RNG status register (RNG_SR) . . . 2293
47.7.3 RNG data register (RNG_DR) . . . 2294
47.7.4 RNG noise source control register (RNG_NSCR) . . . 2295
47.7.5 RNG health test control register (RNG_HTCR) . . . 2296
47.7.6 RNG register map . . . 2296

48 Secure AES coprocessor (SAES) . . . 2297
48.1 Introduction . . . 2297
48.2 SAES main features . . . 2297
48.3 SAES implementation . . . 2298
48.4 SAES functional description . . . 2298
48.4.1 SAES block diagram . . . 2298
48.4.2 SAES internal signals . . . 2299
48.4.3 SAES reset and clocks . . . 2300
48.4.4 SAES symmetric cipher implementation . . . 2300
48.4.5 SAES encryption or decryption typical usage . . . 2301
48.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication . . . 2303
48.4.7 SAES ciphertext stealing and data padding . . . 2304
48.4.8 SAES suspend and resume operations . . . 2304

48.4.9 SAES basic chaining modes (ECB, CBC) 2305
48.4.10 SAES counter (CTR) mode 2309
48.4.11 SAES Galois/counter mode (GCM) 2311
48.4.12 SAES Galois message authentication code (GMAC) 2315
48.4.13 SAES counter with CBC-MAC (CCM) 2317
48.4.14 SAES operation with wrapped keys 2322
48.4.15 SAES operation with shared keys 2326
48.4.16 SAES data registers and data swapping 2327
48.4.17 SAES key registers 2330
48.4.18 SAES initialization vector registers 2331
48.4.19 SAES error management 2332
48.5 SAES interrupts 2334
48.6 SAES DMA requests 2334
48.7 SAES processing latency 2335
48.8 SAES registers 2337
48.8.1 SAES control register (SAES_CR) 2337
48.8.2 SAES status register (SAES_SR) 2340
48.8.3 SAES data input register (SAES_DINR) 2341
48.8.4 SAES data output register (SAES_DOUTR) 2342
48.8.5 SAES key register 0 (SAES_KEYR0) 2342
48.8.6 SAES key register 1 (SAES_KEYR1) 2343
48.8.7 SAES key register 2 (SAES_KEYR2) 2343
48.8.8 SAES key register 3 (SAES_KEYR3) 2343
48.8.9 SAES initialization vector register 0 (SAES_IVR0) 2344
48.8.10 SAES initialization vector register 1 (SAES_IVR1) 2344
48.8.11 SAES initialization vector register 2 (SAES_IVR2) 2344
48.8.12 SAES initialization vector register 3 (SAES_IVR3) 2345
48.8.13 SAES key register 4 (SAES_KEYR4) 2345
48.8.14 SAES key register 5 (SAES_KEYR5) 2345
48.8.15 SAES key register 6 (SAES_KEYR6) 2346
48.8.16 SAES key register 7 (SAES_KEYR7) 2346
48.8.17 SAES suspend registers (SAES_SUSPRx) 2346
48.8.18 SAES interrupt enable register (SAES_IER) 2347
48.8.19 SAES interrupt status register (SAES_ISR) 2348
48.8.20 SAES interrupt clear register (SAES_ICR) 2349
48.8.21 SAES register map 2350

49 Cryptographic processor (CRYP) 2352

49.1 Introduction 2352

49.2 CRYP main features 2352

49.3 CRYP implementation 2353

49.4 CRYP functional description 2354

49.4.1 CRYP block diagram 2354

49.4.2 CRYP internal signals 2355

49.4.3 CRYP reset and clocks 2355

49.4.4 CRYP symmetric cipher implementation 2355

49.4.5 CRYP encryption/ decryption typical usage 2356

49.4.6 CRYP authenticated encryption, decryption, and cipher-based message authentication 2359

49.4.7 CRYP ciphertext stealing and data padding 2359

49.4.8 CRYP suspend and resume operations 2360

49.4.9 CRYP basic chaining modes (ECB, CBC) 2360

49.4.10 CRYP counter mode (CTR) 2365

49.4.11 CRYP AES Galois/counter mode (GCM) 2367

49.4.12 CRYP AES Galois message authentication code (GMAC) 2373

49.4.13 CRYP AES Counter with CBC-MAC (CCM) 2374

49.4.14 AES key sharing with secure AES co-processor 2379

49.4.15 CRYP data registers and data swapping 2380

49.4.16 CRYP key registers 2383

49.4.17 CRYP initialization vector registers 2383

49.4.18 CRYP error management 2384

49.5 CRYP interrupts 2384

49.6 CRYP DMA requests 2385

49.7 CRYP processing time 2386

49.8 CRYP registers 2387

49.8.1 CRYP control register (CRYP_CR) 2387

49.8.2 CRYP status register (CRYP_SR) 2389

49.8.3 CRYP data input register (CRYP_DINR) 2391

49.8.4 CRYP data output register (CRYP_DOUTR) 2391

49.8.5 CRYP DMA control register (CRYP_DMACR) 2392

49.8.6 CRYP interrupt mask set/clear register (CRYP_IMSCR) 2392

49.8.7 CRYP raw interrupt status register (CRYP_RISR) 2393

49.8.8 CRYP masked interrupt status register (CRYP_MISR) 2393

49.8.9 CRYP key register 0L (CRYP_K0LR) 2394
49.8.10 CRYP key register 0R (CRYP_K0RR) 2395
49.8.11 CRYP key register 1L (CRYP_K1LR) 2395
49.8.12 CRYP key register 1R (CRYP_K1RR) 2395
49.8.13 CRYP key register 2L (CRYP_K2LR) 2396
49.8.14 CRYP key register 2R (CRYP_K2RR) 2396
49.8.15 CRYP key register 3L (CRYP_K3LR) 2397
49.8.16 CRYP key register 3R (CRYP_K3RR) 2397
49.8.17 CRYP initialization vector register 0L (CRYP_IV0LR) 2397
49.8.18 CRYP initialization vector register 0R (CRYP_IV0RR) 2398
49.8.19 CRYP initialization vector register 1L (CRYP_IV1LR) 2398
49.8.20 CRYP initialization vector register 1R (CRYP_IV1RR) 2399
49.8.21 CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR) 2399
49.8.22 CRYP context swap GCM registers (CRYP_CSGCMxR) 2400
49.8.23 CRYP register map 2400

50 Hash processor (HASH) 2402

50.1 Introduction 2402
50.2 HASH main features 2402
50.3 HASH implementation 2403
50.4 HASH functional description 2403
50.4.1 HASH block diagram 2403
50.4.2 HASH internal signals 2403
50.4.3 About secure hash algorithms 2404
50.4.4 Message data feeding 2404
50.4.5 Message digest computing 2405
50.4.6 Message padding 2407
50.4.7 HMAC operation 2408
50.4.8 HASH suspend/resume operations 2410
50.4.9 HASH DMA interface 2412
50.4.10 HASH error management 2413
50.4.11 HASH processing time 2413
50.5 HASH interrupts 2414
50.6 HASH registers 2414
50.6.1 HASH control register (HASH_CR) 2414
50.6.2 HASH data input register (HASH_DIN) 2416

50.6.3 HASH start register (HASH_STR) . . . 2417
50.6.4 HASH digest registers . . . 2418
50.6.5 HASH interrupt enable register (HASH_IMR) . . . 2420
50.6.6 HASH status register (HASH_SR) . . . 2420
50.6.7 HASH context swap registers . . . 2421
50.6.8 HASH register map . . . 2422

51 Memory cipher engine (MCE) . . . 2424
51.1 Introduction . . . 2424
51.2 MCE main features . . . 2424
51.3 MCE implementation . . . 2425
51.4 MCE functional description . . . 2425
51.4.1 MCE block diagram . . . 2425
51.4.2 MCE internal signals . . . 2425
51.4.3 MCE programming . . . 2426
51.4.4 MCE reset and clocks . . . 2427
51.4.5 MCE block cipher encryption mode . . . 2427
51.4.6 MCE stream cipher encryption mode . . . 2429
51.4.7 MCE AXI traffic management . . . 2430
51.4.8 MCE encryption disable options . . . 2430
51.4.9 MCE error management . . . 2431
51.5 MCE interrupts . . . 2431
51.6 MCE registers . . . 2432
51.6.1 MCE configuration register (MCE_CR) . . . 2432
51.6.2 MCE status register (MCE_SR) . . . 2433
51.6.3 MCE illegal access status register (MCE_IASR) . . . 2434
51.6.4 MCE illegal access clear register (MCE_IACR) . . . 2434
51.6.5 MCE illegal access interrupt enable register (MCE_IAIER) . . . 2434
51.6.6 MCE illegal address register (MCE_IADDR) . . . 2435
51.6.7 MCE region x configuration register (MCE_REGCRx) . . . 2435
51.6.8 MCE start address for region x register (MCE_SADDRx) . . . 2437
51.6.9 MCE end address for region x register (MCE_EADDRx) . . . 2437
51.6.10 .MCE master key x (MCE_MKEYRx) . . . 2438
51.6.11 MCE fast master key x (MCE_FMKEYRx) . . . 2438
51.6.12 MCE cipher context z configuration register (MCE_CCzCFGR) . . . 2439

51.6.13 MCE cipher context z nonce register 0 (MCE_CCzNR0) 2440
51.6.14 MCE cipher context z nonce register 1 (MCE_CCzNR1) 2441
51.6.15 MCE cipher context z key register 0 (MCE_CCzKEYR0) 2441
51.6.16 MCE cipher context z key register 1 (MCE_CCzKEYR1) 2442
51.6.17 MCE cipher context z key register 2 (MCE_CCzKEYR2) 2442
51.6.18 MCE cipher context z key register 3 (MCE_CCzKEYR3) 2442
51.6.19 MCE register map 2443

52 Public key accelerator (PKA) 2445
52.1 Introduction 2445
52.2 PKA main features 2445
52.3 PKA functional description 2446
52.3.1 PKA block diagram 2446
52.3.2 PKA internal signals 2446
52.3.3 PKA reset and clocks 2446
52.3.4 PKA public key acceleration 2447
52.3.5 Typical applications for PKA 2449
52.3.6 PKA procedure to perform an operation 2451
52.3.7 PKA error management 2452
52.4 PKA operating modes 2453
52.4.1 Introduction 2453
52.4.2 Montgomery parameter computation 2454
52.4.3 Modular addition 2454
52.4.4 Modular subtraction 2455
52.4.5 Modular and Montgomery multiplication 2455
52.4.6 Modular exponentiation 2456
52.4.7 Modular inversion 2458
52.4.8 Modular reduction 2458
52.4.9 Arithmetic addition 2459
52.4.10 Arithmetic subtraction 2459
52.4.11 Arithmetic multiplication 2460
52.4.12 Arithmetic comparison 2460
52.4.13 RSA CRT exponentiation 2460
52.4.14 Point on elliptic curve Fp check 2461
52.4.15 ECC Fp scalar multiplication 2462
52.4.16 ECDSA sign 2463
52.4.17 ECDSA verification 2465

52.4.18 ECC complete addition 2466
52.4.19 ECC double base ladder 2466
52.4.20 ECC projective to affine 2467
52.5 Example of configurations and processing times 2468
52.5.1 Supported elliptic curves 2468
52.5.2 Computation times 2470
52.6 PKA interrupts 2472
52.7 PKA registers 2473
52.7.1 PKA control register (PKA_CR) 2473
52.7.2 PKA status register (PKA_SR) 2475
52.7.3 PKA clear flag register (PKA_CLRFR) 2476
52.7.4 PKA RAM 2476
52.7.5 PKA register map 2477

53 Advanced-control timers (TIM1/TIM8) 2478
53.1 TIM1/TIM8 introduction 2478
53.2 TIM1/TIM8 main features 2478
53.3 TIM1/TIM8 functional description 2479
53.3.1 Block diagram 2479
53.3.2 TIM1/TIM8 pins and internal signals 2480
53.3.3 Time-base unit 2484
53.3.4 Counter modes 2486
53.3.5 Repetition counter 2498
53.3.6 External trigger input 2499
53.3.7 Clock selection 2500
53.3.8 Capture/compare channels 2504
53.3.9 Input capture mode 2506
53.3.10 PWM input mode 2507
53.3.11 Forced output mode 2508
53.3.12 Output compare mode 2509
53.3.13 PWM mode 2510
53.3.14 Asymmetric PWM mode 2518
53.3.15 Combined PWM mode 2519
53.3.16 Combined 3-phase PWM mode 2520
53.3.17 Complementary outputs and dead-time insertion 2521
53.3.18 Using the break function 2524

53.3.19 Bidirectional break inputs . . . 2530
53.3.20 Clearing the tim_ocxref signal on an external event . . . 2531
53.3.21 6-step PWM generation . . . 2532
53.3.22 One-pulse mode . . . 2533
53.3.23 Retriggerable One-pulse mode . . . 2535
53.3.24 Pulse on compare mode . . . 2536
53.3.25 Encoder interface mode . . . 2538
53.3.26 Direction bit output . . . 2555
53.3.27 UIF bit remapping . . . 2556
53.3.28 Timer input XOR function . . . 2556
53.3.29 Interfacing with Hall sensors . . . 2556
53.3.30 Timer synchronization . . . 2558
53.3.31 ADC triggers . . . 2563
53.3.32 ADC synchronization . . . 2563
53.3.33 DMA burst mode . . . 2564
53.3.34 TIM1/TIM8 DMA requests . . . 2565
53.3.35 Debug mode . . . 2565
53.4 TIM1/TIM8 low-power modes . . . 2566
53.5 TIM1/TIM8 interrupts . . . 2566
53.6 TIM1/TIM8 registers . . . 2567
53.6.1 TIMx control register 1 (TIMx_CR1)(x = 1, 8) . . . 2567
53.6.2 TIMx control register 2 (TIMx_CR2)(x = 1, 8) . . . 2568
53.6.3 TIMx slave mode control register (TIMx_SMCR)(x = 1, 8) . . . 2572
53.6.4 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 1, 8) . . . 2576
53.6.5 TIMx status register (TIMx_SR)(x = 1, 8) . . . 2577
53.6.6 TIMx event generation register (TIMx_EGR)(x = 1, 8) . . . 2580
53.6.7 TIMx capture/compare mode register 1 (TIMx_CCMR1) (x = 1, 8) . . . 2581
53.6.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 1, 8) . . . 2583
53.6.9 TIMx capture/compare mode register 2 (TIMx_CCMR2) (x = 1, 8) . . . 2586
53.6.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 1, 8) . . . 2587
53.6.11 TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8) . . . 2590
53.6.12 TIMx counter (TIMx_CNT)(x = 1, 8) . . . 2594
53.6.13 TIMx prescaler (TIMx_PSC)(x = 1, 8) . . . 2594
53.6.14 TIMx autoreload register (TIMx_ARR)(x = 1, 8) . . . 2595

53.6.15 TIMx repetition counter register (TIMx_RCR)(x = 1, 8) 2595
53.6.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 1, 8) 2596
53.6.17 TIMx capture/compare register 2 (TIMx_CCR2)(x = 1, 8) 2596
53.6.18 TIMx capture/compare register 3 (TIMx_CCR3)(x = 1, 8) 2597
53.6.19 TIMx capture/compare register 4 (TIMx_CCR4)(x = 1, 8) 2598
53.6.20 TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) 2599
53.6.21 TIMx capture/compare register 5 (TIMx_CCR5)(x = 1, 8) 2603
53.6.22 TIMx capture/compare register 6 (TIMx_CCR6)(x = 1, 8) 2604
53.6.23 TIMx capture/compare mode register 3 (TIMx_CCMR3) (x = 1, 8) 2605
53.6.24 TIMx timer deadtime register 2 (TIMx_DTR2)(x = 1, 8) 2606
53.6.25 TIMx timer encoder control register (TIMx_ECR)(x = 1, 8) 2607
53.6.26 TIMx timer input selection register (TIMx_TISEL)(x = 1, 8) 2608
53.6.27 TIMx alternate function option register 1 (TIMx_AF1)(x = 1, 8) 2609
53.6.28 TIMx alternate function register 2 (TIMx_AF2)(x = 1, 8) 2612
53.6.29 TIMx DMA control register (TIMx_DCR)(x = 1, 8) 2614
53.6.30 TIMx DMA address for full transfer (TIMx_DMAR)(x = 1, 8) 2616
53.6.31 TIMx register map 2616

54 General-purpose timers (TIM2/TIM3/TIM4/TIM5) 2619

54.1 TIM2/TIM3/TIM4/TIM5 introduction 2619
54.2 TIM2/TIM3/TIM4/TIM5 main features 2619
54.3 TIM2/TIM3/TIM4/TIM5 implementation 2620
54.4 TIM2/TIM3/TIM4/TIM5 functional description 2621
54.4.1 Block diagram 2621
54.4.2 TIM2/TIM3/TIM4/TIM5 pins and internal signals 2622
54.4.3 Time-base unit 2625
54.4.4 Counter modes 2627
54.4.5 Clock selection 2639
54.4.6 Capture/compare channels 2643
54.4.7 Input capture mode 2645
54.4.8 PWM input mode 2646
54.4.9 Forced output mode 2647
54.4.10 Output compare mode 2647
54.4.11 PWM mode 2649
54.4.12 Asymmetric PWM mode 2657
54.4.13 Combined PWM mode 2658

54.4.14 Clearing the tim_ocxref signal on an external event 2659
54.4.15 One-pulse mode 2661
54.4.16 Retriggerable one-pulse mode 2662
54.4.17 Pulse on compare mode 2663
54.4.18 Encoder interface mode 2665
54.4.19 Direction bit output 2683

60.4.4 Controlling the down-counter . . . 2994
60.4.5 How to program the watchdog timeout . . . 2994
60.4.6 Debug mode . . . 2995
60.5 WWDG interrupts . . . 2996
60.6 WWDG registers . . . 2996
60.6.1 WWDG control register (WWDG_CR) . . . 2996
60.6.2 WWDG configuration register (WWDG_CFR) . . . 2997
60.6.3 WWDG status register (WWDG_SR) . . . 2998
60.6.4 WWDG register map . . . 2998

61 Real-time clock (RTC) . . . 2999
61.1 Introduction . . . 2999
61.2 RTC main features . . . 2999
61.3 RTC functional description . . . 3000
61.3.1 RTC block diagram . . . 3000
61.3.2 RTC pins and internal signals . . . 3002
61.3.3 GPIOs controlled by the RTC and TAMP . . . 3003
61.3.4 RTC secure protection modes . . . 3006

61.3.5 RTC privilege protection modes . . . 3007
61.3.6 Clock and prescalers . . . 3008
61.3.7 Real-time clock and calendar . . . 3009
61.3.8 Calendar ultra-low power mode . . . 3010
61.3.9 Programmable alarms . . . 3010
61.3.10 Periodic auto-wake-up . . . 3010
61.3.11 RTC initialization and configuration . . . 3011
61.3.12 Reading the calendar . . . 3014
61.3.13 Resetting the RTC . . . 3015
61.3.14 RTC synchronization . . . 3015
61.3.15 RTC reference clock detection . . . 3016
61.3.16 RTC smooth digital calibration . . . 3017
61.3.17 Timestamp function . . . 3019
61.3.18 Calibration clock output . . . 3019
61.3.19 Tamper and alarm output . . . 3020
61.4 RTC low-power modes . . . 3020
61.5 RTC interrupts . . . 3021
61.6 RTC registers . . . 3022
61.6.1 RTC time register (RTC_TR) . . . 3023
61.6.2 RTC date register (RTC_DR) . . . 3024
61.6.3 RTC subsecond register (RTC_SSR) . . . 3025
61.6.4 RTC initialization control and status register (RTC_ICSR) . . . 3026
61.6.5 RTC prescaler register (RTC_PRER) . . . 3028
61.6.6 RTC wake-up timer register (RTC_WUTR) . . . 3029
61.6.7 RTC control register (RTC_CR) . . . 3029
61.6.8 RTC privilege mode control register (RTC_PRIVCFGR) . . . 3033
61.6.9 RTC secure configuration register (RTC_SECCFGR) . . . 3035
61.6.10 RTC write protection register (RTC_WPR) . . . 3036
61.6.11 RTC calibration register (RTC_CALR) . . . 3037
61.6.12 RTC shift control register (RTC_SHIFTR) . . . 3038
61.6.13 RTC timestamp time register (RTC_TSTR) . . . 3039
61.6.14 RTC timestamp date register (RTC_TSDR) . . . 3040
61.6.15 RTC timestamp subsecond register (RTC_TSSSR) . . . 3041
61.6.16 RTC alarm A register (RTC_ALRMAR) . . . 3041
61.6.17 RTC alarm A subsecond register (RTC_ALRMASSR) . . . 3043
61.6.18 RTC alarm B register (RTC_ALRMBR) . . . 3044
61.6.19 RTC alarm B subsecond register (RTC_ALRMBSSR) . . . 3045

61.6.20 RTC status register (RTC_SR) . . . 3046
61.6.21 RTC nonsecure masked interrupt status register (RTC_MISR) . . . 3047
61.6.22 RTC secure masked interrupt status register (RTC_SMISR) . . . 3048
61.6.23 RTC status clear register (RTC_SCR) . . . 3049
61.6.24 RTC alarm A binary mode register (RTC_ALRABINR) . . . 3050
61.6.25 RTC alarm B binary mode register (RTC_ALRBBINR) . . . 3051
61.6.26 RTC register map . . . 3052

62 Tamper and backup registers (TAMP) . . . 3054

62.1 Introduction . . . 3054
62.2 TAMP main features . . . 3055
62.3 TAMP functional description . . . 3056
62.3.1 TAMP block diagram . . . 3056
62.3.2 TAMP pins and internal signals . . . 3057
62.3.3 GPIOs controlled by the RTC and TAMP . . . 3059
62.3.4 TAMP register write protection . . . 3059
62.3.5 TAMP secure protection modes . . . 3059
62.3.6 Backup registers protection zones . . . 3060
62.3.7 TAMP privilege protection modes . . . 3060
62.3.8 Boot hardware key (BHK) . . . 3061
62.3.9 Tamper detection . . . 3061
62.3.10 TAMP backup registers and other device secrets erase . . . 3062
62.3.11 Tamper detection configuration and initialization . . . 3063
62.4 TAMP low-power modes . . . 3070
62.5 TAMP interrupts . . . 3071
62.6 TAMP registers . . . 3071
62.6.1 TAMP control register 1 (TAMP_CR1) . . . 3071
62.6.2 TAMP control register 2 (TAMP_CR2) . . . 3073
62.6.3 TAMP control register 3 (TAMP_CR3) . . . 3076
62.6.4 TAMP filter control register (TAMP_FLTCR) . . . 3077
62.6.5 TAMP active tamper control register 1 (TAMP_ATCR1) . . . 3078
62.6.6 TAMP active tamper seed register (TAMP_ATSEEDR) . . . 3080
62.6.7 TAMP active tamper output register (TAMP_ATOR) . . . 3081
62.6.8 TAMP active tamper control register 2 (TAMP_ATCR2) . . . 3082
62.6.9 TAMP secure configuration register (TAMP_SECCFGR) . . . 3085
62.6.10 TAMP privilege configuration register (TAMP_PRIVCFGR) . . . 3086

62.6.11 TAMP interrupt enable register (TAMP_IER) 3087
62.6.12 TAMP status register (TAMP_SR) 3089
62.6.13 TAMP nonsecure masked interrupt status register (TAMP_MISR) . . 3091
62.6.14 TAMP secure masked interrupt status register (TAMP_SMISR) 3093
62.6.15 TAMP status clear register (TAMP_SCR) 3094
62.6.16 TAMP monotonic counter 1 register (TAMP_COUNT1R) 3096
62.6.17 TAMP option register (TAMP_OR) 3096
62.6.18 TAMP resources protection configuration register (TAMP_RPCFGR) 3097
62.6.19 TAMP backup x register (TAMP_BKPxR) 3098
62.6.20 TAMP register map 3099

63 Inter-integrated circuit interface (I2C) 3101

63.1 Introduction 3101
63.2 I2C main features 3101
63.3 I2C implementation 3102
63.4 I2C functional description 3102
63.4.1 I2C block diagram 3103
63.4.2 I2C pins and internal signals 3103
63.4.3 I2C clock requirements 3104
63.4.4 I2C mode selection 3104
63.4.5 I2C initialization 3105
63.4.6 I2C reset 3109
63.4.7 I2C data transfer 3110
63.4.8 I2C target mode 3112
63.4.9 I2C controller mode 3121
63.4.10 I2C_TIMINGR register configuration examples 3132
63.4.11 SMBus specific features 3134
63.4.12 SMBus initialization 3136
63.4.13 SMBus I2C_TIMEOUTR register configuration examples 3138
63.4.14 SMBus target mode 3139
63.4.15 SMBus controller mode 3142
63.4.16 Wake-up from Stop mode on address match 3145
63.4.17 Error conditions 3146
63.5 I2C in low-power modes 3148
63.6 I2C interrupts 3148
63.7 I2C DMA requests 3149

63.7.1 Transmission using DMA . . . 3149
63.7.2 Reception using DMA . . . 3149
63.8 I2C debug modes . . . 3150
63.9 I2C registers . . . 3150
63.9.1 I2C control register 1 (I2C_CR1) . . . 3150
63.9.2 I2C control register 2 (I2C_CR2) . . . 3153
63.9.3 I2C own address 1 register (I2C_OAR1) . . . 3155
63.9.4 I2C own address 2 register (I2C_OAR2) . . . 3155
63.9.5 I2C timing register (I2C_TIMINGR) . . . 3156
63.9.6 I2C timeout register (I2C_TIMEOUTR) . . . 3157
63.9.7 I2C interrupt and status register (I2C_ISR) . . . 3158
63.9.8 I2C interrupt clear register (I2C_ICR) . . . 3161
63.9.9 I2C PEC register (I2C_PECR) . . . 3162
63.9.10 I2C receive data register (I2C_RXDR) . . . 3162
63.9.11 I2C transmit data register (I2C_TXDR) . . . 3163
63.9.12 I2C register map . . . 3164

64 Improved inter-integrated circuit (I3C) . . . 3165
64.1 Introduction . . . 3165
64.2 I3C main features . . . 3165
64.3 I3C implementation . . . 3167
64.3.1 I3C instantiation . . . 3167
64.3.2 I3C wake-up from low-power mode(s) . . . 3167
64.3.3 I3C FIFOs . . . 3167
64.3.4 I3C triggers . . . 3167
64.3.5 I3C interrupt(s) . . . 3167
64.3.6 I3C MIPI® support . . . 3168
64.4 I3C block diagram . . . 3169
64.5 I3C pins and internal signals . . . 3169
64.6 I3C reset and clocks . . . 3170
64.6.1 I3C reset . . . 3170
64.6.2 I3C clocks and requirements . . . 3170
64.7 I3C peripheral state and programming . . . 3172
64.7.1 I3C peripheral state . . . 3172
64.7.2 I3C controller state and programming sequence . . . 3172
64.7.3 I3C target state and programming sequence . . . 3177

64.8 I3C registers and programming . . . 3181
64.8.1 I3C register set, as controller/target . . . 3181
64.8.2 I3C registers and fields use versus peripheral state, as controller . . . 3182
64.8.3 I3C registers and fields usage versus peripheral state, as target . . . 3185
64.9 I3C bus transfers and programming . . . 3187
64.9.1 I3C command set (CCCs), as controller/target . . . 3187
64.9.2 I3C broadcast/direct CCC transfer (except ENTDAA, RSTACT), as controller . . . 3191
64.9.3 I3C broadcast ENTDAA CCC transfer, as controller . . . 3193
64.9.4 I3C broadcast/direct RSTACT CCC transfer, as controller . . . 3193
64.9.5 I3C broadcast/direct CCC transfer (except ENTDAA, DEFTGTS, DEFGRPA), as target . . . 3195
64.9.6 I3C broadcast ENTDAA CCC transfer, as target . . . 3197
64.9.7 I3C broadcast DEFTGTS CCC transfer, as target . . . 3198
64.9.8 I3C broadcast DEFGRPA CCC transfer, as target . . . 3199
64.9.9 I3C direct GETSTATUS CCC response, as target . . . 3200
64.9.10 I3C private read/write transfer, as controller . . . 3201
64.9.11 I3C private read/write transfer, as target . . . 3202
64.9.12 Legacy I2C read/write transfer, as controller . . . 3203
64.9.13 I3C IBI transfer, as controller/target . . . 3204
64.9.14 I3C hot-join request transfer, as controller/target . . . 3206
64.9.15 I3C controller-role request transfer, as controller/target . . . 3207
64.10 I3C FIFOs management, as controller . . . 3208
64.10.1 C-FIFO management, as controller . . . 3208
64.10.2 TX-FIFO management, as controller . . . 3209
64.10.3 RX-FIFO management, as controller . . . 3212
64.10.4 S-FIFO management, as controller . . . 3214
64.11 I3C FIFOs management, as target . . . 3216
64.11.1 RX-FIFO management, as target . . . 3216
64.11.2 TX-FIFO management, as target . . . 3217
64.12 I3C error management . . . 3220
64.12.1 Controller error management . . . 3220
64.12.2 Target error management . . . 3222
64.13 I3C wake-up from low-power mode(s) . . . 3223
64.13.1 Wake-up from Stop . . . 3223
64.14 I3C in low-power modes . . . 3226
64.15 I3C interrupts . . . 3227

64.16 I3C registers . . . 3228
64.16.1 I3C message control register (I3C_CR) . . . 3228
64.16.2 I3C message control register [alternate] (I3C_CR) . . . 3230
64.16.3 I3C configuration register (I3C_CFGR) . . . 3232
64.16.4 I3C receive data byte register (I3C_RDR) . . . 3237
64.16.5 I3C receive data word register (I3C_RDWR) . . . 3237
64.16.6 I3C transmit data byte register (I3C_TDR) . . . 3238
64.16.7 I3C transmit data word register (I3C_TDWR) . . . 3239
64.16.8 I3C IBI payload data register (I3C_IBIDR) . . . 3241
64.16.9 I3C target transmit configuration register (I3C_TGTTDR) . . . 3242
64.16.10 I3C status register (I3C_SR) . . . 3243
64.16.11 I3C status error register (I3C_SER) . . . 3244
64.16.12 I3C received message register (I3C_RMR) . . . 3246
64.16.13 I3C event register (I3C_EVR) . . . 3247
64.16.14 I3C interrupt enable register (I3C_IER) . . . 3251
64.16.15 I3C clear event register (I3C_CEVR) . . . 3253
64.16.16 I3C own device characteristics register (I3C_DEVR0) . . . 3255
64.16.17 I3C device x characteristics register (I3C_DEVRx) . . . 3257
64.16.18 I3C maximum read length register (I3C_MAXRLR) . . . 3259
64.16.19 I3C maximum write length register (I3C_MAXWLR) . . . 3260
64.16.20 I3C timing register 0 (I3C_TIMINGR0) . . . 3261
64.16.21 I3C timing register 1 (I3C_TIMINGR1) . . . 3262
64.16.22 I3C timing register 2 (I3C_TIMINGR2) . . . 3264
64.16.23 I3C bus characteristics register (I3C_BCR) . . . 3265
64.16.24 I3C device characteristics register (I3C_DCR) . . . 3266
64.16.25 I3C get capability register (I3C_GETCAPR) . . . 3267
64.16.26 I3C controller-role capability register (I3C_CRCAPR) . . . 3268
64.16.27 I3C get max data speed register (I3C_GETMXDSR) . . . 3269
64.16.28 I3C extended provisioned ID register (I3C_EPIDR) . . . 3271
64.16.29 I3C register map . . . 3272

65 Universal synchronous/asynchronous receiver transmitter (USART/UART) . . . 3275

65.1 Introduction . . . 3275
65.2 USART main features . . . 3275
65.3 USART extended features . . . 3276
65.4 USART implementation . . . 3276

65.5 USART functional description 3278
65.5.1 USART block diagram 3278
65.5.2 USART pins and internal signals 3278
65.5.3 USART clocks 3280
65.5.4 USART character description 3280
65.5.5 USART FIFOs and thresholds 3283
65.5.6 USART transmitter 3283
65.5.7 USART receiver 3286
65.5.8 USART baud rate generation 3293
65.5.9 Tolerance of the USART receiver to clock deviation 3295
65.5.10 USART auto baud rate detection 3296
65.5.11 USART multiprocessor communication 3298
65.5.12 USART Modbus communication 3300
65.5.13 USART parity control 3301
65.5.14 USART LIN (local interconnection network) mode 3302
65.5.15 USART synchronous mode 3304
65.5.16 USART single-wire half-duplex communication 3308
65.5.17 USART receiver timeout 3308
65.5.18 USART smartcard mode 3309
65.5.19 USART IrDA SIR ENDEC block 3313
65.5.20 Continuous communication using USART and DMA 3316
65.5.21 RS232 hardware flow control and RS485 driver enable 3318
65.5.22 USART low-power management 3321
65.6 USART in low-power modes 3324
65.7 USART interrupts 3324
65.8 USART registers 3327
65.8.1 USART control register 1 (USART_CR1) 3327
65.8.2 USART control register 1 [alternate] (USART_CR1) 3331
65.8.3 USART control register 2 (USART_CR2) 3334
65.8.4 USART control register 3 (USART_CR3) 3338
65.8.5 USART control register 3 [alternate] (USART_CR3) 3342
65.8.6 USART baud rate register (USART_BRR) 3346
65.8.7 USART guard time and prescaler register (USART_GTPR) 3346
65.8.8 USART receiver timeout register (USART_RTOR) 3347
65.8.9 USART request register (USART_RQR) 3348
65.8.10 USART interrupt and status register (USART_ISR) 3349
65.8.11 USART interrupt and status register [alternate] (USART_ISR) 3355

65.8.12 USART interrupt flag clear register (USART_ICR) . . . 3360
65.8.13 USART receive data register (USART_RDR) . . . 3361
65.8.14 USART transmit data register (USART_TDR) . . . 3362
65.8.15 USART prescaler register (USART_PRESC) . . . 3362
65.8.16 USART register map . . . 3363

66 Low-power universal asynchronous receiver transmitter (LPUART) . . . 3365

66.1 Introduction . . . 3365
66.2 LPUART main features . . . 3365
66.3 LPUART implementation . . . 3366
66.4 LPUART functional description . . . 3368
66.4.1 LPUART block diagram . . . 3368
66.4.2 LPUART pins and internal signals . . . 3369
66.4.3 LPUART clocks . . . 3370
66.4.4 LPUART character description . . . 3370
66.4.5 LPUART FIFOs and thresholds . . . 3372
66.4.6 LPUART transmitter . . . 3372
66.4.7 LPUART receiver . . . 3376
66.4.8 LPUART baud rate generation . . . 3380
66.4.9 Tolerance of the LPUART receiver to clock deviation . . . 3381
66.4.10 LPUART multiprocessor communication . . . 3382
66.4.11 LPUART parity control . . . 3384
66.4.12 LPUART single-wire half-duplex communication . . . 3385
66.4.13 Continuous communication using DMA and LPUART . . . 3385
66.4.14 RS232 hardware flow control and RS485 driver enable . . . 3388
66.4.15 LPUART low-power management . . . 3390
66.5 LPUART in low-power modes . . . 3393
66.6 LPUART interrupts . . . 3394
66.7 LPUART registers . . . 3395
66.7.1 LPUART control register 1 (LPUART_CR1) . . . 3395
66.7.2 LPUART control register 1 [alternate] (LPUART_CR1) . . . 3398
66.7.3 LPUART control register 2 (LPUART_CR2) . . . 3401
66.7.4 LPUART control register 3 (LPUART_CR3) . . . 3403
66.7.5 LPUART control register 3 [alternate] (LPUART_CR3) . . . 3406
66.7.6 LPUART baud rate register (LPUART_BRR) . . . 3408

66.7.7 LPUART request register (LPUART_RQR) . . . 3408
66.7.8 LPUART interrupt and status register (LPUART_ISR) . . . 3409
66.7.9 LPUART interrupt and status register [alternate] (LPUART_ISR) . . . 3414
66.7.10 LPUART interrupt flag clear register (LPUART_ICR) . . . 3417
66.7.11 LPUART receive data register (LPUART_RDR) . . . 3418
66.7.12 LPUART transmit data register (LPUART_TDR) . . . 3418
66.7.13 LPUART prescaler register (LPUART_PRESC) . . . 3419
66.7.14 LPUART register map . . . 3420

67 Serial peripheral interface (SPI) . . . 3422
67.1 Introduction . . . 3422
67.2 SPI main features . . . 3422
67.3 SPI implementation . . . 3423
67.4 SPI functional description . . . 3424
67.4.1 SPI block diagram . . . 3424
67.4.2 SPI pins and internal signals . . . 3425
67.4.3 SPI communication general aspects . . . 3426
67.4.4 Communications between one master and one slave . . . 3426
67.4.5 Standard multislave communication . . . 3429
67.4.6 Multimaster communication . . . 3432
67.4.7 Slave select (SS) pin management . . . 3432
67.4.8 Ready pin (RDY) management . . . 3436
67.4.9 Communication formats . . . 3436
67.4.10 Configuring the SPI . . . 3438
67.4.11 Enabling the SPI . . . 3439
67.4.12 SPI data transmission and reception procedures . . . 3440
67.4.13 Disabling the SPI . . . 3444
67.4.14 Communication using DMA (direct memory addressing) . . . 3445
67.5 SPI specific modes and control . . . 3447
67.5.1 TI mode . . . 3447
67.5.2 SPI error flags . . . 3447
67.5.3 CRC computation . . . 3451
67.6 SPI in low-power modes . . . 3452
67.7 SPI interrupts . . . 3452
67.8 I2S main features . . . 3454
67.9 I2S functional description . . . 3454

67.9.1 I2S general description . . . 3454
67.9.2 Pin sharing with SPI function . . . 3455
67.9.3 Bitfields usable in I2S/PCM mode . . . 3455
67.9.4 Slave and master modes . . . 3456
67.9.5 Supported audio protocols . . . 3456
67.9.6 Additional serial interface flexibility . . . 3462
67.9.7 Startup sequence . . . 3464
67.9.8 Stop sequence . . . 3466
67.9.9 Clock generator . . . 3467
67.9.10 Internal FIFOs . . . 3469
67.9.11 FIFO status flags . . . 3470
67.9.12 Handling of underrun situation . . . 3470
67.9.13 Handling of overrun situation . . . 3471
67.9.14 Frame error detection . . . 3472
67.9.15 DMA interface . . . 3474
67.9.16 Programing examples . . . 3474
67.10 I2S interrupts . . . 3476
67.11 SPI/I2S registers . . . 3477
67.11.1 SPI/I2S control register 1 (SPI_CR1) . . . 3477
67.11.2 SPI/I2S control register 2 (SPI_CR2) . . . 3479
67.11.3 SPI/I2S configuration register 1 (SPI_CFG1) . . . 3479
67.11.4 SPI/I2S configuration register 2 (SPI_CFG2) . . . 3482
67.11.5 SPI/I2S interrupt enable register (SPI_IER) . . . 3484
67.11.6 SPI/I2S status register (SPI_SR) . . . 3485
67.11.7 SPI/I2S interrupt/status flags clear register (SPI_IFCR) . . . 3488
67.11.8 SPI/I2S transmit data register (SPI_TXDR) . . . 3489
67.11.9 SPI/I2S receive data register (SPI_RXDR) . . . 3489
67.11.10 SPI/I2S polynomial register (SPI_CRCPOLY) . . . 3490
67.11.11 SPI/I2S transmitter CRC register (SPI_TXCRC) . . . 3490
67.11.12 SPI/I2S receiver CRC register (SPI_RXCRC) . . . 3491
67.11.13 SPI/I2S underrun data register (SPI_UDRDR) . . . 3492
67.11.14 SPI/I2S configuration register (SPI_I2SCFGR) . . . 3492
67.11.15 SPI/I2S register map . . . 3494

68 Serial audio interface (SAI) . . . 3496
68.1 Introduction . . . 3496
68.2 SAI main features . . . 3496

68.3 SAI implementation 3497
68.4 SAI functional description 3498
68.4.1 SAI block diagram 3498
68.4.2 SAI pins and internal signals 3499
68.4.3 Main SAI modes 3500
68.4.4 SAI synchronization mode 3501
68.4.5 Audio data size 3502
68.4.6 Frame synchronization 3502
68.4.7 Slot configuration 3505
68.4.8 SAI clock generator 3507
68.4.9 Internal FIFOs 3510
68.4.10 PDM interface 3512
68.4.11 AC’97 link controller 3520
68.4.12 SPDIF output 3522
68.4.13 Specific features 3525
68.4.14 Error flags 3529
68.4.15 Disabling the SAI 3532
68.4.16 SAI DMA interface 3532
68.5 SAI interrupts 3533
68.6 SAI registers 3535
68.6.1 SAI global configuration register (SAI_GCR) 3535
68.6.2 SAI configuration register 1 (SAI_ACR1) 3535
68.6.3 SAI configuration register 2 (SAI_ACR2) 3538
68.6.4 SAI frame configuration register (SAI_AFRCR) 3540
68.6.5 SAI slot register (SAI_ASLOTR) 3541
68.6.6 SAI interrupt mask register (SAI_AIM) 3542
68.6.7 SAI status register (SAI_ASR) 3543
68.6.8 SAI clear flag register (SAI_ACLRFR) 3545
68.6.9 SAI data register (SAI_ADR) 3546
68.6.10 SAI configuration register 1 (SAI_BCR1) 3547
68.6.11 SAI configuration register 2 (SAI_BCR2) 3549
68.6.12 SAI frame configuration register (SAI_BFRCR) 3551
68.6.13 SAI slot register (SAI_BSLOTR) 3552
68.6.14 SAI interrupt mask register (SAI_BIM) 3553
68.6.15 SAI status register (SAI_BSR) 3555
68.6.16 SAI clear flag register (SAI_BCLRFR) 3557
68.6.17 SAI data register (SAI_BDR) 3558

68.6.18 SAI PDM control register (SAI_PDMCR) . . . 3558
68.6.19 SAI PDM delay register (SAI_PDMDLY) . . . 3559
68.6.20 SAI register map . . . 3561

69 SPDIF receiver interface (SPDIFRX) . . . 3563
69.1 SPDIFRX interface introduction . . . 3563
69.2 SPDIFRX main features . . . 3563
69.3 SPDIFRX functional description . . . 3563
69.3.1 SPDIFRX pins and internal signals . . . 3564
69.3.2 S/PDIF protocol (IEC-60958) . . . 3565
69.3.3 SPDIFRX decoder (SPDIFRX_DC) . . . 3567
69.3.4 SPDIFRX tolerance to clock deviation . . . 3571
69.3.5 SPDIFRX synchronization . . . 3571
69.3.6 SPDIFRX handling . . . 3573
69.3.7 Data reception management . . . 3575
69.3.8 Dedicated control flow . . . 3577
69.3.9 Reception errors . . . 3578
69.3.10 Clocking strategy . . . 3580
69.3.11 Symbol clock generation . . . 3580
69.3.12 DMA interface . . . 3582
69.3.13 Interrupt generation . . . 3583
69.3.14 Register protection . . . 3584
69.4 Programming procedures . . . 3584
69.4.1 Initialization phase . . . 3585
69.4.2 Handling of interrupts coming from SPDIFRX . . . 3586
69.4.3 Handling of interrupts coming from DMA . . . 3586
69.5 SPDIFRX interface registers . . . 3587
69.5.1 SPDIFRX control register (SPDIFRX_CR) . . . 3587
69.5.2 SPDIFRX interrupt mask register (SPDIFRX_IMR) . . . 3589
69.5.3 SPDIFRX status register (SPDIFRX_SR) . . . 3590
69.5.4 SPDIFRX interrupt flag clear register (SPDIFRX_IFCR) . . . 3592
69.5.5 SPDIFRX data input register (SPDIFRX_FMT0_DR) . . . 3593
69.5.6 SPDIFRX data input register (SPDIFRX_FMT1_DR) . . . 3593
69.5.7 SPDIFRX data input register (SPDIFRX_FMT2_DR) . . . 3594
69.5.8 SPDIFRX channel status register (SPDIFRX_CSR) . . . 3595
69.5.9 SPDIFRX debug information register (SPDIFRX_DIR) . . . 3595
69.5.10 SPDIFRX interface register map . . . 3596

70 Management data input/output (MDIOS) 3597
70.1 MDIOS introduction 3597
70.2 MDIOS main features 3597
70.3 MDIOS functional description 3598
70.3.1 MDIOS block diagram 3598
70.3.2 MDIOS pins and internal signals 3598
70.3.3 MDIOS protocol 3598
70.3.4 MDIOS enabling and disabling 3599
70.3.5 MDIOS data 3600
70.3.6 MDIOS APB frequency 3601
70.3.7 Write/read flags and interrupts 3601
70.3.8 MDIOS error management 3602
70.3.9 MDIOS in Stop mode 3603
70.3.10 MDIOS interrupts 3603
70.4 MDIOS registers 3603
70.4.1 MDIOS configuration register (MDIOS_CR) 3603
70.4.2 MDIOS write flag register (MDIOS_WRFR) 3604
70.4.3 MDIOS clear write flag register (MDIOS_CWRFR) 3605
70.4.4 MDIOS read flag register (MDIOS_RDFR) 3605
70.4.5 MDIOS clear read flag register (MDIOS_CRDFR) 3606
70.4.6 MDIOS status register (MDIOS_SR) 3606
70.4.7 MDIOS clear flag register (MDIOS_CLRFR) 3607
70.4.8 MDIOS input data register x (MDIOS_DINRx) 3607
70.4.9 MDIOS output data register x (MDIOS_DOUTRx) 3608
70.4.10 MDIOS register map 3608

71 Controller area network with flexible data rate (FDCAN) 3610
71.1 Introduction 3610
71.2 FDCAN main features 3613
71.3 FDCAN implementation 3613
71.4 FDCAN functional description 3614
71.4.1 Operating modes 3615
71.4.2 Error management 3624
71.4.3 Message RAM 3624
71.4.4 FIFO acknowledge handling 3636
71.4.5 Bit timing 3637

71.4.6 Clock calibration on CAN . . . 3638
71.4.7 Application . . . 3642
71.4.8 TTCAN operations (FDCAN1 only) . . . 3643
71.4.9 TTCAN configuration . . . 3644
71.4.10 Message scheduling . . . 3646
71.4.11 TTCAN gap control . . . 3653
71.4.12 Stop watch . . . 3654
71.4.13 Local time, cycle time, global time, and external clock synchronization . . . 3654
71.4.14 TTCAN error level . . . 3657
71.4.15 TTCAN message handling . . . 3658
71.4.16 TTCAN interrupt and error handling . . . 3661
71.4.17 Level 0 . . . 3662
71.4.18 Synchronization to external time schedule . . . 3664
71.4.19 FDCAN Rx buffer and FIFO element . . . 3665
71.4.20 FDCAN Tx buffer element . . . 3667
71.4.21 FDCAN Tx event FIFO element . . . 3669
71.4.22 FDCAN standard message ID filter element . . . 3670
71.4.23 FDCAN extended message ID filter element . . . 3672
71.4.24 FDCAN trigger memory element . . . 3673
71.5 FDCAN registers . . . 3675
71.5.1 FDCAN core release register (FDCAN_CREL) . . . 3675
71.5.2 FDCAN Endian register (FDCAN_ENDN) . . . 3675
71.5.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP) . . . 3675
71.5.4 FDCAN test register (FDCAN_TEST) . . . 3676
71.5.5 FDCAN RAM watchdog register (FDCAN_RWD) . . . 3677
71.5.6 FDCAN CC control register (FDCAN_CCCR) . . . 3678
71.5.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP) . 3680
71.5.8 FDCAN timestamp counter configuration register (FDCAN_TSCC) . 3681
71.5.9 FDCAN timestamp counter value register (FDCAN_TSCV) . . . 3681
71.5.10 FDCAN timeout counter configuration register (FDCAN_TOCC) . . . 3682
71.5.11 FDCAN timeout counter value register (FDCAN_TOCV) . . . 3683
71.5.12 FDCAN error counter register (FDCAN_ECR) . . . 3683
71.5.13 FDCAN protocol status register (FDCAN_PSR) . . . 3684
71.5.14 FDCAN transmitter delay compensation register (FDCAN_TDCR) . . 3686
71.5.15 FDCAN interrupt register (FDCAN_IR) . . . 3686
71.5.16 FDCAN interrupt enable register (FDCAN_IE) . . . 3689

71.5.17 FDCAN interrupt line select register (FDCAN_ILS) 3691
71.5.18 FDCAN interrupt line enable register (FDCAN_ILE) 3692
71.5.19 FDCAN global filter configuration register (FDCAN_GFC) 3693
71.5.20 FDCAN standard ID filter configuration register (FDCAN_SIDFC) . . 3694
71.5.21 FDCAN extended ID filter configuration register (FDCAN_XIDFC) . . 3694
71.5.22 FDCAN extended ID and mask register (FDCAN_XIDAM) 3695
71.5.23 FDCAN high priority message status register (FDCAN_HPMS) 3696
71.5.24 FDCAN new data 1 register (FDCAN_NDAT1) 3696
71.5.25 FDCAN new data 2 register (FDCAN_NDAT2) 3697
71.5.26 FDCAN Rx FIFO 0 configuration register (FDCAN_RXF0C) 3697
71.5.27 FDCAN Rx FIFO 0 status register (FDCAN_RXF0S) 3698
71.5.28 FDCAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A) 3699
71.5.29 FDCAN Rx buffer configuration register (FDCAN_RXBC) 3699
71.5.30 FDCAN Rx FIFO 1 configuration register (FDCAN_RXF1C) 3700
71.5.31 FDCAN Rx FIFO 1 status register (FDCAN_RXF1S) 3701
71.5.32 FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A) 3702
71.5.33 FDCAN Rx buffer element size configuration register (FDCAN_RXESC) 3702
71.5.34 FDCAN Tx buffer configuration register (FDCAN_TXBC) 3703
71.5.35 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS) 3704
71.5.36 FDCAN Tx buffer element size configuration register (FDCAN_TXESC) 3705
71.5.37 FDCAN Tx buffer request pending register (FDCAN_TXBRP) 3705
71.5.38 FDCAN Tx buffer add request register (FDCAN_TXBAR) 3706
71.5.39 FDCAN Tx buffer cancellation request register (FDCAN_TXBCR) . . 3707
71.5.40 FDCAN Tx buffer transmission occurred register (FDCAN_TXBTO) 3707
71.5.41 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF) . . 3708
71.5.42 FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE) 3708
71.5.43 FDCAN Tx buffer cancellation finished interrupt enable register (FDCAN_TXBCIE) 3709
71.5.44 FDCAN Tx event FIFO configuration register (FDCAN_TXEFC) . . . 3709
71.5.45 FDCAN Tx event FIFO status register (FDCAN_TXEFS) 3710
71.5.46 FDCAN Tx event FIFO acknowledge register (FDCAN_TXEFA) . . . 3711
71.5.47 FDCAN register map 3711
71.6 TTCAN registers 3715
71.6.1 FDCAN TT trigger memory configuration register (FDCAN_TTTMC) 3715

71.6.2 FDCAN TT reference message configuration register (FDCAN_TTRMC) . . . 3715
71.6.3 FDCAN TT operation configuration register (FDCAN_TTOCF) . . . 3716
71.6.4 FDCAN TT matrix limits register (FDCAN_TTMLM) . . . 3718
71.6.5 FDCAN TUR configuration register (FDCAN_TURCF) . . . 3719
71.6.6 FDCAN TT operation control register (FDCAN_TTOCN) . . . 3720
71.6.7 FDCAN TT global time preset register (FDCAN_TTGTP) . . . 3722
71.6.8 FDCAN TT time mark register (FDCAN_TTTMK) . . . 3722
71.6.9 FDCAN TT interrupt register (FDCAN_TTIR) . . . 3723
71.6.10 FDCAN TT interrupt enable register (FDCAN_TTIE) . . . 3725
71.6.11 FDCAN TT interrupt line select register (FDCAN_TTILS) . . . 3727
71.6.12 FDCAN TT operation status register (FDCAN_TTOST) . . . 3728
71.6.13 FDCAN TUR numerator actual register (FDCAN_TURNA) . . . 3730
71.6.14 FDCAN TT local and global time register (FDCAN_TTLGT) . . . 3731
71.6.15 FDCAN TT cycle time and count register (FDCAN_TTCTC) . . . 3731
71.6.16 FDCAN TT capture time register (FDCAN_TTCPT) . . . 3732
71.6.17 FDCAN TT cycle sync mark register (FDCAN_TTCSM) . . . 3732
71.6.18 FDCAN TT trigger select register (FDCAN_TTTS) . . . 3733
71.6.19 FDCAN TT register map . . . 3733
71.7 CCU registers . . . 3735
71.7.1 Clock calibration unit core release register (FDCAN_CCU_CREL) . . 3735
71.7.2 Calibration configuration register (FDCAN_CCU_CCFG) . . . 3735
71.7.3 Calibration status register (FDCAN_CCU_CSTAT) . . . 3737
71.7.4 Calibration watchdog register (FDCAN_CCU_CWD) . . . 3737
71.7.5 Clock calibration unit interrupt register (FDCAN_CCU_IR) . . . 3738
71.7.6 Clock calibration unit interrupt enable register (FDCAN_CCU_IE) . . 3739
71.7.7 CCU register map . . . 3739

72 USB subsystem (USBSS) . . . 3741
72.1 Overview . . . 3741
72.2 USB2 OTG high-speed Port 1 . . . 3741
72.2.1 USB2 OTG high-speed Port 1 main features . . . 3741
72.2.2 USB2 OTG high-speed Port 1 functional description . . . 3742
72.2.3 USB2 OTG high-speed Port 1 interrupts . . . 3744
72.2.4 Battery charging . . . 3744
72.2.5 ID management . . . 3745
72.2.6 VBUS detection . . . 3745

72.3 USB2 OTG high-speed Port 2 . . . 3745
72.3.1 USB2 OTG high-speed Port 2 main features . . . 3745
72.3.2 USB2 OTG high-speed Port 2 functional description . . . 3746
72.3.3 USB2 OTG high-speed Port 2 interrupts . . . 3748
72.3.4 Battery charging . . . 3748
72.3.5 ID management . . . 3748
72.3.6 VBUS management . . . 3748
72.4 USB Type-C and power delivery interface . . . 3749
72.4.1 USB Type-C and power delivery interface main features . . . 3749
72.4.2 USB Type-C and power delivery interface implementation . . . 3749
72.4.3 USB Type-C and power delivery interface functional description . . . 3751
72.4.4 USB Type-C and power delivery interrupts . . . 3752
72.5 Debug signals . . . 3753

73 USB on-the-go high-speed (OTG) . . . 3754
73.1 Introduction . . . 3754
73.2 OTG main features . . . 3755
73.2.1 General features . . . 3755
73.2.2 Host-mode features . . . 3756
73.2.3 Peripheral-mode features . . . 3756
73.3 OTG implementation . . . 3756
73.4 OTG functional description . . . 3757
73.4.1 OTG block diagram . . . 3757
73.4.2 OTG pin and internal signals . . . 3757
73.4.3 OTG core . . . 3758
73.4.4 OTG detections . . . 3758
73.4.5 High-speed OTG PHY connected to OTG . . . 3758
73.4.6 Battery charging detection . . . 3758
73.5 OTG dual role device (DRD) . . . 3759
73.5.1 ID line detection . . . 3759
73.6 OTG as a USB peripheral . . . 3759
73.6.1 Peripheral states . . . 3760
73.6.2 Peripheral endpoints . . . 3761
73.7 OTG as a USB host . . . 3763
73.7.1 USB host states . . . 3764
73.7.2 Host channels . . . 3765

73.7.3 Host scheduler . . . 3766
73.8 OTG SOF trigger . . . 3767
73.8.1 Host SOFs . . . 3768
73.8.2 Peripheral SOFs . . . 3768
73.9 OTG low-power modes . . . 3768
73.10 OTG Dynamic update of the OTG_HFIR register . . . 3769
73.11 OTG data FIFOs . . . 3770
73.11.1 Peripheral FIFO architecture . . . 3770
73.11.2 Host FIFO architecture . . . 3771
73.11.3 FIFO RAM allocation . . . 3773
73.12 **OTG** interrupts . . . 3774
73.13 **OTG** control and status registers . . . 3776
73.13.1 CSR memory map . . . 3776
73.14 **OTG** registers . . . 3781
73.14.1 OTG control and status register (OTG_GOTGCTL) . . . 3781
73.14.2 OTG interrupt register (OTG_GOTGINT) . . . 3783
73.14.3 OTG AHB configuration register (OTG_GAHBCFG) . . . 3784
73.14.4 OTG USB configuration register (OTG_GUSBCFG) . . . 3785
73.14.5 OTG reset register (OTG_GRSTCTL) . . . 3787
73.14.6 OTG core interrupt register [alternate] (OTG_GINTSTS) . . . 3790
73.14.7 OTG core interrupt register [alternate] (OTG_GINTSTS) . . . 3794
73.14.8 OTG interrupt mask register [alternate] (OTG_GINTMSK) . . . 3799
73.14.9 OTG interrupt mask register [alternate] (OTG_GINTMSK) . . . 3800
73.14.10 OTG receive status debug read register [alternate] (OTG_GRXSTSR) . . . 3802
73.14.11 OTG receive status debug read register [alternate] (OTG_GRXSTSR) . . . 3803
73.14.12 OTG status read and pop registers (OTG_GRXSTSP) . . . 3804
73.14.13 OTG status read and pop registers [alternate] (OTG_GRXSTSP) . . . 3805
73.14.14 OTG receive FIFO size register (OTG_GRXFSIZ) . . . 3806
73.14.15 OTG host non-periodic transmit FIFO size register [alternate] (OTG_HNPTXFSIZ) . . . 3807
73.14.16 Endpoint 0 transmit FIFO size [alternate] (OTG_DIEPTXF0) . . . 3807
73.14.17 OTG non-periodic transmit FIFO/queue status register (OTG_HNPTXSTS) . . . 3808
73.14.18 OTG general core configuration register (OTG_GCCFG) . . . 3809
73.14.19 OTG core ID register (OTG_CID) . . . 3810

73.14.20 OTG core LPM configuration register (OTG_GLPMCFG) 3811
73.14.21 OTG host periodic transmit FIFO size register (OTG_HPTXFSIZ) 3815
73.14.22 OTG device IN endpoint transmit FIFO x size register (OTG_DIEPTXFx) 3815
73.14.23 Host-mode registers 3815
73.14.24 OTG host configuration register (OTG_HCFG) 3816
73.14.25 OTG host frame interval register (OTG_HFIR) 3816
73.14.26 OTG host frame number/frame time remaining register (OTG_HFNUM) 3817
73.14.27 OTG_Host periodic transmit FIFO/queue status register (OTG_HPTXSTS) 3818
73.14.28 OTG host all channels interrupt register (OTG_HAINT) 3819
73.14.29 OTG host all channels interrupt mask register (OTG_HAINTMSK) 3819
73.14.30 OTG host port control and status register (OTG_HPRT) 3820
73.14.31 OTG host channel x characteristics register (OTG_HCCHARx) 3822
73.14.32 OTG host channel x split control register (OTG_HCSPLTx) 3823
73.14.33 OTG host channel x interrupt register (OTG_HCINTx) 3824
73.14.34 OTG host channel x interrupt mask register (OTG_HCINTMSKx) . . 3825
73.14.35 OTG host channel x transfer size register (OTG_HCTSIZx) 3826
73.14.36 OTG host channel x DMA address register(OTG_HCDMAx) 3827
73.14.37 Device-mode registers 3827
73.14.38 OTG device configuration register (OTG_DCFG) 3827
73.14.39 OTG device control register (OTG_DCTL) 3829
73.14.40 OTG device status register (OTG_DSTS) 3831
73.14.41 OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK) 3832
73.14.42 OTG device OUT endpoint common interrupt mask register (OTG_DOEPMSK) 3833
73.14.43 OTG device all endpoints interrupt register (OTG_DAINT) 3834
73.14.44 OTG all endpoints interrupt mask register (OTG_DAINTMSK) 3835
73.14.45 OTG device threshold control register (OTG_DTHRCTL) 3835
73.14.46 OTG device IN endpoint FIFO empty interrupt mask register (OTG_DIEPEMPMSK) 3836
73.14.47 OTG device IN endpoint x control register [alternate] (OTG_DIEPCTLx) 3837
73.14.48 OTG device IN endpoint x control register [alternate] (OTG_DIEPCTLx) 3839

73.14.49 OTG device IN endpoint x interrupt register (OTG_DIEPINTx) 3841
73.14.50 OTG device IN endpoint 0 transfer size register (OTG_DIEPTSIZ0) 3842
73.14.51 OTG device IN endpoint x DMA address register (OTG_DIEPDMAx) 3843
73.14.52 OTG device IN endpoint transmit FIFO status register (OTG_DTXFSTSx) 3843
73.14.53 OTG device IN endpoint x transfer size register (OTG_DIEPTSIZx) . 3844
73.14.54 OTG device control OUT endpoint 0 control register (OTG_DOEPCTL0) 3844
73.14.55 OTG device OUT endpoint x interrupt register (OTG_DOEPINTx) . . 3846
73.14.56 OTG device OUT endpoint 0 transfer size register (OTG_DOEPTSIZ0) 3848
73.14.57 OTG device OUT endpoint x DMA address register (OTG_DOEPDMAx) 3849
73.14.58 OTG device OUT endpoint x control register [alternate] (OTG_DOEPCTLx) 3849
73.14.59 OTG device OUT endpoint x control register [alternate] (OTG_DOEPCTLx) 3851
73.14.60 OTG device OUT endpoint x transfer size register (OTG_DOEPTSIZx) 3853
73.14.61 OTG power and clock gating control register (OTG_PCGCCTL) . . . 3854
73.14.62 OTG power and clock gating control register 1 (OTG_PCGCCTL1) . 3855
73.14.63 OTG register map 3856
73.15 **OTG** programming model 3863

1 Documentation conventions

1.1 General information

The STM32N6x7xx devices have an Arm®[a] Cortex®-M55 core.

arm

1.2 List of abbreviations for registers

The following abbreviations[b] are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

1.3 Register reset value

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is undefined are marked as X.

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is unmodified are marked as U.

1.4 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- Debug port definition/acronyms:
  - **JTAG**: Joint Test Action Group protocol, provides 4-pin standard + 1 optional
  - **SWD**: Serial Wire Debug protocol, provides 2-pin interface
- **Double word**: data of 65-bit length.
- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **Option bytes**: product configuration bits stored in internal fuses.
- **OTP**: one-time programming (fuses).
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.
- **AXI**: Advanced extensible interface protocol.
- **ECC**: error code correction.
- **DMA**: direct memory access.

1.5 Availability of peripherals

For availability of peripherals and their number across all devices, refer to the particular device datasheet.

2 Memory and bus architecture

2.1 System architecture

2.1.1 Introduction

The device architecture relies on an Arm Cortex-M55 core optimized for execution:

- Main masters:
  - Cortex-M55 with Arm TrustZone mainline with two master ports:
    - > M-AXI provides access to the memory and to peripherals
    - > P-AHB provides access to peripherals
  - NPU (neural processor unit), which includes two master AXI ports
- Memories:
  - AHB and APB peripherals
  - 4.2 Mbytes of SRAM
  - 64 Kbytes I-TCM RAM with ECC for critical real-time routines, and 128 Kbytes of D-TCM RAM with ECC for critical real-time data
  - 8 Kbytes of backup SRAM (BKPSRAM) active in V_{BAT} mode
  - 2 x 16-Kbyte AHB RAMs
  - Flexible external memory controller (FLEXMEM) with cypher engine supporting up to 32-bit data bus: SRAM, PSRAM, SDRAM, LPSDR SDRAM, NOR/NAND flash memories
  - XSPIM port2 8-bit configuration with cypher engine
  - XSPIM port1 16-bit configuration with cypher engine

2.1.2 Bus architecture

The bus architecture is divided in two domains, high- and low-performance (see *Figure 1*).

High-speed, multi-frequency domain, AXI compliant interconnect

This high-performance interconnect is mainly used by the CPU, the NPU, and by the high-bandwidth masters (GPU, DMA2D, GFXMMU, VENC, DCMIPP, LTDC, ETH1, OTG1/2, SDMMC1/2, HPDMA1 AXI port).

This domain manages accesses to:

- external flash memories and SRAMs (through the FMC and the XSPI manager)
- main system internal memories AXISRAM1/2/3/4/5/6, boot ROM, VENCRAM (when the VENC is off), and CACHEAXI RAM (when the NPU is off)
- the CPU internal memory (TCM) when accessed by the HPDMA1 AXI and the NPU

  Note: The CPU has internally access to the TCM.
- the GFXMMU
- the STM (system trace macrocell)

The CPU uses its M-AXI master port to access the above-described targets.

The NPU uses a local interconnect (NPU_NIC) to have a direct access to AXISRAM3/4/5/6 and to the CPU TCM. This results in a high-performance and low-latency bus when accessing these targets.

In addition, data interleaving can be enabled on AXISRAM3/4/5/6 to balance the traffic and to improve access performance.

The CPU and high-bandwidth masters use another local interconnect called CPU_NOC to have high-performance access on AXISRAM1/2 and external flash memories.

Note: The boot ROM is accessible only by the CPU through an intermediate interconnect called CPU_NIC.

Multi-layer AHB interconnect

This interconnect is used to access AHBSRAM1/2, BKPSRAM, and peripherals.

The CPU can reach peripherals mapped in the peripheral region (address range from 0x4000 0000 to 0x5FFF FFFF), using the following masters ports:

- the CPU P-AHB master port for data accesses
- the CPU M-AXI master port for instruction accesses

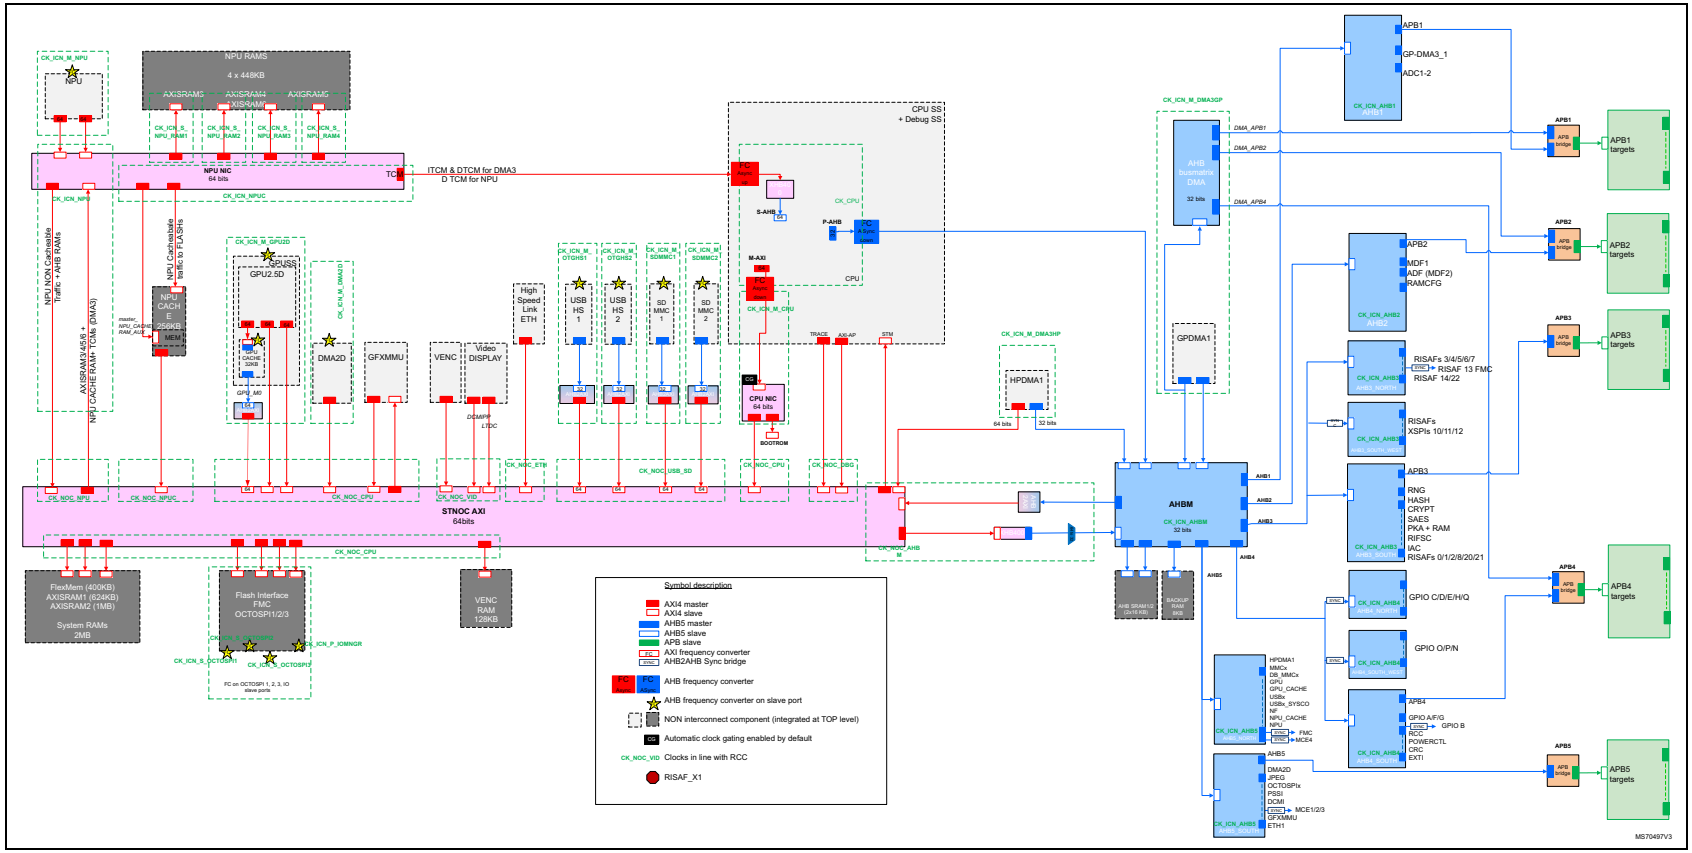
  When P-AHB is disabled, data accesses are performed on M-AXI.

The CPU accesses AHBSRAM1/2 and BKPSRAM through its M-AXI master port. The CPU memory accesses start on the high-performance interconnect before reaching the AHB interconnect.

GPDMA1 and HPDMA1 AHB ports are the other masters on this interconnect.

The GPDMA1_P has a dedicated access to APB1/2/4 peripherals.

Figure 1. Interconnect top view - STM32N6x7 devices



1. The high-performance domain is shown in pink. The low-performance domain is shown in blue.

2.2 Bus network-on-chip (NoC)

2.2.1 STNoC AXI

The STM32N6x7xx STNoC AXI interconnect is built out of the ST in-house network-on-chip. Its main features are:

- Source routed, packet based, wormhole switching forwarding scheme for simultaneous and parallel/pipelined accesses from master to slave
- Independent read and write input/output points to cope with AXI independent channels
- Size and frequency conversion, asynchronism management
- Fine grain automatic clock gating shutting down the clocks to unused network parts at any point in time, with zero delay clock resume
- Internal packets buffering for improved traffic efficiency
- Independent request and response network
- Software accessible registers to observe and report traffic statistics, performance, blocking sources (if any) over the network.

2.2.2 NPU_NIC network interconnect

The NPU_NIC interconnect is based on Arm NIC-400 Network Interconnect. Its main features are:

- High-performance and low-latency interconnect
- Independent read/write request/response channel as defined in AXI protocol
- Asynchronism management
- Address interleaving to AXISRAM3/4/5/6 (can be disabled by software)
- Static QoS assigned by software used at any arbitration node. The highest value has the highest priority. Arbitration with same QoS value uses an LRU (least recently used) algorithm.

2.2.3 Multi-layer AHB interconnect (AHBM)

The multi-layer AHB main features are:

- 32-bit bus matrix running at 200 MHz using a master clock from the RCC
- Simultaneous accesses from different masters to the slaves connected to separated layers
- Five master ports: CPU P-AHB, HPDMA1, GPDMA1_P /M, and CPU_NOC
- Nine slave ports: memories (AHB SRAM1/2 and BKPSRAM), peripherals for AHBx/APBx targets, and CPU_NOC target to reach AXI.

Note: The GPDMA1_P has a direct path to APB1, APB2, and APB4 targets. It bypasses this multi-layer AHB.

2.3 Memory organization

2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

2.3.2 Memory map and register boundary addresses

Program memory, data memory, registers, and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in little-endian format. The lowest numbered byte in a word is considered the word least significant byte, and the highest numbered byte the most significant.

All memory map areas that are not allocated to on-chip memories and peripherals are considered reserved.

The IDAU mapping indicates if a particular memory address is secure or nonsecure.

Table 1. Memory map based on IDAU mapping

IDAU security type	Mapping	Description
-	0xFFFFFFFF	Reserved
-	0xE0100000	Reserved
Cortex-M55 nonsecure	0xE0000000	Cortex-M55 internal peripherals, debug and trace

3 System security

3.1 Key security features

- Security isolation using the TrustZone technology of the Arm Cortex-M55
- OS and dynamic user isolation using the Cortex-M55 MPU technology with firewalling
- Multi-tenancy support: configurable firewalls to allow a trusted OS to ensure software apps installed by different AI providers cannot use the NPU engine or DMA engines to access each other's data
- Secure provisioning of customer keys and firmware
- Secure boot-from-ROM authenticating and decrypting images loaded from an external flash memory or downloaded through UART, USB, I^2C, SPI, FDCAN, or JTAG
- Nonvolatile antifuse storage of, for example:
  - hardware-unique key (HUK) directly wired to DPA-resistant AES engine
  - private key used for secure provisioning of customer keys
  - customer-provisioned firmware signing and encryption keys
  - customer-provisioned key for managing return material analysis (RMA)
  - irreversible counters for key/certificates revocation, updates, factory resets
- Battery-backed volatile storage of, for example:
  - customer-provisioned secret boot hardware key (BHK), directly wired to DPA-resistant AES engine, automatically erased in case of tamper
  - anti-rollback counters
- Provisioning of AES keys in non-volatile storage (for example external flash memory), encrypted with unviewable device-unique keys derived from HUK: a provisioned AES key is never again viewable on the device, and is only used directly in AES hardware accelerators to encrypt and decrypt data
- General-purpose cryptographic acceleration:
  - Two AES 256-bit engine, supporting ECB, CBC, CTR, GCM, and CCM chaining modes: one engine DPA-resistant with side-channel counter-measures, and one fast-implementation engine without DPA-resistance
  - HASH processor, supporting SHA-2 secure hash
  - PKA (public key accelerator) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits): implements side-channel counter measures and mitigations when manipulating secrets
  - RNG (true random number generator), NIST SP800-90B pre-certified
- Memory cipher engines for on-the-fly decryption of data in external memories: implements a key derivation function to increase protection against side-channel attacks (SCA)
- Low-latency encryption engines on NPU bus interfaces: allows AI data to be stored in encrypted format in both external and internal memories
- Arm PSA temporal isolation enforced by hardware using HDPL (hide protection level)
- Debug authentication scheme based on certificates: confers rights on the debugger at an authorized security level

- Active tamper and protection against temperature, voltage, and frequency attacks:
  - Up to seven (inputs, outputs) tamper pins, available in all power modes
  - Immediate erase of battery-backed volatile secrets on confirmed tamper detection

3.2 Secure boot

On an application reset, the Cortex-M55 always boots from the start of an on-chip ROM. This ROM code is used to authenticate and decrypt images loaded into the internal memory from an external flash memory, or through UART, USB, I^2C, SPI, FDCAN, or JTAG.

The lifecycle state of the device is represented in the values of specific fuses. Transforming from one lifecycle state to the next always involves blowing fuses. The boot ROM acts in accordance with what it finds to be the current lifecycle state.

Lifecycle states can be partitioned into two underlying categories: BSEC-open or BSEC-closed (refer to *Section 4.3.7: Lifecycle management* for more details). This is determined by hardware on every system reset by examining the state of the lifecycle fuses.

If the hardware determines at power-up that the device is BSEC-open, it immediately enables debug, and disables any access to fused secrets and secure parts of the ROM. This is referred to as nonsecure boot. The device is in a BSEC-open lifecycle state at the start of manufacturing. It can be transformed back into a BSEC-open lifecycle state if there is a fault requiring the part to be returned for analysis.

If the hardware determines that the device is BSEC-closed, the debug remains disabled. The secure boot from ROM is then enforced, and the boot ROM then consults additional fuses to determine the precise lifecycle state.

Devices are delivered to customers in a BSEC-closed state, so the boot ROM execution is enforced.

On a BSEC-closed device, if the secure_boot fuse bit (see *Section 5: OTP mapping (OTP)*) is still unblown, then the boot ROM behavior depends on the DEV_BOOT pin:

- If the DEV_BOOT pin is set, the boot ROM disables the access to secrets, and opens the debug to allow customer development.
- If the DEV_BOOT pin is not set, the boot ROM executes the boot image regardless of whether it is correctly signed.

However, on a BSEC-closed device, once the secure_boot fuse bit is blown, authenticated secure boot is enforced.

STMicroelectronics supplies signing tools to allow customers to create signed and encrypted boot images. The boot image is sometimes referred as an FSBL (first-stage bootloader), or as an uRoT (updatable root-of-trust firmware).

3.3 Secure provisioning

ST supplies customers with an RSSe (Root Security Services extension) code image to implement SFI (secure firmware install) functionality. The boot ROM authenticates this RSSe code with a hard-coded public key. ST also provisions an ST-certified device-unique key pair into fuses. When customers receive the device, they can boot the supplied SFI image to securely provision their own keys into fuses. The boot ROM uses these keys, whenever it boots, to authenticate and decrypt the customer boot images. The ST-certified

device-unique key pair ensures that this provisioning process is secure and counted. This protects against cloning.

The boot ROM supports up to eight irreversible revocations of firmware signing keys.

The boot image header contains a constant decrypted by the boot ROM using the provisioned firmware encryption key. This derived key is used to decrypt the actual image.

3.4 Temporal isolation

The Arm PSA specification states:

1. The code in each stage must execute its tasks, complete, then terminate, and handover execution to the next stage.
2. The code in each stage must leave boot state to carry forward results and data from one stage to the next.
3. Private data for one stage (especially secrets) must not be directly accessible from later stages.

The STM32N6x7xx devices define four HDPL:

- 0: Boot ROM
- 1: Updatable root of trust (uRoT)
- 2: Level 2
- 3: Level 3

The HDPL is represented with a monotonically increasing 2-bit counter register BSEC_HDPLSR (on the system reset), which does not wrap back to zero. Only a secure privileged software increments this counter (see *Section 4: Boot and security control (BSEC)*).

The SAES (secure AES engine) uses an HDPL input when performing a derivation of the fused HUK to create the DHUK (derived-HUK). The HDPL value seen by the SAES can be increased to a value higher than the current value, to provision data ready for the next temporal stage. However, the generated DHUK with a particular HDPL value cannot be re-generated during later temporal stages (see *Section 48: Secure AES coprocessor (SAES)*).

Temporal isolation can also be implemented in the fuse wrapper (BSEC) via sticky read locks and sticky programming locks. The BSEC hardware also ensures that only the boot ROM accesses certain fuse secrets.

3.5 Resource isolation

In STM32N6x7xx, the runtime software isolation is based on TrustZone.

Each memory address is defined to exist either in the secure or the non-secure world. Some CPU resources (such as stack-pointer registers, MPU registers, interrupt vector tables, or timers), are physically banked between worlds. When the CPU executes a secure code (that is, code fetched from secure-world addresses), it uses the secure-world versions of these resources. When the CPU executes nonsecure code (that is, code fetched from nonsecure world addresses), it uses the nonsecure world versions of these resources. However, for the most part, secure and nonsecure codes use the same CPU hardware.

A nonsecure code is blocked from accessing secure world addresses. It can call only secure code (that is, move into the secure world) via SG (secure gate) instructions, which reside in special secure-world NSC (nonsecure callable) regions.

Trustzone ensures that the operation of a secure code and its data cannot be corrupted by nonsecure code.

3.5.1 Trustzone filtering using IDAU/SAU

The 256-Mbyte address ranges starting at the even addresses 0x00000000, 0x20000000, and 0x40000000, are physically aliased at ranges starting at the odd addresses 0x10000000, 0x30000000, and 0x50000000, respectively.

The intention is that the secure world accesses resources via the odd aliases, and the non-secure world accesses resources via the even aliases.

The address security (S for secure, NSC for nonsecure callable, or NS for non-secure, in descending security order) is determined by the device IDAU (implementation defined attribution unit), and the SAU (security attribution unit). Each of these two units proposes a security level for each address, the resulting level is the higher of the two proposals. The accesses to addresses determined to be S or NSC travel out on the bus marked as secure, those determined to be NS travel out on the bus marked as nonsecure.

The secure OS can define up to eight SAU regions, each of which can be configured as NS or NSC. Any address falling outside a defined SAU region remains secure, hence, at reset, the SAU unilaterally determines that the entire memory is secure.

The SAU is typically configured to open up NS regions for nonsecure code, data, and peripherals in the even address aliases. Locations from 0x10000000 to 0x1FFFFFFF (that contain SG instructions) must be covered by explicit SAU regions configured as NSC.

The IDAU determination of the security of each address is hardwired fixed.

Table 4 shows aliased targets, and the IDAU security assignment.

Table 4. Aliasing

Address region	IDAU assignment	Aliased targets
0x5-------	NSC (secure)	Peripherals
0x4-------	NS (nonsecure)	
0x3-------	NSC (secure)	Internal RAMs, DTCM
0x2-------	NS (nonsecure)	
0x1-------	NSC (secure)	Boot ROM, ITCM
0x0-------	NS (nonsecure)	

If the SAU is configured sensibly, the IDAU is normally irrelevant. The only potential effect of the IDAU is to prevent any attempt via the SAU to demote any of the three “odd” NSC regions listed above to be nonsecure.

A secure software configures the firewalls in front of physical resources (aliased in ranges listed in *Table 4*) to determine in which world the access destination resides. This blocks accesses that arrive marked with a mismatching security attribute. A nonsecure code cannot access destinations that reside in the secure world (as designated by the firewall). Destinations are then dedicated for use by the secure world.

External memories are mapped at addresses from 0x60000000 upwards (not aliased). The SAU can be configured to allocate portions of these memories to the non-secure world. These memories have RISAF firewalls in front of them, that can be configured to mirror SAU settings, and to ensure that DMAs are subject to the same restrictions as CPU code.

3.5.2 Privileged OS-controlled isolation

The Cortex-M55 MPU (memory protection unit) facilitates the isolation between a privileged operating system, and the user processes it schedules.

The MPU is banked between the secure and nonsecure worlds as follows:

- Secure-world accesses to MPU registers update physical registers in the MPU_S, which filters accesses that emerge from the SAU marked secure.
- Nonsecure world accesses to MPU registers update physical registers in the MPU_NS, which filters accesses emerging from the SAU marked nonsecure.

For each world, attributes are defined for 16 non-overlapping regions, and for the remaining background. The MPU blocks user code from accessing regions marked privileged.

If the MPU is configured to designate a memory region as normal, then all transactions initiated by the Cortex-55 on the AXI bus emerge as privileged (even if originated from a user process). Only the MPU prevents CPU user processes from accessing privileged normal data in SRAM and external flash memories.

When switching from one user process to another, the OS can re-program the MPU and peripheral firewalls to ensure each process can only access its own data. A user application may need to use a peripheral with an AXI initiator that continues to operate in background after the user has been descheduled. To avoid the peripheral being blocked by a modified MPU regime, the user process must ask the OS to configure the peripheral to operate in privilege mode on the user's behalf. It is up to the OS to sanity-check the requested operation. The HPDMA on the AXI bus is a special case (see *Section 3.5.4*).

The Cortex-M55 PAHBCR register must enable the P-AHB, and configure it to allow accesses to the peripheral region on the P-AHB bus. The MPU must be configured so that the peripheral region is execute-never device memory. Accesses to peripherals on the P-AHB carry the correct privilege level: to save wasting MPU regions, the MPU can be configured to make the whole peripheral region user-accessible, and to rely on the RISUP downstream filtering to restrict certain peripherals to OS control.

The Cortex-M55 introduces a PXN (privilege-execute-never) region attribute to prevent the OS from being tricked into jumping to user code.

3.5.3 RIF infrastructure

Thanks to hardware mechanisms in the bus, the secure OS ensures that resources and data are available only to agents that operate in the appropriate world, and at the appropriate privilege level. This infrastructure is named RIF (resource isolation framework).

The RIF consists of five components:

- RIMU: placed on AXI bus initiators to determine which attributes are attached to accesses
- RISUP: firewalls placed in front of peripheral bus targets to determine which security and privilege level is allowed to access that peripheral
- RIFSC: centralized block that contains the configuration registers controlling all RIMUs and RISUPs, and determining other general RIF parameters

- RISAF: firewalls placed in front of each memory target, with self-contained (local) configuration registers
- IAC (interrupt access controller): recording all security violation events from all firewalls around the device, in order to present a single interrupt to the CPU

Some peripherals have built-in firewalls, which are configured locally inside the peripheral. These peripherals are called RIF-aware.

The IAC has room for 256 interrupt sources, each corresponding to an IAC index from 0 to 255. Interrupts from the RISUPs occupy most of the first 128 indexes. Interrupts from RIF-aware peripherals and RISAFs occupy indexes from 128 onwards. RISUP and IAC indexes are aligned. The RISUP associated with the IAC index 32 x + y is programmed to be secure by setting RISC_SECCFGx[y]. It is programmed to be privileged by setting RISC_PRIVCFGx[y].

For all RIF firewalling, the security setting of a resource can be configured only by a secure privileged access: the secure OS can assign a RISAF base region to the nonsecure OS. The nonsecure OS determines the position, privilege, and readability of subregions within the base region.

If the resource is set to secure, nonsecure accesses to this resource are blocked. If the resource is set to nonsecure, secure accesses to memories are blocked (no restrictions for peripherals).

For all RIF firewalling, the privilege setting of a resource is only configurable by a privileged access: if the resource has already been configured to be secure, the access must also be secure. If a resource is set to privileged, only privileged accesses are allowed (no restriction if set to unprivileged).

By default, the reset condition for peripheral firewalls is nonsecure unprivileged, for memories is secure privileged. In any case, the Cortex-55 boots in secure mode: the secure software can immediately establish a security regime.

On detecting a violation, a RISAF records locally the attributes of the violating access, and sets an output error signal: its rising edge is captured in the IAC, which can then interrupt the CPU. The handler must first clear the associated flag in the IAC, then clear the error condition recorded in the RISAF.

An illegal access generates a bus error only if it is an instruction fetch.

3.5.4 Multi-tenancy

Several AI network providers may need to have their private NPU data on the device at the same time. This is referred to as multi-tenancy, where providers are considered as tenants on the device.

The secure OS needs to ensure that one tenant cannot snoop or corrupt the private NPU data of another tenant.

Note: Tenants must all trust the secure OS to implement the isolation.

To facilitate the isolation between the NPU networks of distinct tenants, and other CPU software, the RIF and bus infrastructure support the concept of compartments. An AXI bus transaction carries a 3-bit CID value that identifies the transaction initiator compartment. The secure OS configure the RISAF firewalls in front of memories on the AXI buses to filter accesses according to the carried CID.

A RISAF treats a CID = 7 as a wildcard: if it allows an access with CID = n, it also allows it with CID = 7 instead. The CID used by AXI transactions from the DAP is defined by DAPCID in RIFSC_RIMC_CR. This bitfield is reset to seven, but can be changed by a secure privileged access.

The CPU always issues transactions on the AXI bus with CID = 1. Only the CPU initiates transactions on the AHB bus (directly, or indirectly via the DMA). The AHB does not carry a CID bus: implicitly all transactions to peripherals occurring on the AHB bus have CID = 1.

In a multi-tenancy scenario, a distinct CID (values ≠ 1 and ≠7) is assigned to each tenant. The secure OS configures the RISAFs to ensure tenant data are only accessible by accesses carrying the tenant CID. Before allocating temporary exclusive NPU use to a particular tenant, the secure OS configures the RIFSC: the NPU RIMUs ensure AXI reads and writes are made with the CID of this tenant. This ensures the NPU cannot be used to snoop the data of a different tenant.

A mechanism on STM32N6x7xx devices allows a secure tenant to use the HPDMA to move its own data, but no-one else's. The secure OS can allocate an HPDMA channel n to a tenant c by setting SCID = c in HPDMA_CnCIDCFGR. This ensures that transfers on this channel can be set up only by configuration writes that carry CID = c. Tenants operate as user processes, so such an allocated channel n must be configured with bit n = 0 in HPDMA_PRIVCFGR (unprivileged). The mechanism is available only for tenants operating in the secure world, so the secure OS must set bit n = 1 in HPDMA_SECCFGR. AXI transactions made by the channel carry security, privilege, and cid attributes that match what these registers are set to.

Just before scheduling a tenant's user process, the secure OS must write the tenant CID in SYSCFG_SEC_AIDCR. This ensures that all AHB secure user accesses which arrive at the HPDMA, appear to carry that CID. The tenant’s secure user process is then only able to use secure HPDMA channels allocated to its own CID. When descheduling the tenant’s secure user process, the secure OS resets SYSCFG_SEC_AIDCR to 1. The tenant’s HPDMA job continues to operate in the background. Other user processes cannot interfere with HPDMA channels belonging to that tenant.

The SYSCFG_SECPRIV_AIDCR register plays the same role for AHB secure privileged accesses which arrive at the HPDMA. The interrupt handler for a DMA channel allocated to a tenant user must configure this register in order to interrogate and clear the interrupt registers in this DMA channel.

SYSCFG_SEC_AIDCR and SYSCFG_SECPRIV_AIDCR affect only the CID of secure accesses. Nonsecure accesses always carry a CID of 1 (for example the CPU).

All other AXI initiators have RIMUs: what was described above for the NPU can be applied to other AXI initiators (but using the RISUP and RIMUs).

3.5.5 NPU timeslicing

If two AI networks come from different tenants who expect their data to be isolated from each other, a privileged software (trusted by both networks and running at a higher privilege or security level) must decide which tenant has exclusive use of the NPU at any given time. The OS only opens the RISUP on the NPU configuration port to user accesses while this particular tenant user process is running.

Before allocating exclusive NPU use to a tenant network, the secure OS arranges for the following:

- Reprogram all keys in the NPU.

- Clean the internal NPU state (registers and internal RAM).
- Program the NPU RIMC with a CID used in the RISAFs to protect the tenant data.

The RIMUs on the NPU initiator ports ensure that NPU accesses made on behalf of the tenant are made with the appropriate CID.

Note: Any software that accesses the NPU configuration port thereby accesses any data that the NPU accessed to. Each tenant trusts the secure OS to ensure that, while the NPU operates with a tenant CID, only the tenant software driver process accesses the NPU configuration port via the RISUP. When the secure OS switches to another tenant driver process, it must close the NPU RISUP: other processes cannot take control of the NPU while it is still processing the current tenant data.

3.5.6 NPU cache (CACHEAXI) management

The CID and security bits of an access that arrives at the CACHEAXI are treated exactly as if they were four extra address tag bits. This implies that cached data cannot be shared between two NPU networks with distinct CIDs: this may result in the same physical memory data appearing in two distinct cache lines (incoherency). The software must ensure that such shared data is uncacheable.

The privileged bit of an access is also stored in the cache line, and used during eviction. It is not treated as an address tag bit (not taken into account in deciding whether there is a HIT or MISS). The code must not attempt to lower the privilege level in the NPU RIMC without first flushing the cache: this may result in the user-level network reading data that had been left in the cache when the network was privileged.

With these mechanisms, it is not necessary to flush the whole CACHEAXI when the secure OS hands the NPU use from one tenant to another, at a time period boundary.

The CACHEAXI has a configuration port that allows the software to perform maintenance operations. For example, the user software may need to ensure dirty cache lines are cleaned (written back to memory) in order to restore system coherency with the CPU. Some dirty cache lines may must be invalidated without cleaning them (for example, when there is a problem with the downstream memory). Such an invalidate-only operation could be used by an NPU user to subvert the operation of another NPU user. The RISAF filter in front of each cache configuration port can be configured to ensure that invalidate-only operations are performed only by commands (written on the cache configuration port) coming from the secure OS (highest authority).

3.5.7 Memory firewalls

Each RISAF protecting a memory supports up to seven base regions: two subregions are associated with each base region.

Only the secure OS configures the permissions of a base region. Locations outside any enabled region belong to the secure OS.

If the secure OS configures a base region to reside in the nonsecure world, it can delegate control of the corresponding two subregions to the nonsecure OS. The nonsecure OS can then position subregion windows for tenants.

Note: The security level of a subregion cannot be raised relative to its encompassing base region. Although a base region can be made accessible by several CIDs, a subregion is dedicated to a single CID.

If the nonsecure OS needs to control more subregions (for example four), the secure OS can set up two identical base regions, both delegated to the nonsecure OS.

3.5.8 RIF-aware peripherals

Direct memory access controllers (GP/HPDMA)

The security attributes of each DMA channel can be configured separately. When a DMA channel is configured as secure, the source and destination transfers can be independently set as secure or nonsecure by a secure application: this is done with SSEC and DSEC in GP/HPDMA_CxTR1. Linked lists must be in the secure-world memory.

When a DMA channel is configured to be nonsecure, linked lists must be in the nonsecure world memory. SSEC and DSEC must also both be zero, otherwise the transfer does not proceed.

When a DMA channel is configured to be unprivileged, the linked lists, source, and destination must all be in unprivileged locations.

As mentioned in *Section 3.5.4*, HPDMA channels can be allocated to a compartment. The OS can allow a scheduled user process to use this channel. Accesses made by this channel (even after a user process descheduling) carry the compartment CID: this facilitates isolation between user processes.

See *Section 18: High-performance direct memory access controller (HPDMA)*. The software should leave HPDMA_CxCIDCFGR[SEM_EN] = 0, since a semaphore mechanism is intended to allow multiple concurrent CPUs to share a resource, and there is only one CPU.

Power control (PWR)

PWR registers are secured through PWR_SECCFGR and PWR_PRIVCFGR, individually protecting the following features:

- system supply configuration
- voltage scaling
- low-power mode
- wake-up (WKUP) pins
- voltage detection and monitoring
- backup domain control.

When a GPIOx is configured as secure (respectively privileged), the corresponding bits in PWR_IORETENRx and PWR_IORETRx (control the pin standby configuration) become secure (respectively privileged) (see *Section 13: Power control (PWR)* for details).

Secure clock and reset (RCC)

RIFSC security settings are transmitted to the RCC. If a peripheral RISUP is programmed as secure (respectively privileged), the peripheral clock and reset bits become secure (respectively privileged).

The following configurations can be made secure-only and/or privileged-only, using RCC_SECCFGR and RCC_PRIVCFGR:

- external clock (such as HSE or LSE), internal oscillator (such as HSI, MSI, or LSI)
- main PLL and AHB prescaler
- system clock-source selection

- MCO clock output
- reset flag
- automatic internal oscillator wake-up configuration

See *Section 14: Reset and clock control (RCC)* for details.

Real time clock (RTC)

The following RTC features can be individually made secure-only and/or privileged-only: alarm A, alarm B, calibration, initialization, timestamping, and wake-up (see *Section 61: Real-time clock (RTC)* for details).

Note: The RTC security configuration is not affected by a system reset.

Tamper and backup registers (TAMP)

The control of the main tamper functionality can be made secure-only and/or privileged-only.

The TAMP also contains a monotonic counter register for anti-rollback functions. Its use can be made secure-only and/or privileged-only.

The backup registers can be partitioned by a secure privileged software into three zones:

- protection zone 1: fully accessible for both secure and nonsecure
- protection zone 2: secure read/write, but read-only for nonsecure
- protection zone 3: secure-privileged

The privilege level of zones 1 and 2 can also be individually configured (see *Section 62: Tamper and backup registers (TAMP)* for details).

Liquid-crystal thin-film transistor display controller (LTDC)

The LTDC address space is split into three sections (common, layer1, and layer2), which are protected by a RISUP. Security and privilege settings of each region are determined by RIFSC registers.

The hardware ensures that, if both layers are configured to occupy the same virtual level, layer2 is displayed on top of layer1. When both secure and nonsecure softwares use a layer, the secure software must configure:

- layer1 as nonsecure
- layer2 as secure
- layer2 to occupy the top virtual layer (malicious nonsecure software never obscures it)

The common section can be set as secure or nonsecure.

General-purpose I/Os (GPIO)

Each GPIO port contains two 16-bit registers: GPIOx_SECCFGR and GPIOx_PRIVCFGR. These registers are only writable by the secure OS. They determine the security and privilege levels to configure each of the 16 pins of a GPIO port. Outputs of these registers are also wired to the PWR, where they determine permission to configure the retention behavior of each pin.

At reset, unlike all other peripherals, each GPIO pin is configured as secure by default. This simply an extra-physical-robustness feature: the CPU boots in secure-privileged mode, and can initialize all GPIOs as secure anyway.

When a digital AF is used (input/output mode), if the peripheral is configured as secure, the I/O pin must also be secure, otherwise input and output are zeroed. This stops non-secure software snooping or interfering with a secure I/O communication.

The ADC12 can control an analog switch in the GPIO. This switch is forced open when the ADC12 is nonsecure and the I/O is secure: this prevents secure analog inputs to be directed to a nonsecure peripheral.

Table 5 lists input/output signals that are not blocked when the I/O is set as secure and the associated peripheral is nonsecure.

Example: when a secure application sets PA0 as secure to be used as UART4_TX, if TAMP is nonsecure, it can be programmed to capture the USART input traffic through the TAMP_IN signal.

For each case described in the table below, the secure application must decide whether there is a potential effect on data integrity or confidentiality, and whether it is critical or not.

Table 5. Nonsecure peripheral functions that can be connected to secure I/Os

Peripheral	Signal(1)	Input	Output	Bitfield to set to make the peripheral secure
TAMP	TAMP_INx (x = 1 to 7)	X	-	TAMPSEC in TAMP_SECCFGR
	TAMP_OUTx (x = 1 to 6, 8)	-	X	
RTC	RTC_OUTx (x = 1, 2)	-	X	SEC in RTC_SECCFGR
	RTC_TS	X	-	TSSEC in RTC_SECCFGR
PWR	WKUPx (x = 1 to 8)	X	-	WUPxSEC in PWR_SECCFGR
RCC	LSCO	-	X	LSSEC in RCC_SECCFGR
EXTI	EXTIx (x=0 to 22)	X	-	SECx in EXTI_SECCFGR

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

Refer to *Section 15: General-purpose I/Os (GPIO)* for more details.

Extended interrupts and event controller (EXTI)

The EXTI can be configured to make individual events secure-only and/or privileged-only (see *Section 25: Extended interrupts and event controller (EXTI)* for more details).

System configuration controller (SYSCFG)

All SYSCFG registers are secure-writable only (see *Section 16: System configuration controller (SYSCFG)* for more details).

Microcontroller debug unit (DBGMCU)

The MCU debug component (DBGMCU) contains registers to stop (freeze) a peripheral.

If a secure debug is not authorized, the DAP is only able to make nonsecure accesses on the bus. It is not possible to freeze secure peripherals. The stop bits are writable in accordance with the security level of the associated peripheral.

Refer to *Section 78: Debug support (DBG)* for more details

3.6 Secure storage

3.6.1 Battery backup registers

Secrets can be stored in backup registers. The secure-privileged software ensures that some or all registers are not accessible to lower security or privileged levels.
The 256-bit BHK is wired directly to a key derivation block in the SAES: it is used to derive further secret keys. The BHK can be made unreadable after being written.

Use of the BHK and access to backup registers and backup RAM, are blocked while a potential tamper is flagged.

The secrets are erased by a reset of the V_{BAT} battery-backup domain. Such a reset may be as a result of a legitimate “factory-reset” procedure, or because of a confirmed tamper. The secrets can subsequently be updated, if the device needs to be re-deployed.

3.6.2 Secure RAM and registers

The 16-Kbyte AHB SRAM2 aliased at 0x28004000 and 0x38004000 is called secure RAM: it is erased on reset and on a confirmed tamper, and blocked during a potential tamper (reads are zeroed, writes are ineffective). See *Section 62: Tamper and backup registers (TAMP)* for details of the tamper mechanism.

MCE key registers are also considered as security assets: they are immediately erased on a confirmed tamper.

Some SRAMs are erased by hardware on reset (see *Section 10.3: RAMCFG functional description*).

3.6.3 Fuse secrets

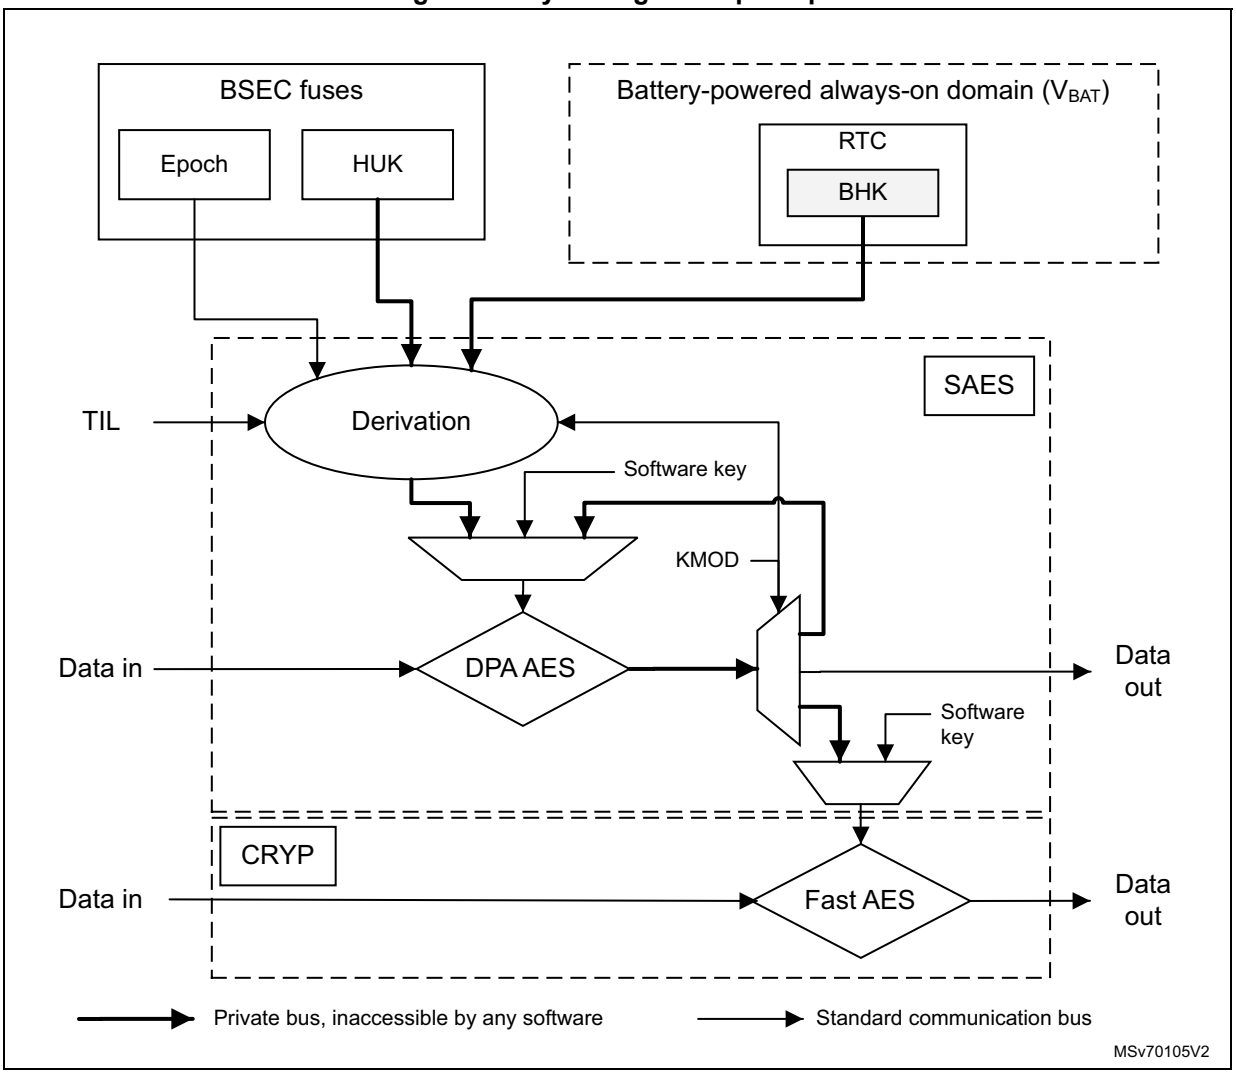
These are provisioned by ST, or by the customer. The secrets can only be read from the BSEC by secure-privileged software. The BSEC offers the possibility to sticky-read-lock fuse secrets: a secure software can hide a secret after it has been used (that is, implement HDPL). Fused secrets can never subsequently be updated.

Fuse words 376 to 383 (HUK) are provisioned automatically with a random number during manufacturing. The fused value is wired directly to the hardware SAES engine, and cannot be handled by software. It is unique to the device, and not readable by it. It constitutes a PU (physically unclonable function).

3.6.4 Hardware key management

Figure 2 shows how key management service applications use the DPA-resistant SAES engine to provision keys to the external flash memory, or fuses in encrypted form (encrypted with a device-unique key derived from HUK and/or BHK). The provisioned key can subsequently be used to encrypt/decrypt data, it cannot be directly handled by the software.

Figure 2. Key management principle



The mechanism is based on KMOD[1:0] and KEYSEL[2:0] in SAES_CR The decryption result is read out and handled by software only when KMOD = 0b00. If KMOD ≠ 0 and KEYSEL is selecting the output of the derivation function, the decryption result goes directly on dedicated buses to key registers in the SAES (when KMOD = 0b01), or (when KMOD = 0b10) to the fast CRYP1. KMOD is also an input to the derivation function that processes the device secret HUK and BHK

A key to be provisioned in the device can be encrypted with a device-unique key (derived from HUK and/or BHK) with KMOD = 0b01 or 0b10 in SAES_CR. This key is then stored somewhere in encrypted format. When this encrypted key needs to be used, it can only be successfully decrypted with the same KMOD setting. The key cannot now be output as clear text and handled by software: it can only be directly placed in unreadable key registers, and used to decrypt or encrypt data. Once the key has been provisioned, it can never again be viewed on the device in clear.

The derivation function depends on the epoch input from the BSEC: if epoch fuses are incremented, any keys provisioned during a previous epoch are never again usable.

The derivation function also depends on the 2-bit TIL input from the BSEC. The software can set this input value to something later than the current HDPL, but can never set it to anything earlier. Keys are always provisioned for use up to a particular HDPL stage. Once that stage has finished, this key is no longer usable.

The KEYSEL field in SAES_CR selects the source of the key used in the SAES.

- 0b001: derived key based only on the HUK
- 0b010: derived key based only on the BHK
- 0b100: derived key based on a combination of HUK and BHK
- 0b000: software loadable (but unreadable) key register

3.6.5 Unique ID

The device stores a 96-bit ID, unique to each device (see *Section 79: Device electronic signature*).

Application services use this unique identity key to identify the product in the cloud network, or to make it difficult for counterfeit devices or clones to inject untrusted data in the network.

Alternatively, the 256-bit device unique key (HUK) can be used (see *Section 3.8.1*).

3.7 Tamper detection and response

The STM32N6x7xx devices include active protection of critical security assets against temperature, voltage, and frequency attacks. The detection of such attacks is managed in the RTC, which resides on V_{BAT} domain (see *Section 61: Real-time clock (RTC)* for details.

The devices support eight input/output tamper pins, which allow four independent active-tamper meshes (or up to seven if the same output pin is shared by several input pins). Four pins are in the V_{BAT} domain.

Active pins are clocked by the LSE, and are functional in all system operating modes (Run, Sleep, Stop, Standby, or Shutdown), and in V_{BAT} mode.

The detection time is programmable, and a digital filtering is available (tamper triggered after two false comparisons in four consecutive comparison samples).

Timestamps are automatically generated when a tamper event occurs.

Table 6. Internal tampers in TAMP

Tamper input	NOER bit number in TAMP_CR3	Tamper source
ITAMP1	0	RTC voltage domain (V_{SW}) monitoring
ITAMP2	1	Temperature monitoring
ITAMP3	2	LSE monitoring(1)
ITAMP4	3	HSE monitoring
ITAMP5	4	RTC calendar overflow (rtc_calovf)
ITAMP6	5	JTAG/SWD access when closed
ITAMP7	6	V_{CORE} monitoring
ITAMP8	7	Monotonic counter overflow

Table 6. Internal tampers in TAMP (continued)

Tamper input	NOER bit number in TAMP_CR3	Tamper source
ITAMP9	8	Fault detected in SAES, PKA, SAES, or RNG
ITAMP10	-	Reserved
ITAMP11	10	IWDG_reset and TAMP_potential_tamper

1. LSE missing or over frequency detection (> 2 MHz), glitch filter (> 2 MHz).

Each tamper source, whether internal or external, can be enabled or disabled.
When the event associated with an enabled tamper source occurs, it is called tamper event, and it results in the following:

- BHK and HUK (dedicated keybuses to SAES) are masked to zero and invalidated.
- PKA, SAES, CRYP, and HASH are reset, unless the boot ROM has set the SYSCFG_POTTAMPRSTCR register to indicate it safely controls them.
- The backup RAM and registers, and the secure RAM (16-Kbyte AHB SRAM2 aliased at 0x28004000 and 0x38004000) are inaccessible (read-as-zero).
- Fuse secrets are un-reloadable by anyone except the boot ROM.

Each tamper source can be further configured to generate an immediate erase of device secrets. An event on a tamper that is configured to do no erase, is called a potential tamper. The secure software must decide on the response.

Note: The boot ROM always sets SYSCONF_POTTAMPRSTCR to override any potential tamper, and to ensure it can access the firmware key, and use the crypto accelerators.

The boot ROM can load the FSBL even if a potential tamper occurs before or during boot.

Once the application analyzes the situation following a potential tamper event notification, there are two possible cases:

- The application launches secret erase with a software command by setting BKERASE in TAMP_CR2.
- The application just clears the flags to release secret blocking (false tamper).

An event on a tamper configured to perform immediate erase of device secrets is called a confirmed tamper. The device secrets consist of the backup registers, MCE key registers, the content of the PKA SRAM, and the secure AHB SRAM2 (erased as soon as V_{DD} is present). There is a configurable option that says that the content of the backup RAM must also be considered as device secrets, and erased on a confirmed tamper. It is optional because the expectation is that the backup RAM only ever contains secrets stored in a form encrypted by a key in backup registers, and when they need to be used, they are decrypted into the secure AHB SRAM2.

Each source of tamper can be configured to trigger the following events:

- Generate an interrupt, able to wake up the device from Stop and Standby modes.
- Generate an hardware trigger for the low-power timers.

The system includes a watchdog that the software needs to refresh regularly (and eventually fires if the software hangs). If the watchdog fires, and there is a potential tamper flagged (not yet analyzed by the software), ITAMP11 is set.

ITAMP11 must be configured as a confirmed tamper (performs an immediate erase of device secrets).

Note: SYSCONF_POTTAMPRSTCR only overrides a potential tamper. If a confirmed tamper occurs while the boot ROM operates, fuse secrets are made inaccessible until the next system reset. This may cause the authentication to fail, and a system reset is eventually triggered by the watchdog. By this time, all device secrets have been erased, and SYSCONF_POTTAMPRSTCR can override blocks that caused the flagging of a tamper event. The software can boot, and, for example, display a message indicating the occurrence of the confirmed tamper.

The effect of low-power modes on a tamper detection are summarized in the table below.

Table 7. Effect of low-power modes on TAMP

Mode	Description
Sleep	No effect on tamper detection features TAMP interrupts cause the device to exit Sleep mode.
Stop	No effect on tamper detection features, except for level detection with filtering and active tamper modes that remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit Stop mode.
Standby	No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit Standby mode.
Shutdown	No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE. Tamper events cause the device to exit Shutdown mode.

3.8 Crypto engines

3.8.1 Accelerators

The device implements cryptographic algorithms as recommended by national security agencies (such as NIST for the U.S.A, BSI for Germany, or ANSSI for France). These algorithms are used to support privacy, authentication, integrity, entropy, and identity attestation.

The embedded crypto engines enable lower processing times, and lower power consumption when performing cryptographic operations. This offloads these computations from the Cortex-M55. The SAES engine offers two important features, which cannot be implemented by software: pure hardware key handling, and DPA resistance.

For product certification purposes, ST provides certified device information on how these security functions are implemented and validated.

For more information on crypto engine processing times, refer to the dedicated section in the reference manual.

Table 8 lists the available accelerated cryptographic operations.

Table 8. Accelerated cryptographic operations

Operations	Algorithm	Specification	Key lengths (in bit)	Modes
Get entropy	RNG	NIST SP800-90B(1)	N/A	Software and hardware(2) modes running in parallel
Encryption, decryption	AES(3)	FIPS PUB 197 NIST SP800-38A	128, 256 (192 in CRYP only)	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D		GCM, CCM
Cipher-based message authentication code		NIST SP800-38D		GMAC
Checksum	SHA-1	FIPS PUB 180-4	N/A	Digest 160-bit
Cryptographic hash	SHA-2			SHA-224, SHA-256, SHA-384, SHA-512
Keyed-hashing for message authentication	HMAC	FIPS PUB 198-1 IETF RFC 2104	Short, long	All supported algorithms
Encryption/decryption key-pair generation(4)	RSA	IETF RFC 8017 NIST SP800-56B	Up to 4160	RSAES-OAEP
Signature(4) with hashing Signature verification	RSA	IETF RFC 8017 FIPS PUB 186-4	Up to 4160	PKCS1-v1_5, PSS
	ECDSA	ANSI X9.62 IETF RFC 7027 FIPS PUB 186-4	Up to 640	Refer to the *Section 52: Public key accelerator (PKA)* for details
Key agreement	ECDH	ANSI X9.42		

1. Certifiable using STMicroelectronics reviewed documents.
2. Random number distribution to the SAES and the PKA, using a dedicated hardware bus.
3. ECB, CBC, CTR, GCM, and CCM chaining modes are protected against side-channel and timing attacks in SAES (see *Section 3.8.2*).
4. Private-key cryptography is protected against side-channel and timing attacks.

The PKA accelerates asymmetric crypto operations (such as key pair generation, ECC scalar multiplication, point on curve check). See *Section 52: Public key accelerator (PKA)* for more details.

The STM32N6x7xx devices have two AES engines:

- The CRYP includes a fast AES engine with 11 cycles per 16-byte block (see *Section 49: Cryptographic processor (CRYP)*).
- The SAES contains a DPA-resistant AES engine, which implements counter-measures and mitigations against power and electromagnetic side-channel attacks. The SAES is much slower.

SAES and CRYP engines support the chaining modes mentioned in *Table 8*.

As shown in *Section 3.6*, the SAES can be used for extra-secure on-chip storage for sensitive information. For more information, refer to *Section 48: Secure AES coprocessor (SAES)*.

3.8.2 Memory cipher engine (MCE)

The MCE implements an on-the-fly encryption/decryption of data to/from external memories, which are more vulnerable to side-channel attack than internal memories (traffic on the interface is accessible). The MCE is then designed to make such attacks prohibitively expensive.

The MCE is instantiated in front of each external memory interface (memory-mapped at addresses above 0x60000000). The MCE is used to define four non-overlapping regions of target memory. Each region can be configured to be encrypted in a different way.

Secure software writes master keys into unreadable MCE registers, and then configure each region: define which master key is used for encrypting data in this region.

For each 32-byte memory block in a region, the MCE uses this block address to derive a specific key for encrypting data in this block. This is done on-the-fly, using the selected master-key. Side-channel attacks are then much more expensive, since an individual attack only uncovers 32 bytes of data.

The user chooses once, at application start, whether to use AES (128 or 256) or NOEKEON for the final data encryption (NOEKEON being faster).

Each master key is defined with an algorithm attribute that determines one of the following:

- It is input to a strong derivation for each block.
- It is input to a faster but weaker derivation.
- It is used directly as a very-fast but weak stream cipher (only suitable for read-only data).

Each key and its attributes are sticky-lockable. A key cannot be partially overwritten. If its attributes are changed, the key is zeroed.

When a tamper event is confirmed in the TAMP, all MCE keys are erased, encrypted regions are read as zero, and writes ignored, until the MCE is properly initialized again.

A typical MCE use is detailed in *Section 3.8.2*. For more details on the MCE programming, refer to *Section 51: Memory cipher engine (MCE).*

3.8.3 NPU encryption

The encryption that uses the MCE has a latency of at least 11 cycles, and a block size of 16 bytes. This imposes an heavy overhead on NPU memory transactions. Therefore the NPU is equipped with its own low-latency encryption engines on its 8-byte-wide AXI initiator ports.

The formula for creating a 64-bit ciphertext C_x, from plaintext P_x, which resides at an address $addr_x$, is:

$$C_x = P_x \oplus H(K_{128}, addr_x, ID_y)$$

where:

- H is the cryptographic function.
- K_{128} is a 128-bit key written to configuration registers in the NPU.

- ID_y is a value that software can modify when the NPU rewrites a new value to the same address.

The latency through the NPU encryption engine is 3 or 4 cycles (depending on a strength option selected by the software). See *Section 20: Neural-ART accelerator™ (NPU)*.

3.9 Access controlled debug

The BSEC and DBGMCU hardware support an Arm PSA-compliant debug authentication mechanism.

A secure debug is where the debugger arranges to make secure privileged accesses on its AXI initiator. A nonsecure debug is more restricted: the debugger can only make non-secure privileged accesses via its AXI port.

On power-up, regardless of whether or not the reset pin is still asserted, fuses are immediately read to determine whether the device is BSEC-open or BSEC-closed. If the device is BSEC-open, an attached debugger can perform a “chip discovery” (reading various CPU identification registers), even while holding the device in reset via the RESET pin.

On a BSEC-closed device, the debug access depends on the content of BSEC_DBGCR and BSEC_AP_UNLOCK, which are only writable once by secure-privileged code after the boot ROM has completed. The debug opens when both conditions are met:

- DBG_UNLOCK = 0xB4 in BSEC_DBGCR.
- UNLOCK = 0xB4 in BSEC_AP_UNLOCK.

The current HDPL (reported in BSEC_HDPLSR) must also be non-zero. It must reach the level defined by DBG_AUTH_TIL in BSEC_DBGCR. DBG_AUTH_SEC in BSEC_DBGCR determines whether it is secure or nonsecure debug (see *Section 4: Boot and security control (BSEC)* for more details).

In order to control the debug reopening, the uRoT can impose a debug authentication protocol. This protocol must implement a challenge response mechanism based on asymmetric cryptography to authenticate requests from the host (relying on an OEM debug public key stored in the device by the OEM).

The protocol can implement a bidirectional communication between the host and the device through a mailbox interface located in the DBGMCU. The host debugger writes to the mailbox via the JTAG/SWD interface, and expects to get responses and messages from the device via the same mailbox.

The debug authentication protocol is launched on a power-up of the device, when an open-request message is posted by the host, while the device is still under reset. Trusted DBG_AUTH code sees this, and generates a random challenge token. The debugger appends this token to a certificate chain that confers certain rights to the debugger, signs this "debug certificate" structure, and submits it back to the device. The DBG_AUTH code validates it with respect to a root public key provisioned in fuses by the OEM. The random token stops any later replay of the same interaction.

The debug certificate determines whether the debug is secure or nonsecure.

BSEC_DBGCR is only reset on power-up: it retains its value through warm resets. The debugger does not have to repeat the authentication procedure on system resets.

4 Boot and security control (BSEC)

4.1 Introduction

The boot and security control (BSEC) peripheral manages the accesses to an embedded one time programmable (OTP) array of fuses. Those fuses are used to store on-chip, non-volatile data like boot and security parameters.

Embedded non-volatile secrets are stored in BSEC upper area that is only accessible while BSEC is operating in its BSEC-closed state. When the BSEC state is BSEC-open, those non-volatile secrets are permanently hidden.

4.2 BSEC main features

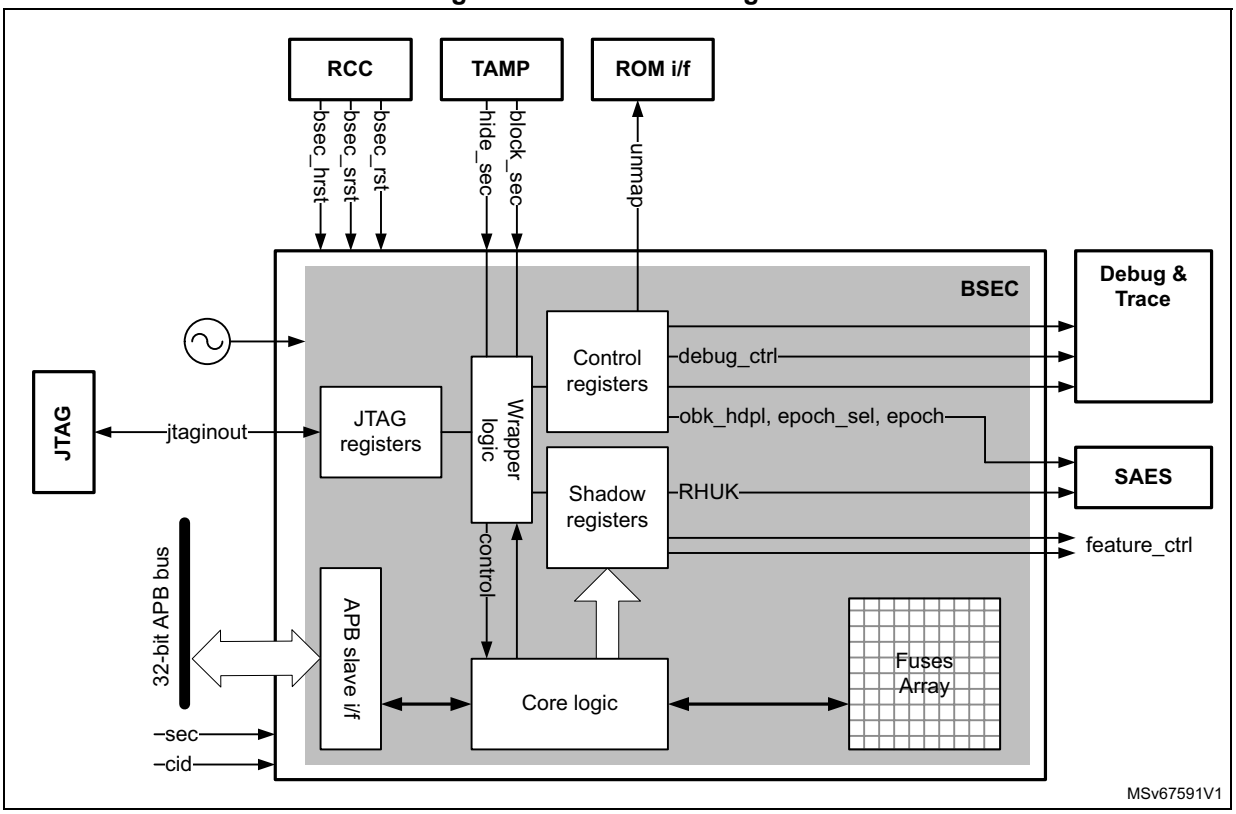
- APB peripheral, accessible through 32-bit word accesses only.
- 12 Kbits of OTP (effective)
  - 4096 lower OTP bits, bitwise (1-bit) programmable
  - 4096 middle OTP bits, bulk (32-bit) programmable
  - 4096 upper OTP bits, bulk (32-bit) programmable, only accessible when BSEC is in the BSEC-closed state.
- Reading and programming of OTP fuses, with detailed status reporting
- Shadowing in register flops of predefined fuse words, loaded at BSEC cold and warm resets. Shadow fuse registers are writable unless write locked until next BSEC cold or warm reset.
- Locking of OTP word programming, permanently or until next BSEC cold and warm resets. Option of global programming lock until next BSEC cold and warm reset.
- Read locking of fuse words (word granularity) until next BSEC cold or warm reset
  - Locked shadowed words cannot be reloaded from the fuse array (fixed value)
  - Locked unshadowed words read as 0.
- Device lifecycle management.
  - Read as 0 of upper fuse words (including RHUK) when STMicroelectronics engineering modes are enabled (BSEC-open state).
  - Possibility to go to BSEC open state using a 128-bit password (four trials).
  - Non-volatile key storage revocation counter (epoch).
- Four 32-bit scratch registers to store values persistent across device warm reboot.
- IN and OUT 32-bit registers to communicate information with external agent via JTAG.
- Monotonic hide protection level counter allowing temporal isolation of keys and debug ability.
- Support for TrustZone® and STM32 resource isolation framework (RIF).
- Non-volatile storage of randomly generated 256-bit root hardware unique key (RHUK), directly delivered to SAES peripheral. This key is never readable by any software, and it can be zeroed until next BSEC cold or warm reset.

4.3 BSEC functional description

4.3.1 BSEC block diagram

Figure 3 shows the BSEC block diagram.

Figure 3. BSEC block diagram



4.3.2 BSEC internal signals

Table 9 describes the user relevant internal signals interfacing the BSEC peripheral.

Table 9. BSEC internal input/output signals

Signal name	Signal type	Description
bsec_rst	Digital input	BSEC cold/warm resets from RCC (see *Section 4.3.17*).
bsec_srst		
bsec_hrst		BSEC hot reset from RCC (see *Section 4.3.17*).
jtaginout	Digital input and output	Interface to JTAG, including clock and reset.
hide_sec	Digital input	Set by TAMP in case of confirmed tamper (see *Section 4.3.17*).
block_sec	Digital input	Set by TAMP in case of potential tamper (see *Section 4.3.17*).
rhuk	Digital output	256-bit root hardware unique key output to SAES peripheral.

Table 9. BSEC internal input/output signals (continued)

Signal name	Signal type	Description
obk_hdpl	Digital output	Control outputs to SAES peripheral to influence generation of DHUK.
epoch_sel epoch	Digital output	Control outputs to SAES peripheral to influence generation of DHUK.
debug_ctrl	Digital output	Device debug and trace control signals (see *Section 4.3.11*).
feature_ctrl	Digital output	Device feature control signals (see *Section 4.3.12*)
bsec_done	Digital output	End of BSEC cold/warm reset operation to RCC.

4.3.3 BSEC reset and clocks

BSEC is clocked by a device-embedded oscillator (RCBSEC). Because BSEC is clocked by an internal oscillator, an access to fuse array is robust against external fault injection on clocks.

The BSEC has three resets:

- a cold POR (power-on reset) directly driving *bsec_srst*.
- a warm system reset (*bsec_rst*) asserted when POR is asserted, but also by other sources of system reset, including a PAD reset.
- a hot reset input (*bsec_hrst*), driven directly by *bsec_done*.

BSEC flops on the cold reset retain their values through warm reset, while the rest of the system remains in reset until the auto-load process has completed (*bsec_done* = 1) and fuse output values are stable.

On a POR, the BSEC temporarily emerges from warm reset for the duration of the auto-load process, even if *bsec_rst* remains asserted, so that the auto-load process can determine values for flops on the cold reset. This means when the device is powered up, the security state is immediately established, so that a debugger may be allowed to perform discovery operations soon after power-up, even if the PAD reset is still being asserted.

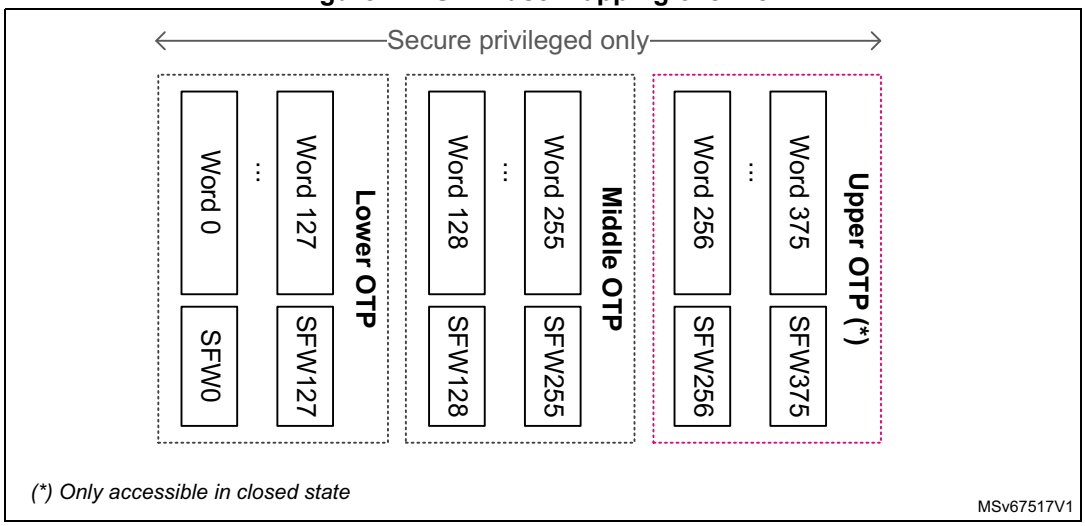
Some flops in the BSEC are on *bsec_hrst*, so they remain in reset until *bsec_done* is asserted. This reset is asserted while the Cortex-M is under reset.

4.3.4 Organization and use of fuses

Organization of fuses

One-time programmable fuse bits are organized in three groups of 32-bit words, as shown on *Figure 4*.

Figure 4. BSEC fuse mapping overview



The **lower** fuses region is used to store non-volatile, non-secret information that may require bitwise update during the life of the product.

The **middle** fuses region is used to store non-volatile, non-secret information that are written once, in 32-bit words bulk.

The **upper** fuses region is similar to the middle region, except that it is hidden when in the BSEC-open state (see *Section 4.3.7*). Hence it is used to store secrets like symmetric keys or private asymmetric keys.

Each fuse word w is either “shadowed” or “unshadowed”, as defined by flag bit SFWw in corresponding BSEC_SFSRx register. A shadowed fuse word is loaded into flops at cold or warm reset, and can be read quickly by software. An unshadowed fuse word is not read out of the fuse memory at reset, then stored permanently in flops. It needs to be reloaded from the fuse memory each time it is needed. See *Reading fuses* in *Section 4.3.5* for details.

Note: The whole OTP space can only be controlled by a secure privileged CPU.

Each individual lower fuse bit is one-time programmable, from 0 to 1. Transitions from 1 to 0 are not possible.

Details on fuse usage are described in *Section 5: OTP mapping (OTP)*.

4.3.5 Operations on fuses

Reading fuses

If fuse word w is shadowed (SFWw bit set in corresponding BSEC_SFSRx register), and either the state is BSEC-closed or w < 256, then BSEC_FVRw register is auto-loaded at cold or warm reset with the contents of fuse word w.

If fuse word w is accessible and shadowed, then if SRLOCKw = 0 the contents of fuse w can be reloaded by software into BSEC_FVRw register.

If fuse word w is accessible and unshadowed (SFWw bit cleared in corresponding BSEC_SFSRx register), a read to BSEC_FVRw register returns the content of fuse word w if the last operation on the fuse memory successfully reloaded word w, and if no unshadowed fuse word has been read since that reload.

Each time the application reloads the content of a word stored in fuse memory using BSEC_OTPCR register with PROG bit cleared, BUSY bit and error status should be checked in BSEC_OTPSR (see *Section 4.3.6*).

Note: Unshadowed fuse word information stored in BSEC_FVRw is cleared as soon as it is read.

Writing shadow registers

When a fuse word w = {i + 32 * x} above word 9 is shadowed (SFWw bit set in BSEC_SFSRx) the application can update its shadowed value by writing directly to BSEC_FVRw register, if SWLOCKw bit is cleared in BSEC_SWLOCKx register.

Note: A shadow register write does not change the underlying fuse value.

Programming fuses

When programming is not blocked, lower fuse words can be blown bit-per-bit at different times. Middle and upper fuses must be programmed 32-bits at a time, only once. As reprogramming middle and upper fuses can let them with invalid content (an ECC error might be reported), it is strongly recommended to set PPLOCK = 1 after the first (and only) programming of the middle and upper fuses.
The procedure for blowing fuse word w is as follows:

1. Write the value to be blown in BSEC_WDR, then set ADDR = w, PROG = 1 and PPLOCK = 0 in BSEC_OTPCR register.
2. When BUSY bit is cleared in BSEC_OTPSR, verify that PROGFAIL is cleared. If PROGFAIL is set try again step 1.
3. Reload the fuse word w using BSEC_OTPCR with PROG bit cleared.
4. When BUSY bit is cleared in BSEC_OTPSR, verify that BSEC_FVRw register returns the correct value. If not, try again step 1.

Note: OTP bits are initially set to 0 and once a bit is set to 1 it cannot be programmed back to 0 (bit stays at 1). Bitfields with 0s in BSEC_WDR are not programmed, while bitfields with 1s are programmed.

As lower fuse words can be programmed multiple times, when the application requests a specific bit to be programmed to 1 more than once, BSEC does the burning only once.

Permanent program lock (PPLOCK)

The application can make further programming of fuse word w impossible by following the sequence:

1. Clear BSEC_WDR register, then set ADDR = w, PROG = 1 and PPLOCK = 1 in BSEC_OTPCR register.
2. When BUSY bit is cleared in BSEC_OTPSR, verify that PROGFAIL is cleared. If PROGFAIL is set try again step 1.
3. Reload the fuse word w using BSEC_OTPCR with PROG bit cleared.
4. When BUSY bit is cleared in BSEC_OTPSR, verify that the PPLF in BSEC_OTPSR is set. If not, try again step 1.

There is no register in BSEC to store PPLOCK information. When the application needs to know if a fuse word programming is permanently locked, it has first to perform a reload of this word using BSEC_OTPCR and then check if the PPLF bit in BSEC_OTPSR register is set. See *Table 11* for details.

Fuse word locking features

In order to make fuse usage suitable for security, for example to implement the isolation scheme detailed in *Section 4.3.10*, BSEC has the following locking features:

Sticky program lock (SPLOCK)

The application can prevent fuse word w = {i + 32* x} programming until next BSEC reset (cold or warm) by setting the SPLOCKw bit in BSEC_SPLOCKx register.

Sticky write lock (SWLOCK)

The application can make the BSEC_FVRw register of a shadowed fuse word w = {i + 32 * x} unwritable until next BSEC reset (cold or warm) by setting the SWLOCKw bit in BSEC_SWLOCKx register.

Sticky reload lock (SRLOCK)

Reload of word w = {i + 32 * x} using BSEC_OTPCR register can be blocked until next BSEC reset (cold or warm) by setting the SRLOCKw bit in BSEC_SRLOCKx register.

When read is sticky-locked, unshadowed fuse words return 0 while shadowed fuse words return their current value (value is not zeroed).

Upper fuses read and write locking (HIDEUP)

When HIDEUP bit is set by hardware in BSEC_OTPSR, neither read nor write are possible to fuse words located in the upper region.

4.3.6 BSEC read and programming status reporting

After a cold and warm reset BSEC performs a first set of OTP reads, reporting the specific status structure defined in *Table 10*.

Table 10. BSEC initial status reporting structure

Bit offset	BSEC_ OTPSR bit	Name	Error flag	Meaning when bit is set
0	[0]	BUSY	No	BSEC ongoing operation is not completed.
1	[1]	INIT_DONE		BSEC initialized following a cold or warm reset.
2	[2]	HIDEUP		Upper fuses are not accessible to the application.
4	[4]	OTPNVIR		BSEC is not virgin. This bit should always be set.
5	[5]	OTPERR	Yes	At least one error has been detected during the reading of shadowed fuse words, as reported in BSEC_OTPVLDR registers (VLDF bit = 0). The recommended mitigation is to reload the faulty fuse word using BSEC_OTPCR and analyze the 8-bit error structure in BSEC_OTPSR, as detailed below.
6	[6]	OTPSEC		At least one single-error has been corrected during the reading of shadowed fuse words, as reported in BSEC_OTPVLDR registers (VLDF bit = 0). In this case the shadowed fuse word value is correct, hence if OTPSEC = 1 and OTPERR = 0 the application does not need to reload the faulty fuse word.

After any read or programming request, the BUSY bit is cleared, and BSEC reports the specific status structure defined in *Table 11*. When this structure is different than 0 the read or program operation might have failed, as indicated in the table.

Table 11. BSEC ad-hoc error/status reporting structure

Bit offset	BSEC_ OTPSR bit	Name	Failed operation	Retry if error(1)	Error description
0	**[16]**	PROGFAIL	Write	Yes	Programming operation failed.
1	**[17]**	DISTURB	Read		Integrity of the fuse value is not guaranteed.
2	**[18]**	DEDF			Double error detected. Fuse word is corrupted.
3	**[19]**	SECF		No	Single bit error correction.
4	**[20]**	PPLF			Permanent programming lock detected.
5	**[21]**	PPLMF			Permanent programming lock information on the two lower fuse values in the array is not identical.
6	**[22]**	AMEF(2)		Yes	Fuse address mismatch. Fuse value cannot be trusted, and should be read again.

1. For reads: need to reload the fuse (reported value cannot be trusted). For writes: need to retry the programming operation.
2. Always be 0 in normal operating conditions.

4.3.7 Lifecycle management

BSEC state initialization

Following a cold or warm reset BSEC can be in the following possible security states, defined in *Table 12*.

Table 12. BSEC states definition

BSEC states(1)	Upper fuses	DHUK in SAES(2)	Full debug	BootROM access	Fuse programming
BSEC-open	Inaccessible(3)	Unusable	yes(4)	partial	Enabled
BSEC-closed	Accessible	Hardware unique	no(5)	full(6)	
BSEC-invalid	Inaccessible(3)	Unusable	no	partial	Disabled

1. Defined in NVSTATE bitfield in BSEC_SR register (0x16: BSEC-open, 0x0D: BSEC-closed).
2. Derived hardware unique key in SAES peripheral uses RHUK information from BSEC (see *Section 4.3.15*).
3. Cannot be read or programmed by any means (functional or non-functional).
4. ST engineering modes are also available.
5. Root of trust application can unlock debug features unless any of the debug_lock bits (25/24/23/22) is blown in WORD18. ST engineering modes are disabled, by hardware, provided bit 20 of fuse word 124 is blown.
6. At the end of its execution the boot ROM writes 0xB9D8 FF1F to BSEC_UNMAPR, reverting boot ROM access to partial.

Errors following a BSEC initialization are detailed in *Section 4.3.6*. Details about reset management can be found in *Section 4.3.17*.

When neither BSEC-open nor BSEC-closed state (NVSTATE different than 0x16 or 0x0D), the security state is considered invalid, and the most conservative security configuration is applied: that is, fuse programming is disabled, upper fuses read as 0, debug is disabled, ROM is partially unmapped and shadow registers are read only. When NVSTATE = 0x23, a confirmed tamper is active in the device (see *Section 4.3.17*).

Note: On any reset, including hot reset, if the state is BSEC-closed, the BSEC_UNMAPR register is set to 0xA1C0 DE0D, ensuring the whole boot ROM is visible.

Opening BSEC

BSEC can transition from BSEC-closed to BSEC-open only if the user enters the programmed 128-bit password via JTAG, and then performs a global reset (JTAG + device), clearing all secrets.

The recommended JTAG password programming sequence is:

1. Write the four password words to upper fuses words 256 to 259 with PPLOCK bit cleared in BSEC_OTPCR. JTAG_PSWD0 is stored in word 256, while JTAG_PSWD3 is stored in word 259.
2. Read back password value to verify it is correct
3. Write 0x0 to the same fuse words 256 to 259, with PPLOCK bit set in BSEC_OTPCR. After this, password words cannot be read nor programmed anymore by the application.

The BSEC opening sequence is described below:

1. Bring the device TAP out of reset, and enter the device secret password sequentially using the JTAG commands 0100 (SET_JTAG_PSWD0), 0101 (SET_JTAG_PSWD1), 0110 (SET_JTAG_PSWD2) then 0111 (SET_JTAG_PSWD3).
2. Trigger a device reset, without causing a TAP reset. When BSEC emerges from reset, it blows the RMA fuse word with adequate values.
3. Trigger a TAP reset to destroy any record of the entered password, and after the next cold or warm reset, the BSEC changes its NVSTATE to “BSEC-open” in BSEC_SR. It can be verified using the JTAG command 0011 (READ_SEC). BSEC returns 0x1 for an BSEC-open device, 0x2 for a BSEC-closed device.
4. Ship the device to STMicroelectronics for field return analysis (RMA)

Once the device has been opened it can be closed again by blowing to 0xF the next unblown 4-bit nibble in BSEC_FVR1 (see *Closing BSEC*). At most four device re-opening attempts are allowed, regardless of whether they are successful or unsuccessful.

By blowing at least one bit in BSEC_FVR1[27:24], the application can reduce the number of re-opening cycles to only one.

If the application blows at least one bit in BSEC_FVR1[31:28] a closed device can never be re-opened.

The application can also ensure that if a closed device is ever re-opened, it is not possible to subsequently re-close it again. It is done by blowing the permanent programming lock (PPLOCK) of fuse word 1, writing 0x00000000 to BSEC_WDR then writing 0x00006001 to BSEC_OTPCR.

Note: By default BSEC opening password is 0x0. It is advised to change it.

Closing BSEC

BSEC can transition from BSEC-open to BSEC-closed by blowing some bits such that *s*[7:0] becomes greater than *r*[7:0], or *s*[7] = 1. Bytes *s*[7:0] and *r*[7:0] are defined as follows:

s[7:0] = OR(BSEC_FVR1[31:28]) | OR(BSEC_FVR1[27:24]) | ... | OR(BSEC_FVR1[3:0])

r[7:0] = AND(BSEC_FVR2[31:28]) | AND(BSEC_FVR2[27:24]) | ... | AND(BSEC_FVR2[3:0])

With the following conventions:

- “|” is concatenation operand
- OR(bits[1:0])= bit[1] OR bit[0]
- AND(bits[1:0])= bit[1] AND bit[0]

When the device is being closed, the application can limit re-opening cycles to only one attempt by blowing at least one bit in BSEC_FVR1[27:24]. To reduce re-opening cycles to zero, the application must blow at least one bit in BSEC_FVR1[31:28].

Note: For the device to become BSEC-closed, the application must perform a BSEC cold or warm reset.

4.3.8 Epoch registers

There are two 32-bit readable registers, BSEC_EPOCHR0 and BSEC_EPOCHR1, that are writable only by boot ROM accesses. It is the responsibility of the boot ROM to read bitwise fuses and populate these registers.

There is a 1-bit programmable register BSEC_EPOCHSELCR (output on *epoch_sel*) that, when programmed to *n*, ensures that BSEC_EPOCHR*n* is output on *epoch*. Both *epoch* and *epoch_sel* are wired to the SAES where they influence the generation of DHUK, derived from the RHUK.

Secure software can blow additional bits in the appropriate fuse word to increment an Epoch, thereby making impossible the use of all keys derived from the RHUK prior to that point.

4.3.9 BSEC local access control

Any access that is not both secure and privileged is blocked, with read data zeroed and write accesses ignored.

4.3.10 Temporal isolation in BSEC

In order to enforce isolation between boot stages the running application in each boot level must hide the secrets it was using before proceeding to the next level of code in the boot chain. Such protections must remain until the next boot sequence.

Four boot levels, with its corresponding hide protection level (HDPL), are defined:

- Level 0 (HDPL0) corresponds to hardware state machine or ROM code execution.
- Level 1 (HDPL1) corresponds to the execution of STMicroelectronics signed code or ROMed code. This code is the first stage of the secure boot.
- Level 2 (HDPL2) corresponds to the execution of the OEM signed code, stored in embedded SRAM. This code is the second stage of the secure boot.
- Level 3 (HDPL3) corresponds to the application run-time.

To help enforcing such isolation between boot stages, the ROM code and the application secure boot can use the following temporal isolation hardware capabilities of BSEC:

- When BSEC is in a closed state, ROM partially hides itself at the end of its execution in level 0 or level 1, writing 0xB9D8 FF1F to BSEC_UNMAPR register.
- When BSEC is in a closed state, fuse words 364 to 375 are reloadable only when BSEC_UNMAP=0xA1C0DE0D
- Any 32-bit OTP word can be made non-readable and/or non-writable until next cold or warm reset. It can also be made non-programmable, permanently. See Fuse word locking features and Permanent program lock (PPLOCK) methods in *Section 4.3.5*.

Note: Details on fuse usage are described in Section 5: OTP mapping (OTP).

The register BSEC_HDPLSR determines the current hide protection level of the device. The encoding offers physical robustness.

Table 13. Current HDPL coding

BSEC_HDPLSR[HDPL]	Level
0xB4	0
0x51	1
0x8A	2
0x6F	3
others	undefined

The register is reset to 0xB4 by *bsec_hrst*. The register is not directly writable. If less than 3, the current level can be incremented by writing a value of 0x60B166E7 to BSEC_HDPLCR.

The 2-bit INCR field of the BSEC_NEXTHDPLCR register is added to the level given by BSEC_HDPLSR (but clamped at a ceiling of 3), and the result is output on *obk_hdpl[7:0]* as follows.

Table 14. BSEC Next HDPL register usage

<table>
<tr><th colspan="2" rowspan="2">obk_hdpl [7:0]</th><th colspan="4">BSEC_NEXTHDPLCR [INCR]</th></tr>
<tr><th>0</th><th>1</th><th>2</th><th>3</th></tr>
<tr><td rowspan="5">BSEC_HDPLSR [HDPL]</td><td>0 (0xB4)</td><td>0xB4</td><td>0x51</td><td>0x8A</td><td rowspan="3">0x6F</td></tr>
<tr><td>1 (0x51)</td><td>0x51</td><td>0x8A</td><td rowspan="2">0x6F</td></tr>
<tr><td>2 (0x8A)</td><td>0x8A</td><td rowspan="2">0x6F</td></tr>
<tr><td>3 (0x6F)</td><td>0x6F</td><td colspan="2"></td></tr>
<tr><td>others (0xPQ)</td><td colspan="4">0xPQ</td></tr>
</table>

The *obk_hdpl* output goes to the SAES where it influences the generation of DHUK, derived from the RHUK. This mechanism allows keys for a later temporal level to be generated in advance.

4.3.11 BSEC debug and trace control

The wrapper contains a BSEC_DBGCR register, reset to zero on the scratch reset, and writeable only once per warm reset. The bytes of this register are named as follows

Table 15. BSEC debug register legal values

BSEC_DBGCR	field name	legal values
31:24	AUTH_SEC	0x00, 0xB4
23:16	AUTH_HDPL	0x00, 0xB4,0x51,0x8A,0x6F
15:8	UNLOCK	0x00, 0xB4
7:0	reserved	-

AUTH_HDPL encodes levels in the same way as HDPL field in BSEC_HDPLSR register.

Any attempt to write a non-legal byte value into these fields results in a 0x00 being written in that byte field.

The register is forced to zero (writes have no effect) whenever the device is BSEC-open.

The *dbg_unlocked* output, when taking the value of 0xB4, signifies that nonsecure debug is possible. The *dbg_unlocked_sec* output, when it also takes the value of 0xB4, signifies that secure debug is possible.

Both outputs are set to 0xB4 whenever the state is BSEC-open.

Whenever the BSEC state is not BSEC-open, then if HDPL = 0xB4, or AUTH_HDPL is undefined or indicates a level greater than that given by HDPL, they are both set to 0x00, otherwise *dbg_unlocked* takes the value of UNLOCK, and *dbg_unlocked_sec* takes the

value of AUTH_SEC. This implies that secure boot is enforced on a BSEC-closed device. It is the responsibility of the customer's signed code to decide on whether debug becomes unlocked at a certain level. This decision (i.e. the register write) only has to made once per power cycle, since the register is on the scratch reset and retains its value across warm resets.

Note: If a warm reset occurs during a debug session, then during the reset, the debugger becomes temporarily locked, since HDPL is reset to 0. On a BSEC-open device, it becomes unlocked again as soon as the BSEC has booted. On a BSEC-closed device, it becomes unlocked again as soon as HDPL is non-zero and matches or surpasses AUTH_HDPL.

The BSEC_AP_UNLOCK register is forced to zero (writes have no effect) whenever the state is BSEC-open. The *ap_unlocked* output, when taking the value 0xB4, indicates that the debugger can access the CM55 Debug Subsystem. It is set to 0xB4 whenever the state is BSEC-open, otherwise it is directly driven by the BSEC_AP_UNLOCK register, which is reset to 0 on a scratch reset.

A rising edge on *hide_sec* (a confirmed tamper) resets these registers to zero, and close debug. They are not writeable until the next cold or warm reset.

Note: These registers are on the scratch reset so that if software authorizes a debug, that authorization survives subsequent warm resets, and doesn't have to be re-authorized.

4.3.12 Device features control

Device features are controlled through read-only shadowed fuse word 9.See *Section 5: OTP mapping (OTP)* for details.

4.3.13 Scratch registers

The four BSEC_SCRATCHRx registers are only reset by a cold boot. They are therefore useful to store values that must remain persistent for the application across warm boots.

The eight BSEC_WOSCRx registers are only reset by a cold or warm boot. They are therefore useful to store values that must remain persistent for the application across hot boots.

Note: BSEC_WOSCRx registers are write once.

4.3.14 JTAG registers

The BSEC_JTAGINR and BSEC_JTAGOUTR registers are available to facilitate communication between the application (for example ROM) and the debug tools connected through the JTAG interface.

4.3.15 STM32 root hardware unique key (RHUK)

BSEC stores a root HUK that has been programmed by STMicroelectronics during the device manufacturing. A successful provisioning is indicated with HVALID bit set in BSEC_SR register.

The value of this key is obtained from the RNG peripheral of the device, without disclosure to the outside word. This key cannot be read or programmed by any secure application nor debugger.

When BSEC detects an integrity issue while reading the key information from non-volatile memory, or when application sets the sticky HKLOCK bit in BSEC_LOCKR, the key is indicated as invalid. When the key is invalid the SAES peripheral uses a default fixed value.

4.3.16 BSEC error management

Shadowed fuse word automatic readout errors

After a cold or warm reset, shadowed fuse words are automatically loaded into BSEC_FVR registers. At the end of this process, when INIT_DONE is set in BSEC_OTPSR, additional error information can be found in this register, as described in *Section 4.3.6*.

Individual fuse loading errors

Upon each fuse loading from OTP memory array, an 8-bit error structure in BSEC_OTPSR register is updated to tell the application if there was a problem with this particular fuse load. This structure is defined in *Section 4.3.6*.

4.3.17 BSEC tamper response mechanisms

This device uses tamper-detection and response mechanisms that can make it immediately inoperable, resulting in the automatic and immediate erasure of any sensitive data that may be stored in the device. The device also supports the concept of potential tamper event, where the device secrets are blocked while application software verifies that such tamper event is confirmed or not.

BSEC manages above mechanisms in the following way:

- When a tamper source triggers a potential tamper event in TAMP peripheral (NOERASE = 1), BSEC masks the RHUK value to SAES, and upper fuses read as 0 (unless BSEC_UNMAP = 0xA1C0 DE0D, meaning that the boot CPU is executing).
- When a tamper source triggers a confirmed tamper event in TAMP peripheral (NOERASE = 0), or a potential tamper becomes a confirmed tamper, fuses cannot be blown or reloaded, upper fuses read as 0, BSEC_DBGCR and BSEC_AP_UNLOCK registers are cleared, RHUK information is physically cleared to 0 & invalidated, and NVSTATE is set to 0x23 in BSEC_SR register. These limitations are deactivated after device secrets have been erased, and a SoC reset has been applied.

Above limitations are deactivated when the application clears the active tamper source(s) in TAMP peripheral.See *Section 62: Tamper and backup registers (TAMP)* for details.

Note: While tamper events are active the boot CPU can always execute the application firmware following an application reset or an exit from Standby for the boot CPU.

4.4 BSEC interrupts

BSEC does not support any interrupt.

4.5 BSEC registers

Those registers are accessible through the register interface of the BSEC peripheral.

4.5.1 BSEC fuse word w value register (BSEC_FVRw)

Address offset: 0x000 + 0x4 * w, (w = 0 to 375)

Reset value: 0xXXXX XXXX

Note: The reset value is 0x0000 0000 if the fuse word is unshadowed, defined by the fuse value if the fuse word is shadowed.

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

See the bitfield description for further details on fuse word accessibility.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FV[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FV[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **FV[31:0]**: fuse value

If fuse word {w} is shadowed (SFW{w} bit set in corresponding BSEC_SFSRx register), and either the state is BSEC-closed or {w} < 256, then this register is auto-loaded at cold or warm reset with the contents of fuse word w.

If fuse word {w} is accessible and shadowed, then:

– if SRLOCK{w} = 0, fuse word {w} can be reloaded by software into this register

– if SWLOCK{w} = 0, and {w} > 9, this register can be written to (otherwise, writes are ignored).

If fuse word {w} is accessible and unshadowed (SFW{w} bit cleared in corresponding BSEC_SFSRx register), writes are ignored and provided:

– the last operation on the fuse memory successfully reloaded word {w}

– no unshadowed fuse words have been read since that reload

then a read to this register returns the content of fuse word {w} (otherwise it returns 0).

If the fuse word {w} is inaccessible, then writes are ignored and reads return 0.

Unshadowed fuse word information stored in this register is cleared as soon as it is read.

When the state is BSEC-closed:

– Fuse words 364 to 375 are accessible only when BSEC_UNMAP=0xA1C0DE0D and when the access is from boot CPU.

– Fuse words 256 to 259 read as zero when permanent programming lock is set for those words.

4.5.2 BSEC sticky programming lock register x (BSEC_SPLOCKx)

Address offset: 0x800 + 0x4 * x (x = 0 to 11)

Reset value: 0x0000 0000

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SPLOCK{i + 32 * x}															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SPLOCK{i + 32 * x}															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **SPLOCK{i + 32 * x}**: Sticky programming lock for word {i + 32 * x} (i = 0 to 31)

Setting this bit prevents permanent programming for the fuse word {i + 32 * x} until next cold or warm reset.

0: Fuse word {i + 32 * x} can be burnt in fuse memory array

1: Attempt to program fuse word {i + 32 * x} in OTP memory array is silently ignored

While BUSY is set in BSEC_OTPSR, writes have no effect, and reads return 0.

4.5.3 BSEC sticky write lock register x (BSEC_SWLOCKx)

Address offset: 0x840 +0x4 * x (x=0 to 11)

Reset value: 0x0000 0000

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWLOCK{i + 32 * x}															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWLOCK{i + 32 * x}															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **SWLOCK{i + 32 * x}**: sticky write lock for shadow register {i + 32 * x} (i = 0 to 31)

When fuse word {i + 32 * x} is shadowed, setting this bit prevents the writing of the shadow register of this fuse word until next cold or warm reset.

0: Write to shadow register BSEC_FVR{i + 32 * x} is allowed

1: Writes to shadow register BSEC_FVR{i + 32 * x} are silently ignored

While BUSY is set in BSEC_OTPSR, writes have no effect, and reads return 0.

4.5.4 BSEC sticky reload lock register x (BSEC_SRLOCKx)

Address offset: 0x880 + 0x4 * x (x = 0 to 11)

Reset value: 0x0000 0000

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRLOCK{i + 32 * x}															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRLOCK{i + 32 * x}															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **SRLOCK{i + 32 * x}**: sticky reload lock for fuse word {i + 32 * x} (i = 0 to 31)

Setting this bit locks reloading of fuse word {i + 32 * x} from the OTP memory array until next cold or warm reset.

0: Fuse word {i + 32 * x} loading through BSEC_OTPCR is authorized.

1: Fuse word {i + 32 * x} loading through BSEC_OTPCR is denied until next cold or warm reset.

While BUSY is set in BSEC_OTPSR, writes have no effect, and reads return 0.

4.5.5 BSEC OTP valid register x (BSEC_OTPVLDRx)

Address offset: 0x8C0 + 0x4 * x (x = 0 to 11)

Reset value: 0x0000 0000

Secure privileged read only (return 0 otherwise).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VLDF{i + 32 * x}															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VLDF{i + 32 * x}															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **VLDF{i + 32 * x}**: Valid flag for shadow register {i + 32 * x} (i = 0 to 31)

This bit represents the validity of the last reload of fuse word {i + 32 * x}.

0: An error occurred while fuse word {i + 32 * x} was last reloaded. The value read from BSEC_FVR{i + 32 * x} register cannot be relied on.

1: Last reload of fuse word {i + 32 * x} was done without error.

Each VLDF bit is updated when BSEC or the allowed application reloads corresponding fuse word from the OTP array.

4.5.6 BSEC shadowed fuses status register x (BSEC_SFSRx)

Address offset: 0x940 + 0x4 * x (x = 0 to 11)

Reset value: 0x0001 EBFF (SFSR0)

Reset value: 0xFF00 000F (SFSR3)

Reset value: 0x0000 000F (SFSR8)

Reset value: 0xFF00 0000 (SFSR11)

Reset value: 0x0000 0000 (others)

Secure privileged read-only (return 0 otherwise).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SFW{i + 32 * x}															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SFW{i + 32 * x}															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SFW{i + 32 * x}**: Shadowed fuse word {i + 32 * x} (i = 0 to 31)

This bit indicates whether fuse word {i + 32 * x} is shadowed or not.

0: Fuse word {i + 32 * x} is not shadowed. Fuse value must be reloaded using BSEC_OTPCR before reading BSEC_FVR{i + 32 * x} register.

1: Fuse word is shadowed in BSEC_FVR{i + 32 * x} register. Reloading the fuse value using BSEC_OTPCR is only required if the fuse value changed since the last BSEC cold or warm reset.

4.5.7 BSEC OTP control register (BSEC_OTPCR)

Address offset: 0xC04

Reset value: 0x0000 0000

Writing to this register causes an access to be made to the fuse memory.

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LASTCID[2:0]			Res.	Res.	Res.
										r	r	r			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	PP LOCK	PROG	Res.	Res.	Res.	Res.	ADDR[8:0]								
	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:19 **LASTCID[2:0]:** Last CID

This always returns the value 001.

Bits 18:15 Reserved, must be kept at reset value.

Bit 14 **PPLOCK:** Permanent programming lock

When this bit is set together with PROG bit, no further write to this fuse word is possible.
0: Fuse word at address ADDR[8:0] is programmed normally.
1: Fuse word at address ADDR[8:0] is locked, preventing further modifications.
Permanent programming lock mechanism is immutable, as it is committed in the fuse memory.

Bit 13 **PROG:** Fuse word programming

This bit determines whether BSEC operation is a read or a write. If a write is selected, the data stored in BSEC_WDR is programmed in the fuse word indexed by ADDR bitfield.
0: Fuse word read operation is required
1: Fuse word programming operation is required
While BUSY is set in BSEC_OTPSR, writes to PROG bit have no effect.

Bits 12:9 Reserved, must be kept at reset value.

Bits 8:0 **ADDR[8:0]:** Fuse word address

This bitfield represents the address of the fuse word in the OTP memory array.
When a lower fuse address is selected two fuse words are addressed by BSEC.
When fuse words 376 to 383 are selected, read or programming requests are denied.
When fuse words 368 to 375 are selected, programming requests are ignored.

4.5.8 BSEC write data register (BSEC_WDR)

Address offset: 0xC08

Reset value: 0x0000 0000

Secure privileged write only. Any reads return 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRDATA[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRDATA[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **WRDATA[31:0]:** OTP write data

The value written to this register can be written to fuse memory. This happens when the BSEC_OTPCR register is written with the PROG bit set.
When a lower fuse address is selected in BSEC_OTPCR (ADDR=0x0 to 0x3F), two fuse words are programmed by BSEC (one fuse word is programmed otherwise).
While BUSY is set in BSEC_OTPSR, writes to this register have no effect.

4.5.9 BSEC scratch register x (BSEC_SCRATCHRx)

Address offset: 0xE00 + 0x4 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is reset when *bsec_srst* is asserted.

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SDATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SDATA[31:0]**: Scratch data

This register can be used to store values that needs to be persistent across warm reset.

4.5.10 BSEC lock register (BSEC_LOCKR)

Address offset: 0xE10

Reset value: 0x0000 0000

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HK LOCK	Res.	GW LOCK
													rs		rs

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **HKLOCK:** Hardware key lock

0: Derived hardware unique key (DHUK) in SAES peripheral is usable if HVALID is set in BSEC_SR

1: Derived hardware unique key (DHUK) in SAES peripheral is not usable.

Once set, this bit is cleared only by BSEC cold or warm reset.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **GWLOCK:** Global write lock

0: Writes to BSEC registers are allowed

1: Writes to BSEC registers are ignored (fuse programming and fuse reload disabled)

Once set, this bit is cleared only by BSEC cold or warm reset.

4.5.11 BSEC JTAG input register (BSEC_JTAGINR)

Address offset: 0xE14

Reset value: 0x0000 0000

Secure privileged read only (return 0 otherwise).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JDATAIN[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JDATAIN[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **JDATAIN[31:0]**: JTAG input data

Reads give the last input value from the JTAG interface

4.5.12 BSEC JTAG output register (BSEC_JTAGOUTR)

Address offset: 0xE18

Reset value: 0x0000 0000

Secure privileged write only (write ignored otherwise).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JDATAOUT[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

JDATAOUT[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **JDATAOUT[31:0]**: JTAG output data

Application can write any value in this field to be output on the JTAG interface.

4.5.13 BSEC unmap register (BSEC_UNMAPR)

Address offset: 0xE24

Reset value: 0xXXXX XXXX

Note: The reset value is 0xA1C0 DE0D on a BSEC-closed device, 0xFFFF FFFF on a BSEC-open device.

Register bits cannot be cleared by application, they can only be set to 1.

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored. Only BootROM code can access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UNMAP[31:16]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

UNMAP[15:0]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **UNMAP[31:0]**: Unmap key
If this bitfield equals 0xA1C0 DE0D, the whole ROM is visible, else ROM is partially hidden.

4.5.14 BSEC status register (BSEC_SR)

Address offset: 0xE40

Reset value: 0x0000 0000

Secure privileged read only (return 0 otherwise).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NVSTATE[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBGREQ
r	r	r	r	r	r										r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HVALID	Res.
														r	

Bits 31:26 **NVSTATE[5:0]**: Non-volatile state
0x16: BSEC-open state
0x0D: BSEC-closed state
0x7: BSEC-invalid state
0x23: BSEC-invalid state, with an active confirmed tamper triggered in the device
The BSEC state is evaluated each time INIT_DONE is set in BSEC_OTPSR.
For more information, refer to *Section 4.3.7: Lifecycle management*

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **DBGREQ**: debug request
0: Host debugger is not requesting debug
1: Host debugger is requesting debug

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **HVALID**: Hardware key valid
0: Derived hardware unique key (DHUK) feature cannot be used in SAES peripheral.
1: Derived hardware unique key (DHUK) feature can be used in SAES peripheral.

Bit 0 Reserved, must be kept at reset value.

4.5.15 BSEC OTP status register (BSEC_OTPSR)

Address offset: 0xE44

Reset value: 0x0000 0000

This register is refreshed each time a fuse operation is triggered through BSEC_OTPCR.

Secure privileged read only (return 0 otherwise).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AMEF	PPLMF	PPLF	SECF	DEDF	DISTURBF	PROGFAIL
									r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTPSEC	OTPERR	OTPNVIR	Res.	HIDEUP	INIT_DONE	BUSY
									r	r	r		r	r	r

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **AMEF**: Addresses mismatch error flag

This bit is set when the address used by BSEC to read a fuse word is different from the programmed address (either by BSEC or by the application). Such event should never happen in normal BSEC operations.

Bit 21 **PPLMF**: Permanent programming lock mismatch flag

This bit is set when the two words constituting a lower fuse word are reporting different permanent programming lock statuses after BSEC reset or after the latest read.
For more details about permanent programming lock, refer to PPLOCK in BSEC_OTPCR.

Bit 20 **PPLF**: Permanent programming lock flag

This bit is set when the most recently read word is detected permanently locked.
For more details about permanent programming lock, refer to PPLOCK in BSEC_OTPCR.

Bit 19 **SECF**: Single error correction flag

This bit is set when a single-bit-error correction is detected after BSEC reset or after the latest read.

Bit 18 **DEDF**: Double error detection flag

This bit is set when a double error is detected after BSEC reset or after the latest read.
When DEDF bit is set after reading fuse word w, the value in BSEC_FVRw is the one read from OTP memory.

Bit 17 **DISTURBF**: Disturb flag

This bit is set when an unexpected error occurred after BSEC reset or after the latest read.
When DISTURBF bit is set after reading fuse word w, the value in BSEC_FVRw is the one read from OTP memory.

Bit 16 **PROGFAIL**: Programming failed

This bit is set when last OTP programming by BSEC failed.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **OTPSEC**: OTP with single error correction

This bit is set when at least one single-error correction is detected during BSEC reset operations. In this case shadow registers are usable.

Bit 5 **OTPERR**: OTP with error
This bit is set when at least one error is detected during BSEC reset operations.

Bit 4 **OTPNVIR**: OTP not virgin
This bit is set when first fuse word 0 is detected non-0 after BSEC reset operations.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **HIDEUP**: Hide upper fuse words
This bit is set when application secret fuse words 256 to 383 becomes physically inaccessible, that is functionally hidden fuse words read as 0 and programming requests are ignored.

Bit 1 **INIT_DONE**: Initialization done
This bit is set when BSEC reset operations are completed. All shadowed fuses are readable in BSEC_FVRw registers, and status bits in BSEC_SR and BSEC_OTPSR are up to date.

Bit 0 **BUSY**: Busy flag
0: BSEC is idle.
1: BSEC is busy.

4.5.16 BSEC epoch register (BSEC_EPOCHRx)

Address offset: 0xE80 + 0x4 * x (x = 0 to 1)

Reset value: 0x0000 0000

Writeable by boot ROM only, readable by secure privileged trusted domain or BootROM code only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EPOCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EPOCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rs

Bits 31:0 **EPOCH[31:0]**: epoch
This value is wired out to the SAES peripheral, depending on the EPOCH_SEL bit in BSEC_EPOCHSELCR.

4.5.17 BSEC epoch selection control register (BSEC_EPOCHSELCR)

Address offset: 0xE88

Reset value: 0x0000 0000

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EPOCH_SEL
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **EPOCH_SEL**: Selection of the epoch value to be sent to the SAES
0: SAES peripheral uses BSEC_EPOCHR0 as EPOCH value.
1: SAES peripheral uses BSEC_EPOCHR1 as EPOCH value.

4.5.18 BSEC debug control register (BSEC_DBGCR)

Address offset: 0xE8C

Reset value: 0x0000 0000

Secure privileged read and write only. Writeable only on a BSEC-closed device, once per warm reset. Illegal reads return 0, illegal writes are ignored. Reset to zero on *bsec_srst* (cold reset).

The AUTH_HDPL byte field indicates a temporal isolation level, as follows: the value 0xB4 means level 0, the value 0x51 means level 1, the value 0x8A means level 2, and the value 0x6F means level 3. All other byte values are undefined.

When the state is BSEC-open, the *dbg_unlocked* and *dbg_unlocked_sec* outputs to the DBG_MCU block are set to 0xB4, and the register is zeroed.

When the state is not BSEC-open, both outputs are zeroed whenever either AUTH_HDPL or BSEC_HDPLSR[HDPL] are undefined, or BSEC_HDPLSR[HDPL] = 0xB4, or the level indicated by AUTH_HDPL is greater than that of BSEC_HDPLSR[HDPL]. Otherwise, the UNLOCK is placed on the *dbg_unlocked* output, and (UNLOCK and AUTH_SEC) is placed on the *dbg_unlocked_sec* output.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
AUTH_SEC[7:0]								AUTH_HDPL[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UNLOCK[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								

Bits 31:24 **AUTH_SEC[7:0]:**

0xB4: Secure debug authorized when UNLOCK = 0xB4 and the level indicated in BSEC_HDPLSR is greater than or equal to the level indicated by AUTH_HDPL

Others: Secure debug not authorized (provided state is not BSEC-open)

Bits 23:16 **AUTH_HDPL[7:0]:** level at which debug may be opened.

0xB4: Level 0

0x51: Level 1

0x8A: Level 2

0x6F: Level 3

Others: Undefined

Bits 15:8 **UNLOCK[7:0]:**

0xB4: Nonsecure debug authorized when the level indicated in BSEC_HDPLSR is greater than or equal to the level given by AUTH_HDPL

Others: Debug not authorized (provided state is not BSEC-open)

Bits 7:0 Reserved, must be kept at reset value.

4.5.19 BSEC AP unlock (BSEC_AP_UNLOCK)

Address offset: 0xE90

Reset value: 0x0000 0000

Secure privileged read and write only. Writeable only on a BSEC-closed device, once per warm reset. Illegal reads return 0, illegal writes are ignored. Reset to zero on *bsec_srst* (cold reset). Bit 5 is reset to zero on every warm reset.

When the state is BSEC-open, the *ap_unlocked* output to the DBG_MCU block is set to 0xB4. and the register is zeroed. When the BSEC state is not BSEC-open, it takes the value of the 8-bit UNLOCK field.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UNLOCK[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **UNLOCK[7:0]:**

0xB4: Unlock debug access port.

Others: Do not unlock.

4.5.20 BSEC HDPL status register (BSEC_HDPLSR)

Address offset: 0xE94

Reset value: 0x0000 00B4

Secure privileged read only. Illegal reads return 0, writes are ignored. Reset to 0xB4 on *bsec_hrst* (hot reset).

When coding a value of less than 3, it can be incremented by writing 0x60B166E7 to BSEC_HDPLCR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDPL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **HDPL[7:0]:** Current HDPL

0xB4: Level 0
0x51: Level 1
0x8A: Level 2
0x6F: Level 3
Others: Undefined

4.5.21 BSEC HDPL control register (BSEC_HDPLCR)

Address offset: 0xE98

Reset value: 0x0000 0000

Secure privileged write only. Illegal reads return 0, writes are ignored.

When BSEC_HDPLSR codes a value of less than 3, BSEC_HDPLSR can be incremented by writing 0x60B166E7 to BSEC_HDPLCR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

INCR_HDPL[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **INCR_HDPL[31:0]**: Increment HDPL

When HDPL is less than 3, writing 0x60B1 66E7 increments HDPL by one in BSEC_HDPLSR.
Otherwise, writes are ignored. Reads return zero.

4.5.22 BSEC next HDPL control register (BSEC_NEXTHDPLCR)

Address offset: 0xE9C

Reset value: 0x0000 0000

Secure privileged read and write only. Illegal reads return 0, writes are ignored.

This value determines the amount to add to the level indicated by BSEC_HDPLSR to output to the SAES on obk_hdpl.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	INCR[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **INCR[1:0]**: Increment
Amount to add to BSEC_HDPLSR to generate *obk_hdpl[7:0]* output (clamped at 3).

4.5.23 BSEC write once scratch register x (BSEC_WOSCRx)

Address offset: 0xF40 + 0x4 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is reset when *bsec_rst* is asserted.

Secure privileged read and write only. Illegal reads return 0, illegal writes are ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WOSDATA[31:16]

WOSDATA[15:0]															
rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo

Bits 31:0 **WOSDATA[31:0]**: Write once scratch data
ROM code can use this register to store values that needs to be persistent across hot resets. It is writable once, reset by either cold or warm BSEC reset.

4.5.24 BSEC hot reset count register (BSEC_HRCR)

Address offset: 0xFE8

Reset value: 0x0000 0000

This register is reset when *bsec_rst* is asserted.

Secure privileged read only (return 0 otherwise).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HRC[31:16]

HRC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **HRC[31:0]**: Hot reset counter

This bitfield counts the number of hot resets since the last BSEC cold/warm reset.

See *Section 4.3.3: BSEC reset and clocks* for details about resets.

4.5.25 BSEC warm reset count register (BSEC_WRCR)

Address offset: 0xFEC

Reset value: 0x0000 0000

This register is reset when *bsec_srst* is asserted.

Secure privileged read only (return 0 otherwise).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRC[31:16]

WRC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **WRC[31:0]**: Warm reset counter

This bitfield counts the number of warm resets since the last BSEC cold reset.

See *Section 4.3.3: BSEC reset and clocks* for details about resets.

4.5.26 BSEC register map

Table 16. BSEC register map and reset values

1. See register description.

Refer to *Section 2.3* for the register boundary addresses.

5 OTP mapping (OTP)

STM32N6x7xx devices have 12032 OTP (one-time programmable) bits, which can be read-accessed in 376 words: BSEC_OTP_DATAx (x = 0 to 375).

OTP bits are read or programmed by the BSEC (boot, security, and OTP control),as detailed in *Section 4: Boot and security control (BSEC)*. They are organized in regions:

- Lower OTP region (OTP0 to OTP127)
- Mid OTP region (OTP128 to OTP255)
- Upper OTP region (OTP256 to OTP375)

Before being programmed, the OTP bits are at 0. The OTP words are listed in *Table 17*:

- *Description*: acronym and function. Words marked “Available to customer” have no predefined usage.
- *Shadowed*: loaded into a register after reset, can be read without a reload. A shadowed word may be sticky-write-locked by earlier software (such as BOOTROM). The first ten shadowed words are never writable.
- *Prog-locked by ST*: words locked during manufacturing.

Table 17. OTP mapping

Word	Description	Shadowed	Prog-locked by ST
Lower OTP region			
OTP0	OTP_HW_WORD0	Yes	Yes
OTP1	OTP_HW_WORD1	Yes	No

OTP373	STM32PRVKEY5	No	Yes
OTP374	STM32PRVKEY6	No	Yes
OTP375	STM32PRVKEY7	No	Yes

The following OTP words are described in detail in *Table 18* or by BSEC:

- OTP0 to OTP4: used by BSEC for the security life cycle (see *Section 4: Boot and security control (BSEC)*)
- OTP9: used to code device part number (see *Section 79: Device electronic signature*)
- OTP10 to OTP22: used for the boot ROM configuration
- OTP56 to OTP58: used to record tamper configuration
- OTP96 to OTP99 and OTP104 to OTP 111: used for analog calibration parameters, set by ST
- OTP112 to OTP 119: used for engineering purposes, set by ST

- OTP120 to OTP123: used for settings such as analog trimming, set by ST
- OTP124: used for the product configuration by the user
- OTP125 to OTP 127: used for memory repair, set by ST.

Table 18. OTP fuse description (lower OTP region)

OTP word	OTP bits	Name or description	Detailed description
OTP0	-	OTP_HW_WORD0	OTP check word (virgin → non-virgin)
OTP1	-	OTP_HW_WORD1	OTP security word to close security state
OTP2	-	OTP_HW_WORD2	OTP word for reopening (close → open) via RMA password: RMA bits
OTP3	-	OTP_HW_WORD3	OTP word for reopening (close → open) via RMA password: RMA tries bits
OTP4	-	OTP_HW_WORD4	OTP word for TK retries (ECIES) and retention cell disabling
OTP5	-	ID0	96-bit unique ID for engineering purpose
OTP6	-	ID1	
OTP7	-	ID2	
OTP8	-	OTP_RPN_CODING	Reserved
OTP9	-	RPN_CODING	See *Section 79: Device electronic signature*
OTP10	-	BOOTROM_CONFIG_1	Boot source configuration word
	[0]	stkeyprov_ecies_attempted	Status of ECIES ST key provisioning when it was attempted: – 0 (failed): ECIES ST key provisioning last attempt failed – 1 (successful): ECIES ST key provisioning last attempt successful
	[1]	stkeyprov_ecies_ok	– 0 (no): HWKEY not provisioned – 1 (yes): HWKEY provisioned
	[6:2]	Reserved	Reserved
	[14:7]	security_counter	Security counter involved in product ID for chip certificate verification by HSM-OEM in SFI context
	[18:15]	st_pub_key_id	ST ECDSA public key ID (ST key instance fuse part) involved in product ID for chip certificate verification by HSM-OEM in SFI context
	[26:19]	rssefw_active_signing_key	[1-256] → [1-8]: Value of monotonic counter is X, where X is the position of the most significant bit at 1. Eight possible ST public keys (ST key revocation feature for RSSe_FW authentication)
	[31:27]	Reserved	Reserved
OTP11	-	BOOTROM_CONFIG_2	-
	[0]	no_data_cache	– 0 (enabled): DCACHE used by boot ROM – 1 (disabled): DCACHE not used by boot ROM
	[1]	no_cpu_pll	– 0 (enabled): PLLs for CPU/AXI enabled for cold boot – 1 (disabled): PLLs for CPU/AXI not enabled for cold boot

Table 18. OTP fuse description (lower OTP region) (continued)

OTP word	OTP bits	Name or description	Detailed description
OTP11	[2]	sdmmc1_not_default_af	– 0 (no): SDMMC1 uses default hard coded AFmux – 1 (yes): SDMMC1 uses AFmux defined in OTP
	[3]	sdmmc2_not_default_af	– 0 (no): SDMMC2 uses default hard coded AFmux – 1 (yes): SDMMC2 uses AFmux defined in OTP
	[4]	Reserved	Reserved
	[8:5]	flash_boot_source	If different from 0, identifies the flash memory used to boot: – 1 (sdcard): SD-Card SDMMC1 – 2 (emmc): *e*.MMC SDMMC1 – 3 (snor): XSPI NOR – 4 (snand): XSPI NAND – 5 (hflash): XSPI HyperFlash – 6 (pnand): FMC pNAND – 7 (sdcard): SD-Card SDMMC2 – 8 (emmc): *e*.MMC SDMMC2 – others: invalid
	[16:9]	boot_source_disable	Each bit disables a boot source (default to UART if all disabled): – 0x01 (usb): USB boot source disabled – 0x02 (uart): UART boot source disabled – 0x04 (fdcan): FDCAN boot source disabled – 0x08 (spi): SPI boot source disabled – 0x10 (i2c): I2C boot source disabled
	[19:17]	spi_instance_disable	– 0b001: SPI1 disabled – 0b010: SPI2 disabled – 0b100: SPI3 disabled
	[22:20]	uart_instance_disable	– 0b001: USART1 disabled – 0b010: USART2 disabled – 0b100: USART3 disabled
	[25:23]	fdcan_instance_disable	– 0b001: disable FDCAN1 disabled – 0b010: disable FDCAN2 disabled – 0b100: disable FDCAN3 disabled
	[28:26]	i2c_instance_disable	– 0b001: I2C1 disabled – 0b010: I2C2 disabled – 0b100: I2C3 disabled
	[29]	dont_boot_on_cfm_tamper	– 0: boot on confirmed tamper – 1: do not boot on confirmed tamper
	[30]	tamp_boot_cfg_glob_enable	Enable the configuration of tampers in boot ROM before boot: – 0: configuration of tampers is disabled – 1: configuration of tampers is enabled
	[31]	Reserved	Reserved

Table 18. OTP fuse description (lower OTP region) (continued)

OTP word	OTP bits	Name or description	Detailed description
OTP12	-	BOOTROM_CONFIG_3	-
	[31:0]	st_fsbl_monotonic_counter	[1-0xFFFF] → [1-32]: Value of monotonic counter is X, where X is the position of the most significant bit at 1
OTP13	-	BOOTROM_CONFIG_4	Boot source configuration word
	[3:0]	mode0	– 0 (af_nopull_ls): AF; no pull; low speed – 1 (af_nopull_ms): AF; no pull; medium speed – 2 (af_nopull_hs): AF; no pull; high speed – 3 (af_pullup_ls): AF; pull up; low speed – 4 (af_pullup_ms): AF; pull up; medium speed – 5 (af_pullup_hs): AF; pull up; high speed – 6 (af_pulldown_ls): AF; pull down; low speed – 7 (af_pulldown_ms): AF; pull down; medium speed – 8 (af_pulldown_hs): AF; pull down; high speed – 9 (gpio_out_high): GPIO output high – 10 (gpio_out_low): GPIO output low – 11 (gpio_in): GPIO input – 12 (gpio_open_nopull): GPIO open drain; No pull – 13 (gpio_open_pullup): GPIO open drain; pull up – 14 (gpio_open_pulldown): GPIO open drain; pull down – 15 (gpio_analog): GPIO analog mode
	[7:4]	afmux0	Values between 0 and 15
	[11:8]	pin0	– [0-15]: pin ID between 0 and 15 for GPIOA to GPIOG and GPIOP – [0-12]: pin ID between 0 and 12 for GPION – [0-8]: pin ID between 0 and 8 for GPIOH and GPIOQ – [0-5]: pin ID between 0 and 5 for GPIOO
	[15:12]	port0	– 0: reserved – 1 (PA): Bank A – 2 (PB): Bank B – 3 (PC): Bank C – 4 (PD): Bank D – 5 (PE): Bank E – 6 (PF): Bank F – 7 (PG): Bank G – 8 (PH): Bank H – 9 (PN): Bank N – 10 (PO): Bank O – 11 (PP): Bank P – 12 (PQ): Bank Q – 0b1111: Invalid configuration

OTP15	-	BOOTROM_CONFIG_6	-
	[3:0]	mode0	idem BOOTROM_CONFIG_4.mode0
	[7:4]	afmux0	idem BOOTROM_CONFIG_4.afmux0
	[11:8]	pin0	idem BOOTROM_CONFIG_4.pin0
	[15:12]	port0	idem BOOTROM_CONFIG_4.port0
	[19:16]	mode1	idem BOOTROM_CONFIG_4.mode0
	[23:20]	afmux1	idem BOOTROM_CONFIG_4.afmux0
	[27:24]	pin1	idem BOOTROM_CONFIG_4.pin0
	[31:28]	port1	idem BOOTROM_CONFIG_4.port0
OTP16	-	BOOTROM_CONFIG_7	-
	[0]	disable_traces	– 0 (no): boot ROM traces disabled – 1 (yes): boot ROM traces enabled
	[1]	disable_hse_freq_detect	– 0 (no): HSE frequency auto-detection disabled – 1 (yes): HSE frequency auto-detection enabled
	[2]	disable_hse_bypass_detect	– 0 (no): HSE bypass detection disabled – 1 (yes): HSE bypass detection enabled
	[4:3]	Reserved	Reserved
	[5]	fmc_force_sw_reset	-
	[6]	emergency_debug_req	– 0 (no): emergency debug not requested – 1 (yes): emergency debug requested
	[7]	emmc_128k_boot_partition	– 0 (no): BootROM does not support e.MMC with 128-Kbyte boot partition – 1 (yes): BootROM supports e.MMC with 128-Kbyte boot partition

Table 18. OTP fuse description (lower OTP region) (continued)

OTP word	OTP bits	Name or description	Detailed description
OTP16	[8]	Reserved	Reserved
	[9]	iomgr_port	-
	[10]	iomgr_muxen	-
	[13:11]	HSE_value	– 0b000 (auto): HSE value is auto-detected among 10, 12, 14, 16, 20, 24, 28, 32, 36, 40, and 48 MHz. – 0b001: HSE = 19.2 MHz – 0b010: HSE = 20 MHz – 0b011: HSE = 24 MHz – 0b100: HSE = 38.4 MHz – 0b101: HSE = 40 MHz – 0b110: HSE = 48 MHz – 0b111: Reserved
	[14]	snand_need_plane_select_1	– 0 (no): serial NAND plane select not needed – 1 (yes): serial NAND plane select needed
	[17:15]	pnand_number_of_ecc_bits_1	– 0 (unset): ECC unset – 1 (hamming): ECC 1 bit (Hamming) – 2 (bch4): ECC 4 bits (BCH4) – 3 (bch8): ECC 8 bits (BCH8) – 4 (ondie): on-die ECC
	[18]	pnand_bus_width_1	– 0 (8 bits): data width is 8 bits – 1 (16 bits): data width is 16 bits
	[26:19]	nand_nb_of_blocks_1	[1-256]: number of block = 256 × value
	[28:27]	nand_block_size_1	[1-4]: block size in number of pages
	[30:29]	nand_page_size_1	– 0 (64): 64 pages per block – 1 (128): 128 pages per block – 2 (256): 256 pages per block
	[31]	pnand_param_stored_in_otp	– 0 (no): BootROM uses ONFI parameter table to get parallel NAND parameters – 1 (yes): parallel NAND parameters are defined in bank1 or bank2, depending on nand_config_distribution value
OTP17	-	BOOTROM_CONFIG_8	-
	[7:0]	oem_ecdsa_active_key	[1-256] → [1-8]: Value of monotonic counter is X, where X is the position of the most significant bit at 1. Eight possible OEM public keys (OEM key revocation feature for OEM-FSBL authentication)
	[31:8]	Reserved	Reserved

Table 18. OTP fuse description (lower OTP region) (continued)

OTP word	OTP bits	Name or description	Detailed description
OTP18	-	BOOTROM_CONFIG_9	-
	[3:0]	secure_boot	– 0 (closed_unlocked): device in CLOSED_UNLOCKED state. Secure boot is not enforced (OEM FSBL authentication is not mandatory). – 1 (closed_locked): device in CLOSED_LOCKED state. Secure boot is enforced (OEM FSBL authentication is mandatory).
	[4]	fsbl_decrypt_prio	– 0 (cryp): BootROM uses CRYP to decrypt FSBL – 1 (saes): BootROM uses SAES to decrypt FSBL
	[8:5]	prov_done	– 0 (no): provisioning not done or not finished successfully. Device is CLOSED_LOCKED_UNPROVD and accepts only ST-BootExtension FSBL. – 1 (yes): provisioning successfully completed. Device is CLOSED_LOCKED_PROVD and accepts only OEM FSBL.
	[12:9]	enable_fingerprint	– 0 (yes): fingerprint feature is disabled – 1 (no): fingerprint feature is enabled
	[15:13]	Reserved	Reserved
	[21:16]	nb_added_secrets	Number of OTP words located in upper area [360 -nb_added_stsecrets ... 359] provisioned (in encrypted mode) with ST secrets. These will be decoded and used by RSSE fw. Coding up to 64 ST secrets to provision in EWS (with DEV_BOOT)
	[25:22]	debug_lock	– 0: do not lock debug enabling – [1-64]: lock debug enabling

6 Resource isolation framework security controller (RIFSC)

6.1 Introduction

Resource isolation framework (RIF) is a set of hardware blocks designed to enforce and manage isolation of STM32 hardware resources like memory and peripherals. Some resources (such as GP/HPDMA) manage their own security configuration internally (they are configured locally). Such resources are called “RIF-aware”. Most resources are “non-RIF-aware”. The RIFSC centralizes the security configuration of such non-RIF-aware resources.

6.2 RIFSC main features

- **RISC** registers associated with **RISUP** logic (resource isolation slave unit for peripherals) sitting in front of the configuration port of non-RIF-aware peripherals, and with RCC peripheral clock control logic, assigning security and privilege levels to peripheral access and peripheral clock control.
- **RIMC** registers associated with **RIMU** logic (resource isolation master unit), assigning non-RIF-aware bus masters the secure, privilege and compartment (CID) information they drive onto the system bus when initiating AXI transactions.
- Secure guard, where an AXI bus master port is forced to be nonsecure when its associated configuration port is programmed nonsecure
- Support for a special debug domain, giving greater access for the debugger

6.3 RIFSC functional description

6.3.1 RIFSC reset and clocks

The RIFSC has a single reset. After a system reset, all non-RIF-aware peripherals become non-secure and unprivileged, reachable by any CID.

6.3.2 RISUP

RISUP blocks are instantiated in front of the AHB configuration port of non-RIF-aware peripherals to filter configuration accesses.

Each non-RIF-aware peripheral is assigned a unique “RISUP index” p < 128. Whenever the RISUP in front of peripheral p blocks an illegal access, it sends an “illegal access event” pulse to the IAC. The IAC records this event in the IAFp bit of the relevant IAC_ISRx register. Thus, the RISUP index is aligned with the IAC index.

For x < 4 and i < 32, the filtering is determined as follows.

- If RIFSC_RISC_SECCFGx[i] = 1, then nonsecure accesses to peripheral p = i + 32x are blocked. Also, nonsecure world attempts to program RCC registers to turn off the clock of (or reset) peripheral p are blocked.

- If RIFSC_RISC_PRIVCFGRx[i] = 1, then user accesses to peripheral p = i + 32x are blocked. Also, attempts by a user process to program RCC registers to turn off the clock of (or reset) peripheral p are blocked.

Whenever the RCC detects an illegal attempt to turn off a clock of (or reset) a peripheral, it sends an event pulse to the IAC (recorded in the IAF136 bit of the relevant IAC_ISRx register).

Note: There is no record of which peripheral was the object of this illegal attempt.

Table 20 identifies the RISUP index of each non-RIF-aware peripheral.

Table 20. RISUP indexes

RISUPs 31 to 0 (see RIFSC_RISC_PRIVCFGR0 / SECCFGR0 / RCFGLOCKR0)																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The RISUP generates a bus error if an instruction fetch arrives at the peripheral.

6.3.3 RCC security settings for RIF-aware peripherals and RAMs

Table 21 shows the use made of the RIFSC to configure the security and privilege access rights for resetting or gating the clock of RIF-aware peripherals and RAMs (resources that do not have RISUPs in front of them). Just as for all the non-RIF-aware peripherals with RISUPs mentioned above, the outputs of the registers below are also wired to the RCC.

Table 21. RISC indexes purely for RCC security control

RCC security controls 159 to 128 (RIFSC_RISC_PRIVCFGR4 / SECCFGR4 / RCFGLOCKR4)																															
159	158	157	156	155	154	153	152	151	150	149	148	147	146	145	144	143	142	141	140	139	138	137	136	135	134	133	132	131	130	129	128

⋮																															
RCC security controls 191 to 160 (RIFSC_RISC_PRIVCFGR5 / SECCFGR5 / RCFGLOCKR5)																															
191	190	189	188	187	186	185	184	183	182	181	180	179	178	177	176	175	174	173	172	171	170	169	168	167	166	165	164	163	162	161	160
-	RAMCFG	-	-	HDP	-	-	XSPIPHY2	XSPIPHY1	XSPIPHYCOMP	-	NPU_RAM3	NPU_RAM2	NPU_RAM1	NPU_RAM0	-	MCO2	MCO1	DTS	-	GPIOQ	GPIOP	GPIOO	GPION	-	GPIOH	GPIOG	GPIOF	GPIOE	GPIOD	GPIOC	GPIOB

Note: For the RIF-aware peripherals, it is the responsibility of the trusted domain software to make sure this security configuration of the control of the clock and reset of the peripheral is consistent with the internal security configuration of this peripheral.

6.3.4 RIMU

The security attributes (CID, security, privilege) of accesses made by a non-RIF-aware peripheral that is an AXI bus master, can be configured in RIMC_ATTRx registers, where x is the “RIMU index” of the peripheral. *Table 22* gives the index of each of these AXI bus master peripherals, and the index of the related RISUP protecting the configuration port of this peripheral. If nonsecure world software is permitted to configure the peripheral, then the RIMU_ATTRx[MSEC] setting is ignored, and all AXI accesses initiated by the peripheral are forced to be nonsecure too. This override mechanism is referred to as “secure guard”.

Table 22. RIMU resource assignment

Master index	Master name	Secure guard RISUP index
0	Trace (ETR)	No RISUP
1	NPU	106
2	SDMMC1	53
3	SDMMC2	54
4	OTG1	56
5	OTG2	57
6	ETH1	60
7	GPU	99
8	DMA2D	101

Table 22. RIMU resource assignment (continued)

Master index	Master name	Secure guard RISUP index
9	DCMIPP	93
10	LTDC_L1	103
11	LTDC_L2	104
12	VENC	97

RIMC registers must be initialized by the secure privileged software after the device reset. Optionally, this software can set the GLOCK bit in RIMC_CR, preventing further writes to all RIMC registers. This bit can only be cleared by a power-on reset.

The RISC_RIMC_CR register contains a DAPCID field that gives the CID value used by debugger (DAP) accesses onto the AXI bus. The reset value of this register is 0x7.
All RISAFs treat a 0x7 as a legal CID value, regardless of their configuration. The secure privileged master can reprogram the DAPCID to allow the DAP to mimic another compartment (for example, to debug the security configuration).

6.4 RIFSC registers

These registers are accessible through the register interface of the RIFSC peripheral.

6.4.1 RIFSC RISC slave configuration register x (RIFSC_RISC_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GLOCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: Global lock

This bit locks the configuration of RIFSC RISC registers until next reset. This bit is cleared by default and, once set, it cannot be reset until global RIFSC reset.

0: RIFSC RISC registers are writable.

1: All writes to RIFSC RISC registers are ignored.

6.4.2 RIFSC RISC slave security configuration register x (RIFSC_RISC_SECCFGRx)

Address offset: 0x010 + 0x4 * x, (x = 0 to 5)

Reset value: 0x0000 0000

Nonsecure or unprivileged writes to this register are ignored, while any read is allowed. Writes are ignored if GLOCK is set in RIFSC_RISC_CR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SEC{i + 32 * x}															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SEC{i + 32 * x}**: security configuration for peripheral {i + 32 * x} (i = 0 to 31)
0: Secure and nonsecure data access are granted to the peripheral {i + 32 * x}.
1: Secure data access only are granted to the peripheral {i + 32 * x}.

6.4.3 RIFSC RISFC slave privileged register x (RIFSC_RISC_PRIVCFGRx)

Address offset: 0x030 + 0x4 * x, (x = 0 to 5)

Reset value: 0x0000 0000

Unprivileged writes to this register are ignored, while any read is allowed. Writes are ignored if GLOCK is set in RIFSC_RISC_CR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PRIV{i + 32 * x}															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIV{i + 32 * x}**: privileged-only access permission for peripheral {i + 32 * x} (i = 0 to 31)
0: Privileged and unprivileged data access are granted to the peripheral {i + 32 * x}.
1: Privileged data access only are granted to the peripheral {i + 32 * x}.

*Note: If corresponding SEC{i + 32 * x} bit is set in RIFSC_RISC_SECCFGRx, this bit can only be written by a secure privileged application.*

6.4.4 RIFSC RISC slave resource configuration lock register x (RIFSC_RISC_RCFGLOCKRx)

Address offset: 0x050 + 0x4 * x, (x = 0 to 5)

Reset value: 0x0000 0000

Secure privileged write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RLOCK{i + 32 * x}															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RLOCK{i + 32 * x}															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **RLOCK{i + 32 * x}**: resource lock for peripheral {i + 32 * x} (i = 0 to 31)
This bit is set to lock the peripheral resource {i + 32 * x}. It is cleared by default and, once set, this bit cannot be cleared until the RIFSC RISC peripheral is reset.
0: SEC{i + 32 * x} in RIFSC_RISC_SECCFGRx and PRIV{i + 32 * x} in RIFSC_RISC_PRIVCFGRx are writable.
1: Writes to SEC{i + 32 * x} and PRIV{i + 32 * x} are ignored.

6.4.5 RIFSC RIMC master configuration register (RIFSC_RIMC_CR)

Address offset: 0xC00

Reset value: 0x0000 0710

Secure privileged write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in RIFSC_RISC_CR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	DAPCID[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	Res.	GLOCK
					rw	rw	rw								rs

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **DAPCID[2:0]**: debug access port compartment ID
This bitfield defines the CID of the DAP.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: global lock
This bit is used to lock the configuration of RIFSC RIMC registers until next reset. This bit is cleared by default and, once set, it cannot be reset until global RIFSC reset.
0: RIFSC RIMC registers are writable.
1: All writes to RIFSC RIMC registers are ignored.

6.4.6 RIFSC RIMC master attribute register x (RIFSC_RIMC_ATTRx)

Address offset: 0xC10 + x * 0x4 (x = 0 to 12)

Reset value: 0x0000 0000

Secure privileged write access only. Any read access is allowed on this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	MPRIV	MSEC	Res.	MCID[2:0]			Res.	Res.	Res.	Res.
						rw	rw		rw	rw	rw				

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **MPRIV**: master privileged
Value of the privileged flag on the interconnect for this master.
0: This master is unprivileged.
1: This master is privileged.

Bit 8 **MSEC**: master secure
Value of the secure flag on the interconnect for this master.
0: This master is nonsecure.
1: This master is secure.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **MCID[2:0]**: master CID
Value of the CID flag on the interconnect for this master. This bitfield cannot be written with a value of 0x7 (write to MCID[2:0] is ignored).

Bits 3:0 Reserved, must be kept at reset value.

6.4.7 RIFSC peripheral protection status register 0 (RIFSC_PPSR0)

Address offset: 0xFB0

Reset value: 0xFFFF FF7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3* for the register boundary addresses.

7 Resource isolation slave unit for address space protection (full version) (RISAF)

7.1 RISAF introduction

The RIF (resource isolation framework) is a comprehensive set of hardware blocks designed to enforce and manage isolation of STM32 hardware resources, like memory and peripherals.

Through RISAF registers, a secure privileged software application or the application to whom the configuration has been delegated, assigns memory regions and subregions to one or more security domains (secure, privileged, compartment).

7.2 RISAF main features

- Assign variable sized address space regions and subregions to security domains.
- Make memory regions:
  - Restricted to one or more than one hardware compartments
  - Secure-only or nonsecure-only
  - Privileged-only or privileged/unprivileged
  - Read-only, write-only, or read/write
- The secure privileged software can delegate configuration and positioning of a subregion (within a region) to another security domain.
- The secure privileged software can delegate configuration and positioning of a subregion (within a nonsecure region) to a nonsecure privileged software.

7.3 RISAF implementation

The following table describes the characteristics of the available RISAFs, including watermark programming details (such as granularity and protected address space).

Table 24. RISAF resource assignment

Protected memory	Resource name	Target bus	IAC index	Number of configurable base regions	Granularity	Address space size and alignment	CID management
TCM	RISAF1	AXI	139	7	4 Kbytes	1 Gbyte	Programmable CID filtering on system bus (CID=0 to 7). To delegate to nonsecure set DCCID = 1.
CPUAXI RAM0	RISAF2		140			1 Mbyte	
CPU AXI RAM1	RISAF3		141				
NPU master 0	RISAF4		142	11		4 Gbytes	
NPU master 1	RISAF5		143				
CPU master	RISAF6		144				
FLEXRAM	RISAF7	AXI	145	7	4 Kbytes	512 Kbytes	
CACHEAXI RAM	RISAF8		146			256 Kbytes	
VENCRAM	RISAF9		147			128 Kbytes	
XSPI1	RISAF11		149			256 Mbytes	
XSPI2	RISAF12		150				
XSPI3	RISAF13		151				
FMC	RISAF14		152				
CACHEAXI configuration port	RISAF15	AHB	153	2	4 bytes	4 Kbytes	Fixed CID0 filtering on system bus. To delegate to nonsecure set DCCID = 0.
AHB RAM1	RISAF21		154	7	512 bytes	16 Kbytes	
AHB RAM2	RISAF22		155				
Backup RAM	RISAF23		156	3		4 Kbytes	

RISAF4/5/6 are used to partition the 2-Mbyte NPU RAM. This memory is implemented as four RAM cuts, each with its own AXI target port, but using an interleaved (re-mapped) addressing scheme. To retain the software normal view of memory addressing, the RISAFs protecting these RAMs are placed on the three entry ports of the NPU interconnect. The user must program an identical partitioning into each of the three RISAFs. These RISAFs are furnished with two extra regions that the secure privileged software must configure to be transparent (permissive) to all accesses either side of the NPU RAMs.

As summarized in the CID management column of *Table 24*, the AHB bus does not carry CID information (it is fixed at 0). The RISAFs on the AHB bus only filter on security and privilege, in read or in write (using RDENC0 or WRENC0 bits, respectively). All accesses are effectively assumed to be owned by the CPU. When a secure privileged application delegates to the nonsecure world the access control configuration of subregions in a nonsecure base region, DCEN must be set, and DCCID and SRCID must stay at 0 for this specific base region.

As summarized in *Table 24* the AXI bus does carry CID information. All AHB configuration accesses to AXI RISAF registers are assumed to come from CID1. When a secure privileged application delegates to the nonsecure world the access control configuration of subregions in a nonsecure base region, DCEN must be set and DCCID must equal 0x1.

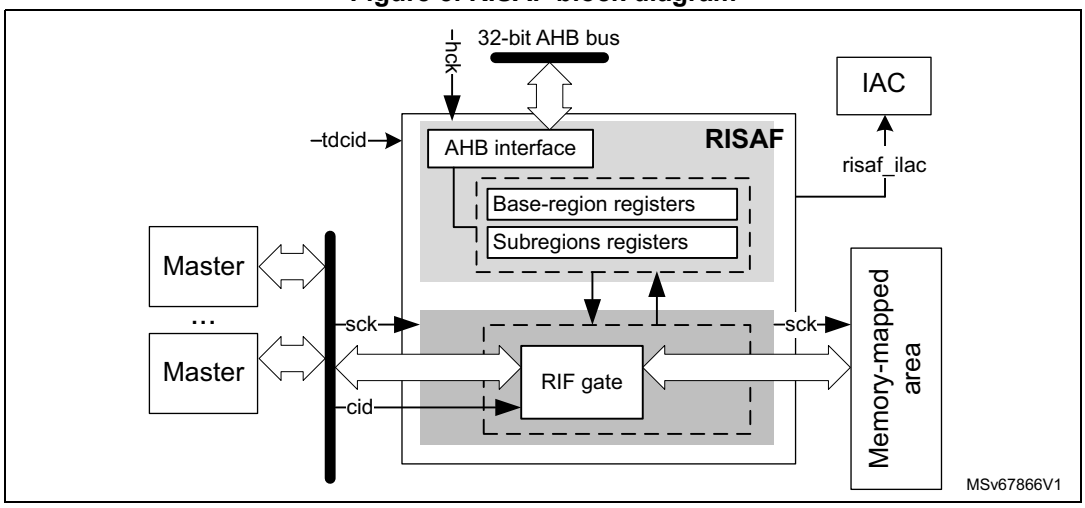
The AHB configuration port of the CACHEAXI is protected by a small RISAF that only offers two base regions. These are expected to be configured to cover the register address spaces either side of the registers controlling cache invalidation. The cache invalidation operation can thus be reserved for use only by the secure privileged software, because the controlling registers are left in the default region 0.

7.4 RISAF functional description

7.4.1 RISAF block diagram

The following figure shows the block diagram of the RISAF associated with the IAC, and optionally, a memory controller.

Figure 5. RISAF block diagram



1. The tdcid input value is equal to CID = 1.

7.4.2 RISAF internal signals

Table 25 describes internal signals available at RISAF level, not at product level (on pins).

Table 25. RISAF internal input/output signals

Name	Type	Description
risaf_sck	Digital input	System bus clock, also used by the protected memory controller
risaf_hclk		AHB bus clock
risaf_ilac	Digital output	Illegal access signal to IAC

7.4.3 RISAF reset and clocks

The RISAF peripheral has two clocks, one for its AHB register interface, and one for its system bus interfaces. The system bus clock is shared with the system bus memory controller target.

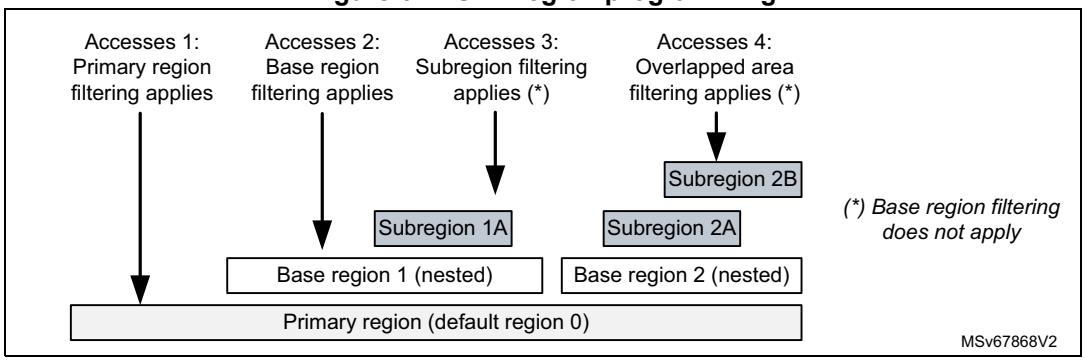
The RISAF peripheral has a single reset input.

Address spaces protected by the RISAF are by default secure, privileged, and CID = 1 only.

7.4.4 RISAF address space management

Through RISAF registers, a secure privileged software application, or the application to which the configuration has been delegated, assigns memory regions to one or more security domains (secure, privilege, compartment ID). *Figure 6* illustrates the principle of this allocation.

Figure 6. RISAF region programming



As shown in *Figure 6*, there are multiple types of access filtered by RISAF:

- Accesses 1 - Default region: access to an area not belonging to any enabled base region. Filtering for such access is fixed to secure, privileged and CID = 1 only.
- Accesses 2 - Application region > 0: access to an area in an enabled base region, not belonging to any enabled subregion. Filtering for such access is defined in the base region, where one or more compartments can be granted specific accesses.
- Accesses 3 - Non overlapped subregion: access to an area in an enabled nested subregion. Filtering for such access is defined in the subregion, with only one compartment that can be granted access.
- Accesses 4 - Overlapped subregion: accesses to an area overlapping two enabled nested subregions. In this case, filtering rules for these subregions are used by the RISAF as follows:
  - If both subregions are secure (resp. nonsecure), the overlap is secure (resp. nonsecure).
  - If one subregion is nonsecure (resp. unprivileged), the overlap is nonsecure (resp. unprivileged).
  - If one of the two subregions grants access to a compartment, the access can go through. Up to two compartments can be granted access to an overlapped subregion.

Note: When a base or subregion is disabled, the associated filtering is disabled as well. For access types 3 or 4 (detailed above), base region filtering rules do not apply.

7.4.5 RISAF programming

Only the secure privileged software can set up the access configuration to base region x through RISAF_REGx_CFGR, RISAF_REGx_CIDCFGR, RISAF_REGx_STARTR, and RISAF_REGx_ENDR.

The secure privileged software, or the application to which the subregion z configuration has been delegated in RISAF_REGx_zNESTR, can set up the access configuration to subregion z of base region x through RISAF_REGx_zCFGR, RISAF_REGx_zSTARTR, and RISAF_REGx_zENDR (z = A or B).

As shown in *Table 26*, subregion right options depend upon the base region privileged and security rights. Base regions can be defined only as privileged.

Table 26. RISAF subregion security setup matrix

Base region rights	Nested subregion rights			
	Secure, privileged	**Secure, unprivileged**	**Nonsecure, privileged**	**Nonsecure, unprivileged**
Secure, privileged	OK(1)	OK	OK	OK
Secure, unprivileged	Not allowed	OK(1)	Not allowed	OK
Nonsecure, privileged	Not allowed	Not allowed	OK(1)	OK
Nonsecure, unprivileged	Not allowed	Not allowed	Not allowed	OK(1)

1. Default configuration

Configuring base regions in RISAF

If the secure privileged software must use a base region x (for example at boot time), the following steps are recommended.

1. The secure privileged software sets start and end addresses for each of the required base region x, using RISAF_REGx_STARTR and RISAF_REGx_ENDR:
   - These registers are initialized with 32-bit physical addresses when protected address space size is 4 Gbytes. For different sizes, refer to the register description.
   - Base regions must be defined within their primary region. The hardware enforces this rule if the application does not follow it.
2. For each of the above region x, the secure privileged software programs RISAF_REGx_CIDCFGR, granting read and/or write access to any compartment.
3. For each of the above region x, the secure privileged software finalizes the programming by configuring RISAF_REGx_CFGR, setting up security parameters (secure or encrypted if applicable), and granting privileged-only access, or not, to each compartment that has access to the region (see step *2*). Privileged parameter is fixed to privileged only.
4. After a final check on the above configuration, the secure privileged software enables each required base region x, setting the BREN bit in RISAF_REGx_CFGR.

Note: The number of regions, the region watermark granularity, and the address space size depend upon the RISAF instance (see Section 7.3).

At any time the secure privileged software can lock the RISAF configuration until the next reset, by setting the GLOCK bit in RISAF_CR. Subregion registers are the exception to this rule, as explained in *Configuring subregions in RISAF*.

Configuring subregions in RISAF

Note: The number of subregions, the subregion watermark granularity, and the primary region address space size depend on the RISAF resource described in Section 7.3.

Important notes on access control programming and delegation are in Section 7.3.

When an application needs to use the subregion z defined in the base region x, there are two configuration options in RISAF_REGx_zNESTR:

- The secure privileged software programs the RIF configuration for this subregion. In this case, DCEN is cleared.
- The secure privileged software delegates the RIF configuration to a single CID, defined with DCCID. In this case, DCEN must also be set.

Configuring a subregion z consists in the following steps.

1. Define the start and end address of the subregion using RISAF_REGx_zSTARTR and RISAF_REGx_zENDR registers.
   - When programming subregion watermarks, use similar rules as for base regions (see *Configuring base regions in RISAF*).
   - Subregions must be defined within their base region. The RISAF enforces this rule if the application does not follow it.
2. Modify WREN and RDEN in RISAF_REGx_zCFGR to modify the access right of allowed compartment (defined with SCID bits).
3. In the same registers, modify the security and privileged access rights for the allowed compartment, if needed (see *Table 26* for applicable restrictions).
4. After a final check on the above configuration, the subregion must be enabled by setting SREN bit in RISAF_REGx_zCFGR.

After a secure privileged software has locked all base regions (using GLOCK bit), subregion owners can lock their configuration using the RLOCK bit in RISAF_REGx_zCFGR.

Note: Only a secure application can change SEC in RISAF_REGx_zCFGR. If the base region is secure, only a secure application can configure subregion registers.

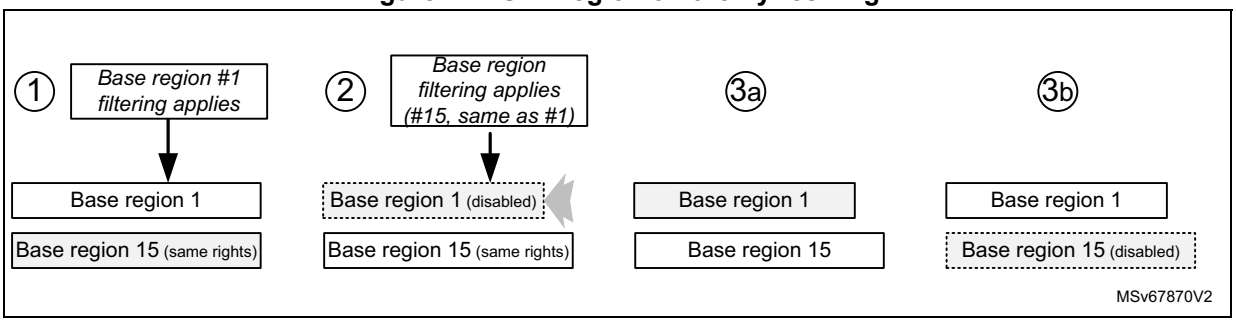
7.4.6 RISAF runtime modification of region or subregion configuration

The RISAF supports the on-the-fly update of the base region and subregion programming, except for the start- and end-address boundaries:

- To change RISAF_REGx_STARTR and RISAF_REGx_ENDR, the base region must be disabled (BREN = 0). In this case, the default primary region access rules apply immediately (secure, privileged, CID = 1 only).
- To change RISAF_REGx_zSTARTR and RISAF_REGx_zENDR (z = A or B), the subregion must be disabled (SREN = 0). In this case, the base region access rules apply immediately.

If the first solution introduces too many constraints, a workaround is shown in *Figure 7*.

Figure 7. RISAF region on-the-fly resizing



The recommended on-the-fly resizing of base region 1 becomes:

1. Define a spare base region (for example 15), exactly as current region 1.
2. Disable region 1 by clearing BREN.The region 15 access control (identical to region 1) immediately applies. No effect is experienced at system level. The region 1 can be safely resized.
3. Enable region 1, then disable region 15. The new region 1 access control immediately applies. Optionally, subregions can be added on top.

7.4.7 Managing illegal accesses

As a RIF component, the RISAF does not use the standard interrupt lines toward NVIC or GIC concentrators. The IAC captures all RIF interrupt events, called illegal access events.

Refer to *Section 8: Illegal access controller (IAC)* for more information on the way illegal accesses are managed.

7.5 RISAF registers

The registers are accessible through the interface of the RISAF. Only word accesses (32 bits) are supported.

7.5.1 RISAF configuration register (RISAF_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, write access only. Any read access is allowed, writes are ignored if GLOCK is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GLOCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: Global lock

This bit locks the. configuration of RISAF registers until next reset. It is cleared by default, and, once set, cannot be reset until global RISAF reset.

0: RISAF registers are writable.

1: All writes to RISAF registers are ignored, except RISAF_IACR, RISAF_REGx_zCFGR, RISAF_REGx_zSTARTR, and RISAF_REGx_zENDR (z = A to B).

7.5.2 RISAF illegal access status register (RISAF_IASR)

Address offset: 0x008

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, read access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IAEF	CAEF
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **IAEF**: Illegal access error flag

This bit is set when an illegal access is detected on the system bus. More details on the error can be found in RISAF_IAESR and RISAF_IADDR.

This bit is cleared by setting corresponding bit in RISAF_IACR.

Bit 0 **CAEF**: Configuration access error flag

This bit is set when an illegal access to any RISAF configuration register is detected. It is cleared by setting the corresponding bit in RISAF_IACR.

7.5.3 RISAF illegal access clear register (RISAF_IACR)

Address offset: 0x00C

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, write access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IAEF	CAEF
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **IAEF**: Illegal access error flag

Set this bit to clear IAEF0 in RISAF_IASR, allowing the capture of a new error information from RIF in RISAF_IAESR and RISAF_IADDR registers.

Note: Clearing this bit does not clear RISAF_IADDR.

Bit 0 **CAEF**: Configuration access error flag

Set this bit to clear CAEF in RISAF_IASR.

7.5.4 RISAF illegal access error status register (RISAF_IAESR)

Address offset: 0x020

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, read access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IANRW	Res.	IASEC	IAPRIV	Res.	IACID[2:0]		
								r		r	r		r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **IANRW**: Illegal access read/write

When IAEF = 1 in RISAF_IASR, IANRW captures the access type of the illegal access that has been detected by RIF gate x.

0: Illegal access was a data read or an instruction fetch

1: Illegal access was a data write

Bit 6 Reserved, must be kept at reset value.

Bit 5 **IASEC**: Illegal access security
When IAEF = 1 in RISAF_IASR, IASEC captures the security type of the illegal access that has been detected by RIF gate x.
0: Illegal access was nonsecure
1: Illegal access was secure

Bit 4 **IAPRIV**: Illegal access privileged
When IAEF = 1 in RISAF_IASR, IAPRIV captures the privilege state of the master that issued the illegal access detected by RIF gate x.
0: Illegal access was unprivileged
1: Illegal access was privileged

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **IACID[2:0]**: Illegal access compartment ID
When IAEF = 1 in RISAF_IASR, IACID[2:0] captures the compartment ID of the master that issued the illegal access detected by RIF gate x.

7.5.5 RISAF illegal address register (RISAF_IADDR)

Address offset: 0x024

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, read access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IADD[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IADD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **IADD[31:0]**: Illegal address
When IAEF = 1 in RISAFB_IASR, IADD[31:0] captures the address of the erroneous access. Additional information can be found in RISAF_IAESR. Captured address information is the byte offset from the base of the protected address space.

7.5.6 RISAF region x configuration register (RISAF_REGx_CFGR)

Address offset: 0x040 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in RISAF_CR.

Refer to *Section 7.3* to verify the number of base regions supported by this RISAF instance.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIVC7	PRIVC6	PRIVC5	PRIVC4	PRIVC3	PRIVC2	PRIVC1	PRIVC0

Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BREN
							rw								rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **PRIVC[7:0]**: Privileged access for compartment y (y = 7 to 0)

This bit is taken into account only if BREN = 1.

0: Application running in compartment y can access to region x in privileged and unprivileged mode.

1: Application running in compartment y can access to region x in privileged mode only.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **SEC**: Secure region

This bit is taken into account only if BREN = 1.

0: Only nonsecure privileged requests can access region x. SEC value in RISAF_REGx_zCFGR is internally treated as 0-ed by RISAF (only nonsecure requests to subregions).

1: Only secure privileged requests can access region x, and optional subregions can be defined as secure or nonsecure.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **BREN**: Base region enable

0: Base region x is disabled. Access control of primary region 0 (secure, privileged, trusted domain CID = 1) applies to any access between region x start and end addresses. Associated subregions are also disabled.

1: Base region x is enabled. Access controls defined in region x apply to any access between region x start and end addresses.

Note: The filtering starts from start address RISAF_REGx_STARTR (included) and ends at end address RISAF_REGx_ENDR (included).

7.5.7 RISAF region x start-address register (RISAF_REGx_STARTR)

Address offset: 0x044 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in RISAF_CR, or if BREN is set in RISAF_REGx_CFGR.

Refer to *Section 7.3* to verify the number of base regions supported by this RISAF instance, and for details on protected address space size and watermark granularity.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BADDSTART[31:16]

BADDSTART[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **BADDSTART[31:0]**: Base region address start

This bitfield defines the byte-address offset (relative to the base address of the protected address space) of the lowest byte-address in base region x.

Address bits less than the granularity and greater than the protected address space size cannot be written to, and remain 0.

7.5.8 RISAF region x end-address register (RISAF_REGx_ENDR)

Address offset: 0x048 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0FFF

The reset value given here applies when the granularity is 4 Kbytes. If the granularity is 2^n, the reset value is 2^n - 1.

Secure, privileged, trusted domain CID = 1, write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in RISAF_CR, or if BREN is set in RISAF_REGx_CFGR.

Refer to *Section 7.3* to verify the number of base regions supported by this RISAF instance, and for details on protected address space size and watermark granularity.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BADDEND[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

BADDEND[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **BADDEND[31:0]**: Base region address end

This bitfield defines the byte-address offset (relative to the base address of the protected address space) of the highest byte-address in base region x.

Address bits less than the granularity cannot be modified, and remain 1.

Address bits greater than the protected address space size cannot be written, and remain 0.

7.5.9 RISAF region x CID configuration register (RISAF_REGx_CIDCFGR)

Address offset: 0x04C + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in RISAF_CR.

Refer to *Section 7.3* to verify the number of base regions supported by this RISAF instance.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **WRENC[7:0]**: Write enable for compartment y (y = 7 to 0)

This bit is taken into account only if BREN = 1 in RISAF_REGx_CFGR.

0: Application running in compartment y cannot write to region x (write ignored).

1: Application running in compartment y can write to region x. Additional control defined by SEC and PRIVCy in RISAF_REGx_CFGR, also applies.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **RDENC[7:0]**: Read enable for compartment y (y = 7 to 0)

This bit is taken into account only if BREN = 1 in RISAF_REGx_CFGR.

0: Application running in compartment y cannot read region x (read as 0).

1: Application running in compartment y can read region x. Additional control defined by SEC and PRIVCy in RISAF_REGx_CFGR, also applies.

7.5.10 RISAF region x subregion A configuration register (RISAF_REGx_ACFGR)

Address offset: 0x050 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Unprivileged writes are ignored. Nonsecure writes are ignored if SEC = 1 in RISAF_REGx_CFGR, or if DCEN = 0 in RISAF_REGx_ANESTR. Any read access is allowed to this register. Writes are ignored if RLOCK = 1 in this register.

When the delegated configuration is enabled (DCEN = 1 in RISAF_REGx_ANESTR), only the compartment DCCID defined in RISAF_REGx_ANESTR can write to this register.

When the delegation is disabled (DCEN = 0), only the secure privileged software can program this register.

Refer to *Section 7.3* to verify the number of base regions and subregions supported by this RISAF instance.

Caution: Check *Section 7.3* before programming SRCID[2:0] bitfield.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

		rw	rw			rw	rw		rw	rw	rw			rs	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **WREN**: Write enable

This bit is taken into account only if SREN = 1 in this register.

0: Any writes to subregion A of region x are ignored

1: Subregion A of region x can be written to

Bit 12 **RDEN**: Read enable

This bit is taken into account only if SREN = 1 in this register.

0: Any read to subregion A of region x returns 0

1: Subregion A of region x can be read

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **PRIV**: Privileged subregion

This bit is taken into account only if SREN = 1 in this register.

0: Privileged and unprivileged accesses are granted in subregion A of region x

1: Only privileged accesses are granted in subregion A of region x

Note: When base region x is defined as unprivileged for the SCID compartment (PRIVCy = 0 in RISAF_REGx_CFGR, with SRCID = Cy), unprivileged accesses to subregion A are always granted.

Bit 8 **SEC**: Secure subregion

This bit is taken into account only if SREN = 1 in this register. Nonsecure modification to it are discarded.

0: Only nonsecure requests can access subregion A of region x

1: Only secure requests can access subregion A of region x

Note: When base region x is defined as nonsecure (SEC = 0 in RISAF_REGx_CFGR), only nonsecure accesses to subregion A are granted.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SRCID[2:0]**: Subregion CID

When SREN = 1 in this register, SRCID[2:0] defines which compartment has access to subregion A of RISAF region x.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **RLOCK**: Resource lock

When this bit is set, the subregion resource is locked.

0: RISAF_REGx_ACFGR, RISAF_REGx_ASTARTR, and RISAF_REGx_AENDR are writable

1: Writes to RISAF_REGx_ACFGR, RISAF_REGx_ASTARTR, and RISAF_REGx_AENDR are ignored

Note: This bit is set once, cleared only by RISAF reset. It cannot be set if GLOCK = 0 in RISAF_CR.

Bit 0 **SREN**: Subregion enable

0: Subregion A is disabled. Access control of base region x applies to any access between this subregion start and end addresses.

1: Subregion A of region x is enabled. Access control defined in subregion A applies to any access between subregion A start and end addresses.

Note: The filtering starts from address RISAF_REGx_ASTARTR (included), and ends at address RISAF_REGx_AENDR (included).

7.5.11 RISAF region x subregion A start-address register (RISAF_REGx_ASTARTR)

Address offset: 0x054 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Unprivileged writes are ignored. Nonsecure writes are ignored if SEC = 1 in RISAF_REGx_CFGR, or if DCEN = 0 in RISAF_REGx_ANESTR. Any read access is allowed to this register. Writes are ignored if RLOCK = 1 or SREN = 1 in RISAF_REGx_ACFGR.

When the delegated configuration is enabled (DCEN = 1 in RISAF_REGx_ANESTR), only the compartment DCCID defined in RISAF_REGx_ANESTR can write to this register. When the delegation is disabled (DCEN = 0), only the secure privileged software can program this register.

Refer to *Section 7.3* to verify the number of base regions and subregions supported by this RISAF instance, and for details on protected address space size and watermark granularity.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SADDSTART[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SADDSTART[31:0]**: Subregion address start

This bitfield defines the byte-address offset (relative to the base address of the protected address space) of the lowest byte-address in subregion A in base region x.

Address bits less than the granularity and greater than the protected address space size cannot be written, and remain 0.

The effective subregion is the intersection of the subregion and its base region (there is no point in programming SADDSTART below the associated BADDSTART).

7.5.12 RISAF region x subregion A end-address register (RISAF_REGx_AENDR)

Address offset: 0x058 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0FFF

Unprivileged writes are ignored. Nonsecure writes are ignored if SEC = 1 in RISAF_REGx_CFGR, or if DCEN = 0 in RISAF_REGx_ANESTR. Any read access is allowed to this register. Writes are ignored if RLOCK = 1 or SREN = 1 in RISAF_REGx_ACFGR.

When the delegated configuration is enabled (DCEN = 1 in RISAF_REGx_ANESTR), only the compartment DCCID defined in RISAF_REGx_ANESTR can write to this register. When the delegation is disabled (DCEN = 0), only the secure privileged software can program this register.

Refer to *Section 7.3* to verify the number of base regions and subregions supported by this RISAF instance, and for details on protected address space size and watermark granularity.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SADDEND[31:0]**: Subregion address end

This bitfield defines the byte-address offset (relative to the base address of the protected address space) of the highest byte-address of subregion A in base region x.

Address bits less than the granularity cannot be modified, and remain 1.

Address bits greater than the protected address space size cannot be written, and remain 0.

The effective subregion is the intersection of the subregion and its base region (there is no point in programming SADDEND higher than the associated BADDEND).

7.5.13 RISAF region x subregion A nested mode register (RISAF_REGx_ANESTR)

Address offset: 0x05C + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in RISAF_CR.

Refer to *Section 7.3* to verify the number of base regions and subregions supported by this RISAF instance.

Caution: Check *Section 7.3* before setting DCEN bit.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw	rw	rw		rw		

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **DCCID[2:0]**: Delegated configuration CID

The secure privileged software can use this bitfield to statically define which compartment can program the RIF configuration of subregion A if DCEN = 1 in this register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCEN**: Delegated configuration enable

0: RIF configuration for subregion A can be written only by the secure privileged software.

1: RIF configuration for subregion A can be written only by compartment DCCID, defined in this register. If base region x is defined as secure (SEC = 1), nonsecure write accesses to this subregion RIF configuration by compartment DCCID are ignored.

Note: RIF configuration of subregion A is defined as RISAF_REGx_ACFGR, RISAF_REGx_ASTARTR, and RISAF_REGx_AENDR.

Bits 1:0 Reserved, must be kept at reset value.

7.5.14 RISAF region x subregion B configuration register (RISAF_REGx_BCFGR)

Address offset: 0x060 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Unprivileged writes are ignored. Nonsecure writes are ignored if SEC = 1 in RISAF_REGx_CFGR, or if DCEN = 0 in RISAF_REGx_BNESTR. Any read access is allowed to this register. Writes are ignored if RLOCK = 1 in this register.

When the delegated configuration is enabled (DCEN = 1 in RISAF_REGx_BNESTR), only the compartment DCCID defined in RISAF_REGx_BNESTR can write to this register.

When the delegation is disabled (DCEN = 0), only the secure privileged software can program this register.

Refer to *Section 7.3* to verify the number of base regions and subregions supported by this RISAF instance.

Caution: Check *Section 7.3* before programming SRCID[2:0] bitfield.

		rw	rw			rw	rw		rw	rw	rw			rs	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **WREN**: Write enable

This bit is taken into account only if SREN = 1 in this register.
0: Any writes to subregion B of region x are ignored
1: Subregion B of region x can be written to

Bit 12 **RDEN**: Read enable

This bit is taken into account only if SREN = 1 in this register.
0: Any read to subregion B of region x returns 0
1: Subregion B of region x can be read

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **PRIV**: Privileged subregion

This bit is taken into account only if SREN = 1 in this register.
0: Privileged and unprivileged accesses are granted in subregion B of region x
1: Only privileged accesses are granted in subregion B of region x

Note: When base region x is defined as unprivileged for the SCID compartment (PRIVCy = 0 in RISAF_REGx_CFGR, with SRCID = Cy), unprivileged accesses to subregion B are always granted.

Bit 8 **SEC**: Secure subregion

This bit is taken into account only if SREN = 1 in this register. Nonsecure modification to it are discarded.

0: Only nonsecure requests can access subregion B of region x

1: Only secure requests can access subregion B of region x

Note: When base region x is defined as nonsecure (SEC = 0 in RISAF_REGx_CFGR), only nonsecure accesses to subregion B are granted.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SRCID[2:0]**: Subregion CID

When SREN = 1 in this register, SRCID[2:0] defines which compartment has access to subregion B of RISAF region x.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **RLOCK**: Resource lock

When this bit is set, the subregion resource is locked.

0: RISAF_REGx_BCFGR, RISAF_REGx_BSTARTR, and RISAF_REGx_BENDR are writable

1: Writes to RISAF_REGx_BCFGR, RISAF_REGx_BSTARTR, and RISAF_REGx_BENDR are ignored

Note: This bit is set once, cleared only by RISAF reset. It cannot be set if GLOCK = 0 in RISAF_CR.

Bit 0 **SREN**: Subregion enable

0: Subregion B of region x is disabled. Access control of base region x applies to any access between this subregion start and end addresses.

1: Subregion B of region x is enabled. Access control defined in subregion B applies to any access between subregion B start and end addresses.

Note: The filtering starts from address RISAF_REGx_BSTARTR (included), and ends at address RISAF_REGx_BENDR (included).

7.5.15 RISAF region x subregion B start-address register (RISAF_REGx_BSTARTR)

Address offset: 0x064 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Unprivileged writes are ignored. Nonsecure writes are ignored if SEC = 1 in RISAF_REGx_CFGR, or if DCEN = 0 in RISAF_REGx_BNESTR. Any read access is allowed to this register. Writes are ignored if RLOCK = 1 or SREN = 1 in RISAF_REGx_BCFGR.

When the delegated configuration is enabled (DCEN = 1 in RISAF_REGx_BNESTR), only the compartment DCCID defined in RISAF_REGx_BNESTR can write to this register. When the delegation is disabled (DCEN = 0), only the secure privileged software can program this register.

Refer to *Section 7.3* to verify the number of base regions and subregions supported by this RISAF instance, and for details on protected address space size and watermark granularity.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SADDSTART[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SADDSTART[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SADDSTART[31:0]**: Subregion address start

This bitfield defines the byte-address offset (relative to the base address of the protected address space) of the lowest byte-address in subregion B in base region x.

Address bits less than the granularity and greater than the protected address space size cannot be written, and remain 0.

The effective subregion is the intersection of the subregion and its base region (there is no point in programming SADDSTART below the associated BADDSTART).

7.5.16 RISAF region x subregion B end-address register (RISAF_REGx_BENDR)

Address offset: 0x068 + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0FFF

Unprivileged writes are ignored. Nonsecure writes are ignored if SEC = 1 in RISAF_REGx_CFGR, or if DCEN = 0 in RISAF_REGx_BNESTR. Any read access is allowed to this register. Writes are ignored if RLOCK = 1 or SREN = 1 in RISAF_REGx_BCFGR.

When the delegated configuration is enabled (DCEN = 1 in RISAF_REGx_BNESTR), only the compartment DCCID defined in RISAF_REGx_BNESTR can write to this register. When the delegation is disabled (DCEN = 0), only the secure privileged software can program this register.

Refer to *Section 7.3* to verify the number of base regions and subregions supported by this RISAF instance, and for details on protected address space size and watermark granularity.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SADDEND[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

SADDEND[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SADDEND[31:0]**: Subregion address end

This bitfield defines the byte-address offset (relative to the base address of the protected address space) of the highest byte-address of subregion B in base region x.

Address bits less than the granularity cannot be modified, and remain 1.

Address bits greater than the protected address space size cannot be written, and remain 0.

The effective subregion is the intersection of the subregion and its base region (there is no point in programming SADDEND higher than the associated BADDEND).

7.5.17 RISAF region x subregion B nested mode register (RISAF_REGx_BNESTR)

Address offset: 0x06C + 0x40 * (x - 1) (x = 1 to 15)

Reset value: 0x0000 0000

Secure, privileged, trusted domain CID = 1, write access only. Any read access is allowed on this register. Writes are ignored if GLOCK is set in RISAF_CR.

Refer to *Section 7.3* to verify the number of base regions and subregions supported by this RISAF instance.

Caution: Check *Section 7.3* before setting DCEN bit.

									rw	rw	rw		rw		

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **DCCID[2:0]**: Delegated configuration CID

The secure privileged software can use this bitfield to statically define which compartment can program the RIF configuration of subregion B if DCEN = 1 in this register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCEN**: Delegated configuration enable

0: RIF configuration for subregion B can be written only by the secure privileged software.

1: RIF configuration for subregion B can be written only by compartment DCCID, defined in this register. If base region x is defined as secure (SEC = 1), nonsecure write accesses to this subregion RIF configuration by compartment DCCID are ignored.

Note: RIF configuration of subregion B is defined as RISAF_REGx_BCFGR, RISAF_REGx_BSTARTR, and RISAF_REGx_BENDR.

Bits 1:0 Reserved, must be kept at reset value.

8 Illegal access controller (IAC)

8.1 IAC introduction

The RIF (resource isolation framework) is a comprehensive set of hardware blocks designed to enforce and manage the isolation of STM32 hardware resources, such as memory and peripherals.

The RIF uses the IAC (illegal access controller) to centralize the detection of RIF-related illegal accesses, managed by a secure application.

8.2 IAC main features

- Centralized detection of RIF-related illegal accesses, managed by a secure application. Supported illegal accesses are: secure, privileged.
- Only accessible by secure privileged CPU

8.3 IAC implementation

The index of the peripherals managed by the IAC in this device is defined in *Table 28*. Indexes 0 to 127 are also used in the RIFSC to configure the proper access control using RISUP blocks.

Table 28. Peripheral indexes in IAC

Peripherals 31 to 0

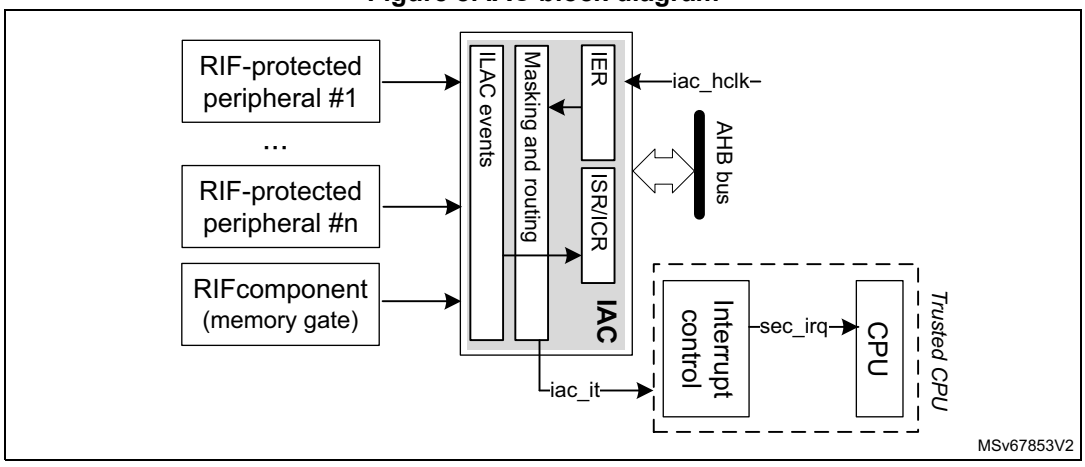
8.4 IAC functional description

8.4.1 IAC block diagram

Figure 8 shows the IAC block diagram, in context.

Figure 8. IAC block diagram



8.4.2 IAC internal signals

Table 29 lists the internal signals available at IAC level, not at product level.

Table 29. IAC internal signals

Name	Type	Description
iac_hclk	Digital input	AHB bus clock
iac_it	Digital output	Global interrupt request

8.4.3 IAC reset and clocks

The IAC peripheral has a dedicated clock and reset control in the RCC.

The IAC requires its clock in order to trigger an interrupt request event.

8.4.4 IAC use in RIF

The IAC gathers illegal events generated within the system when an illegal access is detected. The IAC can then generate a secure interrupt towards the secure CPU, if needed. By default, all events in the IAC are masked.

The IAC has room for 256 interrupt sources. Each source corresponds to an IAC index from 0 to 255. The interrupt sources from non-RIF-aware peripherals occupy most of the first 128 indexes. The interrupt sources from RIF-aware peripherals and RIF firewalls occupy indexes from 128 onwards. All these sources are defined in *Section 8.3*.

8.4.5 IAC management by trusted application

For each interrupt source of index <i>, an illegal access sets the IAFi flag in IAC_ISRx. A secure privileged application can clear this flag using the corresponding bit in IAC_ICRx. An IAC interrupt is triggered when IAFi is set while IAIEi is set in IAC_IERx.

Indexes between 0 to 127 are assigned to non-RIF-aware peripherals, with a RISUP block instantiated in front of its configuration port to filter configuration accesses. The programming of these RISUP blocks (in the RIFSC) uses the same index as the IAC.

Indexes 128 and above are assigned to RIF components and RIF-aware peripherals. These peripherals can block illegal accesses to their configuration registers (without RISUP).

For RIF-aware peripherals that protect a memory, a secure privileged application can obtain, in the peripheral, more details about the cause of the illegal access event:

- The illegal access status register (xx_IASR) indicates if it is a configuration access error (CAEF= 1), or/and a system bus access error (IAEF = 1).
- The illegal access error status register (xx_IAESR) and the illegal address register (xx_IADDR) give detailed information on the system bus access error.

The IAC interrupt handler must clear IAFi in IAC_ISR before clearing the error flag(s) in the firewall peripheral xx (using xx_IACR register). Otherwise, an illegal access can occur between clearing the flags in the firewall and clearing the flag in the IAC, and the application is unaware of this error.

8.5 IAC interrupts

The RIF interrupt management in the IAC is summarized in *Table 30*.

Note: Only secure privileged application can enable, read, and clear illegal access interrupts.

If there is an illegal access to the IAC itself, the status flag corresponding to the IAC index in Section 8.3 is set.

Table 30. IAC interrupt request

Acronym	Interrupt event	Event flag in IAC_ISR	Enable control bit in IAC_IER	Interrupt clear method
IAC	Illegal access error	IAF	IAIE	Set IAF bit in IAC_ICR

8.6 IAC registers

All IAC registers are accessed only by words (32 bits).

8.6.1 IAC interrupt enable register x (IAC_IERx)

Address offset: 0x000 + 0x4 * x (x = 0 to 5)

Reset value: 0x0000 0000

Secure privileged, read and write only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IAIE{i + 32 * x}

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IAIE{i + 32 * x}															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IAIE{i + 32 * x}**: Illegal access interrupt enable for peripheral {i + 32 * x} (i = 0 to 31)
Each bit is set to unmask illegal access events from peripheral {i + 32 * x}.
0: Illegal access event from peripheral {i + 32 * x} does not generate interrupt (masked).
1: Illegal access event from peripheral {i + 32 * x} can generate interrupts (unmasked).

8.6.2 IAC interrupt status register x (IAC_ISRx)

Address offset: 0x080 + 0x4 * x (x = 0 to 5)

Reset value: 0x0000 0000

Secure privileged, read only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IAF{i + 32 * x}

IAF{i + 32 * x}															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **IAF{i + 32 * x}**: Illegal access interrupt enable for peripheral {i + 32 * x} (i = 0 to 31)

Each bit is set when an illegal access event occurs in the peripheral {i + 32 * x} (see *Section 8.3* for details). This bit is cleared when the corresponding IAF bit is set in IAC_ICRx.

0: No illegal access event detected for peripheral {i + 32 * x} (since reset or the last time this bit was cleared).

1: At least one illegal access event has been detected for peripheral {i + 32 * x} (since the last time this bit was cleared).

8.6.3 IAC interrupt clear register x (IAC_ICRx)

Address offset: 0x100 + 0x4 * x (x = 0 to 5)

Reset value: 0x0000 0000

Secure privileged, write only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IAF{i + 32 * x}

Refer to *Section 2.3* for the register boundary addresses.

9 Boot modes

9.1 Boot after system reset

The ROM code is the first one executed after any system reset.

The boot mode is determined by BOOT0 and BOOT1 pins, and one OTP word.

Table 32. Boot modes

BOOT0	BOOT1	Boot source #1
-	1	Development boot
0	0	Flash boot
1	0	Serial boot

BOOT0 is a dedicated pin latched upon reset release.

The BOOT1 is a non dedicated boot pin. The BOOT1 value comes from BOOT1 pin (default pin), or any other pin defined by BSEC BOOTROM_CONFIG10 - OTP_WORD19[28:21] = dev_boot_port + dev_boot_pins, see *Table 18: OTP fuse description (lower OTP region)*.

9.1.1 Flash boot

If a flash boot is selected, the firmware is loaded from an external flash memory. The flash source selection is done through BOOTROM_CONFIG2 - OTP_WORD11[8:5] = boot_source (4 bits). The possible sources are listed below:

- XSPI serial NOR (in SPI mode, single)
- XSPI HyperFlash™ (8-bit)
- *e*.MMC™ SDMMC1 or *e*.MMC™ SDMMC2 (up to JEDEC v5.1)
- SD-Card SDMMC1 (up to SD standard v6.0)

See *Table 18: OTP fuse description (lower OTP region)*.

If no boot source is programmed in OTP, default source is serial NOR.

9.1.2 Serial boot

If serial boot is selected, the image is loaded from a serial interface. Serial interfaces and serial instances can be disabled by BOOTROM_CONFIG2 - OTP_WORD11[16:9] = boot_source_disable (8 bits).

Possible sources are:

- USB boot: USB 2.0 OTG HS
- UART boot: USART1, USART2, and UART4

See *Table 18: OTP fuse description (lower OTP region)*.

9.1.3 Development boot

If BOOT1 is selected, the BootROM code finishes in an endless loop after having reopened debug in a secure way.

This boot mode is available only when the device is in development.

Secure installation

The ROM code is the root-of-trust of secure firmware installation.

9.2 Boot from a low-power mode

In case of boot from a low-power mode (such as Standby mode with SRAM retention), the bootROM is not executed, and the CPU starts from the boot address defined in *Section 16.1: SYSCFG registers*).

10 SRAM configuration controller (RAMCFG)

10.1 RAMCFG introduction

The RAMCFG configures the features of the internal SRAMs: AHBSRAM1/2, AXISRAM1 to 6, BKPSRAM, FLEXRAM, and VENCRAM.

10.2 RAMCFG main features

The internal SRAM supports the following features, configured in the RAMCFG:

- Error code correction (ECC):
  - Single-error detection and correction with interrupt generation
  - Double-error detection with interrupt generation
  - Status with failing address
- SRAM hardware erase: on reset or dedicated event, the RAM content is automatically erased (written as zero).
- SRAM software erase: the software can trigger an SRAM erase through RAMCFG registers.

10.3 RAMCFG functional description

10.3.1 Internal SRAM features

The following SRAMs are embedded in the devices, each with specific features:

- AXISRAM1 to 6 are the main SRAMs. AHBSRAM1/2 are preferably for DMA-controlled peripheral-to-memory data flow.

  AXISRAM2 to 6 can be shut down when the application is in Run mode.
- FLEXMEM can be either allocated as Cortex-M55 TCM, or as system RAM (FLEXRAM).

  80 Kbytes of the FLEXMEM are retained in Standby mode, either allocated as extended ITCM (64 +16-Kbyte ECC), or allocated as FLEXRAM.
- The BKPSRAM content is retained in low-power modes, even when V_{DD} is off in V_{BAT} mode. On a tamper-event detection, the BKPSRAM content is erased.
- The VENCRAM implements hardware and software erases. It can be used at system level when the VENC is not used by the application. Writing one to VENCRAM_EN in SYSCFG_VENCRAMCR allocates the VENCRAM to the system (static allocation).
- The RAMCFG embeds registers that are related to the internal SRAMs ECC, shutdown control, and software erase.

Note: The baseline I/D-TCM content can be retained in Standby mode (as BKPSRAM and 80 Kbytes of FLEXMEM), but this is not under RAMCFG control.

The CACHEAXI internal RAM can be used at system level when the NPU does not use its cache (as the VENCRAM). This is controlled directly in the CACHEAXI, and is not under RAMCFG.

Table 33 summarizes the features supported by each internal SRAM.

Table 33. Internal SRAM features

SRAM feature	AXISRAM1	AXISRAM2	FLEXRAM	AXISRAM3	AXISRAM4	AXISRAM5	AXISRAM6	AHBSRAM1	AHBSRAM2	VENCRAM	BKPSRAM
Size (Kbytes)	624	1024	Up to 400	448	448	448	448	16	16	128	8
Word size	64	64	64	64	64	64	64	32	32	64	39(1)
Retention in Standby mode	-	-	X(2)	-	-	-	-	-	-	-	X
Retention in V_{BAT} mode	-	-	-	-	-	-	-	-	-	-	X
Block on potential tamper, erase on confirmed tamper	-	-	-	-	-	-	-	-	X	-	X
Hardware erase on reset	X	X	-	-	-	-	-	-	X	-	-
Software erase	X	X	X	X	X	X	X	X	X	X	X
ECC	-	-	X(3)	-	-	-	-	-	-	-	X

1. 32 bits of effective data, and 7 bits of embedded ECC.
2. Only the 80 Kbytes that correspond to the first portion of the I-TCM extension can be retained.
3. The ECC concerns only the FLEXMEM when used as extended TCM. It is under control of the Cortex-M55 TCM interface.

Table 34 details the conditions for the hardware erase.

Table 34. Hardware-erase conditions for internal SRAMs

SRAM	Conditional hardware erase	Condition
AXISRAM1	No	Erase on system reset
AXISRAM2		
AHBSRAM2	No	Erase on system reset and on confirmed tamper

10.3.2 FLEXRAM control

STM32N6x7xx devices include a Cortex-M55 core that exposes a TCM interface. This TCM interface is spread in one 39-bit (32 effective data bits + 7 ECC protection bits) I-TCM (instruction TCM interface), and four parallel 39-bit D-TCMs (data TCM interfaces).

STM32N6x7xx devices also embed 4096 Kbytes of RAM accessible on the AXI interconnect. The first half of this memory (FLEXRAM, AXISRAM1/2) is in the CPU frequency domain, and is preferably used for CPU storage. The second half of this memory (AXISRAM3/4/5/6) is in the NPU frequency domain, and is preferably used for the AI computing storage.

To let customers tailor the SRAM use to their needs, the FLEXMEM offers the possibility to allocate part of the CPU side SRAM (FLEXRAM part) as extended TCM, both on I-TCM and D-TCM interfaces. *Table 35* lists the supported allocations.

Table 35. FLEXRAM supported configurations

Config I-TCM	Config D-TCM	I-TCM fix	I-TCM flex (+ ECC)	I-TCM total	D-TCM fix	D-TCM flex (+ ECC)	D-TCM total	AXI-side FLEXRAM
0	0	1 x 64	0	64	4 × 32	0	128	400
0	1	1 x 64	0	64	4 × 32	4 × 32 (+ 8)	256	240
1	0	1 x 64	1 x 64 (+16)	128	4 × 32	0	128	320
1	1	1 x 64	1 x 64 (+16)	128	4 × 32	4 × 32 (+ 8)	256	160
2	0	1 x 64	1 x 192 (+ 48)	256	4 × 32	0	128	160
2	1	1 x 64	1 x 192 (+ 48)	256	4 × 32	4 × 32 (+ 8)	256	0

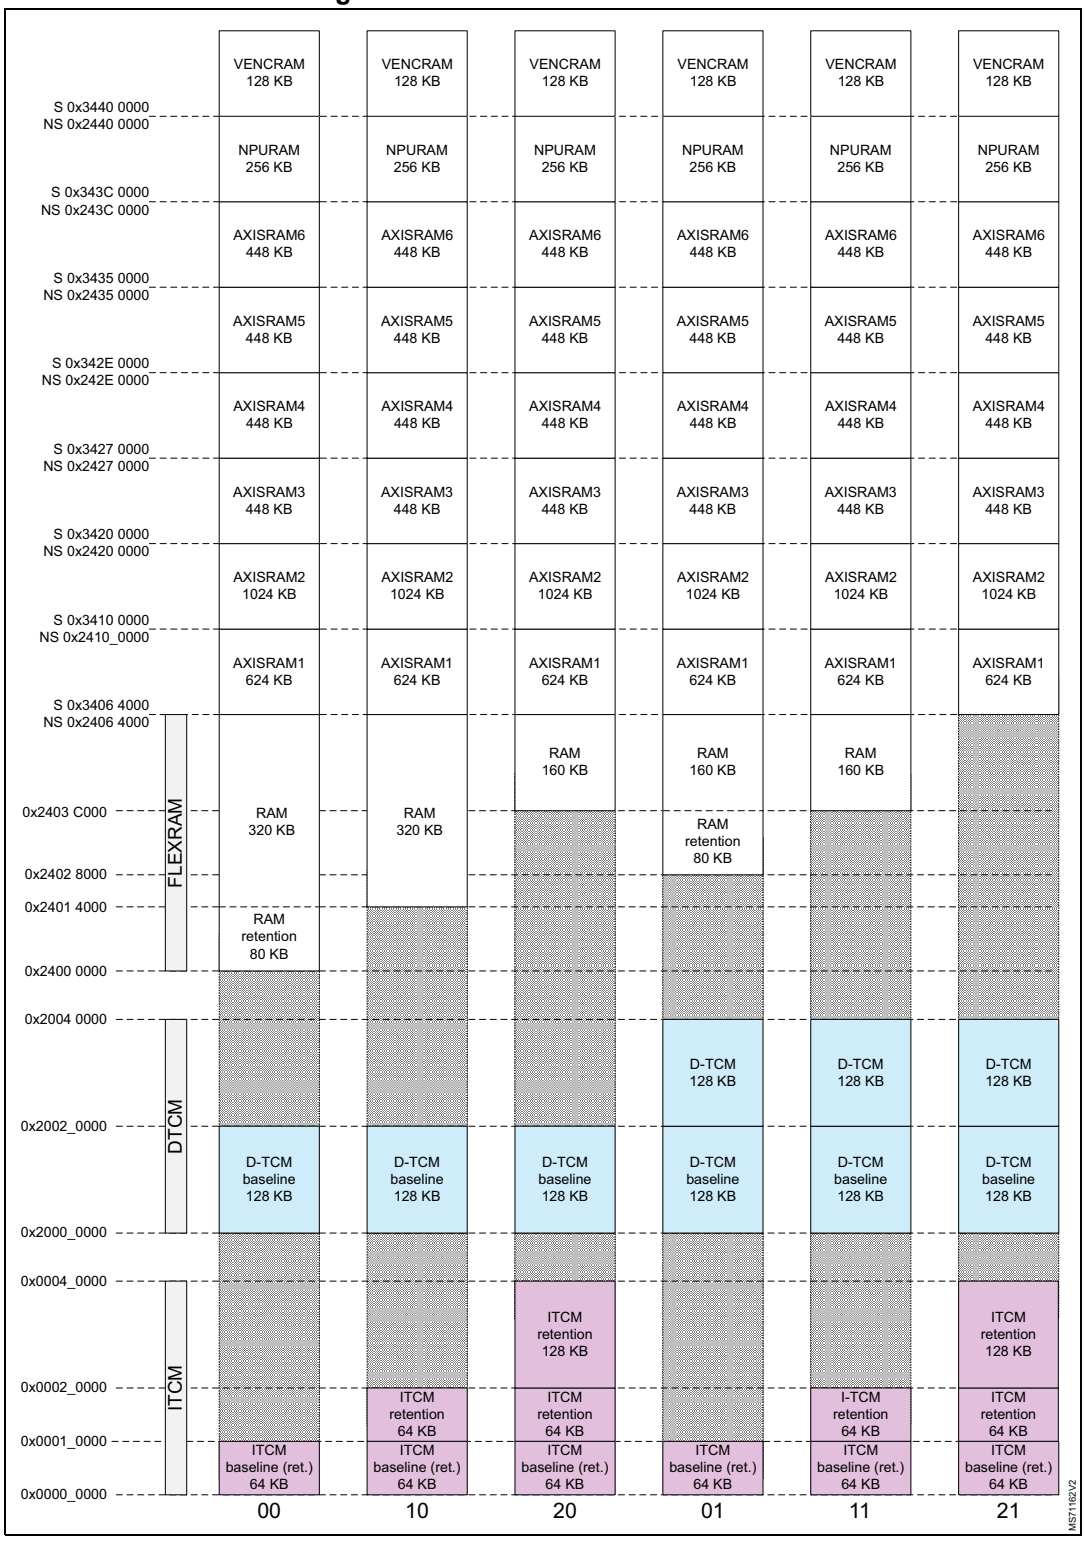
The retention regions are detailed in *Table 36* and *Figure 9*, sharing the same color code.

Table 36. FLEXMEM versus retention

Configuration	FLEXRAM base address(1)	I-TCM extension	D-TCM extension	Retention region
00	0x2400 0000	0 KB	0 KB	RAM region: 0x2400 0000 to 0x2401 3FFF
10	0x2401 4000	64 KB (+16 KB ECC)		I-TCM extension: first 64 KB (+16 KB ECC)
20	0x2403 C000	192 KB (+48 KB ECC)		
01	0x2402 8000	0 KB	128 KB (+32 KB ECC)	RAM region: 0x2402 8000 to 0x2403 BFFF
11	0x2403 C000	64 KB (+16 KB ECC)		I-TCM extension: first 64 KB (+16 KB ECC)
21	No RAM	192 KB (+48 KB ECC)		

1. All addresses considered as their non secure aliases.

Figure 9. FLEXMEM versus retention



Note: AXISRAM1 start address is 0x2406 4000 (aliased at 0x3406 4000 in secure boundary), whatever the FLEXMEM configuration.

The FLEXMEM configuration depends upon CFGDTCMSZ[3:0] and CFGITCMSZ[3:0] in SYSCFG_CM55TCMCR. It configuration cannot be changed at runtime, a reboot is needed.

Use in low-power modes

The I-TCM and D-TCM baselines can be kept in retention when the device is in Standby mode. This allows the CPU to restart from the TCM content.

The first 64 Kbytes (+16 Kbytes for ECC) of extended I-TCM through the FLEXMEM can also be kept in retention. This allows a maximum of 128 Kbytes of I-TCM in retention.

When only the I-TCM baseline is used for the Cortex-M55, 80 Kbytes of the AXI RAM can be kept in retention.

The total amount of TCM that can be kept in retention is 320 Kbytes:

- 64 Kbytes of I-TCM baseline (+ 16 Kbytes for ECC)
- 64 Kbytes of I-TCM extended (+ 16 Kbytes for ECC)
- 4 x 32 Kbytes of D-TCM baseline (+ 4 x 8 Kbytes for ECC)

10.3.3 ECC (BKPSRAM)

The ECC is supported by the BKPSRAM. Seven ECC bits are added per 32 bits of SRAM: this allows a 2-bit error detection, and a 1-bit error correction on memory read access.

As the ECC is calculated and checked for a 32-bit word, byte and half-word write accesses are managed by the SRAM interface: it first reads the whole word, then writes the word again with the new byte/half-word value. ECC double errors are also detected during these byte or half-word AHB write accesses (read/modify/write done by the interface). The byte or half-word write access latency is two AHB clock cycles.

Caution: In case of a byte or half-word write on the SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM two AHB clock cycles after the SRAM AHB is released (when the SRAM is no more accessed).

The ECC is also available on the Cortex-M55 I-TCM and D-TCM.

When the FLEXMEM is used as I/D-TCM, it supports ECC through specific memory cut/word organization. When the FLEXMEM is used as FLEXRAM, it does not support ECC, even for the part that can be set in retention

Single and double ECC errors

When a single error is detected, it is automatically corrected, and SEDC (single error detected and corrected) is set in RAMCFG_BKPSRAMISR.

An interrupt is generated if enabled by SEIE in RAMCFG_BKPSRAMIER. The failing address is stored in RAMCFG_BKPSRAMESEAR, if ALE is set in RAMCFG_BKPRAMCR.

Caution: Single errors are not reported if SEDC is not cleared in time when a new error happens.

When a double error is detected, DED is set in RAMCFG_BKPSRAMISR. An interrupt is generated if enabled by DEIE in RAMCFG_BKPSRAMIER. The failing address is stored in RAMCFG_BKPSRAMEDEAR if ALE is set in RAMCFG_BKPSRAMCR.

Caution: Double errors are not reported if DED is not cleared. Double errors are not corrected, and must be managed by exception.

The ECC can be activated/deactivated by executing the following software sequence:

1. Write 0xAE in RAMCFG_BKSRAMECCKEYR.
2. Write 0x75 in RAMCFG_BKSRAMECCKEYR.
3. Write 1 to ECCE in RAMCFG_BKPSRAMCR to activate the ECC (write 0 to this bit to deactivate the ECC).

Fault injection

The RAMCFG supports a software loop for runtime fault injection in the BKPSRAM when the ECC is activated:

1. With the ECC enabled, the application writes at a given address.
2. The application disables the ECC writing.
3. The application writes a different data at the same address as previously. Data are updated but the matching ECC word is not modified.
4. The application enables ECC writing.
5. The application reads at the same address as previously. An interrupt is expected due to either one error corrected, or several errors detected. The application can check that the desired address appears in RAMCFG_BKPSRAMSEAR or _BKPSRAMDEAR.

10.4 RAMCFG low-power modes

When the NPU is in Run mode, AXISRAM2 to 6 can be set in power down (shutdown) under software control.

When RAMs are in shutdown mode, their content is not retained. SRAMSD in AXISRAMx_CR (x = 2, 3, 4, 5, or 6) controls if the RAM is in shutdown or not. At reset, RAMs are accessible (SRAMSD cleared to 0).

When a RAM is in shutdown, writing in it has no effect, and reading it returns zero. When exiting from shutdown state, the memory is not instantly accessible. A safe period of 40 ns must elapse before the memory is functional.

AXISRAM3 to 6 are interleaved at system level under control of the software through SYSCFG_NPU_ICNCR. Interleaving must be deactivated before shutting down these memories, especially if only part of them are set in shutdown.

The following sequence is proposed to enter/exit safely the memory from to/from shutdown:

- To enter shutdown:
  a) Disable the RAM clock through the RCC.
  b) Shut the RAM down by writing 1 to SRAMSD in RAMCFG_AXISRAMxCR.
- To exit shutdown:
  a) Power the RAM up by writing 0 to SRAMSD in RAMCFG_AXISRAMxCR.
  b) Read back the value from the RAMCFG (alternatively wait 40 ns).
  c) Enable the RAM clock through the RCC.
  d) The RAM is now ready for use.

When the NPU is in Stop mode, RAMs are put in low-power mode under control of PWR.

When the NPU is in Standby mode, the BKPSRAM and 80 Kbytes of the FLEXRAM can be set in retention under software control.

Table 37 details the effect of low-power modes on RAMCFG.

Table 37. Effect of low-power modes on RAMCFG

Mode	Description
Sleep	No effect. RAMCFG interrupts cause the device to exit Sleep mode.
Stop	The content of RAMCFG registers is kept.
Standby	The RAMCFG is powered down.

10.5 RAMCFG interrupts

Two interrupts (maskable by software) are generated internally, and a global interrupt request is exported to the interrupt controller. *Table 38* lists RAMCFG interrupt requests.

Table 38. RAMCFG interrupt requests

Interrupt acronym	Memory	Interrupt event	Event flag(1)	Enable control bit	Interrupt clear method
RAMCFG	BKPSRAM	ECC single error detection and correction	SEDC	SEIE	Write 1 in CSEDC
		ECC double error detection	DED	DEIE	Write 1 in CDED

1. All these bits are in RAMCFG_BKPSRAMISR.

10.6 RAMCFG registers

The RAMCFG registers can be accessed in word, half-word, and byte format, unless differently specified.

10.6.1 RAMCFG AXISRAM1 control register (RAMCFG_AXISRAM1CR)

Address offset: 0x000

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in ERASEKEY of RAMCFG_AXISRAM1ERKEYR. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.2 RAMCFG AXISRAMx interrupt status register (RAMCFG_AXISRAMxISR)

Address offset: 0x008 + 0x80 * (x - 1), (x = 1 to 6)

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMBUSY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							r								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation
Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option is not disabled by software and tamper detection (see *Table 33*).
0: No erase operation ongoing
1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.3 RAMCFG AXISRAMx erase key register (RAMCFG_AXISRAMxERKEYR)

Address offset: 0x028 + 0x80 * (x - 1), (x = 1 to 6)

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key
The following steps are required to unlock the write protection of SRAMER in RAMCFG_AXISRAMxCR.
a) Write 0xCA into this field.
b) Write 0x53 into this field.
Note: Writing a wrong key reactivates the write protection.

10.6.4 RAMCFG AXISRAMx control register (RAMCFG_AXISRAMxCR)

Address offset: 0x080 + 0x80 * (x - 2), (x = 2 to 6)

Reset value: 0x0000 0000, 0x0010 0000, 0x0010 0000, 0x0010 0000, 0x0010 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMSD	Res.	Res.	Res.	Res.
											rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw								

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **SRAMSD**: Shutdown AXISRAMx
0: AXISRAMx memory is powered.
1: AXISRAMx memory is in shutdown, and its content is not retained.

Bits 19:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase
This bit can be set by software only after writing the unlock sequence in ERASEKEY of RAMCFG_AXISRAMxERKEYR. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.
0: No erase operation ongoing
1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.5 RAMCFG AHBSRAMx control register (RAMCFG_AHBSRAMxCR)

Address offset: 0x300 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase
This bit can be set by software only after writing the unlock sequence in ERASEKEY of RAMCFG_AHBSRAMxERKEYR. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.
0: No erase operation ongoing
1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.6 RAMCFG AHBSRAMx interrupt status register (RAMCFG_AHBSRAMxISR)

Address offset: 0x308 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM BUSY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							r								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation
Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option is not disabled by software and tamper detection (see *Table 33*).
0: No erase operation ongoing
1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.7 RAMCFG AHBSRAMx erase key register (RAMCFG_AHBSRAMxERKEYR)

Address offset: 0x328 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key
To unlock the write protection of SRAMER in RAMCFG_AHBSRAMxCR.
a) Write 0xCA into this field.
b) Write 0x53 into this field.
Note: Writing a wrong key reactivates the write protection.

10.6.8 RAMCFG VENCRAM control register (RAMCFG_VENCRAMCR)

Address offset: 0x400

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM ER	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in ERASEKEY of RAMCFG_VENCRAMERKEYR. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.9 RAMCFG VENCRAM interrupt status register (RAMCFG_VENCRAMISR)

Address offset: 0x408

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM BUSY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							r								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation

Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option is not disabled by software and tamper detection (see *Table 33*).

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.10 RAMCFG VENCRAM erase key register (RAMCFG_VENCRAMERKEYR)

Address offset: 0x428

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key

To unlock the write protection of SRAMER in RAMCFG_VENCRAMCR.

a) Write 0xCA into this field.

b) Write 0x53 into this field.

Note: Writing a wrong key reactivates the write protection.

10.6.11 RAMCFG BKPSRAM control register (RAMCFG_BKPSRAMCR)

Address offset: 0x480

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	ALE	Res.	Res.	Res.	ECCE
							rw				rw				rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in ERASEKEY of RAMCFG_BKPSRAMERKEYR. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ALE**: Address latch enable

0: Failing address not stored in RAMCFG_BKPSRAMESEAR or _BKPSRAMEDEAR

1: Failing address stored in RAMCFG_BKPSRAMESEAR or _BKPSRAMEDEAR

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ECCE**: ECC enable

When set, this bit can be cleared by software only after writing the unlock sequence in RAMCFG_BKPSRAMECCKEYR.

0: ECC disabled

1: ECC enabled

10.6.12 RAMCFG BKPSRAM interrupt enable register (RAMCFG_BKPSRAMIER)

Address offset: 0x484

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DEIE	SEIE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **DEIE**: ECC double error interrupt enable
0: Double error interrupt disabled
1: Double error interrupt enabled

Bit 0 **SEIE**: ECC single error interrupt enable
0: Single error interrupt disabled
1: Single error interrupt enabled

10.6.13 RAMCFG BKPSRAM interrupt status register (RAMCFG_BKPSRAMISR)

Address offset: 0x488

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM BUSY	Res.	Res.	Res.	Res.	Res.	Res.	DED	SEDC
							r							r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation
Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option is not disabled by software and tamper detection (see *Table 33*).
0: No erase operation ongoing
1: Erase operation ongoing

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DED**: ECC double-error detected
0: No double error
1: Double error detected

Bit 0 **SEDC**: ECC single error detected and corrected
0: No single error detected
1: Single error detected and corrected

10.6.14 RAMCFG BKPSRAM single error address register (RAMCFG_BKPSRAMESEAR)

Address offset: 0x48C

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	ESEA[10:0]										
					w	w	w	w	w	w	w	w	w	w	w

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **ESEA[10:0]**: ECC single error address
When ALE is set in RAMCFG_BKPSRAMCR, this field is updated with the word address corresponding to the ECC single error.

10.6.15 RAMCFG BKPSRAM double error address register (RAMCFG_BKPSRAMEDEAR)

Address offset: 0x490

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	EDEA[10:0]										
					w	w	w	w	w	w	w	w	w	w	w

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **EDEA[10:0]**: ECC double error address
When ALE is set in RAMCFG_BKPSRAMCR, this field is updated with the word address corresponding to the ECC double error.

10.6.16 RAMCFG BKPSRAM interrupt clear register (RAMCFG_BKPSRAMICR)

Address offset: 0x494

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CDED	CSEDC
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **CDED**: Clear ECC double-error interrupt
Writing 1 to this flag clears DED in RAMCFG_BKPSRAMISR.

Bit 0 **CSEDC**: Clear ECC single-error interrupt
Writing 1 to this flag clears SEDC in RAMCFG_BKPSRAMISR.

10.6.17 RAMCFG BKPSRAM ECC key register (RAMCFG_BKPSRAMECCKEYR)

Address offset: 0x4A4

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ECCKEY[7:0]**: ECC write protection key
The following steps are required to unlock the write protection of ECCE in RAMCFG_BKPSRAMCR.
a) Write 0xAE into this field.
b) Write 0x75 into this field.

Note: Writing a wrong key reactivates the write protection.

10.6.18 RAMCFG BKPSRAM erase key register (RAMCFG_BKPSRAMERKEYR)

Address offset: 0x4A8

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key

The following steps are required to unlock the write protection of SRAMER in RAMCFG_BKPSRAMCR.

a) Write 0xCA into this field.

b) Write 0x53 into this field.

Note: Writing a wrong key reactivates the write protection.

10.6.19 RAMCFG FLEXRAM control register (RAMCFG_FLEXRAMCR)

Address offset: 0x500

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in ERASEKEY of RAMCFG_FLEXRAMERKEYR. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.20 RAMCFG FLEXRAM interrupt status register (RAMCFG_FLEXRAMISR)

Address offset: 0x508

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM BUSY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							r								

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation

Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option is not disabled by software and tamper detection (see *Table 33*).

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:0 Reserved, must be kept at reset value.

10.6.21 RAMCFG FLEXRAM erase key register (RAMCFG_FLEXRAMERKEYR)

Address offset: 0x528

Reset value: 0x0000 0000

Reset on any system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key

The following steps are required to unlock the write protection of SRAMER in RAMCFG_FLEXRAMCR.

a) Write 0xCA into this field.

b) Write 0x53 into this field.

Note: Writing a wrong key reactivates the write protection.

10.6.22 RAMCFG register map

Table 39. RAMCFG register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

11 Texture cache (ICACHE)

11.1 ICACHE introduction

The texture cache (ICACHE) is introduced on the AXI read-only texture port of the GPU to improve performance when reading texture data from internal and external memories.

The texture cache is an assembly of ICACHE (a peripheral with AHB ports) and an AXI-to-AHB bus bridge plugged on ICACHE AHB slave port, providing an AXI interface on the texture cache slave port.

The following sections only describe the AHB ICACHE peripheral itself.

Some specific features like hit-under-miss, and critical-word-first refill policy, allow close to zero-wait-state performance in most use cases.

11.2 ICACHE main features

The main features of ICACHE are listed below:

- Bus interface
  - One 64-bit AHB slave port, the read port (input from GPU texture read interface)
  - One 64-bit AHB master port: master1 port (output to texture bus of main AXI/AHB bus matrix)
  - One 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, **w**, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile
- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls
- Performance counters

  The ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)
- Error management
  - Possibility to detect an unexpected cacheable write access, to flag an error and optionally to raise an interrupt
- Maintenance operation
  - Cache invalidate: full cache invalidation, fast command, noninterruptible

11.3 ICACHE implementation

Table 40. ICACHE features

Feature	ICACHE
Number of ways	4
Cache size	32 Kbytes
Cache line width	32 bytes
Number of regions to remap	0
Data size of AHB slave interface	64 bits
Data size of AHB fast master1 interface	64 bits
Data size of AHB slow master2 interface	0

11.4 ICACHE functional description

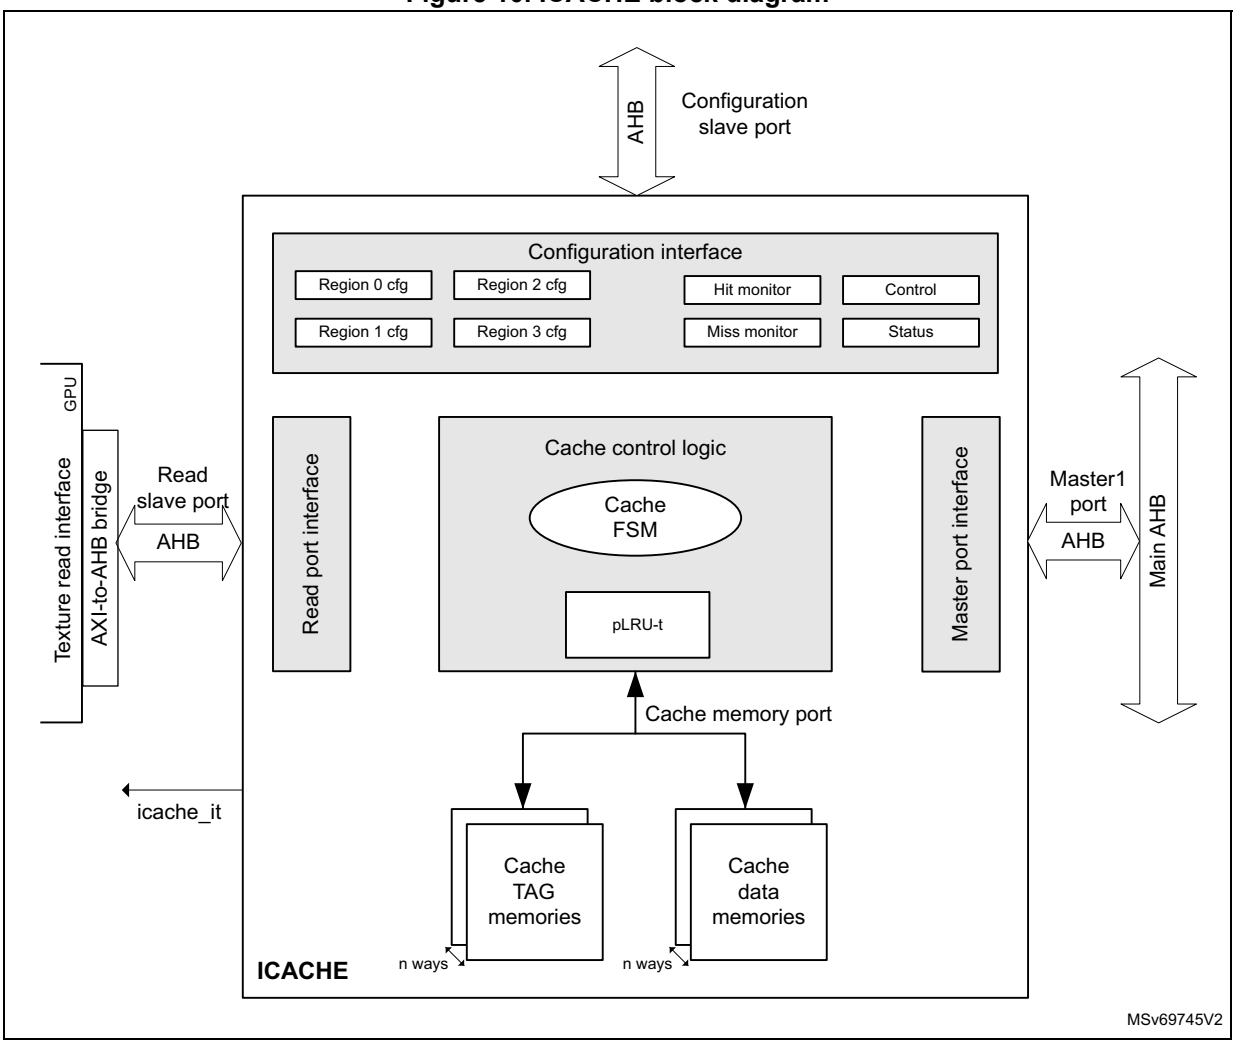
The purpose of the texture cache is to cache GPU read accesses to texture data. As such, the ICACHE only manages cacheable read transactions and does not manage cacheable write transactions.

The noncacheable transactions (both read and write ones) bypass the ICACHE.

For the error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

11.4.1 ICACHE block diagram

Figure 10. ICACHE block diagram



11.4.2 ICACHE reset and clocks

The ICACHE is clocked on the texture AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making the ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:

- the ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no longer busy)
- the ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (=0).

Note: When disabled, the ICACHE is bypassed: slave input requests are forwarded to the master port.

11.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:

- address tags that indicate which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:

- after the ICACHE reset is released
- when the cache is disabled, by setting EN = 0 in ICACHE_CR (by software)
- when executing an ICACHE invalidate command, by setting CACHEINV = 1 in ICACHE_CR (by software)

When a cacheable transaction is received at the execution input port, its AHB address (HADDR_in) is split into the following fields (see *Table 41* for B and W definitions):

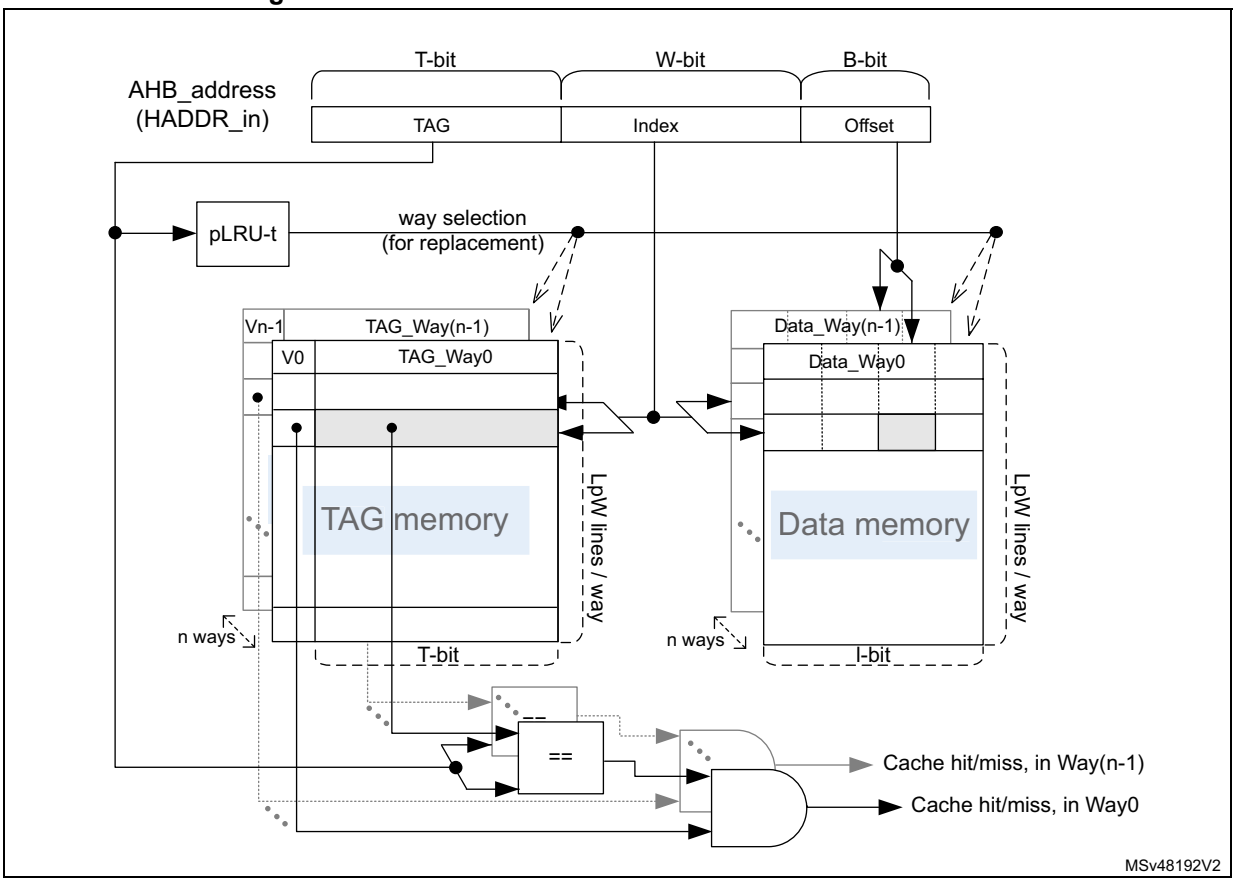
- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to the TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The following table gives a summary of the ICACHE main parameters for TAG memory dimensioning. *Figure 11* shows the functional view of TAG and data memories, for an n-way set associative ICACHE.

Table 41. TAG memory dimensioning parameters for n-way set associative operating mode (default)

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines (per way)	LpW = s / (n x L) lines / way	256 lines / way
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	8-bit
TAG address size	T = (32 - W - B) bit	20-bit

Figure 11. ICACHE TAG and data memories functional view



11.4.4 Direct-mapped ICACHE (1-way cache)

The default configuration (at reset) is an n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure the ICACHE as direct mapped by writing WAYSEL = 0 (only possible when the cache is disabled, EN = 0 in ICACHE_CR).

The following table gives a summary of ICACHE main parameters for TAG memory when the direct-mapped cache operating mode is selected.

Table 42. TAG memory dimensioning parameters for direct-mapped cache mode

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	1	1
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines	LpW = s / L lines	512 lines
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	9-bit
TAG address size	T = (32 - W - B) bit	19-bit

All cache operations (such as read, refill, invalidation) remain the same in the direct-mapped configuration. The only difference is the absence of a replacement algorithm in case of line eviction (as explained in *Section 11.4.7*): only one way (the unique one) is possible for any data refill.

11.4.5 ICACHE enable

To activate the ICACHE, the EN bit must be set to 1 in ICACHE_CR.

When the ICACHE is disabled, it is bypassed and all transactions are copied from the slave port to the master port in the same clock cycle.

It is recommended to initialize or modify the main memory content (region to be later cached) with the ICACHE disabled, and to enable the ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

To ensure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This procedure occurs when the hardware reset signal is released, when CACHEINV is set, or when EN is cleared in ICACHE_CR. During the procedure, BUSYF is set in ICACHE_SR, and once finished, BUSYF is cleared and BSYENDF is set in the same register (raising the ICACHE interrupt if enabled on such a busy end condition).

The software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if the ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF = 1) is treated as noncacheable, and its performance depends on the main memory access time.

The ICACHE is by default disabled at boot.

11.4.6 Cacheable and noncacheable traffic

The ICACHE is placed on the GPU texture bus, and thus caches all internal and external memory regions (ranging from address 0x0000 0000 to 0x3FFF FFFF, respectively 0x6000 0000 to 0x9FFF FFFF, of the memory map).

An incoming memory request to the ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in *Table 43*. This AHB attribute depends on the GPU setting for the addressed region.

Table 43. ICACHE cacheability for AHB transaction

AHB lookup attribute	Cacheability
1	Cacheable
0	Noncacheable

In the case of a noncacheable access (either a noncacheable read or a noncacheable write), the ICACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port.

The bypass does not increase the latency of the access to the targeted memory.

In the case of a cacheable access, the ICACHE behaves as explained in *Section 11.4.7*.

11.4.7 Cacheable accesses

When the ICACHE receives a cacheable transaction from the GPU, the ICACHE checks if the address requested is present in its TAG memory, and if the corresponding cache line is valid.

There are then three alternatives:

- The address is present inside the TAG memory, the cache line is valid: **cache hit**, the data is read from the cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first policy ensures minimum wait cycles for the processor, since read data can be provided while the cache still performs a cache line refill (associated latency is the latency of fetching one word from the main memory).

  The burst generated on the ICACHE master bus is WRAPw (w being the cache line width, in words).

  The AHB transaction attributes are also propagated to the main AHB bus matrix on the master port.
- The address is not present in TAG memory, but belongs to the refill burst from the main memory currently ongoing: **cache hit** (hit-under-miss feature).

  This happens during cache-line refill. The ICACHE can provide the requested data as soon as the data is available at its master interface, thus avoiding a miss (fetching data from the main memory).

In the case of cache refill (due to cache miss), the ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data: the line pointed by the index of the input address.
- In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm that points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written is already valid, the targeted cache line must be invalidated first. This is true whatever the direct map or n-way set associative cache mode.

11.4.8 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming CACHEINV in the ICACHE_CR register.

When CACHEINV = 1, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). CACHEINV is automatically cleared.

Once the invalidate operation is finished (all valid bits reset to 0), the ICACHE automatically clears BUSYF, and sets BSYENDF in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised. Then, the (empty) cache is available again.

11.4.9 ICACHE performance monitoring

The ICACHE provides the following monitors for performance analysis:

- The 32-bit hit monitor counts the cacheable AHB-transactions on the slave cache port that hits the ICACHE content.

  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from the cache master port) (see *Section 11.4.7*).
- The 16-bit miss monitor counts the cacheable AHB-transactions on the slave cache port that misses the ICACHE content.

  It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, these monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through HITMEN in ICACHE_CR.
- Reset the hit monitor by setting HITMRST in ICACHE_CR.
- Enable/stop the miss monitor through MISSMEN in ICACHE_CR.
- Reset the miss monitor by setting MISSMRST in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

11.4.10 ICACHE boot

The ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.

Once the boot is finished, the ICACHE can be enabled (software setting EN = 1 in CACHE_CR).

11.5 ICACHE low-power modes

At device level, using the ICACHE reduces the power consumption by reading textures from the internal ICACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with lower performance profile (in terms of hit ratio) and stringent power consumption constraints may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single-way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see *Figure 11*). The power consumption is reduced by accessing, for each request, only the necessary cut of TAG and data memories. The cache effect still improves memory access performance, even if for most texture accesses, it is less efficient than with an n-way set associative cache mode.

11.6 ICACHE error management and interrupts

If an unsupported cacheable write request is detected (functional error), the ICACHE generates an error by setting the ERRF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, the ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

All ICACHE interrupt sources raise the same and unique interrupt signal, icache_it, and then use the same interrupt vector.

Table 44. ICACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
ICACHE	Functional error	ERRF in ICACHE_SR	ERRIE in ICACHE_IER	Set CERRF to 1 in ICACHE_FCR
	End of busy state (invalidate finished)	BSYENDF in ICACHE_SR	BSYENDIE in ICACHE_IER	Set CBSYENDF to 1 in ICACHE_FCR

The ICACHE also propagates all AHB bus errors (such as address decoding issues) from the master1 port back to the slave read port.

11.7 ICACHE registers

11.7.1 ICACHE control register (ICACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WAYSEL	CACHEINV	EN
													rw	w	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **MISSMRST**: miss monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache miss monitor

Bit 18 **HITMRST**: hit monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache hit monitor

Bit 17 **MISSMEN**: miss monitor enable
0: cache miss monitor switched off. Stopping the monitor does not reset it.
1: cache miss monitor enabled

Bit 16 **HITMEN**: hit monitor enable
0: cache hit monitor switched off. Stopping the monitor does not reset it.
1: cache hit monitor enabled

Bits 15:3 Reserved, must be kept at reset value.

Bit 2 **WAYSEL**: cache associativity mode selection
This bit allows user to choose ICACHE set-associativity. It can be written by software only when cache is disabled (EN = 0).
0: direct mapped cache (1-way cache)
1: n-way set associative cache (reset value)

Bit 1 **CACHEINV**: cache invalidation
Set by software and cleared by hardware when the BUSYF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN**: enable
0: cache disabled
1: cache enabled

11.7.2 ICACHE status register (ICACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRF	BSYENDF	BUSYF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRF**: cache error flag
0: no error
1: an error occurred during the operation (cacheable write)

Bit 1 **BSYENDF**: busy end flag
0: cache busy
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF**: busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

11.7.3 ICACHE interrupt enable register (ICACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRIE	BSYENDIE	Res.
													rw	rw	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRIE**: interrupt enable on cache error

Set by software to enable an interrupt generation in case of cache functional error (cacheable write access)

0: interrupt disabled on error

1: interrupt enabled on error

Bit 1 **BSYENDIE**: interrupt enable on busy end

Set by software to enable an interrupt generation at the end of a cache invalidate operation.

0: interrupt disabled on busy end

1: interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

11.7.4 ICACHE flag clear register (ICACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CERRF	CBSYENDF	Res.
													w	w	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CERRF**: clear cache error flag

Set by software.

0: no effect

1: clears ERRF flag in ICACHE_SR

Bit 1 **CBSYENDF**: clear busy end flag

Set by software.

0: no effect

1: clears BSYENDF flag in ICACHE_SR.

Bit 0 Reserved, must be kept at reset value.

11.7.5 ICACHE hit monitor register (ICACHE_HMONR)

Address offset: 0x010

Reset value: 0x0000 0000

12 AXI cache (CACHEAXI)

12.1 CACHEAXI introduction

The AXI cache (CACHEAXI) is introduced on the AXI interconnect driven by the NeuralNetwork peripheral (NPU), to improve the performance of data traffic, by caching the NPU data accessed in the external memories.

When configured as an SRAM, the CACHEAXI can be accessed by the NPU, and also by the Cortex-M55 processor or by any AXI master peripheral.

12.2 CACHEAXI main features

The main features of the CACHEAXI are described below:

- Bus interface
  - 64-bit AXI slave port (from AXI interconnect, receiving master requests), with independent read and write channels (read address and data channels; write address, data and response channels)
  - 64-bit AXI master port (to AXI interconnect, accessing main memories), with independent read and write channels (read address and data channels; write address, data, and response channels)
  - 32-bit AHB slave port for control (input from AHB peripherals interconnect, for CACHEAXI registers access)
- The CACHEAXI can be configured to behave as an SRAM:
  - Reuse all data SRAM banks (so same size as in cache mode)
  - Dedicated 64-bit AXI slave SRAM port, to access the CACHEAXI in SRAM mode, with independent read and write channels (read address and data channels; write address, data, and response channels)
  - Pipelined AXI accesses with a deep acceptance capability of up to six requests on the read AXI channel and up to five requests on the write AXI channel
- Cache access
  - One read or write access per cycle (priority to write access in case of simultaneous read and write requests)
  - Pipelined AXI accesses with a deep acceptance capability of up to 7 requests on both read and write AXI channels
  - Throughput: 1 read or write hit access served per AXI clock cycle
  - N-ways set-associative cache
  - Supports both write-back and write-through policies (selectable with AXI transaction WT/WB attribute)
  - Supports both allocate and nonallocate policies (selectable with AXI transaction allocate attribute):

    - Read can allocate or not

    - Write-back always allocate

    - Write-through always nonallocate (write-around)
  - Supports byte (8-bit), half-word (16-bit), word (32-bit), or double-word (64-bit) read or write transfer beat sizes
- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Allocation size: on cache miss, refill request size set as cache line size
  - Prefetch hint forwarded to master port to inform downstream logic/memory to prefetch data
  - Two eviction buffers, for missing requests with cache line refill (allocate) not to be blocked by potential cache line eviction operation
- System compartments support:
  - Cache lines tagged by a 3-bit compartment identifier that reflects compartment attribute of the input request on slave port, and that is used on eviction or clean

operation to set compartment attribute at the output master port

- TrustZone security support
- Maintenance operations
  - Cache invalidate: full cache invalidation (fast command, noninterruptible)
  - a Cache clean range: cleans cache lines whose address belongs to programmed range (background task, interruptible)
  - Cache clean and invalidate range: cleans and invalidates cache lines whose address belongs to a programmed range (background task, interruptible)
- Performance counters
  - 2 hit monitor counters (32-bit): number of read hits, number of write hits
  - 2 miss monitor counters (32-bit): number of read misses, number of write misses
  - 2 allocation monitor counters (32-bit): number of read-allocate misses, number of write-allocate misses
  - Write-through monitor counter: number of write-through transactions
  - Eviction monitor counter: number of dirty cache line evictions (on read-allocate misses or on write-allocate misses).
- Error management
  - Propagates the AXI bus error on the AXI master cache port back to the corresponding AXI slave cache port (on noncacheable request, or on refill of cacheable request with allocation that misses).
  - Detects error for master port request initiated by the CACHEAXI itself (a dirty cache line written back into the main memory, because of an eviction or a clean operation), flags this error, and optionally raises an interrupt

12.3 CACHEAXI implementation

In STM32N6xx, the CACHEAXI1 is a read/write cache placed on the AXI interconnect driven by two master ports of the NeuralNetwork peripheral (NPU).

The CACHEAXI1 caches the external memory regions accessed through Octo-SPI, Hexa-SPI, or FMC interfaces.

By placing an interconnect demultiplexing node in front of its slave cache port, the CACHEAXI1 only receives NPU memory requests that address the external memories (address in range 0x6000 0000:0xDFFF FFFF), and that are cacheable. Noncacheable memory requests are routed away from the slave cache port and address directly the external memories.

Table 46. CACHEAXI features

Features	CACHEAXI1
RW cache	1 (read-write)
SRAM port	1 (support SRAM port)
Cache size	256 Kbytes
Number of ways	8
Cache line width	64 bytes

Table 46. CACHEAXI features (continued)

Features	CACHEAXI1
Data size of AXI Slave and Master interfaces	64 bits
No Privilege	0 (Privilege bit in TAG)
No CID	0 (CID bits in TAG)

12.4 CACHEAXI functional description

The purpose of the CACHEAXI is to cache external memories data, when accessed by a master peripheral through an AXI interconnect.

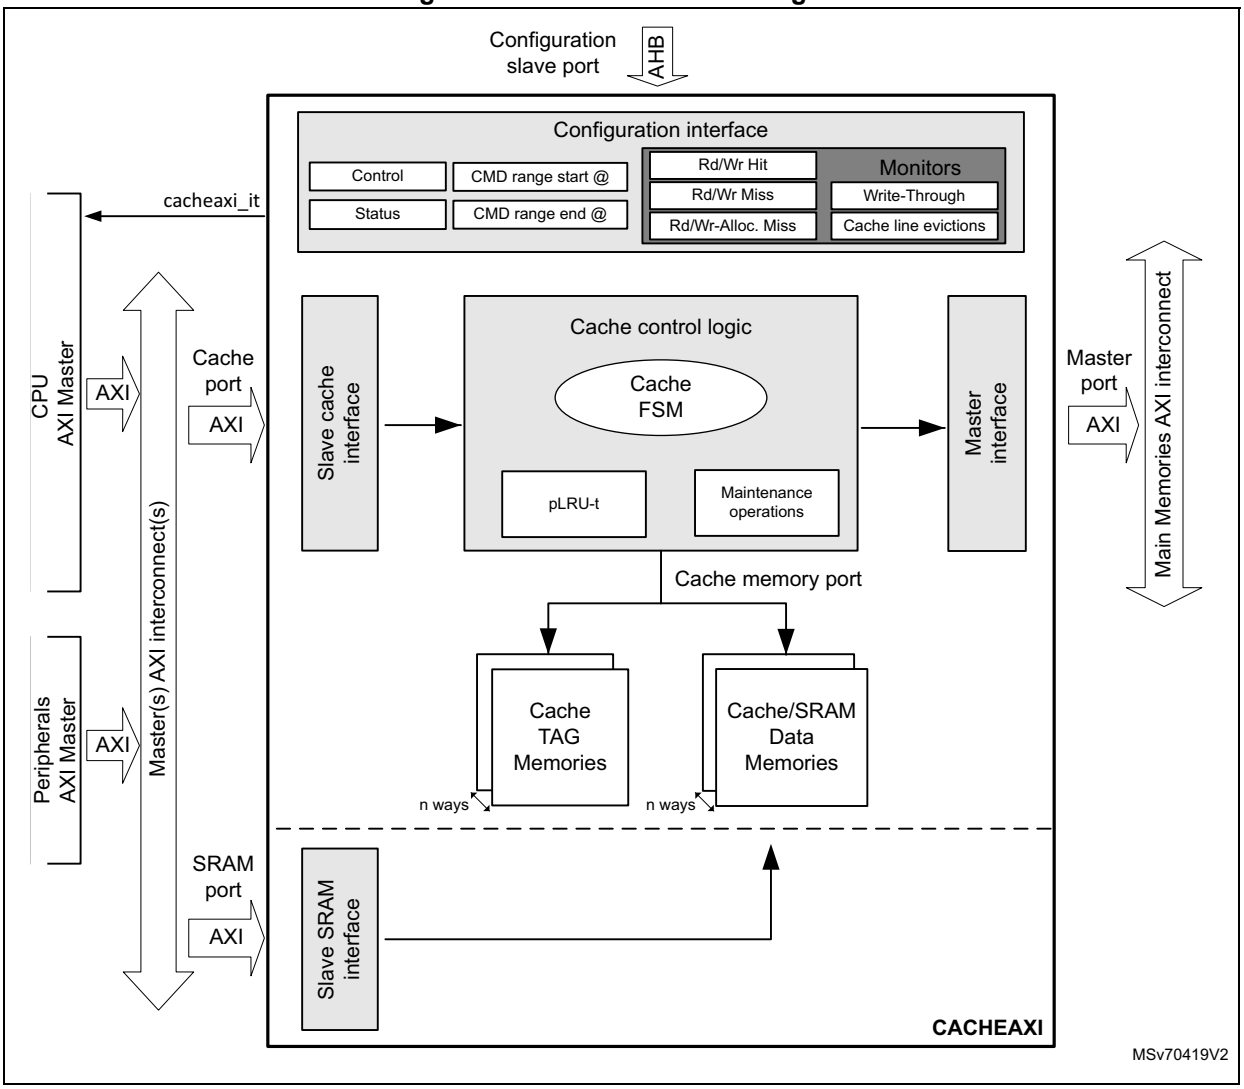
By default (at reset), EN = 0 in CACHEAXI_CR1, and the CACHEAXI behaves as an SRAM.

When its hardware configuration is read-write cache, the CACHEAXI manages both read and write transactions (received on its AXI read slave port, AXI write slave port, respectively).

When configured (by software) to behave as an SRAM, the CACHEAXI manages memory request received on its slave SRAM port (CACHEAXI internal data memories are mapped as a dedicated SRAM region in the system global memory map). Both read and write transactions are supported in SRAM mode.

12.4.1 CACHEAXI block diagram

Figure 12. CACHEAXI block diagram



12.4.2 CACHEAXI reset and clocks

At reset, cache is disabled (EN = 0 in CACHEAXI_CR1), which means that cache mode is disabled.

CACHEAXI transactions on slave cache port are clocked on the (Master) AXI interconnect clock received on slave cache port. The CACHEAXI master port clock is always a copy of the slave cache port clock, in any of the following conditions:

- The cache mode is disabled, and input requests received on slave cache port are just copied to the CACHEAXI master port (including the AXI clock).
- The cache mode is enabled, and the CACHEAXI master port drives the refill requests or the noncacheable transactions (that are forwarded from the slave cache port).

When the CACHEAXI hardware configuration supports the optional SRAM mode and logic, and when the CACHEAXI is disabled, it is configured in SRAM mode:

- The CACHEAXI is clocked on the Master AXI interconnect clock received on slave SRAM port.
- CACHEAXI data memories can be accessed by data request on slave SRAM port.
- The cache mode is disabled, but cache TAG memories are initialized (see invalidate procedure below).

When the CACHEAXI reset signal is released, a cache invalidate procedure is automatically launched, making the CACHEAXI busy (CACHEAXI_SR = 0x0000 0001).

When this procedure is finished:

- The cache control logic and TAG memories are initialized: all cache line valid, dirty, compartment ID and privilege TAG bits = 0.
- CACHEAXI_SR = 0x0000 0002 (reflecting the cache control logic is no longer busy).
- The cache mode is still disabled (EN bit in CACHEAXI_CR1 holds its reset state = 0), but CACHEAXI is ready to be switched in cache mode.

Then, when cache mode is enabled (EN = 1 in CACHEAXI_CR1):

- The CACHEAXI is clocked on the (Master) AXI interconnect clock received on its slave cache port.
- The CACHEAXI is in “cold cache” state, and can serve input requests received on its slave cache port.

When the cache mode is enabled, the SRAM mode is disabled, and input requests received on slave SRAM port are not served: write requests are ignored, and read requests are responded with 0s.

Access to CACHEAXI registers is always clocked by the clock of the AHB configuration slave port.

12.4.3 CACHEAXI TAG memory

The CACHEAXI TAG memory contains:

- Address tags that indicate which data are contained in the cache data memories
- Valid bits
- Dirty bits
- Privilege bits
- Compartment ID (CID) bits

There is one valid bit (V), one privilege bit (P), one 3-bit CID (C[2:0]) and one dirty bit (D) per cache line (per way).

The valid bit enables/disables access to the data cache line: if the line is not valid, the data access (read or write) is performed in the main memory.

The valid bit is set when the cache line is written (allocated by either a read-allocate miss or a write-back miss).

The valid bits are reset in any of the below cases:

- After CACHEAXI reset is released
- When cache mode is disabled (by setting EN low in CACHEAXI_CR1, by software)
- When executing the full invalidate command, when software sets CACHEINV = 1 in CACHEAXI_CR1
- When executing the clean and invalidate range command, when software sets CACHECMD = 0b11 and STARTCMD = 1 in CACHEAXI_CR2.

See *Section 12.4.10: CACHEAXI maintenance* for details on cache maintenance commands.

The dirty bit indicates that the cache line has up-to-date values with respect to the main memory content (in other words, cache has last right value, main memory is not up to date).

The dirty bit is set when the cache line is written by a slave cache port write transaction (only in case of an access with write-back attribute).

The dirty bits are reset in any of the below cases:

- After CACHEAXI reset is released
- When a line refill is performed on a read miss (on a write-back miss, the refilled cache line is modified by the written data and dirty bit = 1)
- When cache invalidation is performed
- When executing one of the CACHEAXI clean operations (cache line written back to the main memory), setting by software CACHECMD = 0b01 or 0b011 in CACHEAXI_CR2

The privilege bit indicates if the data is managed by a privileged entity. It is assigned according to the value of AXI privileged attribute at slave cache port, for the first access to this line (it is written only during a line allocation). The privilege bit holds same polarity as the privileged attribute: 1 for privileged access, 0 for unprivileged access.

The privilege bits are reset:

- After CACHEAXI reset is released
- When the cache is invalidated.

The 3-bit CID indicates to which processing compartment a data belongs to. It is assigned according to the value of AXI user-defined CID attribute at slave cache port for the first access to this line (it is written only during a line allocation).

The CID bits (C[2:0]) are reset:

- After CACHEAXI reset is released
- When the cache is invalidated.

When a cacheable transaction is received at the slave cache port, its AXI transfer address (AxADDR_in[31:0]; either ARADDR_in if on the AXI read channel, or AWADDR_in if on AXI write channel) is split into the following fields (see the table below for B and W values):

- AxADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line
- AxADDR_in[B+W-1:B]: address way index indicates which cache line to select inside each way
- AxADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) inside CACHEAXI

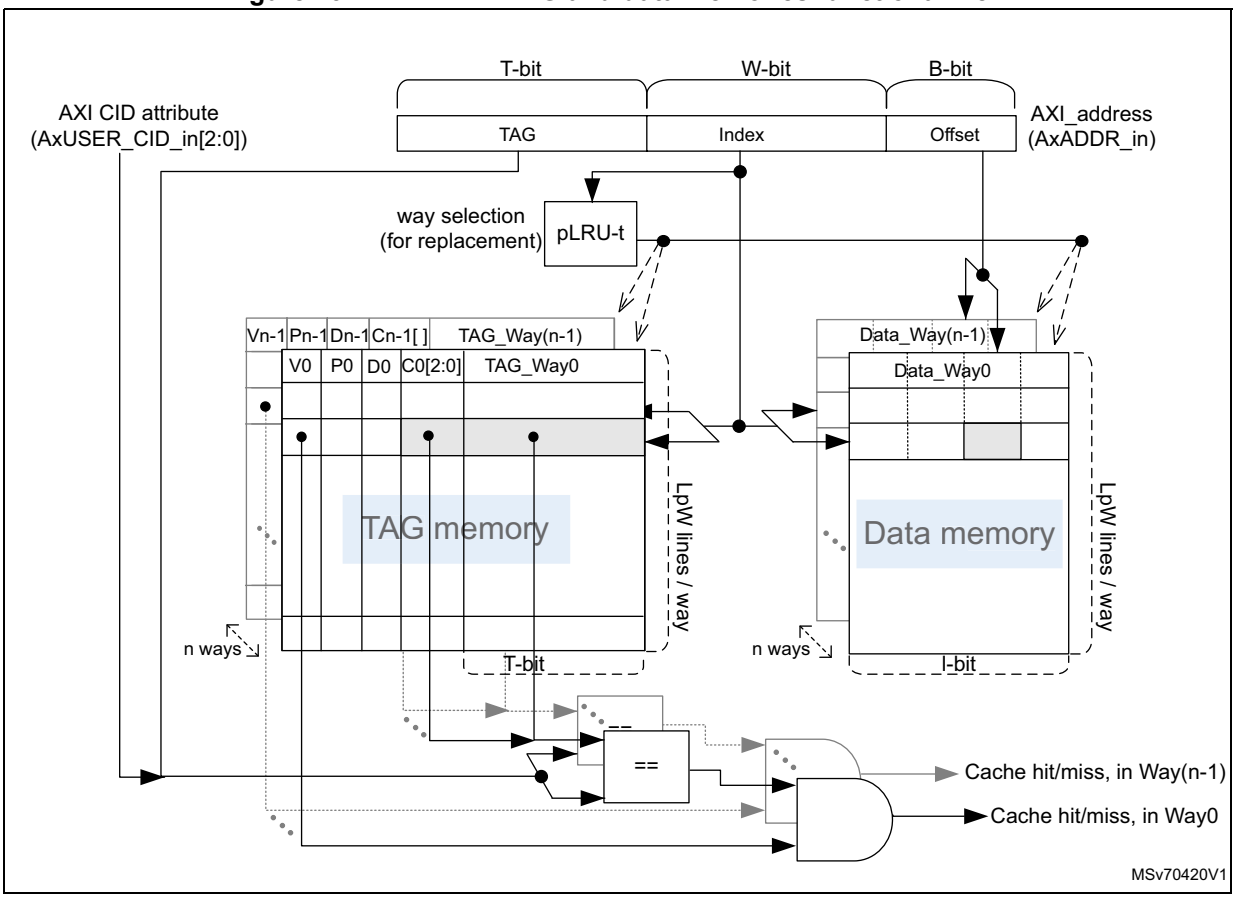
The table below gives the main CACHEAXI parameters for TAG memory dimensioning.

Table 47. TAG memory dimensioning parameters

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	256 Kbytes = 262144 bytes
Cache number of ways	n	8
Cache line size	L-byte = l-bit (l = 8 x L)	64-byte = 512-bit
Number of cache lines (per way)	LpW = s / (n x L) lines/way	512 lines/way
Address byte offset size	B = log2(L) bit	6-bit
Address way index size	W = log2(LpW) bit	9-bit
TAG address size	T = (32 - W - B) bit	17-bit

Figure 13. shows the functional view of TAG and data memories, for an n-way set associative CACHEAXI.

Figure 13. CACHEAXI TAG and data memories functional view



12.4.4 CACHEAXI enable

To activate the CACHEAXI functioning as a cache, EN must be set in CACHEAXI_CR1.

When the CACHEAXI is disabled, it is in SRAM mode, and then bypassed by input requests received on the slave cache port (all these transactions are copied from slave cache port to master port in the same clock cycle, and no comparison is performed with TAG memory).

CACHEAXI is in SRAM mode at boot time (cache mode disabled by default) and can be addressed by any memory request received on slave SRAM port.

12.4.5 Cacheable and noncacheable AXI traffic to slave cache port

The CACHEAXI is developed for AXI bus master peripheral and, when in cache mode, it caches the memory regions addressable by the AXI bus connected to its master port.

The AXI bus traffic to the main memory regions can also be cacheable or noncacheable. An incoming memory request to CACHEAXI slave cache port is defined as cacheable according to its AXI 4-bit memory attribute (cache attribute).

The CACHEAXI supports the allocate or nonallocate policy for both read or write missing transactions. In case of write transaction, the CACHEAXI write policy can be defined as write-through or write-back. Allocation and write policies are defined by the AXI 4-bit memory attribute. This attribute is driven by the master peripheral that initiates the memory request.

Table 48. CACHEAXI supported AXI 4-bit memory/cache attribute

Read or write AXI channel	AXI memory attribute	CACHEAXI behavior
Read	ARCACHE[3:0] = **00**10	Read, noncacheable nonbufferable: no look-up, read from memory (cache bypassed, read forwarded to master port)
	ARCACHE[3:0] = **11**11	Read, cacheable allocate: hit read from cache, miss read from memory, with allocation
	ARCACHE[3:0] = **10**10	Read, cacheable nonallocate: hit read from cache, miss read from memory, without allocation
Write	AWCACHE[3:0] = **00**10	Write, noncacheable nonbufferable: no look-up, write to memory (cache bypassed, write forwarded to master port)
	AWCACHE[3:0] = **11**11	Write-back, cacheable allocate: hit write to cache, miss read-allocate-modify (write data only into allocated cache line)
	AWCACHE[3:0] = **01**10	Write-through, cacheable nonallocate: hit write to cache and to memory, miss write to memory only, without allocation.

In case of noncacheable access, the CACHEAXI is bypassed: the AXI transaction is propagated unchanged from the slave cache port to the master output port, including all the standard AXI4 attributes (except the cache type ones, which are useless for an AXI request to a main memory), and also the user-defined attributes.

- A noncacheable read transaction on the AXI read channel (of slave cache port) is forwarded to the AXI read channel (of master port).
- A noncacheable write transaction on the AXI write channel (of slave cache port) is forwarded to the AXI write channel (of master port).

The bypass does not increase the latency of the access to the targeted memory.

AXI attribute signals are set by the master peripheral that initiates the AXI memory request.

In case of cacheable access on slave cache port, the CACHEAXI behaves as explained in the next section.

12.4.6 Cacheable accesses

When the CACHEAXI receives a cacheable transaction from the AXI master peripheral on its slave cache port, it checks if the requested address and the compartment ID are present in its TAG memory, and if the corresponding cache line is valid. Regarding the hit/miss check, the compartment ID can be seen as a 3-bit extension of the address. In the next paragraphs, the address considered for the comparison with the TAG addresses is made of both the address itself and of the CID: the address matches if both the actual address and the CID match; the address mismatches if one of them mismatches.

For **read transaction**, the following alternatives exist:

- The address matches the one of a valid cache line TAG: **cache read hit**, the data is read from the cache and provided to the master peripheral.
- The address does not match a valid cache line TAG: **cache read miss**, the data is read from the main memory and provided to the master peripheral.

  Depending on the read transaction allocate attribute, a cache line refill is performed, or not. If the allocation must be done, the read request to main memory has the cache line size. If not, the read request to main memory has simply the size of the input request (propagated from slave cache port to master port).

  The AXI protection attribute and CID/prefetch user-defined attributes are also propagated from the slave cache port to the master port, for the (nonallocated) simple data access or cache line refill request.

  Note: The first read transaction that misses, blocks the cache slave port: no further cacheable transaction makes a lookup in cache lines TAG until missing read is served by the CACHEAXI (data read, and if a read-allocate, cache line refilled).

For **write-back transaction** (write transaction, with cacheable write-back allocate attributes, the following alternatives exist:

- The address matches the one of a valid cache line TAG: **cache write-back hit**, the data is written in cache (in the matching cache line).
- The address does not match a valid cache line TAG: **cache write-back miss**.

  A line allocation is performed by reading the entire cache line data from main memory.

  The AXI protection attribute and the user-defined attribute for the cache line refill request are propagated from the slave cache port to the master port.

  Once the refilled line has been written in the CACHEAXI, the initial data provided on slave cache port is written in the CACHEAXI (it overwrites a part of the cache line that was refilled just before).

  Note: The first write-back transaction that misses, blocks the cache slave port: no further cacheable transaction makes a lookup in cache lines TAG until missing write-back is served by the CACHEAXI (cache line refilled and data written).

For **write-through transaction** (write transaction, with cacheable write-through nonallocate attributes, the following alternatives exist:

- Address matches the one of a valid cache line TAG: **cache write-through hit**, the data is written both in cache and in main memory (through master port).
- Address does not match a valid cache line TAG: **cache write-through miss**, the data incoming at slave cache port is written only in main memory (unlike the write-back miss, there is no line allocation and data is not written in cache).

In case of cache refill (due to cache miss), the CACHEAXI selects which cache line is written with the refill data: as an n-way set associative cache, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm. This algorithm points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written is already valid, the targeted cache line must be evicted first:

- If the dirty tag of this line equals 0 (a clean cache line), the line is simply invalidated.
- If the dirty tag of this line equals 1 (a dirty cache line), the evicted cache line is written into an eviction buffer, before to be written back in the main memory (see *Section 12.4.7*).

  The CACHEAXI generates an AXI burst write transaction on its master port, with burst type set to INCR and with AXI memory transaction attribute signals set as detailed below:

  – privileged = evicted line TAG privilege bit (P)
  – data (not instruction)
  – CID[2:0] = evicted line TAG CID bits (C[2:0])

  These AXI attributes cannot be propagated from the slave port (as it is the case for all other transactions emitted on CACHEAXI master port) because the evicting transaction has no relation with the initial missing transaction (that made the refill of the cache line to evict).

12.4.7 AXI traffic to master port

To improve the throughput of the refill traffic generated by the CACHEAXI on its master port (to improve global CACHEAXI performance), the CACHEAXI implements the following feature:

- Prefetch hint forwarded from slave read cache port to master port to inform downstream logic/memory to prefetch extra data from main memory (in addition to the ones requested by this master port refill request)

In order to improve CACHEAXI eviction performance, the following feature is implemented:

- An eviction buffer receives the AXI write transaction that corresponds to the dirty cache line evicted from cache. When either a cache read-with-allocation, or a cache write-back request misses, it initiates a cache line refill operation, that potentially implies the eviction of a dirty cache line (when the n ways of the cache line index to be used for the refill are already all valid).

  The eviction buffer allows the CACHEAXI not to block a missing request beyond the occurrence of the refill operation, and not to wait for the evicted cache line operation (write to main memory) to be performed on the CACHEAXI master port. The eviction operation is just sent to the eviction buffer, that initiates it on master port in the background (when the master port is available for that).

12.4.8 AXI traffic to slave SRAM port

If this optional feature is supported, the CACHEAXI can behave as an SRAM.

The addressable SRAM region is mapped in the system global memory map, and the SRAM size equals the CACHEAXI (cache) size.

When in SRAM mode (CACHEAXI_CR1.EN = 0), the CACHEAXI SRAM can be addressed by the Cortex core or other AXI bus master peripheral on its dedicated slave SRAM port (hardware configuration option).

This AXI slave SRAM port has independent read and write channels (read address and data channels; write address, data and response channels), as the AXI slave cache port.

The read or write AXI transaction received on AXI slave SRAM port has the following characteristics:

- The relevant address field is restricted to the CACHEAXI size (for instance, only the 17 last significant bits of the address are relevant to address a 128-Kbyte CACHEAXI).
- Byte (8-bit), half-word (16-bit), word (32-bit) or double-word (64-bit) transfer beat size.
- No cache type attribute (useless to access an SRAM).
- No support of AXI standard protection attributes, and no support of AXI user-defined attributes (since they are filtered, upstream of AXI slave SRAM port).

12.4.9 CACHEAXI security

The CACHEAXI implements an Armv8-M TrustZone.

CACHEAXI configuration registers are protected at system level.

12.4.10 CACHEAXI maintenance

The CACHEAXI features several maintenance operations that the software can program in CACHEAXI_CR1 and CACHEAXI_CR2 control registers:

- **Full invalidate**: invalidates the whole cache, noninterruptible task.

  The software can invalidate the whole CACHEAXI content by programming CACHEINV in CACHEAXI_CR1.

  When CACHEINV is set, the CACHEAXI control logic sets the BUSYF flag in CACHEAXI_SR, and performs the operation of cache invalidation, in each cache line TAG, reseting:

  – the valid bit (V = 0)
  – the dirty bit (D = 0)
  – the privilege bit (P = 0)
  – the compartment ID bits (C[2:0] = 000)

  to prevent unknown values at next cache line validation.

  CACHEINV in CACHEAXI_CR1 is automatically cleared.

  Once the full invalidate operation is finished, the CACHEAXI automatically clears BUSYF and sets BSYENDF in CACHEAXI_SR.

  If enabled on this flag condition (BSYENDIE = 1 in CACHEAXI_IER), the CACHEAXI interrupt is raised, on **cacheaxi_it** signal. The (empty) cache is available again.

  This full invalidate operation is not interruptible, meaning that the cache does not treat any cacheable request while BUSYF is set (the incoming request is blocked until the

full invalidate is finished). However, the noncacheable traffic is treated (since the request address is not compared to TAG ones) as the CACHEAXI is bypassed in the same clock cycle (same behavior as when CACHEAXI cache mode is disabled).

- **Clean range**: cleans a certain range of addresses in the cache, background task (interruptible).

  Cleaning a cache line means making sure that main memory content is up-to-date with the data which may have been modified in cache. The clean operation consists in performing the write-back in main memory of the cache lines that are tagged as “dirty” (the ones with TAG dirty bit set).

  The software can clean a given data region in the CACHEAXI by programming STARTCMD = 1, and CACHECMD = 0b01 in CACHEAXI_CR2, after the address range was programmed into CACHEAXI_CMDRSADDRR (range start address) and CACHEAXI_CMDREADDRR (range end address).

  The CACHEAXI control logic then parses the whole TAG memory. If the read line address (TAG address + line index) falls in the programmed address range (CACHEAXI_CMDRSADDRR ≤ Line Addr ≤ CACHEAXI_CMDREADDRR) and the corresponding line is dirty, this line is cleaned: the whole cache line is written-back in memory through the CACHEAXI master port, and its TAG dirty bit is cleared.

  When STARTCMD is set, the CACHEAXI control logic sets BUSYCMDF in CACHEAXI_SR, and launches the clean range operation. STARTCMD in CACHEAXI_CR2 is also automatically cleared.

  Once the operation is finished (all TAG memory parsed), the CACHEAXI automatically clears BUSYCMDF and sets CMDENDF in CACHEAXI_SR.

  If enabled on this flag condition (CMDENDIE = 1 in CACHEAXI_IER), the CACHEAXI interrupt is raised, on **cacheaxi_it** signal.

  During this clean range operation, the CACHEAXI is interruptible: it can accept new incoming requests that take higher priority than the cleaning process. The TAG memory is accessed for clean range operation only if not already accessed by an external cache request. This implies that clean range execution is usually not performed in one go, but can be interrupted.

  It is under the software responsibility that no bus initiator attempts to change the content of the region being cleaned until the clean range is completed. The software must take advantage of BUSYCMDF in CACHEAXI_SR, and polls this flag to prevent any spurious access to the area being cleaned. Alternatively the software can also rely on the command end flag (CMDENDF) or on the CACHEAXI interrupt to detect the end of the clean range execution.

- **Clean and invalidate range**: cleans and invalidates a certain range of addresses in the cache, background task (interruptible).

  This operation cleans the “dirty” cache lines that belong to the operation address range (the same as clean range operation), and also invalidates all the (valid) cache lines that belong to this address range (whether they are dirty or not).

  Note: When a cache line is invalidated, the pLRU-t pointer (for this cache line index) is updated to point to the way that was just invalidated (best candidate for the next allocation).

  The software can launch this clean and invalidate range operation, by programming STARTCMD = 1, and CACHECMD = 0b11 in CACHEAXI_CR2, after the address

range was programmed into CACHEAXI_CMDRSADDRR (range start address) and CACHEAXI_CMDREADDRR (range end address).

This sets and clears the same flags, and potentially the same interrupt as clean range operation.

12.4.11 CACHEAXI performance monitoring

The CACHEAXI provides the following monitors for performance analysis:

- The read-hit monitor counts the cacheable AXI read transactions on the slave cache port that hit the CACHEAXI content.
- The write-hit monitor counts the cacheable AXI write transactions on slave cache port that hit the CACHEAXI content.
- The read-miss monitor counts the cacheable AXI read transactions on slave cache port that miss the CACHEAXI content.
- The write-miss monitor counts the cacheable AXI write transactions on slave cache port that miss the CACHEAXI content.

  The hit and miss monitors above actually count the number of lookups (in the CACHEAXI TAG memory) implied by the AXI transactions:

  – when an AXI burst transaction results in several data transfers (or beats) that target the same cache line address range, only one lookup occurs, and the hit or miss monitor only increments by 1.

  – when the data transfers (or beats) of a given AXI burst target several cache line address ranges, the hit/miss monitor increment globally by the number of looked-up cache lines (some can hit, others can miss).
- The read-allocate-miss monitor counts the cache line refill operations (main memory reads) implied by cacheable AXI read-allocate transactions that miss.
- The write-allocate-miss monitor counts the cache line refill operations (main memory reads) implied by cacheable AXI write-back transactions, that miss (and then allocate).
- The write-through monitor counts the total amount of main memory write operations implied by cacheable AXI write-through transactions (whether they hit or miss).
- The eviction monitor counts:

  – the total amount of (dirty) cache lines evicted by the refill operations resulting from either read-allocate misses or write-allocate (write-back) misses,

  – and also, the amount of cache lines ‘evicted’ by a clean operation, meaning the number of dirty lines with an address included in the address range specified by a given 'clean range' or 'clean and invalidate range' maintenance operation, and that are dirty.

  Only dirty cache lines written back to main memory are counted; eviction of non dirty cache lines, that are simply invalidated, are not counted.

The monitors count is effective only when the CACHEAXI is enabled (in cache mode).

Noncacheable read or write transactions are not counted.

Upon reaching their maximum values, the monitors do not wrap over.

The software can perform the following tasks:

- Enable/stop the read (write) hit monitor, through R(W)HITMEN in CACHEAXI_CR1.
- Reset the read (write) hit monitor, by setting R(W)HITMRST in CACHEAXI_CR1.
- Enable/stop the read (write) miss monitor, through R(W)MISSMEN in CACHEAXI_CR1.
- Reset the read (write) miss monitor, by setting R(W)MISSMRST in CACHEAXI_CR1.
- Enable/stop the read-allocate (write-allocate) miss monitor, through R(W)AMMEN in CACHEAXI_CR1.
- Reset the read-allocate (write-allocate) miss monitor, by setting R(W)AMMRST in CACHEAXI_CR1.
- Enable/stop the write-through monitor, through WTMEN in CACHEAXI_CR1.
- Reset the write-through monitor, by setting WTMRST in CACHEAXI_CR1.
- Enable/stop the eviction monitor, through EVIMEN in CACHEAXI_CR1.
- Reset the eviction monitor, by setting EVIMRST in CACHEAXI_CR1.

To reduce power consumption, these monitors are disabled (stopped) by default.

12.4.12 CACHEAXI boot

The CACHEAXI is disabled (EN = 0 in CACHEAXI_CR1) at boot: cache mode is disabled and the CACHEAXI behaves as an SRAM.

Once the boot is finished, the CACHEAXI cache mode can be enabled (by setting EN in CACHEAXI_CR1).

12.5 CACHEAXI low-power modes

Using the CACHEAXI reduces the power consumption at device level by, most of the time, loading/storing data from/to the internal CACHEAXI rather than from the bigger main memories (more power consuming). This reduction is even much higher when the cached main memories are external.

At CACHEAXI level, the access to a given cache line is pipelined: the TAG memory is accessed first (for lookup operation to determine if the access misses all the ways, or hits a given way). In case of hit, the data memory is accessed in a second cycle, and only the data memory cut holding the hitting way is accessed. Accessing only one way among all the n ways available reduces CACHEAXI power consumption to the minimum.

12.6 CACHEAXI error management and interrupts

A transaction initiated on the CACHEAXI master port may return an error (a write attempt into a read-only memory, a security issue or an address decoding issue, for instance).

If the master port request was propagated from a slave cache port request (non-cacheable request, or cacheable request with allocation that misses), the CACHEAXI propagates the AXI bus error from the AXI master cache port back to the corresponding AXI slave cache port.

If ever the master port request is initiated by the CACHEAXI itself (dirty cache line written-back into the main memory because of an eviction or a clean operation), the CACHEAXI

receives this functional error, and flags it internally by setting ERRF in CACHEAXI_SR. And an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in CACHEAXI_IER).

Another case of interrupt generation is at the end of a full invalidate operation: when the cache busy state is finished, the CACHEAXI sets BSYENDF in CACHEAXI_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in CACHEAXI_IER).

The last case is at the end of a maintenance range operation (clean/invalidate range): when the command busy state is finished, the CACHEAXI sets CMDENDF in CACHEAXI_SR. An interrupt is generated if the corresponding interrupt enable bit is set (CMDENDIE = 1 in CACHEAXI_IER).

The CACHEAXI has a unique interrupt signal, **cacheaxi_it** (and then use the same interrupt vector whatever the interrupt source).

Table 49. CACHEAXI interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
CACHEAXI	Functional error	ERRF flag in CACHEAXI_SR	ERRIE bit in CACHEAXI_IER	Set CERRF bit to 1 in CACHEAXI_FCR
CACHEAXI	End of busy state (full invalidate finished)	BSYENDF flag in CACHEAXI_SR	BSYENDIE bit in CACHEAXI_IER	Set CBSYENDF bit to 1 in CACHEAXI_FCR
CACHEAXI	End of cache range operation (address range based)	CMDENDF flag in CACHEAXI_SR	CMDENDIE bit in CACHEAXI_IER	Set CCMDENDF bit to 1 in CACHEAXI_FCR

12.7 CACHEAXI registers

12.7.1 CACHEAXI control register 1 (CACHEAXI_CR1)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EVIMRST	WTMRST	EVIMEN	WTMEN	WAMMRST	RAMMRST	WAMMEN	RAMMEN	WMISSMRST	WHITMRST	WMISSMEN	WHITMEN	RMISSMRST	RHITMRST	RMISSMEN	RHITMEN
w	w	rw	rw	w	w	rw	rw	w	w	rw	rw	w	w	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CACHEINV	EN
														w	rw

Bit 31 **EVIMRST:** eviction monitor reset
0: no effect
1: reset cache eviction monitor

Bit 30 **WTMRST:** write-through monitor reset
0: no effect
1: reset cache write-through monitor

Bit 29 **EVIMEN:** eviction monitor enable
0: cache eviction monitor switched off. Stopping the monitor does not reset it.
1: cache eviction monitor enabled

Bit 28 **WTMEN:** write-through monitor enable
0: cache write-through monitor switched off. Stopping the monitor does not reset it.
1: cache write-through monitor enabled

Bit 27 **WAMMRST:** write-allocate miss monitor reset
0: no effect
1: reset cache write-allocate miss monitor

Bit 26 **RAMMRST:** read-allocate miss monitor reset
0: no effect
1: reset cache read-allocate miss monitor

Bit 25 **WAMMEN:** write-allocate miss monitor enable
0: cache write-allocate miss monitor switched off. Stopping the monitor does not reset it.
1: cache write-allocate miss monitor enabled

Bit 24 **RAMMEN:** read-allocate miss monitor enable
0: cache read-allocate miss monitor switched off. Stopping the monitor does not reset it.
1: cache read-allocate miss monitor enabled

Bit 23 **WMISSMRST:** write-miss monitor reset
0: no effect
1: reset cache write-miss monitor

Bit 22 **WHITMRST:** write-hit monitor reset
0: no effect
1: reset cache write-hit monitor

Bit 21 **WMISSMEN:** write-miss monitor enable
0: cache write-miss monitor switched off. Stopping the monitor does not reset it.
1: cache write-miss monitor enabled

Bit 20 **WHITMEN:** write-hit monitor enable
0: cache write-hit monitor switched off. Stopping the monitor does not reset it.
1: cache write-hit monitor enabled

Bit 19 **RMISSMRST:** read-miss monitor reset
0: no effect
1: reset cache read-miss monitor

Bit 18 **RHITMRST:** read-hit monitor reset
0: no effect
1: reset cache read-hit monitor

Bit 17 **RMISSMEN:** read-miss monitor enable
0: cache read-miss monitor switched off. Stopping the monitor does not reset it.
1: cache read-miss monitor enabled

Bit 16 **RHITMEN:** read-hit monitor enable
0: cache read-hit monitor switched off. Stopping the monitor does not reset it.
1: cache read-hit monitor enabled

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CACHEINV:** full cache invalidation
Can be set by software, only when EN = 1.
Cleared by hardware when the BUSYF flag is set (during full cache invalidation operation).
Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN:** enable
0: cache mode disabled (cache port bypassed and SRAM port active)
1: cache mode enabled (SRAM port not active)

12.7.2 CACHEAXI status register (CACHEAXI_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDENDF	BUSYCMDF	ERRF	BSYENDF	BUSYF
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CMDENDF:** command end flag
Cleared by writing CACHEAXI_FCR.CCMDENDF = 1.
0: cache busy or in idle
1: CACHECMD command finished

Bit 3 **BUSYCMDF:** command busy flag
0: cache not busy on a CACHECMD command
1: cache busy on a CACHECMD command (clean or clean-and-invalidate an address range)

Bit 2 **ERRF:** cache error flag
Cleared by writing CACHEAXI_FCR.CERRF = 1.
0: no error
1: an error occurred during the operation (eviction or clean operation write-back error).

Bit 1 **BSYENDF:** full invalidate busy end flag
Cleared by writing CACHEAXI_FCR.CBSYENDF = 1.
0: cache busy or in idle
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF:** full invalidate busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

12.7.3 CACHEAXI interrupt enable register (CACHEAXI_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDENDIE	Res.	ERRIE	BSYENDIE	Res.
											rw		rw	rw	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CMDENDIE**: interrupt enable on command end
Set by software to enable an interrupt generation at the end of a cache command (clean or clean-and-invalidate an address range)
0: interrupt disabled on command end
1: interrupt enabled on command end

Bit 3 Reserved, must be kept at reset value.

Bit 2 **ERRIE:** interrupt enable on cache error
Set by software to enable an interrupt generation in case of cache functional error (eviction or clean operation write-back error)
0: interrupt disabled on error
1: interrupt enabled on error

Bit 1 **BSYENDIE:** interrupt enable on busy end
Set by SW to enable an interrupt generation at the end of a cache full invalidate operation.
0: Interrupt disabled on busy end
1: Interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

12.7.4 CACHEAXI flag clear register (CACHEAXI_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCMDENDF	Res.	CERRF	CBSYENDF	Res.
											w		w	w	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CCMDENDF:** clear command end flag
Set by software.
0: no effect
1: clears CMDENDF flag in CACHEAXI_SR.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CERRF:** clear cache error flag
Set by software.
0: no effect
1: clears ERRF flag in CACHEAXI_SR.

Bit 1 **CBSYENDF:** clear full invalidate busy end flag
Set by software.
0: no effect
1: clears BSYENDF flag in CACHEAXI_SR.

Bit 0 Reserved, must be kept at reset value.

12.7.5 CACHEAXI read-hit monitor register (CACHEAXI_RHMONR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RHITMON[31:16]

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RMISSMON[31:0]:** cache read-miss monitor counter

12.7.7 CACHEAXI read-allocate miss monitor register (CACHEAXI_RAMMONR)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RAMMON[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RAMMON[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RAMMON[31:0]:** cache read-allocate miss monitor counter

12.7.8 CACHEAXI eviction monitor register (CACHEAXI_EVIMONR)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EVIMON[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EVIMON[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **EVIMON[31:0]:** cache eviction monitor counter

12.7.9 CACHEAXI write-hit monitor register (CACHEAXI_WHMONR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

WTMON[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **WTMON[31:0]:** cache write-through monitor counter

12.7.13 CACHEAXI control register 2 (CACHEAXI_CR2)

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CACHECMD [1:0]		START CMD
													rw	rw	w

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:1 **CACHECMD[1:0]:** cache command maintenance operation (clean or clean-and-invalidate an address range)

This field can be set and cleared by software, only when no maintenance command is ongoing (BUSYCMDF = 0).

00: no operation

01: clean range

11: clean and invalidate range

others: reserved

Bit 0 **STARTCMD:** starts maintenance range command (maintenance operation defined in CACHECMD).

This bit can be set by software, only when EN = 1, BUSYCMDF = 0, BUSYF = 0, and CACHECMD[1:0] = 0b01 or 0b11.

It is cleared by hardware when BUSYCMDF is set (during cache maintenance operation). Writing 0 to this bit has no effect.

0: command operation (cache maintenance) finished

1: start maintenance command (cache maintenance)

12.7.14 CACHEAXI command range start address register (CACHEAXI_CMDRSADDRR)

Address offset: 0x104

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CMDSTARTADDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDSTARTADDR[15:6]										Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw						

Bits 31:6 **CMDSTARTADDR[31:6]:** start address of range to which the cache maintenance command specified in CACHEAXI_CR2.CACHECMD field applies

This field must be set before CACHEAXI_CR2.CACHECMD is written.

Bits 5:0 Reserved, must be kept at reset value.

12.7.15 CACHEAXI command range end address register (CACHEAXI_CMDREADDRR)

Address offset: 0x108

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CMDENDADDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDENDADDR[15:6]										Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw						

Bits 31:6 **CMDENDADDR[31:6]:** end address of range to which the cache maintenance command specified in CACHEAXI_CR2.CACHECMD field applies

This field must be set before CACHEAXI_CR2.CACHECMD is written.

Bits 5:0 Reserved, must be kept at reset value.

12.7.16 CACHEAXI register map

Table 50. CACHEAXI register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1. Bit 5 is reserved (=0) for CACHEAXI configuration with 64-bytes cache line width.

Refer to *Section 2.3* for the register boundary addresses.

13 Power control (PWR)

13.1 PWR introduction

This section gives an overview of the supply architecture for the different power domains and of the supply configuration controller. It also describes the features of the power-supply supervisors, and explains how the V_{CORE} supply domain is configured, depending upon the operating modes, the selected performance (clock frequency), and the voltage scaling.

13.2 PWR main features

- Power supplies and supply domains
  - Core domains (V_{CORE} = V_{DDCORE})
  - V_{DD} domain (V_{RET})
  - Backup domain (V_{SW}, V_{BKP})
  - Analog domain ($V_{DDA18ADC}$)
- System supply voltage regulation
  - Switched-mode power supply power-efficient voltage down-converter (SMPS step-down converter)
  - 0v8 backup regulator (external to the PWR)
- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - VDDA18PMU monitor
  - PVD monitor
  - PVM monitor (V_{DDIO2}, V_{DDIO3}, V_{DDIO4}, V_{DDIO5}, $V_{DD33USB}$, $V_{DDA18ADC}$)
  - V_{08CAP} thresholds
  - Temperature thresholds

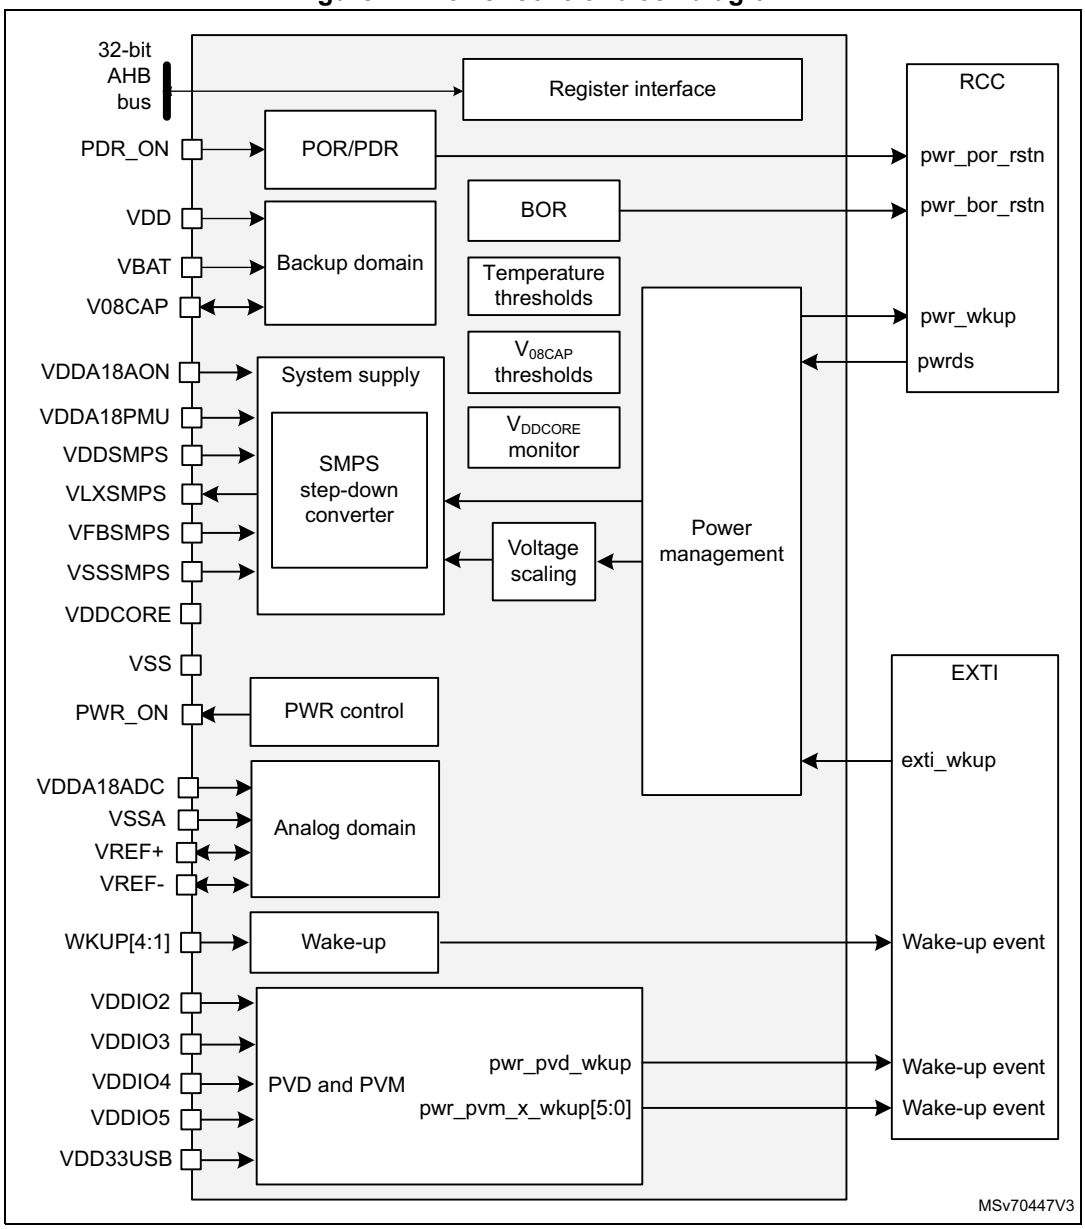
13.3 PWR block diagram

Figure 14. Power control block diagram



13.3.1 PWR pins and internal signals

Table 51 lists the PWR inputs and output signals connected to package pins or balls, while *Table 52* shows the internal PWR signals.

Table 51. PWR input/output signals connected to package pins or balls

Pin name	Signal type	Description
VDD	Input	Main I/O and V_{DD} domain supply input
VDDA18AON	Input	Main analog supply input
VBAT	Input	Backup battery supply input
VDDA18PMU	Input	Step-down converter analog supply input
VDDSMPS	Input	Step-down converter supply input
VLXSMPS	Output	Step-down converter supply output
VFBSMPS	Input	Step-down converter feedback voltage sense
VSSSMPS	Input	Step-down converter ground
V08CAP	Input/output	Digital backup domain supply
VDDCORE	Input	Core domain supply
VDDA18ADC	Input	ADC analog supply
VREF+, VREF-	Input/output	External reference voltage for ADCs
VDDIO2	Input	Independent I/O supply 2 (PO[5:0] and PP[15:0]), usually for XSPI1M_P1 (XSPI)
VDDIO3	Input	Independent I/O supply 3 (PN[12:0])., usually for XSPI1M_P2 (XSPI)
VDDIO4	Input	Independent I/O supply 4 (PC[1], PC[12:6] and PH[2,9]), usually for eMMC
VDDIO5	Input	Independent I/O supply 5 (PC[0], PC[5:2] and PE[4]), usually for SD-Card.
VDD33USB	Input	USB HS PHYs and USB Type C PHY 3V3 supply input
VDDA18USB	Input	USB HS PHYs analog supply input
VDDA18PLL	Input	PLL analog supply
VDDCSI	Input	CSI PHY digital supply input
VDDA18CSI	Input	CSI PHY analog 1v8 supply input
VSS	Input	Main ground
VSSA	Input	Analog ground
PWR_ON	Output	Step-down converter or core supply enable output
NRST	Input/output	System reset, can be used to provide reset to external devices
PDR_ON	Input	Power-down reset enable
WKUPx	Input	Wake-up pins
PWR_CSLEEP	Output	MCU in Sleep mode
PWR_CSTOP	Output	MCU in Stop modes

Table 52. PWR internal input/output signals

Signal name	Signal type	Description
AHB	Input/output	AHB register interface
pwr_pvd_wkup	Output	Programmable voltage detector output

Table 52. PWR internal input/output signals (continued)

Signal name	Signal type	Description
pwr_pvm_x_wkup[5:0]	Output	Peripheral voltage monitor output
pwr_por_rstn	Output	Power-on reset
pwr_bor_rstn	Output	Brownout reset
exti_wkup	Input	Wake-up request
pwr_wkup	Output	Bus matrix clock wake-up request (system clock)

Each of the four wake-up events, WKUPx, can be generated from four pins or internal events.

Table 53. Wake-up source selection

Port	Wake-up event
PA0	WKUP1
PA2	WKUP2
PC13	WKUP3
PD2	WKUP4

13.4 Power supplies

The system requires supply on VDD, VDDA18AON, VDDA18PMU, VDDSMPS, and VDDCORE to start, and allows independent supplies for VDDA18ADC, VBAT, VDD33USB, VDDIO2, VDDIO3, VDDIO4, and VDDIO5.

- V_{DD}: external power supply for I/Os (can be 1.8 V or 3.3 V typical)
- V_{BAT}: optional external power supply for backup domain when V_{DD} is not present (V_{BAT} mode)

  This power supply must be connected to V_{DD} when no battery is used.
- $V_{DDA18AON}$: external power supply for system analog such as reset, power management, oscillators, and OTP
- V_{DDSMPS}: external power supply for the SMPS step-down converter

  This power supply must be tied to V_{SS} when the SMPS is not used.
- $V_{DDA18PMU}$: external analog power supply for the SMPS step-down converter

  This power supply can be connected to V_{DDSMPS} through an inductor-based filter. It must be tied to V_{SS} when the SMPS is not used.
- V_{LXSMPS}: step-down converter supply output
- V_{FBSMPS}: step-down converter sense feedback
- V_{SSSMPS}: separate step-down converter ground
- V_{DDCORE}: digital core domain supply, dependent on V_{DD} supply

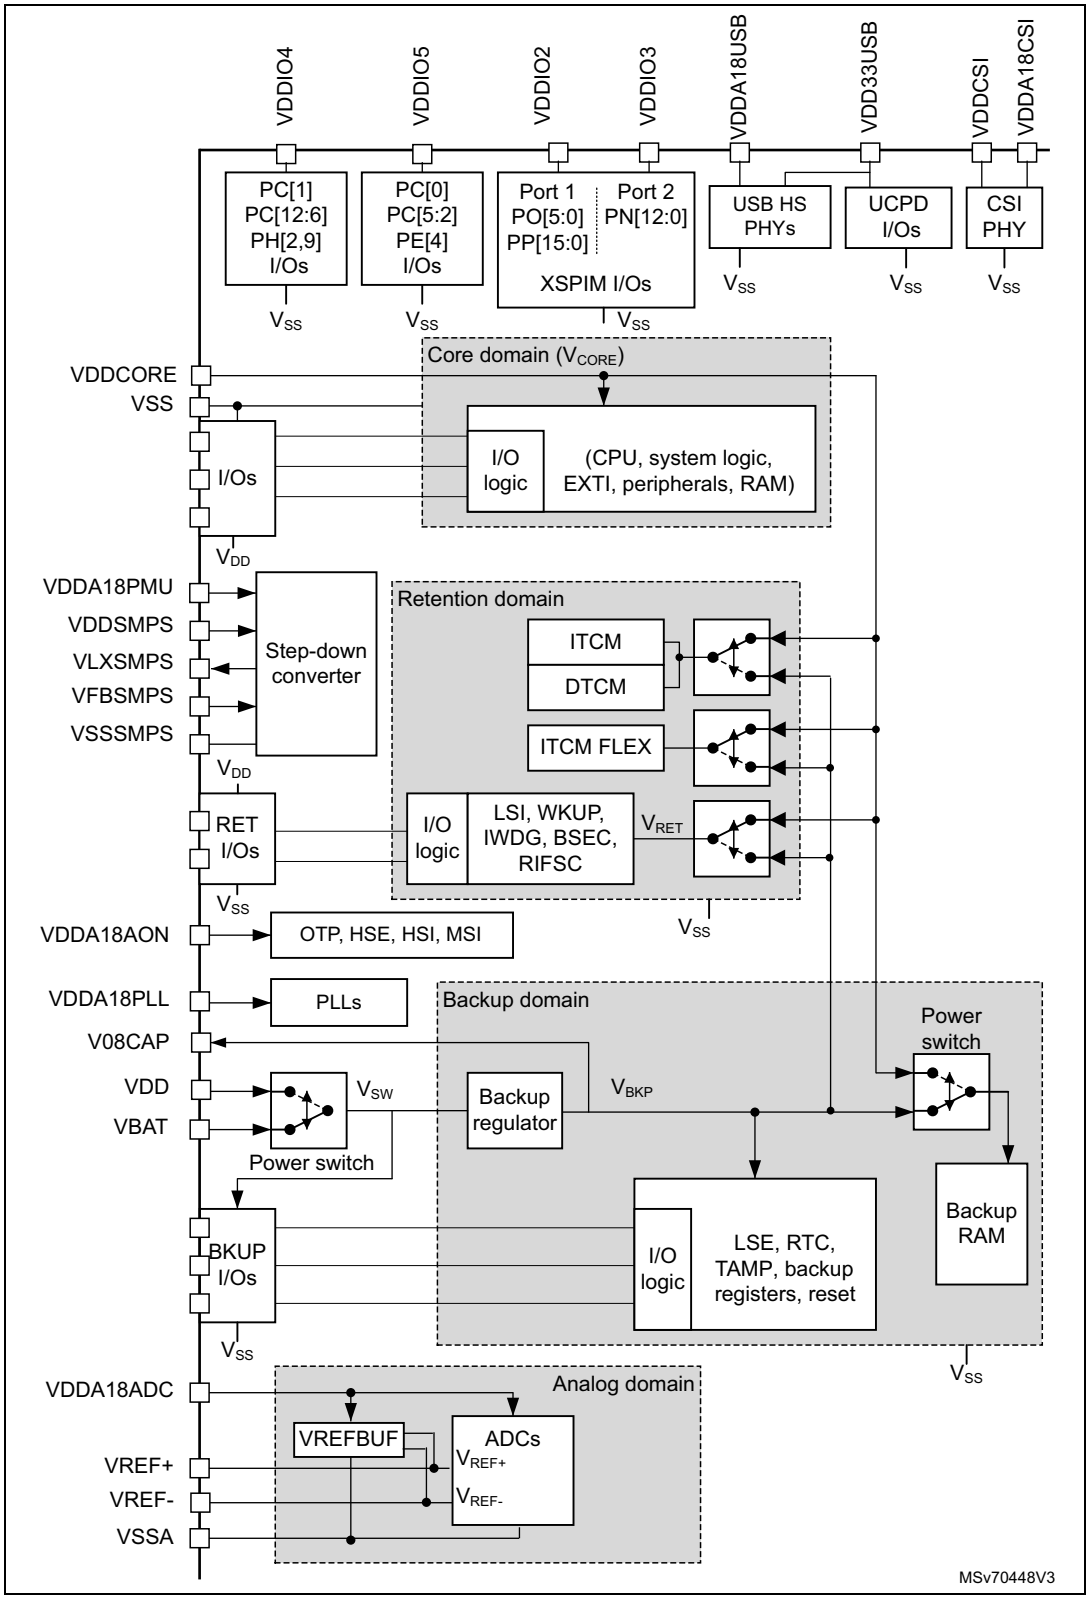
  V_{DD} must be present before V_{DDCORE}. The V_{CORE} is delivered by an external power supply through VDDCORE pin, or by the SMPS step-down converter.

  V_{DDCSI} must usually be connected to V_{DDCORE}.

- $V_{DDA18ADC}$: external analog power supply for ADCs and voltage reference buffers, independent from any other supply
- V_{REF+}: external reference voltage for ADCs, independent from any other supply
  - When the voltage reference buffer is enabled, V_{REF+} and V_{REF-} are delivered by the internal voltage reference buffer.
  - When the voltage reference buffer is disabled, V_{REF+} is delivered by an independent external reference supply.
- V_{SSA}: separate analog and reference voltage ground
- V_{DDIO2}: external power supply for 22 I/Os (PO[5:0] and PP[15:0]), independent from any other supply
- V_{DDIO3}: external power supply for 13 I/Os (PN[12:0]), independent from any other supply
- V_{DDIO4}: external power supply for 10 I/Os (PC[1], PC[12:6], and PH[9,2]), independent from any other supply
- V_{DDIO5}: external power supply for six I/Os (PC[0], PC[5:2], and PE[4]), independent from any other supply
- $V_{DD33USB}$: external power supply for USB2 HS PHYs and USB Type-C® (CC1 and CC2 pins), independent from any other supply
- $V_{DDA18USB}$: external analog power supply for USB2 HS PHYs
- $V_{DDA18CSI}$: external analog power supply for CSI D-PHY
- $V_{DDA18PLL}$: external analog power supplies for PLLs
- V_{SS}: common ground for all supplies except for step-down converter and analog peripherals.

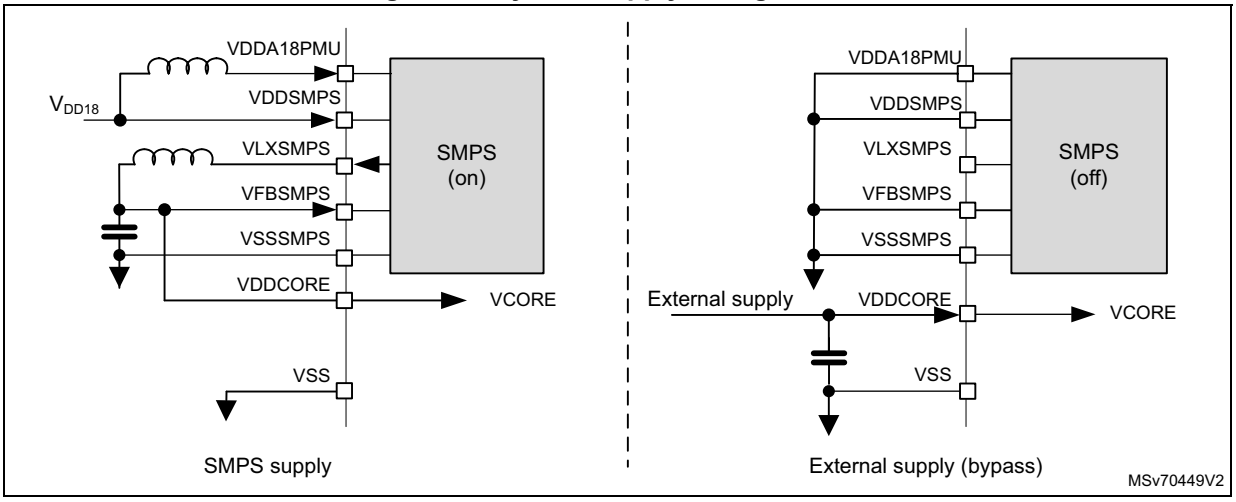
Note: Depending upon the operating power supply range, some peripherals can be used with limited features and performance. For more details, refer to General operating conditions in the datasheet.

Figure 15. Power supply overview



By configuring the SMPS step-down converter, the supply configurations shown in *Figure 16* are supported for the V_{CORE} domain.

Figure 16. System supply configurations



The different supply configurations are controlled through SDEN in PWR_CR1 according to *Table 54*. When the internal SMPS step-down converter is disabled, write SDEN bit in PWR_CR1 to 0 as soon as possible

Table 54. Supply configuration control

Supply configuration	SDEN	Description
Startup configuration	1	V_{CORE} power domains are supplied from external source. SMPS step-down converter enabled at 0.8 V can be used to supply the V_{CORE}.
SMPS step-down converter supply	1	V_{CORE} power domains are supplied from SMPS step-down converter according to VOS. SMPS step-down converter power mode (MR, LP, off) follows system low-power modes.
SMPS step-down converter disabled	0	V_{CORE} supplied from external source. SMPS step-down converter disabled, voltage monitoring still active.

13.4.1 System supply startup

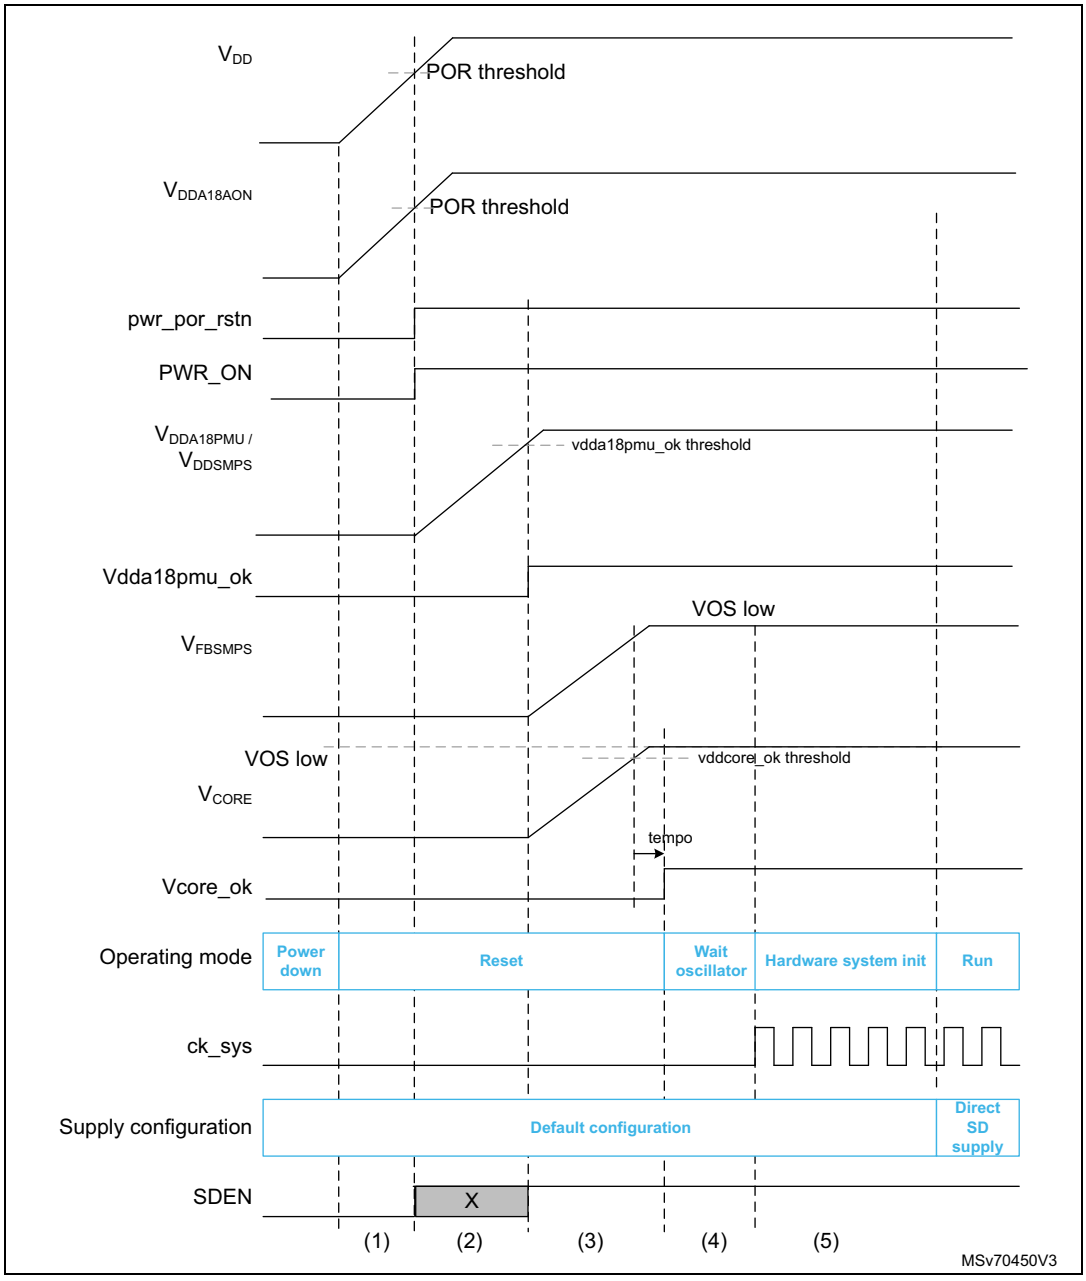
The system startup sequence from power-on in different supply configurations is the following (see *Figure 16* for direct SMPS supply and external supply, respectively):

V_{CORE} directly supplied from the SMPS step-down converter

1. When the system is powered on, the POR monitors V_{DD} and $V_{DDA18AON}$ supplies. Once the supplies are above the POR threshold level, the external voltage regulator providing $V_{DDA18PMU}$ and V_{DDSMPS} supplies is enabled via the PWR_ON signal.
2. The SMPS step-down converter is kept in reset as long as $V_{DDA18PMU}$ and V_{DDSMPS} are not stable.
3. Once $V_{DDA18PMU}$ and V_{DDSMPS} supplies are above the Vdda18pmu_ok threshold level, the SMPS step-down converter is taken out of reset, and the output level is set by default at 0.8 V (VOS low). The system is kept in reset mode as long as V_{DDCORE} is stable.

4. Once V_{DDCORE} supply is above the Vddcore_ok threshold level, the system is taken out of reset, and the HSI oscillator is enabled.
5. Once the oscillator is stable, the system is initialized: option bytes are loaded, and the CPU starts in Run mode.

Figure 17. Device startup (V_{CORE} supplied directly from SMPS step-down converter)



When exiting Standby mode, the supply configuration is known by the system, as the PWR_CR1 content is retained.

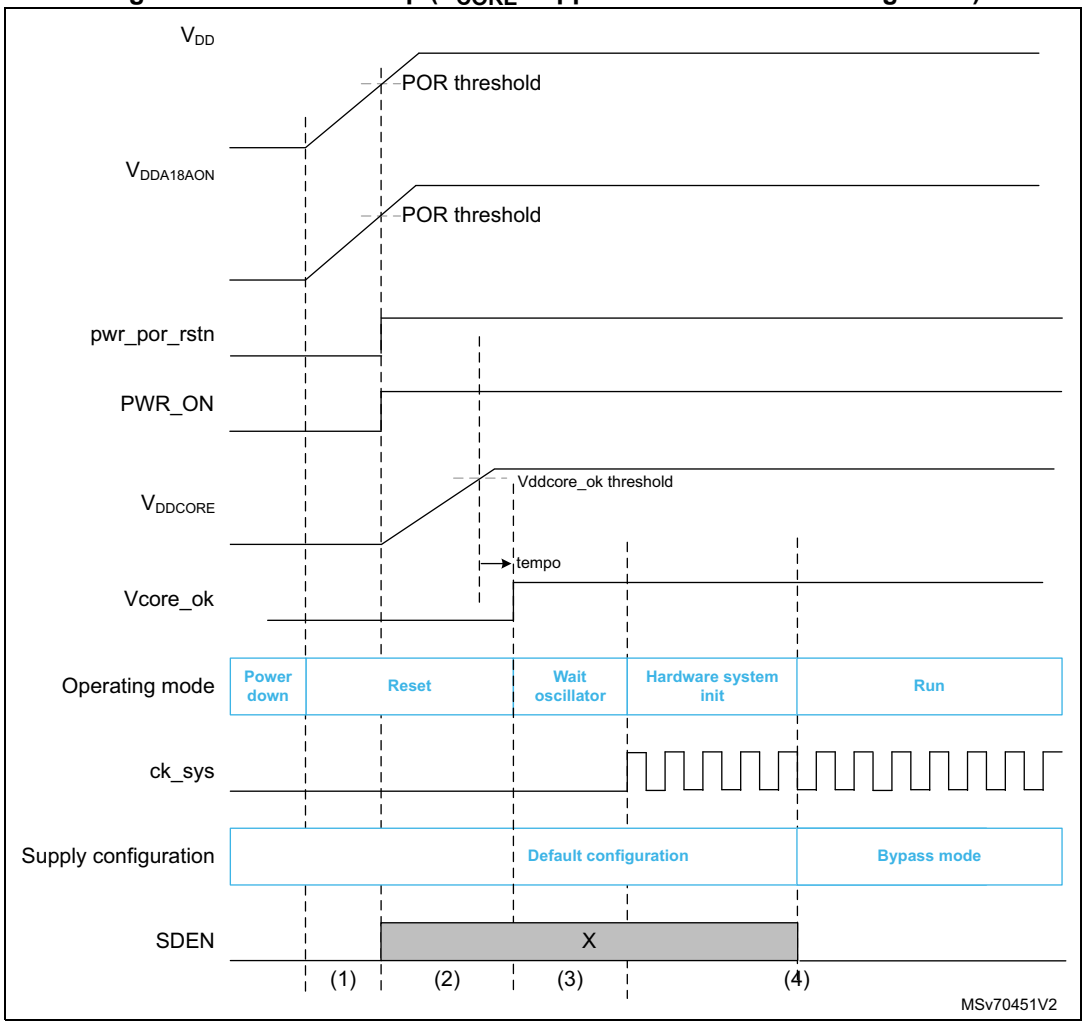
V_{CORE} supplied in bypass mode (SMPS off)

The devices that feature the SMPS can be used in bypass mode.

1. When the system is powered on, the POR monitors V_{DD} and $V_{DDA18AON}$ supplies. Once the supplies are above the POR threshold level, the external voltage regulator providing the V_{DDCORE} supply is enabled via the PWR_ON signal.
2. The system is kept in reset mode as long as V_{DDCORE} is not stable.
3. Once V_{DDCORE} supply is above the Vddcore_ok threshold level, the system is taken out of reset, and the HSI oscillator is enabled.
4. Once the oscillator is stable, the system is initialized: option bytes are loaded, and the CPU starts in Run mode. The software must disable SMPS bit clearing SDEN in PWR_CR1.

Note: In SMPS off mode or bypass mode, reading SDEN returns 0. The SW must write 0 to SDEN in PWR_CR1 register for the low power features to work properly.

Figure 18. Device startup (V_{CORE} supplied from an external regulator)



13.4.2 Core domain

The V_{CORE} core domain supply can be provided by the SMPS step-down converter, or by an external supply (V_{DDCORE}). V_{CORE} supplies all the digital circuitries, except for the backup domain and the retention domain in Standby mode. When a system reset occurs,

the SMPS step-down converter is enabled to deliver 0.8 V. This allows the system to start up in any supply configuration (see *Figure 16*).

After a power-on reset, the software must configure the used supply configuration in PWR_CR1 before changing VOS in PWR_VOSCR, or the RCC sys_ck frequency. The different system supply configurations are controlled as shown in *Table 54*.

SMPS step-down converter regulator

The SMPS requires an external coil to be connected between the VLXSMPS pin and (via a capacitor) VSS. The converter can be used to supply directly the V_{CORE} domain. It works in three different power modes: main (MR), low-power (LP), or off.

The converter operating modes depend upon the system modes (Run, Stop, or Standby mode), and are configured through the associated VOS and SVOS levels:

- Run mode

  The SMPS step-down converter operates in MR mode, and provides full power to the V_{CORE} domain (core, memories, and digital peripherals). PWR_ON is set high. The regulator output voltage can be scaled by software to different voltage levels (VOS low and VOS high) that are configured through VOS in PWR_VOSCR . The VOS voltage scaling is used to optimize the power consumption when the system is clocked below the maximum frequency. By default, VOS low is selected after a system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- Stop mode

  The SMPS step-down converter supplies the V_{CORE} domain to retain the content of registers and internal memories, and must be set in low-power mode. The voltage regulator mode is selected through SVOS in PWR_CPUCR. In low-power mode, only SVOS low and SVOS high scaling are allowed. Due to a lower voltage level for the SVOS low, the Stop mode consumption can be further reduced.

- Standby mode

  The SMPS step-down converter is off, and V_{CORE} domains are powered down. The content of registers and memories are lost except for the retention domain, and the backup domain.

  The PWR_ON signal is set low. The external regulator supplying $V_{DDA18PMU}$ and V_{DDSMPS} can be switched off.

13.4.3 PWR external supply

When V_{CORE} is supplied from an external source (bypass mode), different operating modes can be used, depending upon the system operating modes:

- In Run mode

  The external source supplies full power to the V_{CORE} domain. PWR_ON is set high. The external source output voltage is scalable through different voltage levels (VOS low and VOS high). Setting VOS in PWR_VOSCR has no effect on the external supply. The application can use the register value to track the status of the external supplied voltage, it is responsible to set properly the external supply voltage. Other PWR_VOSCR register fields have default settings, and are "don't care" in external supply.

- In Stop mode

  The external source supplies V_{CORE} domain to retain the content of registers and internal memories. In low-power mode, only SVOS high scaling is allowed.

- In Standby mode

  The PWR_ON signal is set low, the external regulator is switched off, and the V_{CORE} domain is powered down. The content of registers and memories is lost except for the retention domain and the backup domain.

13.4.4 Backup domain

To retain the content of the backup domain (RTC, backup registers, and backup RAM) when V_{DD} is turned off, the VBAT pin can be connected to an optional voltage supplied from a battery or from another source.

The switching to V_{BAT} is controlled by the power-down reset (PDR) embedded in the reset block that monitors the V_{DD} supply.

Warning: **During $t_{RSTTEMPO}$ (temporization at V_{DD} startup), or after a PDR is detected, the power switch between V_{BAT} and V_{DD} remains connected to VBAT.**
During the startup phase, if V_{DD} is established in less than $t_{RSTTEMPO}$ (see the datasheet for the value of $t_{RSTTEMPO}$), and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into VBAT through an internal diode connected between V_{DD} and the power switch (V_{BAT}).
If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

When the V_{DD} supply is present, the backup domain is supplied from V_{DD}, to save V_{BAT} power supply battery life time. If no external battery is used in the application, it is recommended to connect VBAT externally to VDD, and add a 100 nF external ceramic capacitor between VBAT and VSS.

When the backup domain is supplied by VBAT (analog switch connected to VBAT), the following pins are available:

- PC13, PC14, and PC15, which can be configured by RTC or LSE (see *Section 61.3: RTC functional description*).
- PC13, PQ7 (TAMP_IN/OUT), and PD8, PH4 (only TAMP_IN) when they are configured by the TAMP peripheral as tamper pins.

Accessing the backup domain

After reset, the backup domain (RCC_BDCR, RCC_RTC, TAMP registers, backup registers, and backup RAM) is protected against possible unwanted write accesses. To enable access to the backup domain, set DBP in PWR_DBPCR.

For more detail on RTC and backup RAM access, refer to *Section 14: Reset and clock control (RCC)*.

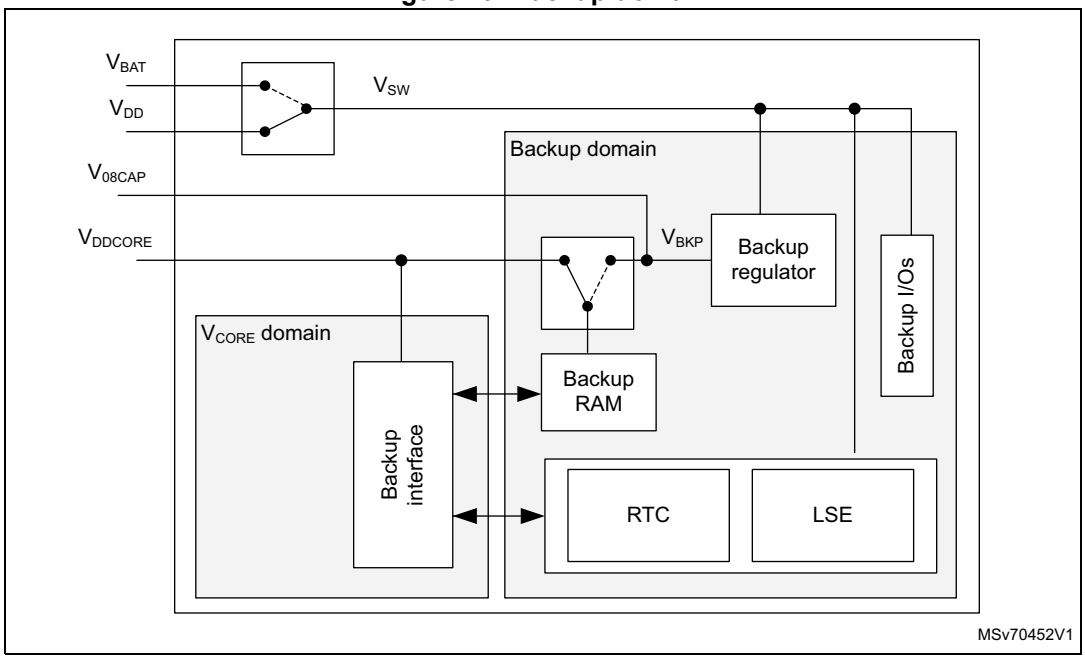
Backup RAM (BKPSRAM)

The backup domain includes 8 Kbytes of BKPSRAM accessible in 32-, 16-, or 8-bit data mode.

- In Run and Stop (SVOS high) modes, the BKPSRAM is supplied from V_{CORE} supply.
- In Stop (SVOS low) mode, the BKPSRAM is supplied through the backup regulator in V_{SW} domain.
- In Standby and V_{BAT} modes, the BKPSRAM can be supplied through the backup regulator in V_{SW} domain.

When the backup supply is enabled through BKPRBSEN in PWR_BDCR2, the BKPSRAM content is retained even in Standby and/or V_{BAT} mode.

Figure 19. Backup domain



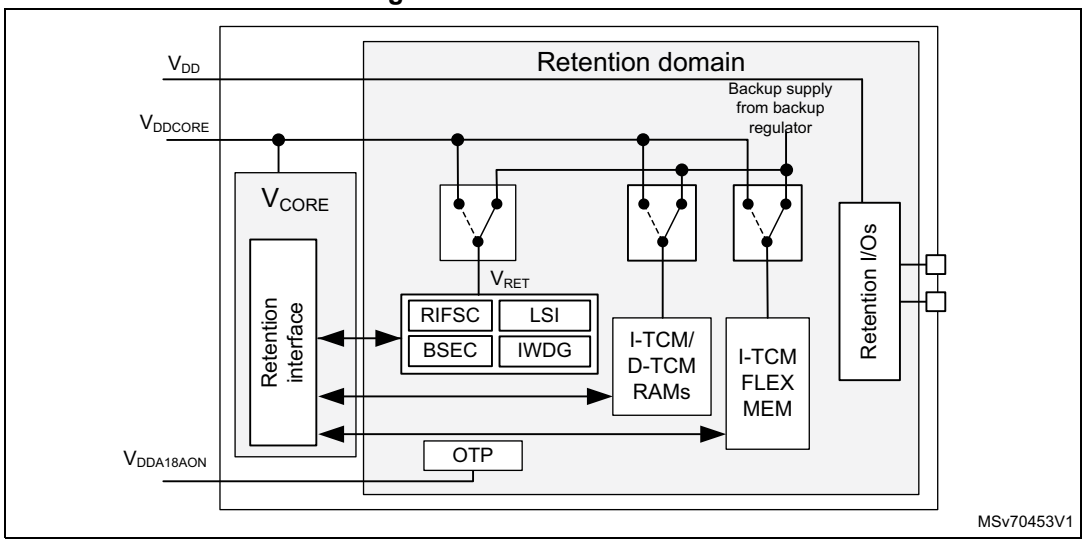
13.4.5 Retention domain

The retention domain includes boot, OTP controller (BSEC), independent watchdog (IWDG), resource isolation framework controller (RIFSC), I-TCM, D-TCM, and I-TCM FLEXRAMs.

- In Run and Stop (SVOS high) modes, the retention domain is supplied from the V_{CORE} supply.
- In Stop (SVOS low) and Standby modes, the retention domain is supplied through the backup regulator.

The content of the domain is retained in Standby mode (not powered in V_{BAT} mode).

Figure 20. Retention domain



I-TCM and D-TCM RAMs

The retention domain includes 64 + 128 K bytes (instruction/data) of TCM for Cortex-M55.

- In Run and Stop (SVOS high) modes, I-TCM, and D-TCM memories are supplied from the V_{CORE} supply.
- In Stop (SVOS low) mode, I-TCM, and D-TCM memories are supplied through the backup regulator in the V_{SW} domain.
- In Standby mode, I-TCM and D-TCM memories can be supplied through the backup regulator in the V_{SW} domain.

When the backup supply is enabled by TCMRBSEN in PWR_CR4, the content of these memories is retained even in Standby mode.

I-TCM FLEXMEM

The retention domain includes 64 Kbytes of extended TCMs for the Cortex-M55 (the I-TCM FLEXMEM extension). This memory can be allocated to I-TCM or to system AXI RAM (see *Section 10: SRAM configuration controller (RAMCFG)* for details

- In Run and Stop (SVOS high) modes, the I-TCM FLEXMEM is supplied from the V_{CORE} supply.
- In Stop (SVOS low) mode, the I-TCM FLEXMEM is supplied through the backup regulator in the V_{SW} domain.
- In Standby mode, the I-TCM FLEXMEM can be supplied through the backup regulator in the V_{SW} domain.

When the backup supply is enabled by t TCMFLXRBSEN in PWR_CR4, the content of these memories is retained even in Standby mode.

13.4.6 Analog supply

Separate $V_{DDA18ADC}$ analog supply

The analog supply domain is powered by dedicated VDDA18ADC and VSSA pins that allow the supply to be filtered and shielded from noise on the PCB, thus improving ADC conversion accuracy:

- The analog supply voltage input is available on a separate VDDA18ADC pin.
- An isolated supply ground connection is provided on VSSA pin.

Analog reference voltage V_{REF+}/V_{REF-}

To achieve better accuracy low-voltage signals, the ADC has a separate reference voltage, available on VREF+ pin. The user can connect a separate external reference voltage on V_{REF+}.

V_{REF+} controls the highest voltage, represented by the full scale value. The lower voltage reference (V_{REF-}) must be connected to V_{SSA}.

When enabled by ENVR in VREFBUF_CSR, V_{REF+} is provided from the internal voltage reference buffer, which can also deliver a reference voltage to external components through VREF+/VREF- pins.

When the internal voltage reference buffer is disabled by ENVR, V_{REF+} is delivered by an independent external reference supply voltage.

13.5 Power supply supervision

Power supply level monitoring is available on the following supplies:

- V_{DD}/$V_{DDA18AON}$ via POR/PDR (see *Section 13.5.1*), BOR (see *Section 13.5.2*), and PVD monitor (see *Section 13.5.6*)
  - The POR/PDR monitoring flag is available from PORRSTF in the RCC.
  - The BOR monitoring flag is available from BORRSTF in the RCC.
  - The PVD monitoring flag is available from PVDO in PWR_CR2. In addition, an interrupt and wake-up can be generated via the EXTI.
- $V_{DDA18PMU}$ via Vdda18pmu_ok, which keeps in reset the SMPS, as long as the level is not correct.
  - The $V_{DDA18PMU}$ monitoring has no flags.
- V_{BAT} via V_{BAT} threshold (see *Section 13.5.8*)
  - The V_{08CAP} monitoring flags are available from V08CAPH and V08CAPL in PWR_BDCR1. In addition, an interrupt and wake-up can be generated via EXTI.
- V_{DDCORE} via Vcore_ok, which keeps the V_{CORE} domain in reset as long as the level is not correct (see *Section 13.5.3*).
  - The V_{DDCORE} ok monitoring flag is available from SBF in PWR_CPUCR when exiting the Standby mode.
- V_{DDCORE} via V_{CORE} threshold (see *Section 13.5.5*)
  - The V_{DDCORE} monitoring flags are available from VCOREH and VCOREL in PWR_CR3. In addition, an interrupt and wake-up can be generated via EXTI.
- V_{DDIO2}, V_{DDIO3}, V_{DDIO4}, V_{DDIO5}, $V_{DD33USB}$, $V_{DDA18ADC}$ via peripheral voltage monitor (see *Section 13.5.7*)

- V_{SW} via rst_vsw, which keeps V_{SW} domain in reset mode as long as the level is not the correct one
  - The V_{SW} monitoring has no flag. V_{SW} registers reset value can be used.
- V_{FBSMPS} can be monitored via VOSRDY in PWR_VOSCR.

13.5.1 Power-on reset (POR)/power-down reset (PDR)

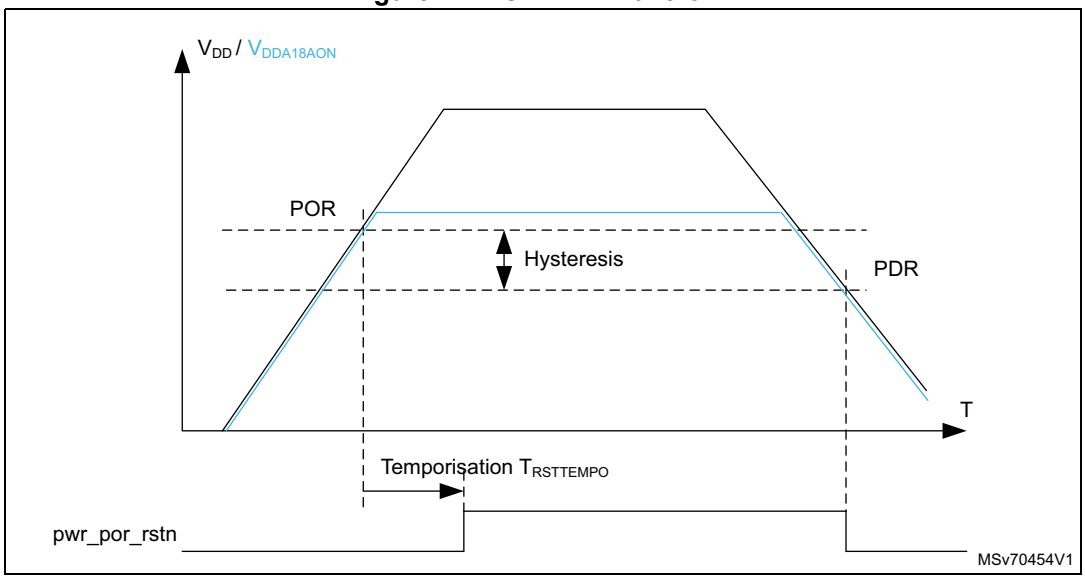
The system has an integrated POR/PDR circuitry that ensures proper start-up operation.

The system remains in reset mode when V_{DD} and $V_{DDA18AON}$ are below a specified V_{POR} threshold, without the need for an external reset circuit. Once these supply levels are above the V_{POR} threshold, the system is taken out of reset (see *Figure 21*). For more details concerning these thresholds, refer to the electrical characteristics in the datasheet.

The POR/PDR generate also an application reset (NRST).

The PDR can be enabled/disabled by the device PDR_ON input pin.

Figure 21. POR/PDR waveform



1. For thresholds and hysteresis values, refer to the datasheets.

13.5.2 Brownout reset (BOR)

During power-on, the brownout reset (BOR) keeps the system under reset until the V_{DD} supply voltage reaches the specified V_{BOR} threshold.

The V_{BOR} threshold is configured through system option bytes. By default, the BOR is off. The selection of another BOR threshold takes effect only after the device has loaded the option bytes. The following programmable V_{BOR} thresholds can be selected:

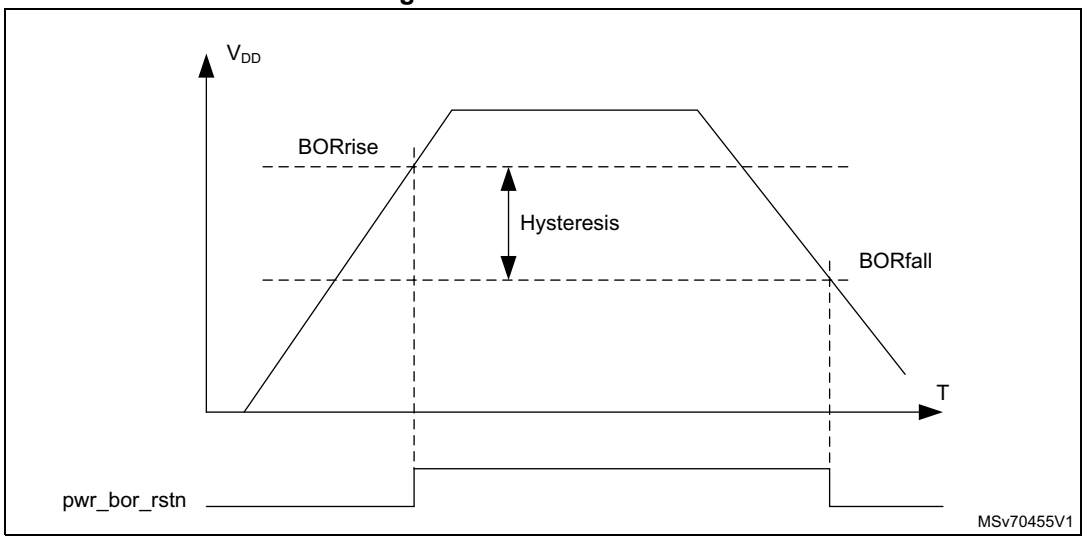
- BOR off (V_{BOR0}): reset threshold level above 1.67 V
- BOR level 1 (V_{BOR1}): reset threshold level above 2.7 V

For more details on these thresholds, refer to the electrical characteristics in the datasheet.

When the BOR is enabled and the V_{DD} supply voltage drops below the selected V_{BOR} threshold, an application reset (NRST) is generated.

The BOR can be disabled by programming the system option bytes. To disable it, V_{DD} must have been higher than V_{BOR0} to start the system option byte programming sequence. The power-down is then monitored by the PDR (see *Section 13.5.1*).

Figure 22. BOR thresholds



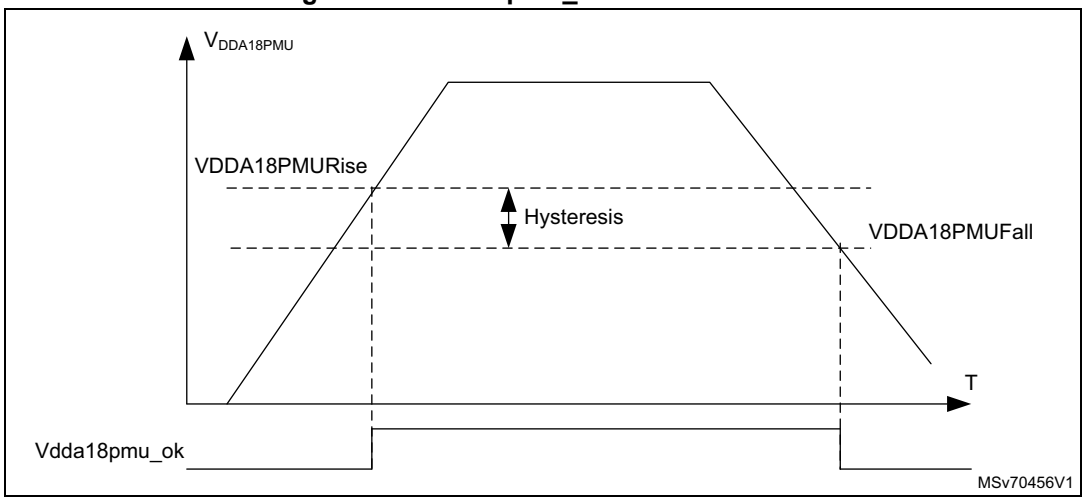
1. For thresholds and hysteresis values, refer to the datasheets.

13.5.3 Vdda18pmu_ok reset

The system integrates a circuit for proper startup of the integrated SMPS.

The SMPS remains in reset mode when $V_{DDA18PMU}$ is below the threshold Vdda18pmu_ok. Once the $V_{DDA18PMU}$ supply level is above Vdda18pmu_ok, the SMPS is taken out of reset, and the output level is set by default at 0.8 V (VOS low). For more details concerning this reset threshold, refer to the electrical characteristics in the datasheet.

Figure 23. Vdda18pmu_ok reset threshold



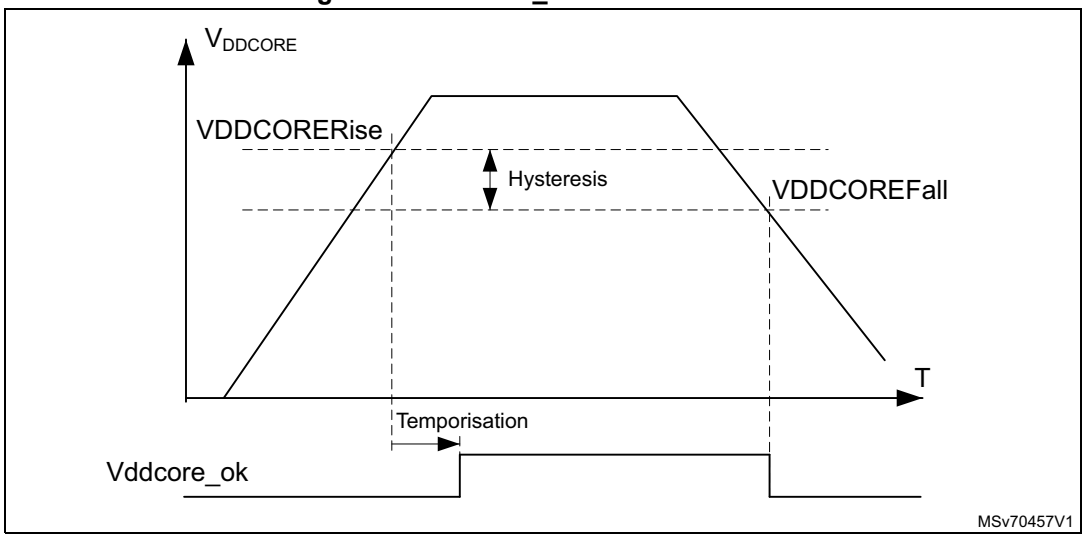
13.5.4 Vddcore_ok reset

The system has in integrated circuit for proper startup of the V_{CORE} domain.

The V_{CORE} domain remains in reset mode when V_{DDCORE} is below the operation threshold Vddcore_ok. Once the V_{DDCORE} supply level is above Vddcore_ok, the V_{CORE} domain is taken out of reset. For more details concerning this reset threshold, refer to the electrical characteristics in the datasheet.

When SVOS is cleared in PWR_CPUCR, the V_{DDCORE} supply level can be lowered in Stop mode (SVOS low).

Figure 24. Vddcore_ok reset thresholds



13.5.5 V_{DDCORE} monitoring

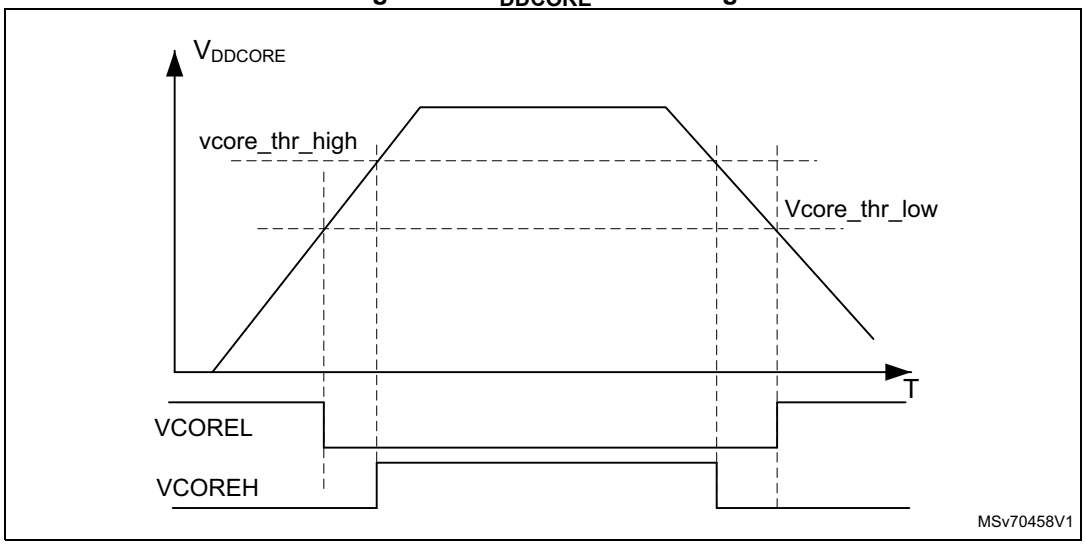
The system has a detection circuitry that detects if the V_{DDCORE} supply voltage is below or above the operating range. The detection is done by comparing the V_{DDCORE} with two thresholds (high and low threshold). The level of the low threshold can be selected by VCORELLS in PWR_CR3. The high level is fixed.

VCOREH and VCOREL flags are available in PWR_CR3, to indicate if V_{DDCORE} is higher or lower than the thresholds. VCOREH and VCOREL flags are available on tamper signals but also connected to the EXTI, and can generate an interrupt if enabled through EXTI registers.

The detection is enabled by setting VCOREMONEN in PWR_CR3.

The V_{DDCORE} voltage thresholds, when enabled, are not available in Stop, Standby, and V_{BAT} modes. For more details concerning vcore_thr_high and vcore_thr_low thresholds, refer to the electrical characteristics in the datasheet.

Figure 25. V_{DDCORE} monitoring



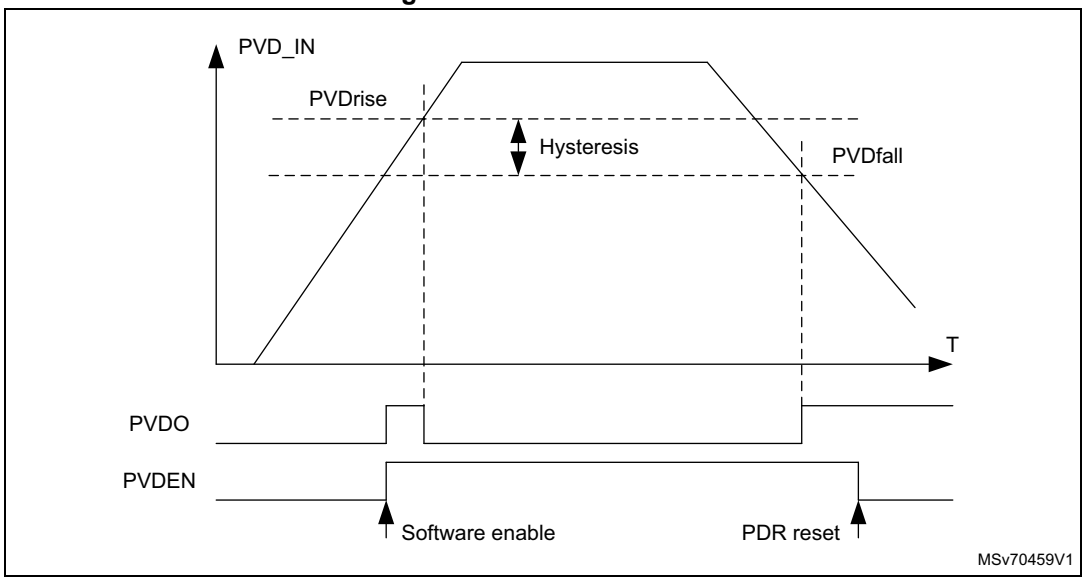
13.5.6 Programmable voltage detector (PVD)

The PVD can be used to monitor a voltage level on PVD_IN pin. The voltage level on PVD_IN is compared to the internal VREFINT level. The PVD is enabled by setting PVDEN in PWR_CR2. The PVD is not available in Standby mode.

A PVDO flag is available in PWR_CR2 to indicate if the voltage level on PVD_IN is higher or lower than the PVD threshold. This event is internally connected to the EXTI, and can generate an interrupt if enabled through the EXTI registers.

The PVDO output interrupt can be generated when the voltage level on PVD_IN drops below the PVD threshold, and/or when the voltage level on PVD_IN rises above the PVD threshold depending on EXTI rising/falling edge configuration. As an example, the service routine can perform emergency shutdown tasks.

Figure 26. PVD thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

13.5.7 Peripheral voltage monitoring (PVM)

Only V_{DD} is monitored by default, as it is the only supply required for all system-related functions. The other supplies (V_{DDIO2}, V_{DDIO3}, V_{DDIO4}, V_{DDIO5}, VDD33USB, and $V_{DDA18ADC}$) can be independent from V_{DD}, and can be monitored with six peripheral voltages (PVM):

- VDDIO2VM monitors the PO[5:0] and PP[15:0] I/Os supply V_{DDIO2}. VDDIO2RDY indicates if V_{DDIO2} is higher or lower than the VIO2VM threshold.
- VDDIO3VM monitors the PN[12:0] I/Os supply V_{DDIO3}. VDDIO3RDY indicates if V_{DDIO3} is higher or lower than the VIO3VM threshold.
- VDDIO4VM monitors PC[1], PC[12:6], and PH[9,2] I/Os supply V_{DDIO4}. VDDIO4RDY indicates if V_{DDIO4} is higher or lower than the VIO4VM threshold.
- VDDIO5VM monitors the PC[0], PC[5:2] and PE[4] I/Os supply V_{DDIO5}. VDDIO5RDY indicates if V_{DDIO5} is higher or lower than the VIO5VM threshold.
- USB33VM monitors the USB supply $V_{DD33USB}$. USB33RDY indicates if $V_{DD33USB}$ is higher or lower than the VUSB33VM threshold.
- AVM monitors the ADC supply $V_{DDA18ADC}$. ARDY indicates if $V_{DDA18ADC}$ is higher or lower than the VAVM threshold.

For thresholds and hysteresis, refer to the datasheet.

Each PVM output is connected to an EXTI line, and can generate an interrupt if enabled through the EXTI registers. The EXTI_PVM_x output interrupt is generated when the independent power supply drops below the PVM threshold, and/or when it rises above the PVM threshold, depending on EXTI line rising/falling edge configuration.

The PVM is not available in Standby mode.

The independent supplies (V_{DDIO2}, V_{DDIO3}, V_{DDIO4}, V_{DDIO5}, $V_{DD33USB}$, and $V_{DDA18ADC}$) are not considered as present by default, and a logical and electrical isolation is applied to ignore any information coming from the peripherals supplied by these dedicated supplies.

- If these supplies are shorted externally to V_{DD}, the application must assume they are available without enabling any peripheral voltage monitoring, and the power isolation can be removed by setting the corresponding supply valid bits.
- If these supplies are independent from V_{DD}, the PVM can be enabled to confirm whether the supply is present or not.

The following sequence must be done before using the USB HS PHYs:

1. If $V_{DD33USB}$ is independent from V_{DD}:
   a) Enable the USB33VM by setting USB33VMEN in PWR_SVMCR3.
   b) Wait for the USB33VM wake-up time.
   c) Wait until USB33RDY is set in PWR_SVMCR3.
   d) Optional: Disable the USB33VM for consumption saving.
2. Set USB33SV in PWR_SVMCR3 to remove the $V_{DD33USB}$ power isolation.

The following sequence must be done before using the analog-to-digital converters:

1. If $V_{DDA18ADC}$ is independent from V_{DD}:
   a) Enable the AVM by setting AVMEN in PWR_SVMCR3.
   b) Wait for the AVM wake-up time.
   c) Wait until ARDY is set in PWR_SVMCR3.
   d) Optional: Disable the AVM for consumption saving.

2. Set ASV in PWR_SVMCR3 to remove the $V_{DDA18ADC}$ power isolation.

GPIOs can work in the 1.8 V or 3.3 V power supply ranges. It is needed to select the supply range of the I/Os before using them (the 3.3 V range is selected by default). The voltage range configuration for V_{DD}, V_{DDIO2}, and V_{DDIO3} is retained in Standby mode.

The configuration can be retained for V_{DDIO4} and V_{DDIO5} in Standby mode when VDDIO4VRSTBY is set in PWR_SVMCR1(and VDDIO5VRSTBY in PWR_SVMCR2). The voltage range must not be retained if the supply range may change when exiting Standby mode (SD card).

The following sequence must be done before using VDDIO4 I/Os:

1. If V_{DDIO4} is independent from V_{DD}:
   a) Enable the VDDIO4VM by setting VDDIO4VMEN in PWR_SVMCR1.
   b) Wait for the VDDIO4VM wake-up time.
   c) Wait until VDDIO4RDY is set in PWR_SVMCR1.
   d) Optional: Disable the VDDIO4VM for consumption saving.
   e) If V_{DDIO4} is in 1.8 V range: Set the V_{DDIO4} voltage range by setting VDDIO4VRSEL in PWR_SVMCR1.
   f) Optional: Retain VDDIO4VRSEL configuration by setting VDDIO4VRSTBY in PWR_SVMCR1.
2. Set VDDIO4SV in PWR_SVMCR1 to remove the V_{DDIO4} power isolation.

Same sequence must be done for VDDIO5 I/Os.

The following sequence must be done before using VDDIO2 I/Os:

1. If V_{DDIO2} is independent from V_{DD}:
   a) Enable the VDDIO2VM by setting VDDIO2VMEN in PWR_SVMCR3.
   b) Wait for the VDDIO2VM wake-up time.
   c) Wait until VDDIO2RDY is set in PWR_SVMCR3.
   d) Optional: Disable the VDDIO2VM for consumption saving.
   e) If V_{DDIO2} is in 1.8 V range: Set the V_{DDIO2} voltage range by setting VDDIO2VRSEL in PWR_SVMCR3.
2. Set VDDIO2SV in PWR_SVMCR3 to remove the V_{DDIO2} power isolation.

Same sequence must be done for the VDDIO3 I/Os.

13.5.8 Battery voltage thresholds

The battery voltage V_{BAT} supply can be monitored by comparing it with two threshold levels: $V_{08CAPhigh}$ and $V_{08CAPlow}$. V08CAPH and V08CAPL flags in PWR_BDCR1 indicate if V_{SW} is higher or lower than the thresholds.

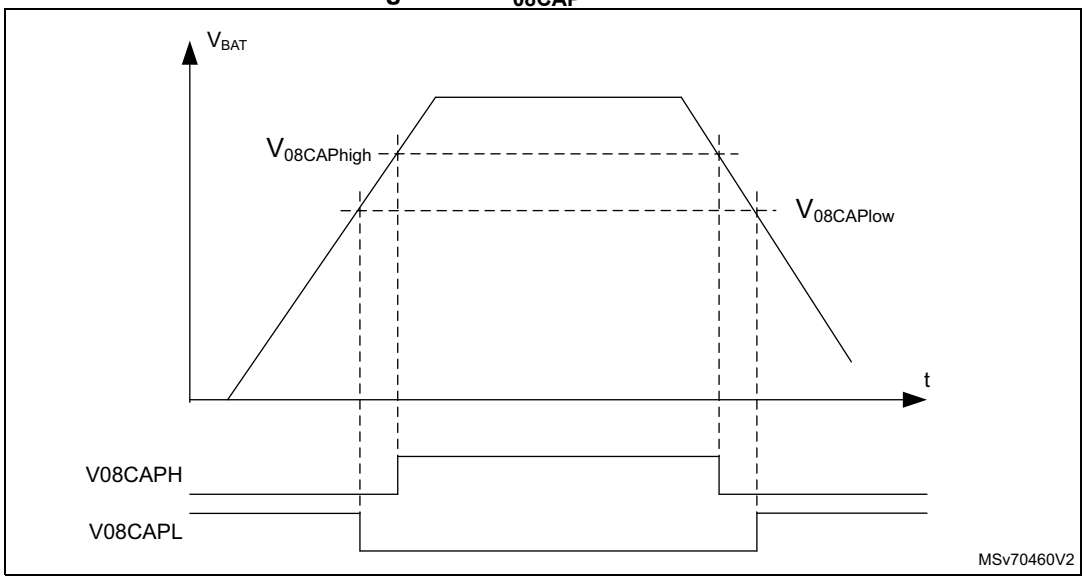
The V_{BAT} supply monitoring can be enabled/disabled via MONEN in the PWR_BDCR1. When V_{08CAP} monitoring is enabled, the battery voltage thresholds increase the power consumption. As an example, V_{SW} levels monitoring can be used to trigger a tamper event for an over or under voltage of the RTC power supply domain (available in V_{BAT} mode).

The battery voltage thresholds, when enabled, are also available in Standby and V_{BAT} modes.

V08CAPH and V08CAPL are connected to RTC tamper signals (see *Section 61: Real-time clock (RTC)*.

Note: When the device does not operate in V_{BAT} mode, the battery voltage monitoring checks the V_{DD} level. When V_{DD} is available, V_{SW} is connected to V_{DD} through the internal power switch (see Section 13.4.4).

Figure 27. V_{08CAP} thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

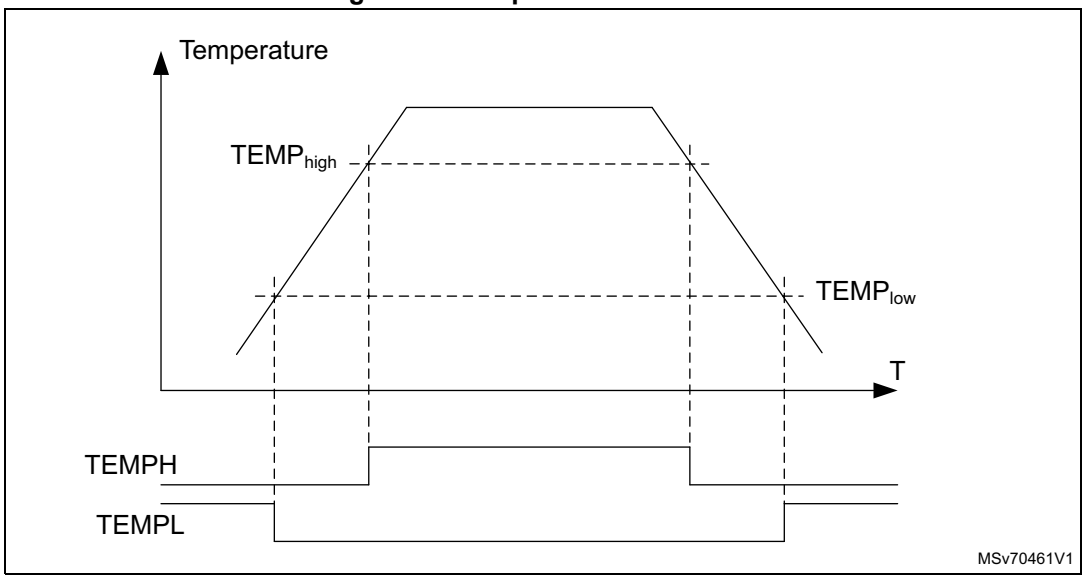
13.5.9 Temperature thresholds

The junction temperature can be monitored by comparing it with two threshold levels, $TEMP_{high}$ and $TEMP_{low}$. TEMPH and TEMPL flags in PWR_BDRC1 indicate whether the device temperature is higher or lower than the thresholds. The temperature monitoring can be enabled/disabled via MONEN in PWR_BDRC1. When the temperature monitoring is enabled, the temperature thresholds increase the power consumption. As an example, threshold levels can be used to trigger a routine to perform temperature control tasks.

The temperature thresholds, when the monitoring is enabled, are also available in Standby and V_{BAT} modes.

TEMPH and TEMPL wake-up interrupts are available on the RTC tamper signals (see *Section 61: Real-time clock (RTC)*).

Figure 28. Temperature thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

13.6 Power management

The power management block controls the V_{CORE} supply in accordance with the system operation modes (see *Section 13.6.1*).

The device power domains can operate in one of the following operating modes:

- Run (power on, clock on)
- Sleep (power on, core clock stopped, peripherals kept running)
- Stop (power on, clock off)
- Standby (power off, clock off)

The V_{CORE} supply level follows the system operating mode (Run, Stop, or Standby mode).

The following voltage scaling features allow the power to be controlled with respect to the required system performance (see *Table 55*):

- To obtain a given system performance, the corresponding voltage scaling must be set in accordance with the system clock frequency. To do this, configure VOS bits to the Run mode voltage scaling.
- To obtain the best trade-off between power consumption and latency when exiting Stop mode, configure SVOS bit to Stop mode voltage scaling.

13.6.1 Operating modes

Several system operating modes are available to tune the system according to the performance required (when the CPU does not need to execute code, and waits for an external event). The user must select the operating mode that gives the best compromise between low power consumption, short start-up time, and available wake-up sources.

The operating modes are used to control the clock distribution to the different system blocks, and to power them.

In Run mode, the power consumption can be reduced by one of the following means:

- Lower the system performance by slowing down the system clocks, and reducing the V_{CORE} supply level through VOS voltage scaling bit.
- Gate the clocks to APBx and AHBx peripherals when they are not used, through PERxEN bits.

Table 55. Operating mode summary

System	Entry	Wake-up	System oscillator	System clock	Peripheral clock	CPU clock	Voltage regulator	PWR_ON
Run	-	-	ON	ON	ON	ON[1]	ON (VOS low/high)	1
Sleep	WFI or return from ISR or WFE[2]	See *Table 56*			ON/OFF[3]			
Stop SVOS high	SVOS + SLEEPDEEP + WFI or return from ISR, WFE, or wake-up source cleared[4]		ON/OFF[5]	OFF		OFF	ON (SVOS high)	
Stop SVOS low	SLEEPDEEP + WFI or return from ISR, WFE, or wake-up source cleared[3]		OFF		OFF		ON (SVOS low)	
Standby	PDDS + SLEEPDEEP + WFI or return from ISR, WFE, or wake-up source cleared[3]	WKUP pins rising or falling edge, RTC alarm (alarm A or alarm B), RTC wake-up event, RTC tamper events, RTC timestamp event, external reset in NRST pin, IWDG reset	OFF	OFF	OFF	OFF	OFF	0[6]

1. The clock is gated in the core in Sleep mode.
2. WFI = wait for interrupt, ISR = interrupt service routine, WFE = wait for event.
3. The CPU subsystem peripherals that have a PERxLPEN bit, operate accordingly.
4. When the CPU is in Stop mode, the last EXTI wake-up source must be cleared by software.
5. When HSI or MSI is used, the state is controlled by HSISTOPEN and MSISTOPEN, otherwise the system oscillator is off.
6. A guaranteed minimum PWR_ON pulse low time can be defined by POPL bits in PWR_CR1.

Table 56. Functionalities depending on system operating mode

1. Legend: Y = Yes (enable). O = Optional (disable by default. Can be enabled by software). R = data/state retained. -= not available.
2. Only the first 80 Kbytes can optionally be retained (see *Section 10: SRAM configuration controller (RAMCFG)* for details).
3. Only the first 64 Kbytes can optionally be retained (see *Section 10: SRAM configuration controller (RAMCFG)* for details).

Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop or Standby mode while debug features are used (the Cortex-M55 core is no longer clocked or powered).

However, by setting some configuration bits in DBGMCU control registers, the software can be debugged even when using the low-power modes extensively. For more details, refer to *Debug and low-power modes*.

13.6.2 Voltage scaling

The V_{CORE} domain is supplied from a single voltage regulator that supports voltage scaling with the following features:

- Run mode voltage scaling
  - VOS low
  - VOS high
- Stop mode voltage scaling
  - SVOS low
  - SVOS high

For more details on voltage scaling values, refer to the product datasheets.

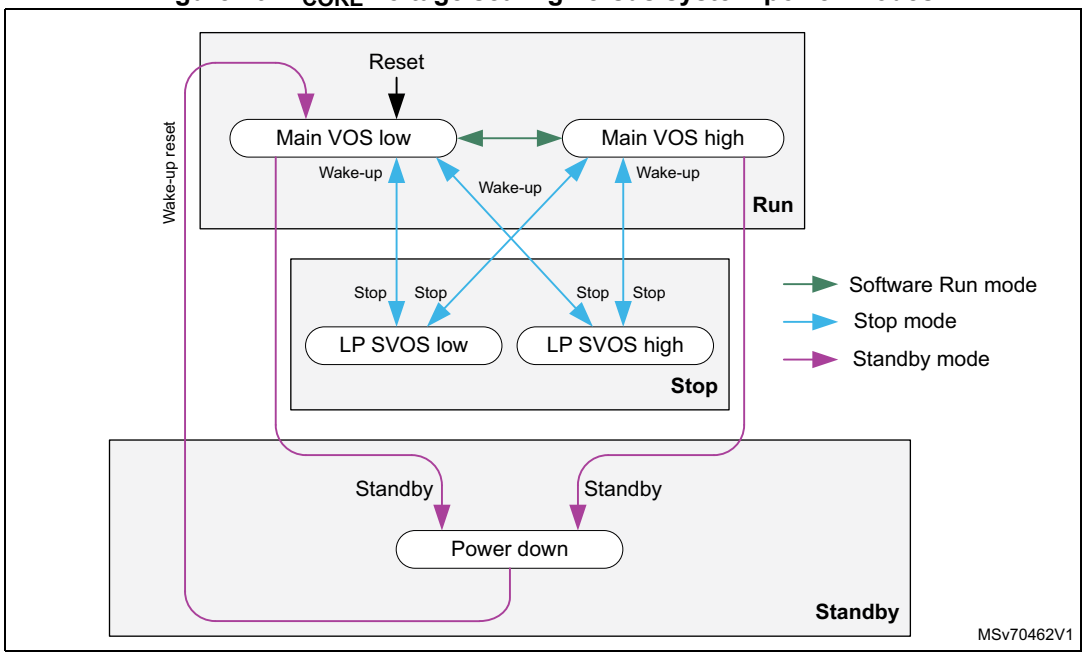
When using the internal SMPS step-down converter, after reset, the system starts on the lowest Run mode voltage scaling (VOS low). The voltage scaling can be changed on-the-fly by programming VOS in PWR_VOSCR, according to the required system performance.

Before entering Stop mode, the software can preselect the SVOS level in PWR_CPUCR. The Stop mode voltage scaling for SVOS low and SVOS high also sets the voltage regulator in low-power mode, to further reduce power consumption.

When exiting Stop mode, the MCU is in Run mode same range as before entering Stop mode. When exiting Standby mode, the Run mode voltage scaling is reset to the default VOS low value.

In Standby mode, the V_{CORE} supply is switched off.

Figure 29. V_{CORE} voltage scaling versus system power modes



13.6.3 Power management examples

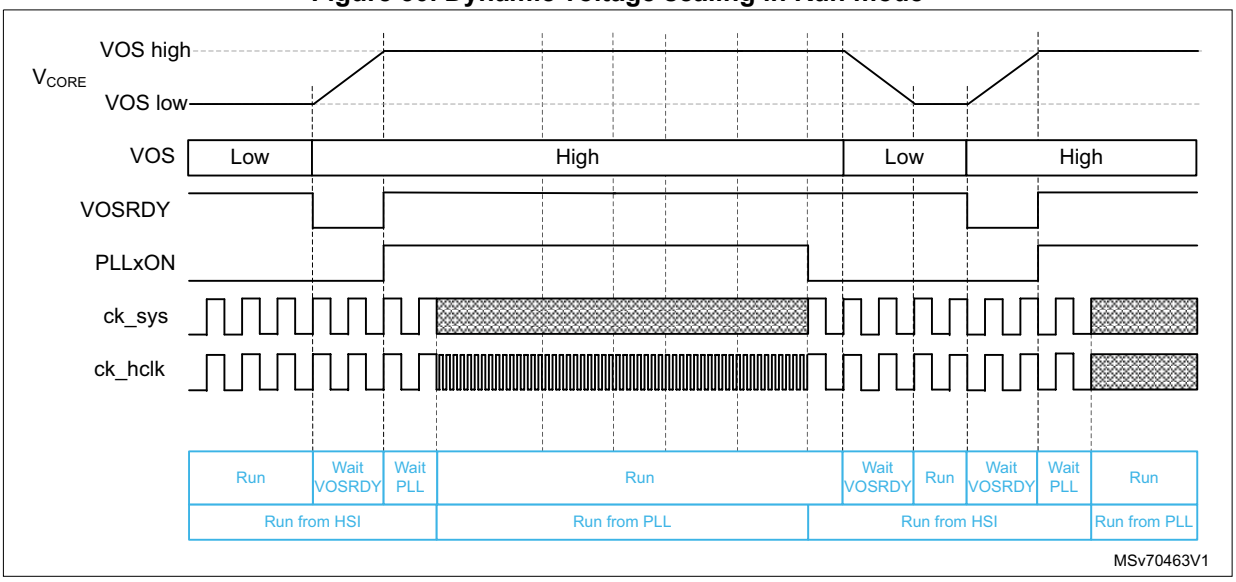
Example of V_{CORE} voltage scaling behavior in Run mode

Figure 30 illustrates the following system operation sequence example:

1. After reset, the system starts from HSI with VOS low.
2. The system performance is then increased to a high-speed clock from the PLL with voltage scaling VOS high. To do this:
   a) Program the voltage scaling to VOS high.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.
3. Reduce the system performance to HSI clock with voltage scaling VOS low. To do this:
   a) Switch the clock to HSI.
   b) Disable the PLL.
   c) Decrease the voltage scaling to VOS low.
4. The system performance can then be increased to high-speed clock from the PLL. To do this:
   a) Program the voltage scaling to VOS high.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS must be set accordingly.

Figure 30. Dynamic voltage scaling in Run mode



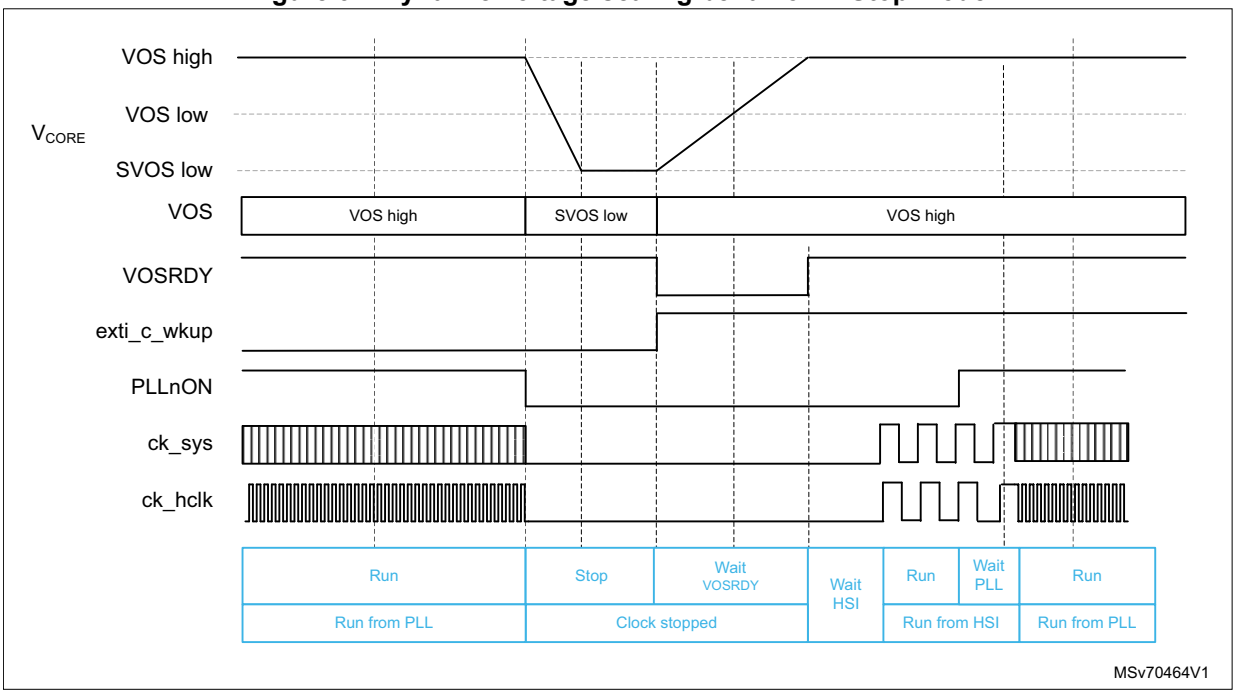
1. The status of the register bits at each step is shown in blue.

Example of V_{CORE} voltage scaling behavior in Stop mode

Figure 31 illustrates the following system operation sequence example:

1. The system runs from the PLL in high-performance mode (VOS high voltage scaling).
2. The CPU subsystem enters Stop mode, and the system enters Stop mode. The system clock is stopped, and the hardware lowers the voltage scaling to the software preselected SVOS low.
3. The CPU subsystem is then woken up. The system exits Stop mode, and the CPU subsystem exits Stop mode. The hardware always sets the same voltage range as before entering Stop mode, and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock is enabled and switch in Run mode under HSI clock.
4. The clock frequency can be increased by enabling the PLL. Once the PLL is locked, the system clock can be switched.

Figure 31. Dynamic voltage scaling behavior in Stop mode



1. The status of the register bits at each step is shown in blue.

Example of V_{CORE} voltage regulator and voltage scaling behavior in Standby mode

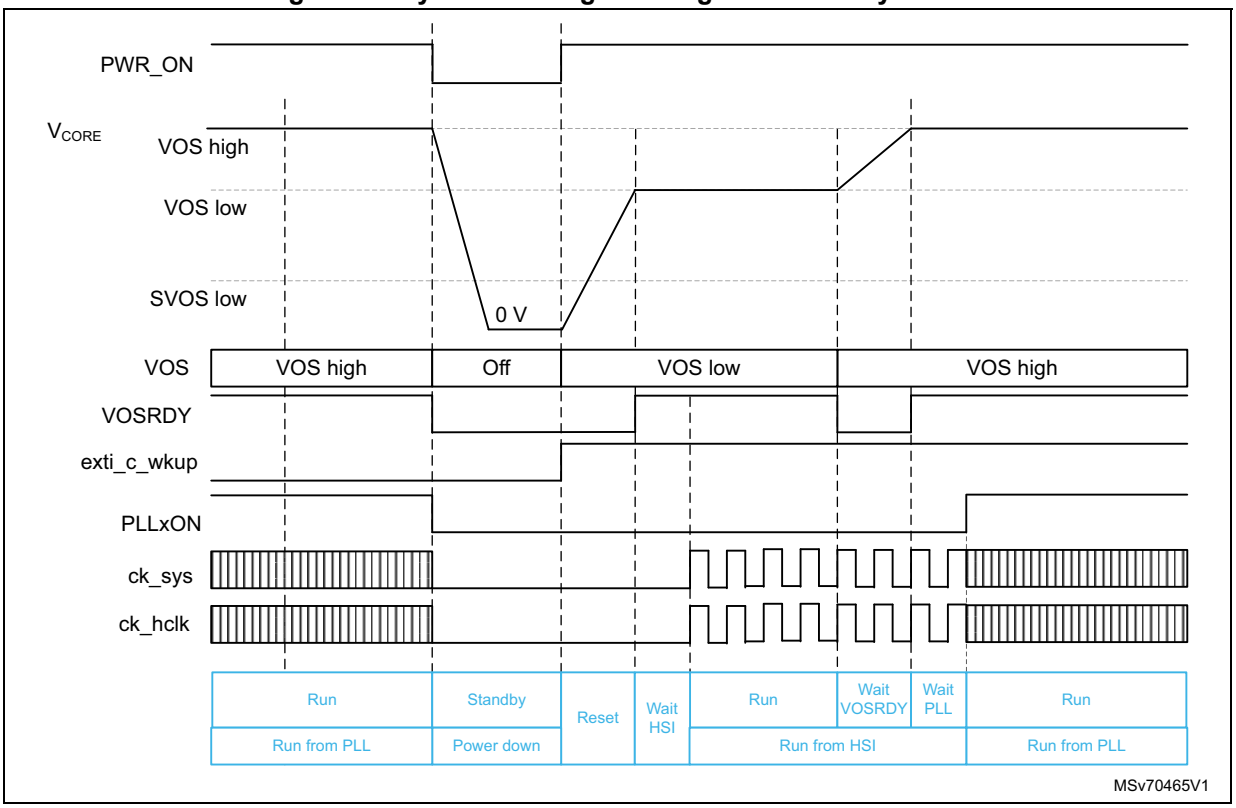
Figure 32 illustrates the following system operation sequence example:

1. The system runs from the PLL in high-performance mode (VOS high voltage scaling).
2. The CPU subsystem deallocates all the peripherals, and the V_{CORE} supply is switched off. The system enters Standby mode. The PWR_ON signal request $V_{DDA18PMU}$ and V_{DDSMPS} supplies to be powered off. If needed, a guarantee minimum PWR_ON pulse low time can be defined by POPL bits in PWR_CR1.
3. On a wake-up event, the external regulator suppling $V_{DDA18PMU}$ and V_{DDSMPS} is requested, via the PWR_ON signal. The system exits Standby mode. The hardware sets the voltage scaling to the default VOS low, and waits for the requested supply level

to be reached before enabling the default HSI oscillator. Once the HSI clock is stable, the system clock is enabled.

4. In a next step, increase the system performance with the following:
   a) The software first increases the voltage scaling to VOS high.
   b) Before enabling the PLL, the software waits for the requested supply level to be reached by monitoring VOSRDY.
   c) Once the PLL is locked, the system clock can be switched.

Figure 32. Dynamic Voltage Scaling from Standby mode



1. The status of the register bits at each step is shown in blue.

13.7 Low-power modes

Several low-power modes are available to save power when the CPU does not need to execute code (when waiting for an external event). The user must select the mode that gives the best compromise between low power consumption, short start-up time, and available wake-up sources:

- slowing down system clocks (see *Section 14.6.6: System clocks*)
- controlling individual peripheral clocks (see *Section 14.6.11: Peripheral clock-gating control*)
- low-power modes
  - Sleep (CPU clock stopped and still in Run mode)
  - Stop (system clock stopped)
  - Standby (system powered down)

13.7.1 Slowing down system clocks

In Run mode, the speed of the system clocks sys[a,b,c,d]_ck can be reduced. For more details, refer to *Section 14.6.6: System clocks*.

13.7.2 Controlling peripheral clocks

In Run mode, the peripherals bus clock can be stopped by configuring at any time PERxEN in RCC_xxxxENR to reduce power consumption.

To reduce power consumption in Sleep mode, the individual peripheral clocks can be disabled by configuring PERxLPEN bit in RCC_xxxxLPENR. For the peripherals still receiving a clock in Sleep mode, their clock can be slowed down before entering Sleep mode.

Example: For APB2 peripherals, the RCC register is RCC_APB2ENR, which contains bits like SPI4EN or SAI1EN.

13.7.3 Entering low-power modes

CPU subsystem Sleep and Stop modes are entered by the device when executing WFI or WFE instructions, or when SLEEPONEXIT is set on return-from-ISR in the Cortex-M55 System Control register.

The system can enter Stop or Standby mode when all EXTI wake-up sources are cleared.

13.7.4 Exiting low-power modes

The CPU subsystem exits Sleep mode through any interrupt or event; depending on how the low-power mode was entered:

- If the WFI instruction or return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the system.
- If the WFE instruction is used to enter the low-power mode, the CPU exits the low-power mode as soon as an event occurs. The wake-up event can be generated by:
  - an NVIC IRQ interrupt

    When SEVONPEND = 0 in the Cortex-M55 System Control register, the interrupt must be enabled in the peripheral control register, and in the NVIC.

    When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit in the NVIC interrupt clear pending register, have to be cleared. Only NVIC interrupts with sufficient priority wake up and interrupt the MCU.

    When SEVONPEND = 1 in the Cortex-M55 System Control register, the interrupt must be enabled in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and, when enabled, the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

    All NVIC interrupts wake up the MCU, even the disabled ones.

    Only enabled NVIC interrupts with sufficient priority wake-up and interrupt the MCU.
  - an event

    An EXTI line must be configured in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI interrupt pending bit or the NVIC IRQ

channel pending bit, as pending bit corresponding to the event line is not set. The interrupt flag may have to be cleared in the peripheral.

The CPU subsystem exits Stop mode by enabling an EXTI interrupt or event depending on how the low-power mode was entered (see above).

The CPU subsystem exits Standby mode by enabling an external reset (NRST pin), an IWDG reset, an enabled WKUPx pin, or an RTC event.

Program execution restarts as after a system reset by fetching the vector tables in SYSCFG_INITSVTORCR and SYSCFG_INITNSVTORCR registers.

The default boot address can be changed to allow a fast restart on TCM when exiting a low power mode. The content of the vector table registers is maintained in Standby mode.

13.7.5 Sleep mode

The Sleep mode applies only to the CPU subsystem. In Sleep mode, the CPU clock is stopped. The CPU subsystem peripheral clocks operate according to the values of PERxLPEN bits in RCC_xxxxLPENR.

Entering Sleep mode

This mode is entered according to *Section 13.7.3*, when SLEEPDEEP bit in Cortex-M55 System Control register is cleared. Refer to *Table 57* for details on how to enter Sleep mode.

Exiting Sleep mode

The Sleep mode is exited according to *Section 13.7.4*. Refer to the table below for more details on how to exit Sleep mode.

Table 57. Sleep mode

Sleep mode	Description
Mode entry	WFI or WFE while: – SLEEPDEEP = 0 (refer to the Cortex-M55 System Control register) – CPU NVIC interrupts and events cleared
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 (refer to the Cortex-M55 System Control register) – CPU NVIC interrupts and events cleared
Mode exit	If WFI or return from ISR was used for entry: – any interrupt enabled in NVIC (see *Table 135: STM32N6x7xx vector table*) If WFE was used for entry and SEVONPEND = 0: – any event (see *Section 25: Extended interrupts and event controller (EXTI)*) If WFE was used for entry and SEVONPEND = 1: – any interrupt even when disabled in NVIC (see *Table 135: STM32N6x7xx vector table*) or any event (see *Section 25: Extended interrupts and event controller (EXTI)*
Wake-up latency	None

13.7.6 Stop mode

The Stop mode applies to the MCU. In Stop mode, the CPU clock is stopped. All CPU subsystem peripheral clocks are stopped too, and only the CPU subsystem peripherals having a PERxLPEN bit operate accordingly.

In Stop mode, CPU subsystem peripherals having a kernel clock request can still request their kernel clock. For the peripheral having a PERxLPEN bit, this bit must be set to be able to request the kernel clock.

HSI or MSI can remain enabled in system Stop mode (HSISTOPEN and MSISTOPEN set in RCC_STOPCR). After exiting Stop mode, the clock is quickly available as kernel clock for peripherals. Other system oscillator sources are stopped in Stop mode, and require a starting time after exiting Stop mode.

In Stop mode and SVOS high, peripherals using the LSI or LSE clock, and peripherals having a kernel clock request, are still able to operate.

In system Stop mode, the following features can be selected to remain active by programming individual control bits:

- independent watchdog (IWDG)

  The IWDG is started by writing to its key register or by hardware option. Once started, it cannot be stopped except by a reset (see *Section 59: Independent watchdog (IWDG)*.
- real-time clock (RTC) that is configured via RTCEN in RCC_BDCR
- internal RC oscillator (LSI RC) that is configured via LSION in RCC_CSR
- external 32.768 kHz oscillator (LSE OSC) that is configured via LSEON in RCC_CSR.
- peripherals capable of running on the LSI or LSE clock
- peripherals having a kernel clock request
- internal RC oscillators (HSI and MSI) that are configured via HSISTOPEN and MSISTOPEN in RCC_STOPCR
- The ADCs can also consume power during Stop mode, unless they are disabled before entering this mode. To disable them, ADON bit in ADC_CR2 must be written to 0.

The selected SVOS low levels add an additional start-up delay when exiting from system Stop mode.

Entering Stop mode

The Stop mode is entered according to *Section 13.7.3*, when SLEEPDEEP bit in the Cortex-M55 System Control register is set.

The low-power mode security filter must be disabled by system option bytes (NRST_STOP) to enter Stop mode. Refer to *Section 14.5.4: Low-power mode security reset (lpwr_rst)* for details.

Refer to the tables below for details on how to enter to Stop mode.

Table 58. Stop mode SVOS high

Stop mode	Description
Mode entry	WFI or WFE while: SLEEPDEEP = 1 (refer to the Cortex-M55 System Control register) CPU NVIC interrupts and events cleared All CPU EXTI wake-up sources cleared
	On return from ISR while: SLEEPDEEP = 1 and SLEEPONEXIT = 1 (refer to the Cortex-M55 System Control register) CPU NVIC interrupts and events cleared All CPU EXTI wake-up sources cleared
Mode exit	If WFI or return from ISR was used for entry: EXTI interrupt enabled in NVIC (see *Table 135: STM32N6x7xx vector table*, for peripheral that are not stopped or powered down) If WFE was used for entry and SEVONPEND = 0: EXTI event: Refer to *Section 25: Extended interrupts and event controller (EXTI)* for peripheral that are not stopped or powered down. If WFE was used for entry and SEVONPEND = 1: EXTI Interrupt even when disabled in NVIC: refer to *Table 135: STM32N6x7xx vector table* or EXTI event: refer to *Section 25: Extended interrupts and event controller (EXTI)* for peripheral that are not stopped or powered down.
Wake-up latency	SMPS wake-up time from low-power mode (Run mode operating supply level to restore) + EXTI and RCC wake-up synchronization (see *Section 14: Reset and clock control (RCC)*)

Table 59. Stop mode SVOS low

Stop mode	Description
Mode entry	WFI or WFE while: SLEEPDEEP = 1 (refer to the Cortex-M55 System Control register) CPU NVIC interrupts and events cleared All CPU EXTI wake-up sources cleared
	On return from ISR while: SLEEPDEEP = 1 and SLEEPONEXIT = 1 (refer to the Cortex-M55 System Control register) CPU NVIC interrupts and events cleared All CPU EXTI wake-up sources cleared

Table 59. Stop mode SVOS low (continued)

Stop mode	Description
Mode exit	WKUP pins rising or falling edge, RTC alarm (alarm A and alarm B), RTC wake-up, tamper event, timestamp event, external reset in NRST pin, IWDG reset
Wake-up latency	SMPS wake-up time from low-power mode (Run mode operating supply level to restore) + EXTI and RCC wake-up synchronization (see *Section 14.5.12: Power-on and wake-up sequences*)

To allow peripherals having a kernel clock request to operate in Stop mode, the system must use SVOS high.

Note: Use a DSB instruction to ensure that outstanding memory transactions complete before entering Stop mode.

Exiting Stop mode

The Stop mode is exited according to *Section 13.7.4*.

Refer to *Table 58* and *Table 59* for more details on how to exit Stop mode.

When exiting Stop mode, the MCU is in Run mode same range as before entering Stop mode. The system starts on HSI or MSI.

STOPF status flag in PWR_CPUCR indicates that the system exited Stop mode.

I/O states in Stop mode

I/O pin configuration remains unchanged in Stop mode.

13.7.7 Standby mode

The Standby mode is used to achieve the lowest power consumption. Like Stop mode, it is based on CPU subsystem Stop mode. However, the V_{CORE} supply regulator is powered off.

When the system enters Standby mode, the voltage regulator is disabled. The complete V_{CORE} domain is consequently powered off. PLLs, HSI oscillator, MSI oscillator, and HSE oscillator are also switched off. SRAM and register contents are lost except for backup domain registers (RTC registers, RTC backup register, and backup RAM), and the retention domain (see *Section 13.4.4* and *Section 13.4.5*).

In system Standby mode, the following features can be selected by programming individual control bits:

- independent watchdog (IWDG)

  The IWDG is started by programming its key register or by hardware option. Once started, it cannot be stopped except by a reset (see *Section 42.3* in IDWG).
- real-time clock (RTC) that is configured via RTCEN in RCC_BDCR
- internal RC oscillator (LSI RC) that is configured by LSION in RCC_CSR
- External 32.768 kHz oscillator (LSE OSC) that is configured by LSEON in RCC_CSR

Entering Standby mode

The Standby mode is entered according to *Section 13.7.3*, when PDDS is set to one in PWR_CPUCR.

The low-power mode security filter must be disabled by system option bytes (nRST_STDBY) to enter in Standby mode. Refer to *Section 14.5.4: Low-power mode security reset (lpwr_rst)* for details.

Refer to *Table 61* for more details on how to enter Standby mode.

Exiting Standby mode

The Standby mode is exited according to *Section 13.7.4*.

The system exits Standby mode when an external reset (NRST pin), an IWDG reset, a WKUP pin event, an RTC alarm, a tamper event, or a timestamp event is detected.
All registers are reset after waking up from Standby except for power control and status registers:

- PWR_CR1, PWR_CR4, PWR_BDCR1, PWR_BDCR2
- SBF and PDDS in PWR_CPUCR
- VDDIO4VRSTBY and VDDIO4VRSEL in PWR_SVMCR1
- VDDIO5VRSTBY and VDDIO5VRSEL in PWR_SVMCR2
- VDDIOxVRSEL in PWR_SVMCR3
- PWR_WKUPCR, PWR_WKUPSR, PWR_WKUPEPR

A pad or watchdog reset during Standby mode causes the program execution to start as after an application reset (rerun the boot ROM).

An enabled WKUP pin or an RTC event during Standby mode causes the program execution to start as after a system reset (fetch from SYSCFG_INITSVTORCR)

The default boot address can be changed to allow a fast restart on TCM when exiting a low power mode.

Refer to *Table 61* for more details on how to exit Standby mode.

SBF in PWR_CPUCR indicates that the system has exited Standby mode.

Table 60. Standby and Stop flags

SBF	STOPF	Description
0	1	System has been in Stop mode.
1	0	System has been in Standby mode.

Table 61. Standby mode

Standby mode	Description
Mode entry	The CPU subsystem is in Stop mode, and there is no active EXTI wake-up source. PDDS bit for select Standby All WKUPF bits in PWR_WKUPSR cleared
Mode exit	WKUP pins rising or falling edge, RTC alarm (alarm A and alarm B), RTC wake-up, tamper event, timestamp event, external reset in NRST pin, IWDG reset
Wake-up latency	System reset phase (see *Section 14.5.2: System and application resets (sys_rst, nreset_rstn)*)

I/O states in Standby mode

In Standby mode, all I/O pins are high impedance without pull, except for:

- RESET and PWR_ON pins (still available)
- RTC_AF1 pin if configured for tamper, time stamp, RTC alarm out, or RTC clock calibration out
- WKUP pins (if enabled): WKUP pin pull configuration can be defined through WKUPPUPD bits in PWR_WKUPEPR

13.7.8 Power mode output pins

To help the debug, the following signals are available as alternate functions:

- PWR_CSLEEP

  When set, PWR_CSLEEP indicates that the CPU is in Sleep mode:

  – WFI or WFE has been executed, and CPU stops execution.

  When cleared, PWR_CSLEEP indicates that the CPU is in Run mode.
- PWR_CSTOP

  When set, PWR_CSTOP indicates that the device is in Stop mode, meaning that the following conditions are true:

  – WFI or WFE has been executed with CPU SLEEPDEEP = 1.

  When cleared, PWR_CSTOP indicates that the device is in Run mode.

Table 62. Power mode output states versus MCU power modes

PWR_CSTOP	PWR_CSLEEP	MCU power modes(1)
X	0	Run mode (CPU executing)
0	1	Sleep mode (CPU sleep)
1	1	Stop mode (CPU SleepDeep)

1. PWR_CSLEEP and PWR_CSTOP are generated in the core domain, then they are not driven in Standby mode.

13.8 PWR security and privileged protection

After any application reset or system reset, the PWR does not filter any access (default configuration: nonsecure, any privileged) until the trusted agent has programmed the security and privileged protection.

The PWR is able to protect register bits from being modified by nonsecure and unprivileged accesses. The protection can be activated for the following features through PWR_SECCFGR and PWR_PRIVCFGR:

- system supply configuration
- voltage scaling
- low-power mode
- wake-up (WKUP) pins
- voltage detection and monitoring
- V_{BAT} mode

Table 63 summarizes the security and privilege configuration bits.

Table 63. PWR register security overview

PWR register	Secure/privilege configuration bit	Access type(1)	Description
PWR_CR1	PWR_SECCFGR.SEC[0] PWR_PRIVCFGR.PRIV[0]	RW/RWO	System supply configuration
PWR_CR2	PWR_SECCFGR.SEC[1] PWR_PRIVCFGR.PRIV[1]	RW	Programmable voltage detector
PWR_CR3	PWR_SECCFGR.SEC[2] PWR_PRIVCFGR.PRIV[2]	RW	V_{DDCORE} monitor
PWR_CR4	PWR_SECCFGR.SEC[3] PWR_PRIVCFGR.PRIV[3]	RW	I-TCM, D-TCM, and I-TCM FLEX MEM low-power control
PWR_VOSCR	PWR_SECCFGR.SEC[4] PWR_PRIVCFGR.PRIV[4]	RW	Voltage scaling selection
PWR_BDCR1	PWR_SECCFGR.SEC[5] PWR_PRIVCFGR.PRIV[5]	RW	V_{BAT} and temperature monitor
PWR_BDCR2		RW	BKPSRAM low-power control
PWR_DBPCR		RW	Disable backup domain write protection
PWR_CPUCR	PWR_SECCFGR.SEC[6] PWR_PRIVCFGR.PRIV[6]	RW	CPU power control
PWR_SVMCR1	PWR_SECCFGR.SEC[7] PWR_PRIVCFGR.PRIV[7]	RW	V_{DDIO4} peripheral voltage monitor
PWR_SVMCR2		RW	V_{DDIO5} peripheral voltage monitor
PWR_SVMCR3		RW	V_{DDIO2}, V_{DDIO3}, $V_{DD33USB}$, and $V_{DDA18ADC}$ peripheral voltage monitor
PWR_WKUPCR	PWR_SECCFGR.WKUPSEC[x] PWR_PRIVCFGR.WKUPPRIV[x] (X = 1 to 4)	W	Wake-up pin x (x = 1 to 4) clear register
PWR_WKUPSR		R	Wake-up pin x (x = 1 to 4) status register
PWR_WKUPEPR		RW	Wake-up pin x (x = 1 to 4) enable and polarity register

1. RW: read or write, R: read, W: write, RWO: read or write once.
   RC_W0: read or clear by writing 0. Writing 1 has no effect on the bit value.

13.8.1 Secure/nonsecure access filtering

To enable the filtering access based on this attribute, the authorized master agent must set SECx in PWR_SECCFGR related to the PWR feature.

When a register is configured as secure, read and write operations are allowed only by a secure access. Nonsecure read or write accesses are denied (RAZ/WI).

An illegal secure access event is generated to the IAC (illegal access controller). There is no bus error generated.

When a register is configured as nonsecure, read and write operations are allowed by both secure and nonsecure accesses.

13.8.2 Privileged/unprivileged access filtering

To enable the filtering access based on this attribute, the authorized master agent has to set PRIVx in PWR_PRIVCFGR related to the PWR feature.

When a register is configured as privileged, read and write operations are only allowed by a privileged access. Unprivileged read or write accesses are denied (RAZ/WI). An illegal privileged access event is generated to the IAC. There is no bus error generated.

When a register is configured as unprivileged, read and write operations are allowed by both privileged and unprivileged accesses.

13.9 PWR registers

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

13.9.1 PWR control register 1 (PWR_CR1)

Address offset: 0x000

Reset value: 0x0000 002X

This register is not reset by wake-up from Standby mode and application reset (such as NRST or IWDG), but only reset by V_{DD} POR.

Secure restriction is defined by SEC0 in PWR_SECCFGR. Privileged restriction is defined by PRIV0 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	POPL[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LPDS08V	MODE_PDN	Res.	SDEN	Res.	Res.
										rw	rw		rwo		

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **POPL[4:0]**: pwr_on pulse low configuration.

These bits are set and cleared by software. They define the minimum guaranteed duration of the pwr_on low pulse in Standby mode. The LSI oscillator is automatically enabled when needed by the POPL pulse low configuration.

00000: No guaranteed minimum low time

00001: ~ 1 ms guaranteed minimum low time (1 x 32 LSI cycles)

00010: ~ 2 ms guaranteed minimum low time (2 x 32 LSI cycles)

...

11111: ~ 31 ms guaranteed minimum low time (31 x 32 LSI cycles)

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **LPDS08V:** SMPS low-power mode enable (SVOS high only)

This bit is used to keep the SMPS in PWM mode (MR) in Stop SVOS high.

0: SMPS low-power mode disabled

1: SMPS low-power mode enabled (high-efficiency mode) (default)

Bit 4 **MODE_PDN**: Enables the pull down on output voltage during power-down mode
0: Pull-down disabled. The output is in high impedance during the shutdown (default).
1: Pull-down enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SDEN**: SMPS step-down converter enable
0: SMPS step-down converter disabled
1: SMPS step-down converter enabled (default)
This bit must be written as soon as possible after device start, and it can be written only once after POR.
When in bypass mode, SMPS is off, reading this bit returns 0, Write it to 0 as soon as possible after POR, or it will be impossible to enter low power modes. When SMPS is on, reading this bit returns 1 (default).

Bits 1:0 Reserved, must be kept at reset value.

13.9.2 PWR control register 2 (PWR_CR2)

Address offset: 0x004

Reset value: 0x0000 0000

Reset on any system reset.

Secure restriction is defined by SEC1 in PWR_SECCFGR. Privilege restriction is defined by PRIV1 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDO	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDEN
							r								rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **PVDO**: Programmable voltage detect output
This bit is set and cleared by hardware. It is valid only if PVD is enabled by PVDEN.
0: Voltage level on PVD_IN is equal or higher than the internal VREFINT.
1: Voltage level on PVD_IN is lower than the internal VREFINT.
Note: The PVD is disabled in Standby mode, and after a system reset. For this reason, this bit is equal to 0 after Standby and system reset.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **PVDEN:** Programmable voltage detector enable
This bit is read only when PVDL is set in SYSCFG_CBR (when PVDL is set, there is no bus errors generated when writing this register).
0: PVD disabled
1: PVD enabled

13.9.3 PWR control register 3 (PWR_CR3)

Address offset: 0x008

Reset value: 0x0000 0000

Reset on any system reset.

Secure restriction is defined by SEC2 in PWR_SECCFGR. Privilege restriction is defined by PRIV2 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	VCOREH	VCOREL	Res.	Res.	Res.	VCORELLS	Res.	Res.	Res.	VCOREMONEN
						r	r				rw				rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **VCOREH**: Monitored V_{DDCORE} level above high threshold

0: V_{DDCORE} level below high threshold level, or monitor disabled

1: V_{DDCORE} level equal or above high threshold level

Bit 8 **VCOREL**: Monitored V_{DDCORE} level above low threshold

0: V_{DDCORE} level above low threshold level, or monitor disabled

1: V_{DDCORE} level equal or below low threshold level

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **VCORELLS**: V_{DDCORE} voltage detector low-level selection

This bit selects the low-voltage threshold detected by the monitoring.

0: V_{DDCORE} low-voltage threshold 1 selected (VOS low)

1: V_{DDCORE} low-voltage threshold 2 selected (VOS high)

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **VCOREMONEN:** V_{DDCORE} monitoring enable

When this bit is set, the V_{DDCORE} supply monitoring is enabled.

0: V_{DDCORE} monitoring disabled

1: V_{DDCORE} monitoring enabled

13.9.4 PWR control register 4 (PWR_CR4)

Address offset: 0x00C

Reset value: 0x0000 0000

This register is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG). Access 6 wait states when writing this register.

When a system reset occurs during the register write cycle, the written data are not guaranteed.

Secure restriction is defined by SEC3 in PWR_SECCFGR. Privilege restriction is defined by PRIV3 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TCMFLXRBSEN	Res.	Res.	Res.	TCMRBSEN
											rw				rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **TCMFLXRBSEN:** I-TCM FLEXMEM backup supply enable (used to maintain I-TCM FLEX MEM content in Standby mode)

When this bit is set, the I-TCM FLEXMEM is supplied from backup regulator in Standby mode. When this bit is reset, the I-TCM FLEXMEM can still be used in Run and Stop modes, but its content is lost in Standby mode.

0: I-TCM FLEXMEM backup supply disabled

1: I-TCM FLEXMEM backup supply enabled in Standby mode

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TCMRBSEN:** I-TCM and D-TCM RAMs backup supply enable (used to maintain TCM RAMs content in Standby mode)

When this bit is set, I-TCM and D-TCM RAMs are supplied from backup regulator in Standby mode. When this bit is reset, I-TCM and D-TCM RAMs can still be used in Run and Stop modes, but their content is lost in Standby mode.

0: I-TCM and D-TCM RAMs backup supply disabled

1: I-TCM and D-TCM RAMs backup supply enabled in Standby mode

13.9.5 PWR voltage scaling control register (PWR_VOSCR)

Address offset: 0x020

Reset value: 0x0002 0002

Reset on any system reset.

Secure restriction is defined by SEC4 bit in PWR_SECCFGR. Privilege restriction is defined by PRIV4 bit in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACTVOSRDY	ACTVOS
														r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VOSRDY	VOS
														r	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **ACTVOSRDY**: Voltage level ready bit for currently used ACTVOS
This bit is set to 1 by hardware when the SMPS step-down converter is disabled in PWR_CR1.
0: Voltage level invalid, above or below current ACTVOS
1: Voltage level valid, at current ACTVOS

Bit 16 **ACTVOS**: VOS currently applied for V_{CORE} voltage scaling selection
When the SMPS step-down converter is disabled, this bit is tied to 0, when the converter is enabled, this bit reflects the last VOS value applied to the PMU.
0: VOS low
1: VOS high

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **VOSRDY**: VOS ready bit for V_{CORE} voltage scaling output selection
When the internal SMPS step-down converter is used, this bit indicates that all features allowed by the selected VOS can be used.
This bit is set to 1 by hardware when the SMPS step-down converter is disabled in PWR_CR1.
0: Not ready, voltage level below VOS selected level
1: Ready, voltage level at or above VOS selected level

Bit 0 **VOS**: Voltage scaling selection according to performance
When the SMPS step-down converter is disabled, this bit has no impact on the external supply voltage. It can be read/written to keep track of the external supply voltage setting.
When the SMPS step-down converter is enabled this bit controls the V_{CORE} voltage level, and is used to obtain the best trade-off between power consumption and performance:
– When increasing the performance, the voltage scaling must be changed before increasing the system frequency.
– When decreasing performance, the system frequency must be decreased before changing the voltage scaling.
0: VOS low level (default)
1: VOS high level

Note: Refer to electrical characteristics in the datasheet for more details.

13.9.6 PWR backup domain control register 1 (PWR_BDCR1)

Address offset: 0x024

Reset value: 0x0000 0000

This register is not reset by wake-up from Standby mode, application reset (such as NRST or IWDG), or V_{DD} POR, but it only by V_{SW} POR and VSWRST.

This register must not be accessed when VSWRST in RCC_BDCR resets the V_{SW} domain.

After reset, PWR_BDCR1 is write-protected. Prior to modifying its content, DBP must be set in PWR_DBPCR to disable the write protection.

Secure restriction is defined by SEC5 in PWR_SECCFGR. Privilege restriction is defined by PRIV5 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MONEN
															rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **TEMPH**: Temperature level monitoring versus high threshold
0: Temperature below high threshold level
1: Temperature equal or above high threshold level

Bit 18 **TEMPL**: Temperature level monitoring versus low threshold
0: Temperature above low threshold level
1: Temperature equal or below low threshold level

Bit 17 **V08CAPH**: V_{08CAP} level monitoring versus high threshold
0: V_{BAT} level below high threshold level.
1: V_{BAT} level equal or above high threshold level

Bit 16 **V08CAPL**: V_{08CAP} level monitoring versus low threshold
0: V_{BAT} level above low threshold level
1: V_{BAT} level equal or below low threshold level

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MONEN:** V_{BAT} and temperature monitoring enable
When this bit is set, the V_{BAT} supply and temperature monitoring are enabled.
0: V_{BAT} and temperature monitoring disabled
1: V_{BAT} and temperature monitoring enabled

13.9.7 PWR backup domain control register 2 (PWR_BDCR2)

Address offset: 0x028

Reset value: 0x0000 0000

This register is not reset by wake-up from Standby mode, application reset (such as NRST or IWDG), or V_{DD} POR, but it is only reset by V_{SW} POR and VSWRST.

This register must not be accessed when VSWRST in RCC_BDCR resets the V_{SW} domain.

After reset, PWR_BDCR2 is write-protected. Prior to modifying its content, DBP must be set in PWR_DBPCR register to disable the write protection.

Secure restriction is defined by SEC5 in PWR_SECCFGR. Privilege restriction is defined by PRIV5 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BKPRBSEN
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **BKPRBSEN:** BKPSRAM backup supply enable (used to maintain BKPSRAM content in Standby and V_{BAT} modes).

When this bit is set, the backup ram is supplied from backup regulator in Standby and V_{BAT} modes. When this bit is reset, the backup ram can still be used in Run and Stop modes, but its content is lost in Standby and V_{BAT} modes.

0: BKPSRAM backup supply disabled

1: BKPSRAM backup supply enabled

13.9.8 PWR disable backup protection control register (PWR_DBPCR)

Address offset: 0x02C

Reset value: 0x0000 0000

Reset on any system reset

Secure restriction is defined by SEC5 in PWR_SECCFGR. Privilege restriction is defined by PRIV5 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **DBP*:*** Disable backup domain write protection

In reset state, all registers and SRAM in backup domain are protected against parasitic write access. This bit must be set to enable write access to these registers.

0: Write access to backup domain disabled

1: Write access to backup domain enabled

13.9.9 PWR CPU control register (PWR_CPUCR)

Address offset: 0x030

Reset value: 0x0001 0000

See individual bits for reset condition. Access six wait states when writing this register.

When a system reset occurs during the register write cycle, the written data are not guaranteed.

Secure restriction is defined by SEC6 in PWR_SECCFGR. Privilege restriction is defined by PRIV6 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	SBF	STOPF	Res.	Res.	Res.	Res.	Res.	Res.	CSSF	PDDS
						r	r							rc_w1	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SVOS**: System Stop mode voltage scaling selection
This bit is reset on any system reset.
0: SVOS low
1: SVOS high (default)

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **SBF**: Standby flag
This bit is set by hardware and cleared only by a POR or by setting the CSSF bit.
0: System has not been in Standby mode.
1: System has been in Standby mode.

Bit 8 **STOPF**: Stop flag
This bit is set by hardware and cleared by any reset, or by setting the CSSF bit.
0: System has not been in Stop mode.
1: System has been in Stop mode.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CSSF**: Clear Standby and Stop flags (always read as 0)
This bit is reset on any system reset.
0: No effect
1: When written, clears the CPU flags (STOPF, SBF).
Note: This bit is cleared to 0 by hardware.

Bit 0 **PDDS**: Power-down deepsleep selection
This bit is reset only by a V_{DD} POR reset (not reset when exit standby mode). It allows the CPU to define the deepsleep mode for the system.
0: Stop mode when device enters deepsleep
1: Standby mode when device enters deepsleep

13.9.10 PWR supply voltage monitoring control register 1 (PWR_SVMCR1)

Address offset: 0x034

Reset value: 0x0000 0000

See individual bits for reset condition. Access six wait states when writing this register.

When a system reset occurs during the register write cycle, the written data are not guaranteed.

Secure restriction is defined by SEC7 in PWR_SECCFGR. Privilege restriction is defined by PRIV7 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	VDDIO4 SV	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VDDIO4 VMEN
							rw								rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **VDDIO4VRSTBY:** V_{DDIO4} I/O voltage range Standby mode

When this bit is set, the VDDIO4VRSEL configuration is retained in Standby mode.

This bit must be set if the V_{DDIO4} is in 1v8 range in Standby mode, and when exiting Standby mode. It must not be set when V_{DDIO4} is in 3v3 range in Standby mode, or when exiting Standby mode. This bit is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG).

0: VDDIO4VRSEL not retained in Standby mode

1: VDDIO4VRSEL retained in Standby mode

Bit 24 **VDDIO4VRSEL:** V_{DDIO4} I/O voltage range selection

This bit is used to select the voltage range supported by I/Os supplied by V_{DDIO4}. It is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG), when VDDIO4VRSTBY is set, otherwise this bit is reset on any system reset.

0: 3v3 voltage range selected. If V_{DDIO4} is in 1v8 range with this setting, I/Os work in degraded mode.

1: 1v8 voltage range selected. HSLV_VDDIO4 option bit must be set to allow 1v8 voltage range operation. Setting this configuration while V_{DDIO4} is in 3v3 range damages the device.

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **VDDIO4RDY**: V_{DDIO4} ready

0: V_{DDIO4} is below the threshold of the V_{DDIO4} voltage monitor.

1: V_{DDIO4} is equal or above the threshold of the V_{DDIO4} voltage monitor.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **VDDIO4SV**: V_{DDIO4} independent I/O supply valid.

This bit is used to validate the V_{DDIO4} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use PC[1], PC[12:6], and PH[9:2] I/Os. If V_{DDIO4} is not always present in the application, the V_{DDIO4} voltage monitor can be used to determine whether this supply is ready or not. This bit is reset on any system reset.

0: V_{DDIO4} is not present. Logical and electrical isolation is applied to ignore this supply.

1: V_{DDIO4} is valid.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **VDDIO4VMEN:** V_{DDIO4} independent I/O voltage monitor enable

This bit is reset on any system reset.

0: V_{DDIO4} voltage monitor disabled

1: V_{DDIO4} voltage monitor enabled

13.9.11 PWR supply voltage monitoring control register 2 (PWR_SVMCR2)

Address offset: 0x038

Reset value: 0x0000 0000

See individual bits for reset condition. Access six wait states when writing this register.

When a system reset occurs during the register write cycle, the written data are not guaranteed.

Secure restriction is defined by SEC7 in PWR_SECCFGR. Privilege restriction is defined by PRIV7 in PWR_PRIVCFGR.

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **VDDIO5VRSTBY:** V_{DDIO5} I/O voltage range Standby mode

When this bits is set, VDDIO5VRSEL configuration is retained in Standby mode.

This bit must be set if the V_{DDIO5} is in 1v8 range in Standby mode, and when exiting Standby mode. It must not be set when V_{DDIO5} is in 3v3 range in Standby mode, or when exiting Standby mode. This bit is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG).

0: VDDIO5VRSEL not retained in Standby mode

1: VDDIO5VRSEL retained in Standby mode.

Bit 24 **VDDIO5VRSEL:** V_{DDIO5} I/O voltage range selection

This bit is used to select the voltage range supported by I/Os supplied by V_{DDIO5}. It is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG), when VDDIO5VRSTBY bit is set, otherwise this bit is reset on any system reset.

0: 3v3 voltage range selected. If V_{DDIO5} is in 1v8 range with this setting, I/Os work in degraded mode.

1: 1v8 voltage range selected. HSLV_VDDIO5 option bit must be set to allow 1v8 voltage range operation. Setting this configuration while V_{DDIO5} is in 3v3 range damages the device.

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **VDDIO5RDY**: V_{DDIO5} ready

0: V_{DDIO5} is below the threshold of the V_{DDIO5} voltage monitor.

1: V_{DDIO5} is equal or above the threshold of the V_{DDIO5} voltage monitor.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **VDDIO5SV**: V_{DDIO5} independent supply valid

This bit is used to validate the V_{DDIO5} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use PC[0], PC[5:2] and PE[4] I/Os. If V_{DDIO5} is not always present in the application, the V_{DDIO5} voltage monitor can be used to determine whether this supply is ready or not. This bit is reset on any system reset.

0: V_{DDIO5} is not present. Logical and electrical isolation is applied to ignore this supply.

1: V_{DDIO5} is valid.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **VDDIO5VMEN:** V_{DDIO5} independent voltage monitor enable
This bit is reset on any system reset.
0: V_{DDIO5} voltage monitor disabled
1: V_{DDIO5} voltage monitor enabled

13.9.12 PWR supply voltage monitoring control register 3 (PWR_SVMCR3)

Address offset: 0x03C

Reset value: 0x0000 0000

See individual bits for reset condition. Access six wait states when writing this register.

When a system reset occurs during the register write cycle, the written data are not guaranteed.

Secure restriction is defined by SEC7 in PWR_SECCFGR. Privilege restriction is defined by PRIV7 in PWR_PRIVCFGR.

			rw		rw	rw	rw				rw		rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **VDDIO3VRSEL:** V_{DDIO3} I/O voltage range selection
This bit is used to select the voltage range supported by I/Os supplied by V_{DDIO3}. it is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG).
0: 3v3 voltage range selected. If V_{DDIO3} is in 1v8 range with this setting, I/Os work in degraded mode.
1: 1v8 voltage range selected. HSLV_VDDIO3 option bit must be set to allow 1v8 voltage range operation. Setting this configuration while V_{DDIO3} is in 3v3 range damages the device.

Bit 25 **VDDIO2VRSEL:** V_{DDIO2} I/O voltage range selection
This bit is used to select the voltage range supported by I/Os supplied by V_{DDIO2}. It is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG).
0: 3v3 voltage range selected. If V_{DDIO2} is in 1v8 range with this setting, I/Os work in degraded mode.
1: 1v8 voltage range selected. HSLV_VDDIO2 option bit must be set to allow 1v8 voltage range operation. Setting this configuration while V_{DDIO2} is in 3v3 range damages the device.

Bit 24 **VDDIOVRSEL:** V_{DD} I/O voltage range selection
This bit is used to select the voltage range supported by I/Os supplied by V_{DD}. It is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG).
0: 3v3 voltage range selected. If V_{DD} is in 1v8 range with this setting, I/Os work in degraded mode.
1: 1v8 voltage range selected. HSLV_VDD option bit must be set to allow 1v8 voltage range operation. Setting this configuration while V_{DD} is in 3v3 range damages the device.

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **ARDY**: $V_{DDA18ADC}$ ready
0: $V_{DDA18ADC}$ is below the threshold of the VDDA18ADC voltage monitor.
1: $V_{DDA18ADC}$ is equal or above the threshold of the VDDA18ADC voltage monitor.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **USB33RDY**: $V_{DD33USB}$ ready
0: $V_{DD33USB}$ is below the threshold of the USB33 voltage monitor.
1: $V_{DD33USB}$ is equal or above the threshold of the USB33 voltage monitor.

Bit 17 **VDDIO3RDY**: V_{DDIO3} ready
0: V_{DDIO3} is below the threshold of the VDDIO3 voltage monitor.
1: V_{DDIO3} is equal or above the threshold of the VDDIO3 voltage monitor.

Bit 16 **VDDIO2RDY**: V_{DDIO2} ready
0: V_{DDIO2} is below the threshold of the VDDIO2 voltage monitor.
1: V_{DDIO2} is equal or above the threshold of the VDDIO2 voltage monitor.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **ASV**: $V_{DDA18ADC}$ independent supply valid
This bit is used to validate the $V_{DDA18ADC}$ supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the analog to digital converters. If $V_{DDA18ADC}$ is not always present in the application, the $V_{DDA18ADC}$ voltage monitor can be used to determine whether this supply is ready or not. This bit is reset on any system reset.
0: $V_{DDA18ADC}$ is not present. Logical and electrical isolation is applied to ignore this supply.
1: $V_{DDA18ADC}$ is valid.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **USB33SV**: $V_{DD33USB}$ independent supply valid
This bit is used to validate the $V_{DD33USB}$ supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the USB2 HS PHYs. If $V_{DD33USB}$ is not always present in the application, the $V_{DD33USB}$ voltage monitor can be used to determine whether this supply is ready or not. This bit is reset on any system reset.
0: $V_{DD33USB}$ is not present. Logical and electrical isolation is applied to ignore this supply.
1: $V_{DD33USB}$ is valid.

Bit 9 **VDDIO3SV**: V_{DDIO3} independent supply valid
This bit is used to validate the V_{DDIO3} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use PN[12:0] I/Os. If V_{DDIO3} is not always present in the application, the V_{DDIO3} voltage monitor can be used to determine whether this supply is ready or not. This bit is reset on any system reset.
0: V_{DDIO3} is not present. Logical and electrical isolation is applied to ignore this supply.
1: V_{DDIO3} is valid.

Bit 8 **VDDIO2SV**: V_{DDIO2} independent supply valid.
This bit is used to validate the V_{DDIO2} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use PO[5:0] and PP[15:0] I/Os. If V_{DDIO2} is not always present in the application, the V_{DDIO2} voltage monitor can be used to determine whether this supply is ready or not. This bit is reset on any system reset.
0: V_{DDIO2} is not present. Logical and electrical isolation is applied to ignore this supply.
1: V_{DDIO2} is valid.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **AVMEN:** $V_{DDA18ADC}$ independent ADC voltage monitor enable
This bit is reset on any system reset.
0: $V_{DDA18ADC}$ voltage monitor disabled
1: $V_{DDA18ADC}$ voltage monitor enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **USB33VMEN:** $V_{DD33USB}$ independent USB 33 voltage monitor enable.
This bit is reset on any system reset.
0: $V_{DD33USB}$ voltage monitor disabled
1: $V_{DD33USB}$ voltage monitor enabled

Bit 1 **VDDIO3VMEN:** V_{DDIO3} independent voltage monitor enable
This bit is reset on any system reset.
0: V_{DDIO3} voltage monitor disabled
1: V_{DDIO3} voltage monitor enabled

Bit 0 **VDDIO2VMEN:** V_{DDIO2} independent voltage monitor enable
This bit is reset on any system reset.
0: V_{DDIO2} voltage monitor disabled
1: V_{DDIO2} voltage monitor enabled

13.9.13 PWR wake-up clear register (PWR_WKUPCR)

Address offset: 0x050

Reset value: 0x0000 0000

This register is not reset on any system reset. Access six wait states when writing this register.

When a system reset occurs during the register write cycle, the written data are not guaranteed.

Secure restriction of each it WKUPCx (x = 1 to 4) is defined by WUPxSEC in PWR_SECCFGR. Privilege restriction of each WKUPCx (x = 1 to 4) is defined by WUPxPRIV in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WKUPC4	WKUPC3	WKUPC2	WKUPC1
												w	w	w	w

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **WKUPC4:** Clear wake-up flag for WKUP4 pin
These bits are always read as 0.
0: No effect
1: Writing 1 clears WKUPF4 in PWR_WKUPSR.
Note: This bit is cleared to 0 by hardware.

Bit 2 **WKUPC3:** Clear wake-up flag for WKUP3 pin
These bits are always read as 0.
0: No effect
1: Writing 1 clears WKUPF3 in PWR_WKUPSR.
Note: This bit is cleared to 0 by hardware.

Bit 1 **WKUPC2:** Clear wake-up flag for WKUP2 pin
These bits are always read as 0.
0: No effect
1: Writing 1 clears WKUPF2 in PWR_WKUPSR.
Note: This bit is cleared to 0 by hardware.

Bit 0 **WKUPC1:** Clear wake-up flag for WKUP1 pin
These bits are always read as 0.
0: No effect
1: Writing 1 clears WKUPF1 in PWR_WKUPSR.
Note: This bit is cleared to 0 by hardware.

13.9.14 PWR wake-up status register (PWR_WKUPSR)

Address offset: 0x054

Reset value: 0x0000 0000

This register is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG).

When clearing a WKUPFx, the AHB write access completes after the WKUPFx has been cleared.

When a system reset occurs during the register write cycle, the written data are not guaranteed.

Secure restriction of each WKUPFx (x = 1 to 4) is defined by WUPxSEC in PWR_SECCFGR. Privilege restriction of each WKUPFx (x = 1 to 4) is defined by WUPxPRIV in PWR_PRIVCFGR.

												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **WKUPF4:** Wake-up flag for WKUP4 pin before enable
This bit is set by hardware and cleared only by a NRST reset, or by setting the WKUPC4 bit.
0: No wake-up event occurred
1: A wake-up event was received from WKUP4 pin.

Bit 2 **WKUPF3:** Wake-up flag for WKUP3 pin before enable
This bit is set by hardware and cleared only by a NRST reset, or by setting the WKUPC3 bit.
0: No wake-up event occurred
1: A wake-up event was received from WKUP3 pin.

Bit 1 **WKUPF2:** Wake-up flag for WKUP2 pin before enable
This bit is set by hardware and cleared only by a NRST reset, or by setting the WKUPC2 bit.
0: No wake-up event occurred
1: A wake-up event was received from WKUP2 pin.

Bit 0 **WKUPF1:** Wake-up flag for WKUP1 pin before enable
This bit is set by hardware and cleared only by a NRST reset, or by setting the WKUPC1 bit.
0: No wake-up event occurred
1: A wake-up event was received from WKUP1 pin.

13.9.15 PWR wake-up enable and polarity register (PWR_WKUPEPR)

Address offset: 0x058

Reset value: 0x0000 0000

This register is not reset by wake-up from Standby mode, but by any application reset (such as NRST or IWDG). Access six wait states when writing this register.

When a system reset occurs during the register write cycle, the written data are not guaranteed.

Secure restriction of each WKUPENx, WKUPPx, and WKUPPUPDx (x = 1 to 4) is defined by WUPxSEC in PWR_SECCFGR. Privilege restriction of each WKUPENx, WKUPPx, and WKUPPUPDx (x = 1 to 4) is defined by WUPxPRIV in PWR_PRIVCFGR.

				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **WKUPPUPD4[1:0]**: Wake-up pull configuration for WKUP4 pin
These bits define the I/O pad pull configuration used when WKUPEN4 = 1 (the associated GPIO port pull configuration must be set to the same value or 00). The WKUP pin pull configuration is maintained in Standby mode.
00: No pulls
01: Pull-up
10: Pull-down
11: Reserved

Bits 21:20 **WKUPPUPD3[1:0]**: Wake-up pull configuration for WKUP3 pin

These bits define the I/O pad pull configuration used when WKUPEN3 = 1 (the associated GPIO port pull configuration must be set to the same value or 00). The WKUP pin pull configuration is maintained in Standby mode.

00: No pulls
01: Pull-up
10: Pull-down
11: Reserved

Bits 19:18 **WKUPPUPD2[1:0]**: Wake-up pull configuration for WKUP2 pin

These bits define the I/O pad pull configuration used when WKUPEN2 = 1 (the associated GPIO port pull configuration must be set to the same value or 00). The WKUP pin pull configuration is maintained in Standby mode.

00: No pulls
01: Pull-up
10: Pull-down
11: Reserved

Bits 17:16 **WKUPPUPD1[1:0]**: Wake-up pull configuration for WKUP1 pin

These bits define the I/O pad pull configuration used when WKUPEN1 = 1 (the associated GPIO port pull configuration must be set to the same value or 00). The WKUP pin pull configuration is maintained in Standby mode.

00: No pulls
01: Pull-up
10: Pull-down
11: Reserved

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **WKUPP4**: Wake-up polarity bit for WKUP4 pin

This bit defines the polarity used for event detection on external WKUP4 pin.
0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

Bit 10 **WKUPP3**: Wake-up polarity bit for WKUP3 pin

This bit defines the polarity used for event detection on external WKUP3 pin.
0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

Bit 9 **WKUPP2**: Wake-up polarity bit for WKUP2 pin

This bit defines the polarity used for event detection on external WKUP2 pin.
0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

Bit 8 **WKUPP1**: Wake-up polarity bit for WKUP1 pin

This bit defines the polarity used for event detection on external WKUP1 pin.
0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **WKUPEN4:** Enable WKUP4 pin

0: An event on WKUP4 pin does not wake up the system from Standby and Stop modes.
1: A rising or falling edge on WKUP4 pin wakes up the system from Standby and Stop modes.

Bit 2 **WKUPEN3:** Enable WKUP3 pin

0: An event on WKUP3 pin does not wake up the system from Standby and Stop modes.
1: A rising or falling edge on WKUP3 pin wakes up the system from Standby and Stop modes.

Bit 1 **WKUPEN2:** Enable WKUP2 pin

0: An event on WKUP2 pin does not wake up the system from Standby and Stop modes.
1: A rising or falling edge on WKUP2 pin wakes up the system from Standby and Stop modes.

Bit 0 **WKUPEN1:** Enable WKUP1 pin

0: An event on WKUP1 pin does not wake up the system from Standby and Stop modes.
1: A rising or falling edge on WKUP1 pin wakes up the system from Standby and Stop modes.

13.9.16 PWR security configuration register (PWR_SECCFGR)

Address offset: 0x070

Reset value: 0x0000 0000

Reset on any system reset.

Nonsecure or unprivileged writes to this register are ignored, while any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **WKUPSEC4**: WKUP4 pin secure protection

0: Bits related to WKUP4 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written with secure or nonsecure access.
1: Bits related to WKUP4 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written only with secure access.

Bit 18 **WKUPSEC3**: WKUP3 pin secure protection

0: Bits related to WKUP3 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written with secure or nonsecure access.
1: Bits related to WKUP3 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written only with secure access.

Bit 17 **WKUPSEC2**: WKUP2 pin secure protection

0: Bits related to WKUP2 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written with secure or nonsecure access.
1: Bits related to WKUP2 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written only with secure access.

Bit 16 **WKUPSEC1**: WKUP1 pin secure protection
0: Bits related to WKUP1 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written with secure or nonsecure access.
1: Bits related to WKUP1 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written only with secure access.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **SEC7**: Peripheral voltage monitor secure protection
0: PWR_SVMCR1, PWR_SVMCR2, and PWR_SVMCR3 can be read and written with secure or nonsecure access.
1: PWR_SVMCR1, PWR_SVMCR2, and PWR_SVMCR3 can be read and written only with secure access.

Bit 6 **SEC6**: CPU power control secure protection
0: PWR_CPUCR can be read and written with secure or nonsecure access.
1: PWR_CPUCR can be read and written only with secure access.

Bit 5 **SEC5**: Backup domain secure protection
0: PWR_BDCR1, PWR_BDCR2, and PWR_DBPCR can be read and written with secure or nonsecure access.
1: PWR_BDCR1, PWR_BDCR2, and PWR_DBPCR can be read and written only with secure access.

Bit 4 **SEC4**: Voltage scaling selection secure protection
0: PWR_VOSCR can be read and written with secure or nonsecure access.
1: PWR_VOSCR can be read and written only with secure access.

Bit 3 **SEC3**: I-TCM, D-TCM, and I-TCM FLEXMEM low power control secure protection
0: PWR_CR4 can be read and written with secure or nonsecure access.
1: PWR_CR4 can be read and written only with secure access.

Bit 2 **SEC2**: V_{DDCORE} monitor secure protection
0: PWR_CR3 can be read and written with secure or nonsecure access.
1: PWR_CR3 can be read and written only with secure access.

Bit 1 **SEC1**: Programmable voltage detector secure protection
0: PWR_CR2 can be read and written with secure or nonsecure access.
1: PWR_CR2 can be read and written only with secure access.

Bit 0 **SEC0**: System supply configuration secure protection
0: PWR_CR1 can be read and written with secure or nonsecure access.
1: PWR_CR1 can be read and written only with secure access.

13.9.17 PWR privilege configuration register (PWR_PRIVCFGR)

Address offset: 0x074

Reset value: 0x0000 0000

Reset on any system reset.

Write access to this register is privileged only. Any read access is allowed on this register.

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **WKUPPRIV4**: WKUP4 pin privileged protection

0: Bits related to WKUP4 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written with privileged or unprivileged access.

1: Bits related to WKUP4 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written only with privileged access.

This bit can only be written by privileged application. If corresponding WKUPSEC4 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 18 **WKUPPRIV3**: WKUP3 pin privileged protection

0: Bits related to WKUP3 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written with privileged or unprivileged access.

1: Bits related to WKUP3 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written only with privileged access.

This bit can only be written by privileged application. If corresponding WKUPSEC3 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 17 **WKUPPRIV2**: WKUP2 pin privileged protection

0: Bits related to WKUP2 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written with privileged or unprivileged access.

1: Bits related to WKUP2 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written only with privileged access.

This bit can only be written by privileged application. If corresponding WKUPSEC2 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 16 **WKUPPRIV1**: WKUP1 pin privileged protection

0: Bits related to WKUP1 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written with privileged or unprivileged access.

1: Bits related to WKUP1 pin in PWR_WKUPCR, PWR_WKUPSR, and PWR_WKUPEPR can be read and written only with privileged access.

This bit can only be written by privileged application. If corresponding WKUPSEC1 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **PRIV7**: Peripheral voltage monitor privileged protection

0: PWR_SVMCR1, PWR_SVMCR2, and PWR_SVMCR3 can be read and written with privileged or unprivileged access.

1: PWR_SVMCR1, PWR_SVMCR2, and PWR_SVMCR3 can be read and written only with privileged access.

This bit can only be written by privileged application. If corresponding SEC7 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 6 **PRIV6**: CPU power control privileged protection
0: PWR_CPUCR can be read and written with privileged or unprivileged access.
1: PWR_CPUCR can be read and written only with privileged access.
This bit can only be written by privileged application. If corresponding SEC6 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 5 **PRIV5**: Backup domain privileged protection
0: PWR_BDCR1, PWR_BDCR2, and PWR_DBPCR can be read and written with privileged or unprivileged access.
1: PWR_BDCR1, PWR_BDCR2, and PWR_DBPCR can be read and written only with privileged access.
This bit can only be written by privileged application. If corresponding SEC5 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 4 **PRIV4**: Voltage scaling selection privileged protection
0: PWR_VOSCR can be read and written with privileged or unprivileged access.
1: PWR_VOSCR can be read and written only with privileged access.
This bit can only be written by privileged application. If corresponding SEC4 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 3 **PRIV3**: I-TCM, D-TCM, and I-TCM FLEX MEM low power control privileged protection
0: PWR_CR4 can be read and written with privileged or unprivileged access.
1: PWR_CR4 can be read and written only with privileged access.
This bit can only be written by privileged application. If corresponding SEC3 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 2 **PRIV2**: V_{DDCORE} monitor privileged protection
0: PWR_CR3 can be read and written with privileged or unprivileged access.
1: PWR_CR3 can be read and written only with privileged access.
This bit can only be written by privileged application. If corresponding SEC2 is set in PWR_SECCFGR ,his bit can only be written by secure privileged application.

Bit 1 **PRIV1**: Programmable voltage detector privileged protection
0: PWR_CR2 can be read and written with privileged or unprivileged access.
1: PWR_CR2 can be read and written only with privileged access.
This bit can only be written by privileged application. If corresponding SEC1 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

Bit 0 **PRIV0**: System supply configuration privileged protection
0: PWR_CR1 can be read and written with privileged or unprivileged access.
1: PWR_CR1 can be read and written only with privileged access.
This bit can only be written by privileged application. If corresponding SEC0 is set in PWR_SECCFGR, this bit can only be written by secure privileged application.

13.9.18 PWR debug control register 1 (PWR_CRCFG1)

Address offset: 0x080

Reset value: 0xD000 0000

Bits [15:0] are not reset by wake-up from STANDBY mode, application reset (such as NRST, IWDG) and V_{DD} POR, but only by V_{SW} POR and VSWRST. Bits [31:16] are reset by system reset and when waking up from STANDBY mode.

Write access is protected and software must write a KEY (0XCAFECAFE) as a word access in this register to unlock a single write access. Once unlocked, the register accepts a single written access (byte, half word, or word), after it relocks.

Secure privileged write access only. Any read access is allowed on this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SD_OKSTART	SD_VS_READY	SD_LPM	VDDA18PMURDY	SD_STATUS_SPARE[3:0]				Res.	Res.	Res.	RLPSN	Res.	Res.	MODE_DVS	SYNC_ADC
r	r	r	r	r	r	r	r				rw			rw	rw

					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SD_OKSTART**: Step down converter start up phase status

Bit 30 **SD_VS_READY**: Step down converter voltage scaling status

Bit 29 **SD_LPM**: Step down converter low power mode status

Bit 28 **VDDA18PMURDY**: $V_{DDA18PMU}$ ready.
0: $V_{DDA18PMU}$ is below the threshold of the VDDA18PMU voltage monitor.
1: $V_{DDA18PMU}$ is equal or above the threshold of the VDDA18PMU voltage monitor.

Bits 27:24 **SD_STATUS_SPARE[3:0]:** Step down converter spare status bits

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **RLPSN**: RAM low power mode disable in STOP.
When set the RAMs does not enter low power mode when the system enters STOP
0: RAM enters low power mode when system enters STOP
1: RAM remains in normal mode when system enters STOP

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **MODE_DVS**: Mode selection during voltage scaling of the SD converter

Bit 16 **SYNC_ADC**:
0: SD_Converter clock free running
1: SD_Converter clock synchronized to ADC

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SEL_DLY_NOVL[2:0]**: NOVL delay selection

Bits 7:6 **SEL_LC[1:0]**: External inductor/capacitor selection for SD converter

Bits 5:4 **SLOPE_SFST[1:0]**: Set slope of the voltage ramp during the startup.

Bit 3 **SDFPWMEN**: Step down converter force PWM mode
0: SD_Converter Normal mode
1: SD_Converter forced PWM mode

Bit 2 **SDDISILM**: Step down converter current limitation disabling
0: Current limitation disabled
1: Current limitation enabled

Bit 1 **MERGE_CLK_FSM**: Synchronous clk in Ramp and Mos FSM

Bit 0 **UNLOCKED**: Debug register unlocked
0: accessed locked: key was not written and after each register write access
1: after key 0xCAFECAFE was written in this register

13.9.19 PWR debug control register 2 (PWR_CRCFG2)

Address offset: 0x084

Reset value: 0x0000 0000

Reset on any system reset.

Write access is protected and software must write a KEY (0XCAFECAFE) as a word access in this register to unlock a single write access. Once unlocked, the register accepts a single written access (byte, half word, or word), after it relocks.

Secure privileged write access only. Any read access is allowed on this register.

Refer to *Section 2.3* for the register boundary addresses.

14 Reset and clock control (RCC)

The RCC manages the clock and reset generation for the whole microcontroller.

The operating modes to whom this section refers are defined in *Section 13.6.1: Operating modes* of the PWR.

14.1 RCC main features

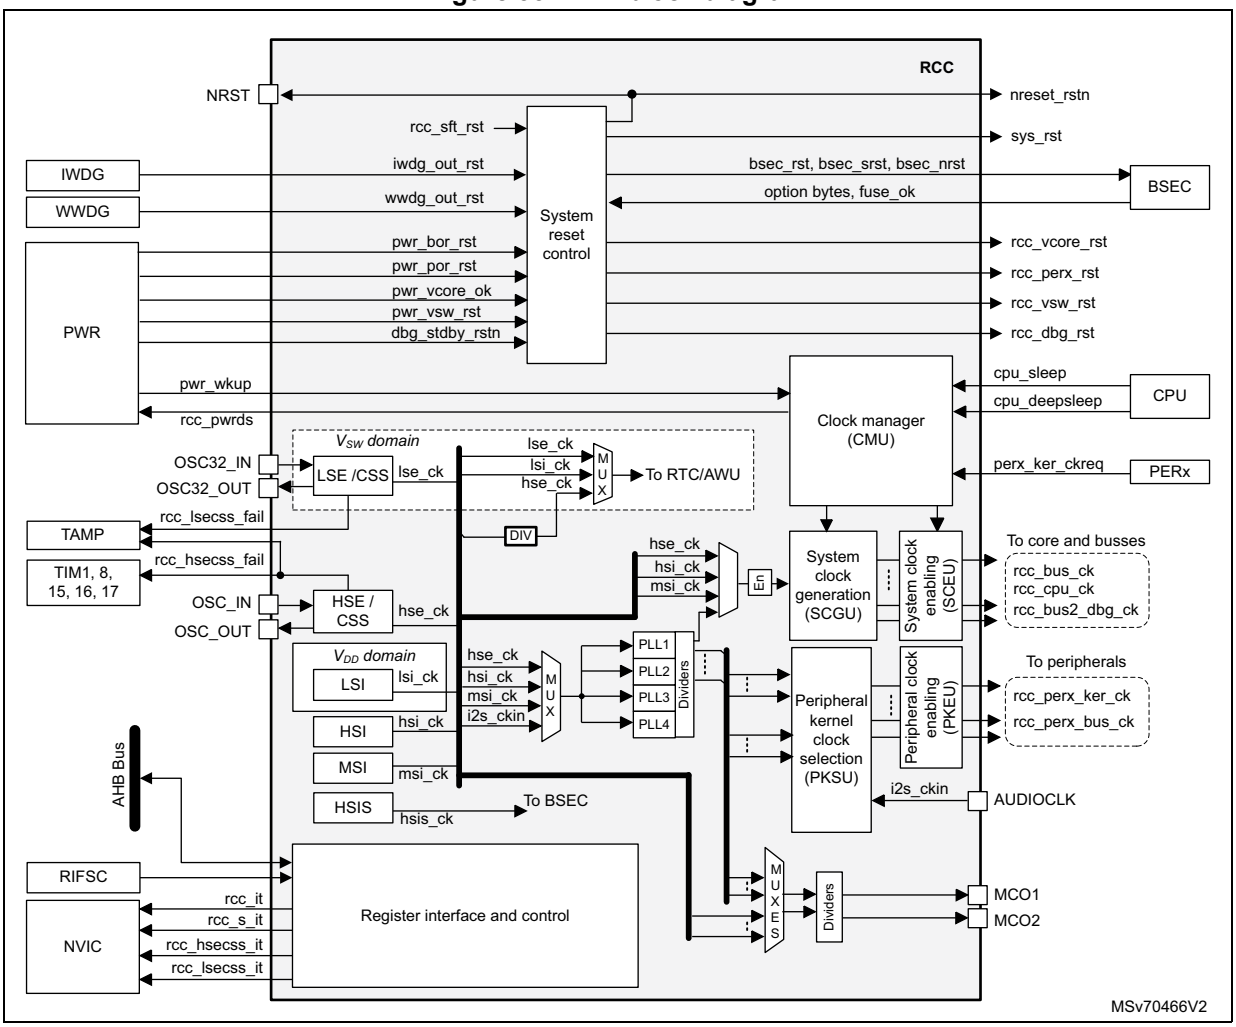
- AHB-Lite bus interface
- RIF (resource isolation framework) aware
- Reset part:
  - Generation of local and system reset
  - Bidirectional pin to reset the microcontroller and/or external devices
  - WWDG and IWDG reset supported
  - Power-on (POR) and brownout (BOR) resets initiated by the PWR
- Clock generation:
  - Generation and dispatching of clocks for the complete device
  - Four separate PLLs using integer or fractional ratios
  - Clock gating to reduce power dissipation
  - Two external oscillators:
    - High-speed external oscillator (HSE) supporting a wide range of crystals from 8 to 48 MHz (when the USBHSPHY is used, the HSE frequency must be 19.2, 20, or 24 MHz)
    - Low-speed external oscillator (LSE) for a 32.768 kHz crystal
  - Four internal oscillators:
    - High-speed internal oscillator (HSI)
    - Low-power internal oscillator (MSI)
    - Low-speed internal oscillator (LSI)
    - High-speed internal secure oscillator (HSIS)
  - Buffered clock outputs for external devices
  - Generation of two types of interrupt lines:
    - Dedicated interrupt lines for clock failure management
    - General interrupt line for other events (separated into secure and nonsecure)
  - Clock generation handling in Stop and Standby modes

14.2 RCC power domains

RCC interfaces with four power domains, namely core (V_{DDCORE}), retention (V_{DD}, V_{RET}), backup (V_{SW}, V_{BKP}), and analog ($V_{DDA18ADC}$).

14.3 RCC block diagram

Figure 33. RCC block diagram



14.4 RCC pins and internal signals

Table 65. RCC input/output signals connected to package pins or balls

Name	Type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input
OSC_OUT	O	System oscillator output
MCO1	O	Output clock 1 for external devices

Table 65. RCC input/output signals connected to package pins or balls (continued)

Name	Type	Description
MCO2	O	Output clock 2 for external devices
AUDIOCLK	I	External kernel clock input for digital audio interfaces: SPI/I2S, SAI, MDF, ADF

The RCC exchanges signals with all components of the product. *Table 66* shows only the most significant internal signals.

Table 66. RCC internal input/output signals

Name	Type	Description
rcc_it	O	General interrupt request line (nonsecure)
rcc_s_it	O	General interrupt request line (secure)
rcc_hsecss_it	O	HSE clock security failure interrupt
rcc_lsecss_it	O	LSE clock security failure interrupt
rcc_hsecss_fail	O	Event indicating that an HSE clock security failure is detected
rcc_lsecss_fail	O	Event indicating that an LSE clock security failure is detected
nreset_rstn	I/O	Application reset
sys_rst	I/O	System reset
bsec_rstn	O	BSEC warm reset
bsec_srstn	O	BSEC scratch (cold) reset
bsec_hrstn	O	BSEC hot reset
fuse_ok	I	BSEC has finished loading the OTP (one-time programmable, which contains the option bytes)
option bytes	I	Configuration bits from BSEC, affecting RCC behavior (reset, clock, osc)
iwdg_out_rst	I	Reset line driven by the IWDG, indicating that a timeout occurred
wwdg_out_rst	I	Reset line driven by the WWDG, indicating that a timeout occurred
pwr_bor_rst	I	Brownout reset generated by the PWR
pwr_por_rst	I	Power-on reset generated by the PWR
pwr_vsw_rst	I	Power-on reset of the V_{SW} domain generated by the PWR
dbg_stdby_rstn	I	Standby emulation mode reset generated by the PWR
rcc_perx_rst	O	Reset generated by the RCC for the peripherals
pwr_wkup	I	Wake-up request generated by the PWR, and used to restore the clocks
rcc_pwrds	O	Informs the PWR that the RCC has stopped all clocks (PWR can then go to Stop or Standby mode)
cpu_sleep	I	Signals generated by the CPU, indicating if it is in Run, Sleep, or Stop mode
cpu_deepsleep	I	
cpu_SLEEPHOLDACKn	I	When this signal is asserted, the CPU does not advance in execution, and does not perform any memory operation

Table 66. RCC internal input/output signals (continued)

Name	Type	Description
rcc_SLEEPHOLDREQn	O	Request to extend the CPU sleep state regardless of wake-up events. If the CPU acknowledges this request (SLEEPHOLDACKn asserted), the CPU remains idle even when it receives a wake-up event.
perx_ker_ckreq	I	Generated by some peripherals to request the activation of their kernel clock
rcc_perx_ker_ck	O	Kernel clock signals generated by the RCC for some peripherals
rcc_perx_bus_ck	O	Bus interface clock signals generated by the RCC for peripherals

14.5 Functional description of RCC reset

The RCC handles the reset generation for the complete product, using events coming from different sources:

- assertion of the NRST pin from an external device
- a failure on the supply voltage applied to V_{DD} or V_{BAT}
- an exit from Standby mode
- a watchdog timeout
- a software command

The reset scope depends on the source that generates it.

14.5.1 Reset from the PWR

The PWR provides several reset signals to the RCC:

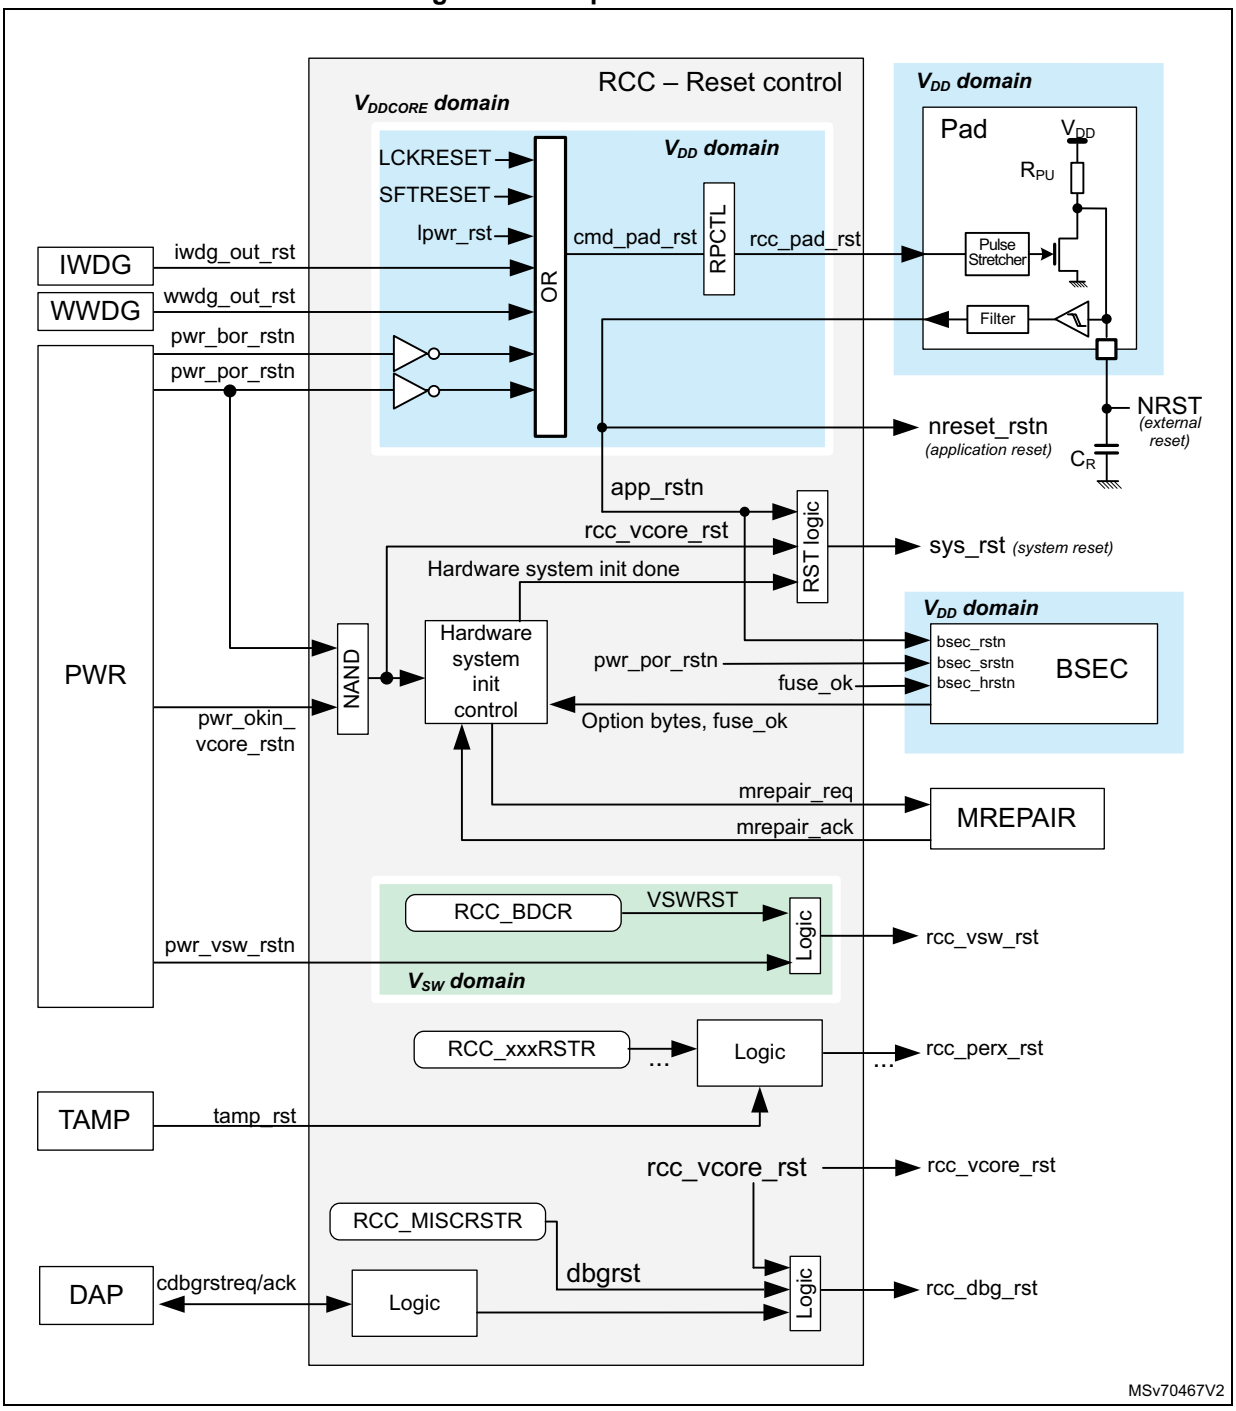
- power-on/off reset signal (pwr_por_rstn): asserted when the V_{DD} supply is lower than the V_{POR} threshold
- brownout reset signal (pwr_bor_rstn): asserted when the V_{DD} supply is lower than the V_{BOR} threshold
- core reset signal (pwr_okin_vcore_rstn): asserted when the V_{DDCORE} supply is not valid or available

Note: V_{DDCORE} is switched off when the product is in Standby mode. When the system exits Standby mode, pwr_okin_vcore_rstn is asserted while V_{DDCORE} from the regulator is not valid. pwr_okin_vcore_rstn is also asserted when the V_{DD} supply is not valid.

- V_{SW} domain reset signal (pwr_vsw_rstn): asserted when the V_{SW} supply is lower than the expected threshold

Refer to *Table 67* for more details.

Figure 34. Simplified reset circuit



14.5.2 System and application resets (sys_rst, nreset_rstn)

A system reset (sys_rst) resets most of the registers to their default values, unless otherwise specified in the register description (summary in *Table 67*).

A system reset can be generated from one of the following sources:

- an assertion of the NRST pin (external reset)

- a reset from the power-on/off reset block (pwr_por_rstn)
- a reset from the brownout reset block (pwr_bor_rstn), see *Section 13.5.2: Brownout reset (BOR)* for a detailed description of the BOR function
- a reset from the independent watchdogs (iwdg_out_rst)
- an exit from Standby mode (rcc_vcore_rst)
- a reset from the window watchdogs depending on WWDG configuration (wwdg_out_rst)
- a software reset (SFTRESET) signal, connected to SYSRESETREQ from the Cortex-M55 core
- a lockup reset (LCKRESET) signal, connected to LOCKUP from the Cortex-M55 core
- a reset from the low-power mode security reset, depending on the option byte configuration (lpwr_rst)

The application reset (nreset_rstn) is similar to the system reset, but it is not asserted when the system exits Standby mode.

Note: The sys_rst is actually a combination the native internal reset signal (int_sys_rstn) and the debug Standby reset signal (dbg_stdby_rstn). Some registers are reset by int_sys_rstn only. See Section 14.6.13 for more details about dbg_stdby_rstn.

The SYSRESETREQ bit in Cortex-M55 must be set to force a software reset on the device. Refer to the Cortex-M55 with FPU Technical Reference Manual for more details. There is also a SYSCFG register, which affects SYSRESETREQ.

14.5.3 NRST reset

The NRST is active low. A pulse stretcher guarantees a minimum reset pulse duration of 20 µs (see the datasheet for details). The NRST assertion can also be extended by adding the C_R capacitor.

It is not recommended to leave the NRST pin unconnected. When not used, connect this pin to ground via a 10 to 100 nF capacitor (C_R in *Figure 34*). As shown in *Figure 34*, a filter is present to suppress spurious coming from the NRST pin.

14.5.4 Low-power mode security reset (lpwr_rst)

To prevent critical applications from mistakenly entering a low-power mode, two low-power mode security resets are available. When enabled through RST_STOP and RST_STDBY option bytes, a system reset (sys_rst) is generated if the following conditions are met:

- The CPU mistakenly enters Stop mode.

  This type of reset is enabled by setting RST_STOP user option byte. If a Stop mode entry sequence is successfully executed, a system reset is generated.
- The system mistakenly enters Standby mode.

  This type of reset is enabled by setting RST_STDBY user option byte. If a Standby mode entry sequence is successfully executed, a system reset is generated.

LPWRRSTF bit in RCC_RSR indicates that a low-power mode security reset occurred (see row 8 in *Table 68*).

The lpwr_rst input is activated when a low-power mode security reset is required. This signal is generated by the PWR.

See *Section 5: OTP mapping (OTP)* for additional information, and *Table 55: Operating mode summary* for the overview of existing power modes.

14.5.5 Backup domain reset

A backup domain reset (rcc_vsw_rst) is generated when one of the following occurs:

- a software reset, triggered by setting VSWRST in RCC_BDCR: the BKPSRAM is not affected.
- V_{SW} voltage outside the operating range: the BKPSRAM content is no longer valid.

The RCC_BDCR register and all bitfields in the backup domain (including RTC) return to their reset values: these include RTCEN, RTCLPEN, RTCPRE, RTCSEL, LSECSSRA, LSECSSD, LSECSSON, LSERDY, LSERDYF, LSEON, LSEDRV, LSEEXT, LSEBYP, LSEGFON.

See *Section 13.4.4: Backup domain* and *Section 3: System security* for additional information.

14.5.6 CoreSight debug reset

CoreSight debug components can be reset in three different ways:

- using the DAP by setting CDBGRSTREQ in DP_CTRLSTAT

  This asserts the debug reset request signal (cdbgrstreq) connected to the RCC. The RCC then asserts the debug reset (rcc_dbg_rst), and a handshake signal cdbgrstack acknowledges the DAP request. The debug reset remains asserted while cdbgrstreq is asserted (see *Figure 34* for details).
- when the application sets DBGRST in RCC_MISCRSTR

  This asserts the rcc_dbg_rst reset, which is deasserted when DBGRST is cleared to 0.
- when a V_{DDCORE} power-on reset occurs (rcc_vcore_rst)

  This reset is asserted after a POR, or when the product exits Standby mode.

Refer to *Section 14.5.6* for details.

14.5.7 Option-byte loading

As shown in *Figure 36*, the option-byte loading (OBL via OTP_LD) sequence happens after a POR or a pin reset.

The system reset (sys_rst) is released only after the OBL has completed.

The BSEC manages an OTP array of fuse words, which hold the option-byte configuration for the device. This configuration must be set every time an app_rstn is asserted, and the system stays in reset until this configuration has been properly loaded (fuse_ok signal is received from the BSEC module).

The BSEC handles the following reset sources:

- a main reset (bsec_rstn) asserted when an app_rstn is asserted
- a scratch reset (bsec_srstn) asserted when a pwr_por_rstn is asserted
- a hot reset (bsec_hrstn) asserted when fuse_ok is low

14.5.8 Reset of peripherals

The application can reset individually any peripheral, whenever requested. This can be done via registers named RCC_xxxxRSTR (xxxx is the bus name on which the peripheral is connected).

To reset a peripheral, the corresponding reset bit must be set to 1 (peripheral clock not required), and then set back to 0 (peripheral clock must be enabled and running in advance). There is no need to enable a peripheral clock to reset a peripheral.

Caution: PKA, CRYP, SAES, and HASH may be reset directly in hardware upon a tamper event.

14.5.9 Reset pulse control (RPCTL)

The RPCTL allows the application to control the minimum activation time of the NRST pad. This feature is particularly helpful because some external devices may require a specific reset duration. In addition, the internal reset pulse, for example from IWDG, may be too short for external devices.

The RPCTL is located in the V_{DD} domain, and is reset only after a power-on reset.

The RPCTL is controlled by MRD[4:0] in RCC_RDCR.

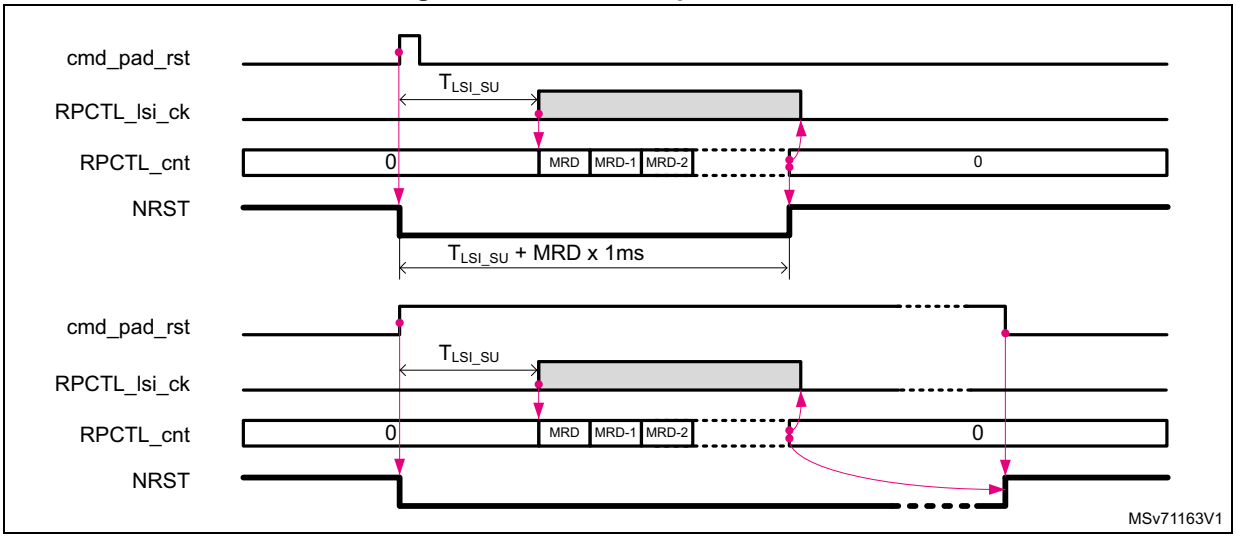
If MRD is 0, then the RPCTL is bypassed. The minimum activation time in this case is given by the pulse stretcher embedded in the reset pad (typically 20 µs).

If MRD is non-0, then the rising edge of cmd_pad_rst causes NRST to be immediately driven low, for at least the duration set by MRD[4:0]. The duration of the reset is unchanged if the cmd_pad_rst signal is active for longer than the duration set by MRD[4:0]. The minimum activation time is between 1 and 31 ms.

The RPCTL uses the LSI clock to measure time. When the cmd_pad_rst goes high, the RPCTL requests the LSI clock to control the reset duration. If the LSI was not enabled by another function, it may take some microseconds before obtaining LSI ready (TLSI_SU).

Figure 35 shows two scenarios.

Figure 35. NRST reset pulse control



14.5.10 Reset coverage summary

Table 67 gives a detailed view of the coverage of the most important reset sources.

Note: When V_{DD} is not valid, V_{DDCORE} is not valid as well.

Table 67. Reset coverage summary (1)

Reset functions		Main reset lines						
		pwr_por_rstn(2)	rcc_vcore_rst(3)	sys_rst	nreset_rstn(4)	rcc_dbg_rst	rcc_perx_rst	rcc_vsw_rstn
V_{DD} domain		X	-	-	-	-	-	-
MCU		X	X	X	-	-	-	-
WWDG		X	X	X	-	-	-	-
IWDG		X	-	-	X	-	-	-
AXI/AHB interconnections		X	X	X	-	-	-	-
Debug components (including DBGMCU): reset all the debug parts except the SWJ-DP function, which is reset by the NJTRST or rcc_vcore_rst resets.		X	X	-	-	X	-	-
Hardware system init: includes the memory repair.		X	X	-	-	-	-	-
RCC	RCC reset register (RCC_RSR)	X	-	-	-	-	-	-
	RCC control register (RCC_CR) and RCC APB5 Sleep enable register (RCC_RDCR)	X	-	-	-	-	-	-
	RCC bitfields in the backup domain	-	-	-	-	-	-	X
	Other RCC registers	X	X	X	-	-	-	-
PWR	PWR_CSR1	-	-	-	-	-	-	X
	PWR_CSR2	X	-	-	-	-	-	-
	PWR_CSR3: individual bits of this register do not have the same reset condition (see *Section 13: Power control (PWR)* for details).	X	X	X	-	-	-	-
	PWR_WKUPCR, PWR_WKUPFR, and PWR_WKUPEPR	X	-	-	X	-	-	-
	Other registers	X	X	X	-	-	-	-
RTC	Peripheral (except APB)	-	-	-	-	-	-	X
	Peripheral APB	X	X	X	-	-	X	-
BKPSRAM: after a reset of the V_{SW} domain, the BKPSRAM backup regulator is disabled. This function is controlled via BKPRBSEN (in PWR_BDCR2). If the rcc_vsw_rst reset is due to a too low V_{SW} voltage, the BKPSRAM content is lost.		-	-	-	-	-	-	X
Other peripherals		X	X	X	-	-	X	-

1. 'X' means that the function is reset by the corresponding reset line. '-' means that the function is not reset by the corresponding reset line.
2. pwr_por_rstn is asserted when the voltage applied to VDD is not valid. When pwr_por_rstn is asserted, the rcc_vcore_rst, NRST, sys_rst, and nreset_rstn are asserted as well.

3. rcc_vcore_rst is asserted when the voltage applied to VDD is not valid, or when the system exits Standby mode (because V_{DDCORE} is switched off). When rcc_vcore_rst is asserted, sys_rst and pwr_dbg_rst are asserted as well.
4. When nreset_rstn is asserted, sys_rst is asserted as well.

14.5.11 Reset source identification

The CPU can identify the reset source by checking reset flags in RCC_RSR or PWR_CSR3 registers.

The CPU can clear flags in RCC_RSR by setting RMVF bit in this register.

Table 68 shows how the status bits behave according to the situation that generated the reset. For example, when an IWDG timeout occurs (row 7), if the CPU reads RCC_RSR during the boot phase, both PINRSTF and IWDGRSTF bits are set, indicating that the IWDG also generated a pin reset.

Table 68. Reset source identification(1)

#	Situation generating a reset	SBF (2)	LPWRRSTF	IWDGRSTF	WWDGRST	LCKRSTF	SFTRSTF	BORRSTF	PINRSTF	PORRSTF
1	Power-on reset (pwr_por_rstn)	0	0	0	0	0	0	1	1	1
2	Pin reset (NRST)	0	0	0	0	0	0	0	1	0
3	Brownout reset (pwr_bor_rstn)	0	0	0	0	0	0	1	1	0
4	System reset generated by the CPU (SFTRESET)	0	0	0	0	0	1	0	1	0
5	System reset generated by the CPU (LCKRESET)	0	0	0	0	1	0	0	1	0
6	WWDG reset (wwdg_out_rst)	0	0	0	1	0	0	0	1	0
7	IWDG reset (iwdg_out_rst)	0	0	1	0	0	0	0	1	0
8	CPU erroneously enters Stop or Standby mode	0	1	0	0	0	0	0	1	0
9	The product exits Standby mode	1	0	0	0	0	0	0	1	0

1. Grayed cells highlight the register bits that are set.
2. The SBF bit is located in PWR_CSR3 register.

14.5.12 Power-on and wake-up sequences

For detailed diagrams, refer to *Section 13.4.1: System supply startup* in the PWR.

The time interval between the event that exits the device from a low-power, and the moment where the CPU is able to execute code, depends on the system state and on its configuration. *Figure 36* shows the most usual examples.

Power-on wake-up sequence

The sequence shown in *Figure 36* gives the most significant phases of the power-on wake-up. It is the longest sequence since the circuit was not powered.

Note: This sequence remains unchanged whatever V_{BAT} is present or not.

Boot from pin reset (NRST)

When a pin reset occurs, V_{DD} is still present. As a result:

- the regulator settling time is faster since the reference voltage is already stable
- the HSI restart delay may be needed if the HSI was not enabled when the NRST occurred, otherwise this restart delay phase is skipped.

Boot from system standby

When waking up from system standby, the reference voltage is stable since V_{DD} has not been removed. As a result, the regulator settling time is fast. Since V_{DDCORE} was not present, the restart delay for the HSI and HSIS cannot be skipped.

sys_rst remains asserted until HSIS runs and the memory repair completes.

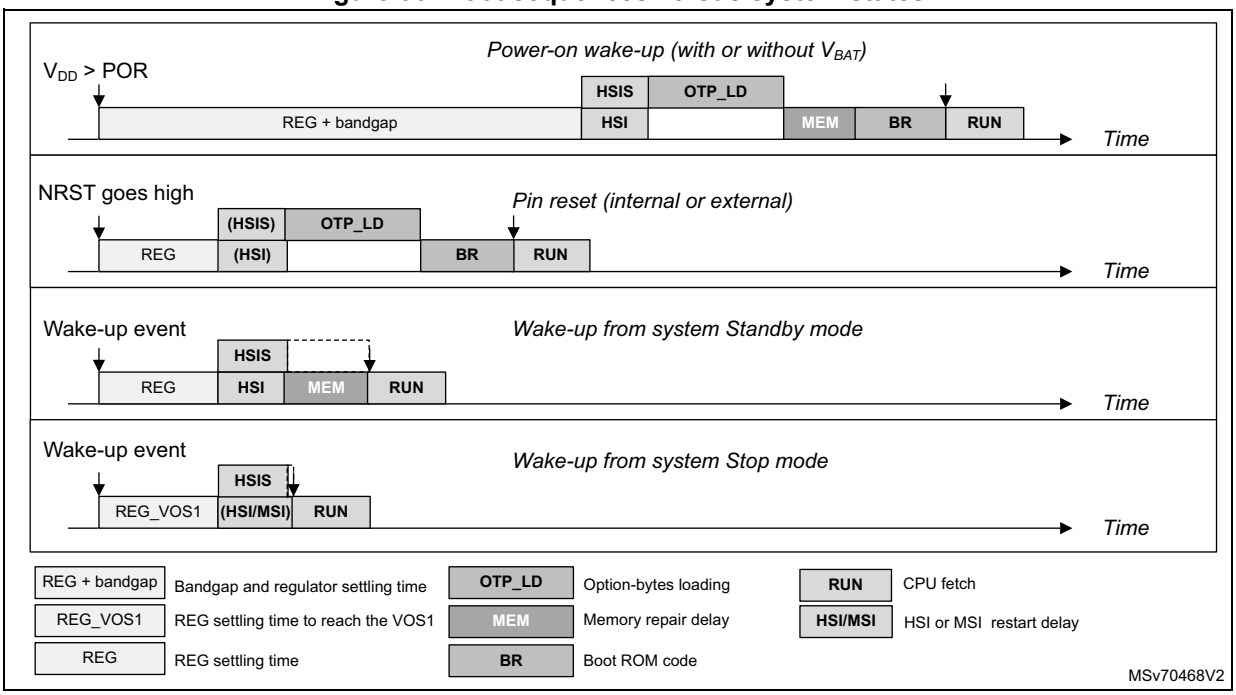
Restart from system stop

When restarting from system stop, V_{DD} is still present. As a result, the sequence is mainly composed of two steps:

1. The regulator settling time reaches V_{OS1} (default voltage).
2. HSI/MSI restart delay. This step can be skipped if HSISTOPEN = MSISTOPEN = 1 in RCC_STOPCR.

sys_rst remains asserted until HSIS runs.

Figure 36. Boot sequences versus system states



14.6 Functional description of RCC clocks

The RCC provides a wide choice of clock generators:

- HSI (high-speed internal oscillator) clock: ~ 8, 16, 32, or 64 MHz

- HSE (high-speed external oscillator) clock: 8 to 48 MHz
- LSE (low-speed external oscillator) clock: 32 kHz
- LSI (low-speed internal oscillator) clock: ~ 32 kHz
- MSI (low-power internal oscillator) clock: ~ 4 or 16 MHz

The RCC offers a high flexibility for the application to select the appropriate clock for the CPU and peripherals (in particular for peripherals that require a specific clock, such as SPI/I2S and SAI).

To optimize the power consumption, each clock source can be switched ON or OFF independently.

The RCC provides up to four PLLs; each of them can be configured in integer mode (with or without SSCG - spread spectrum clock generation), or fractional mode.

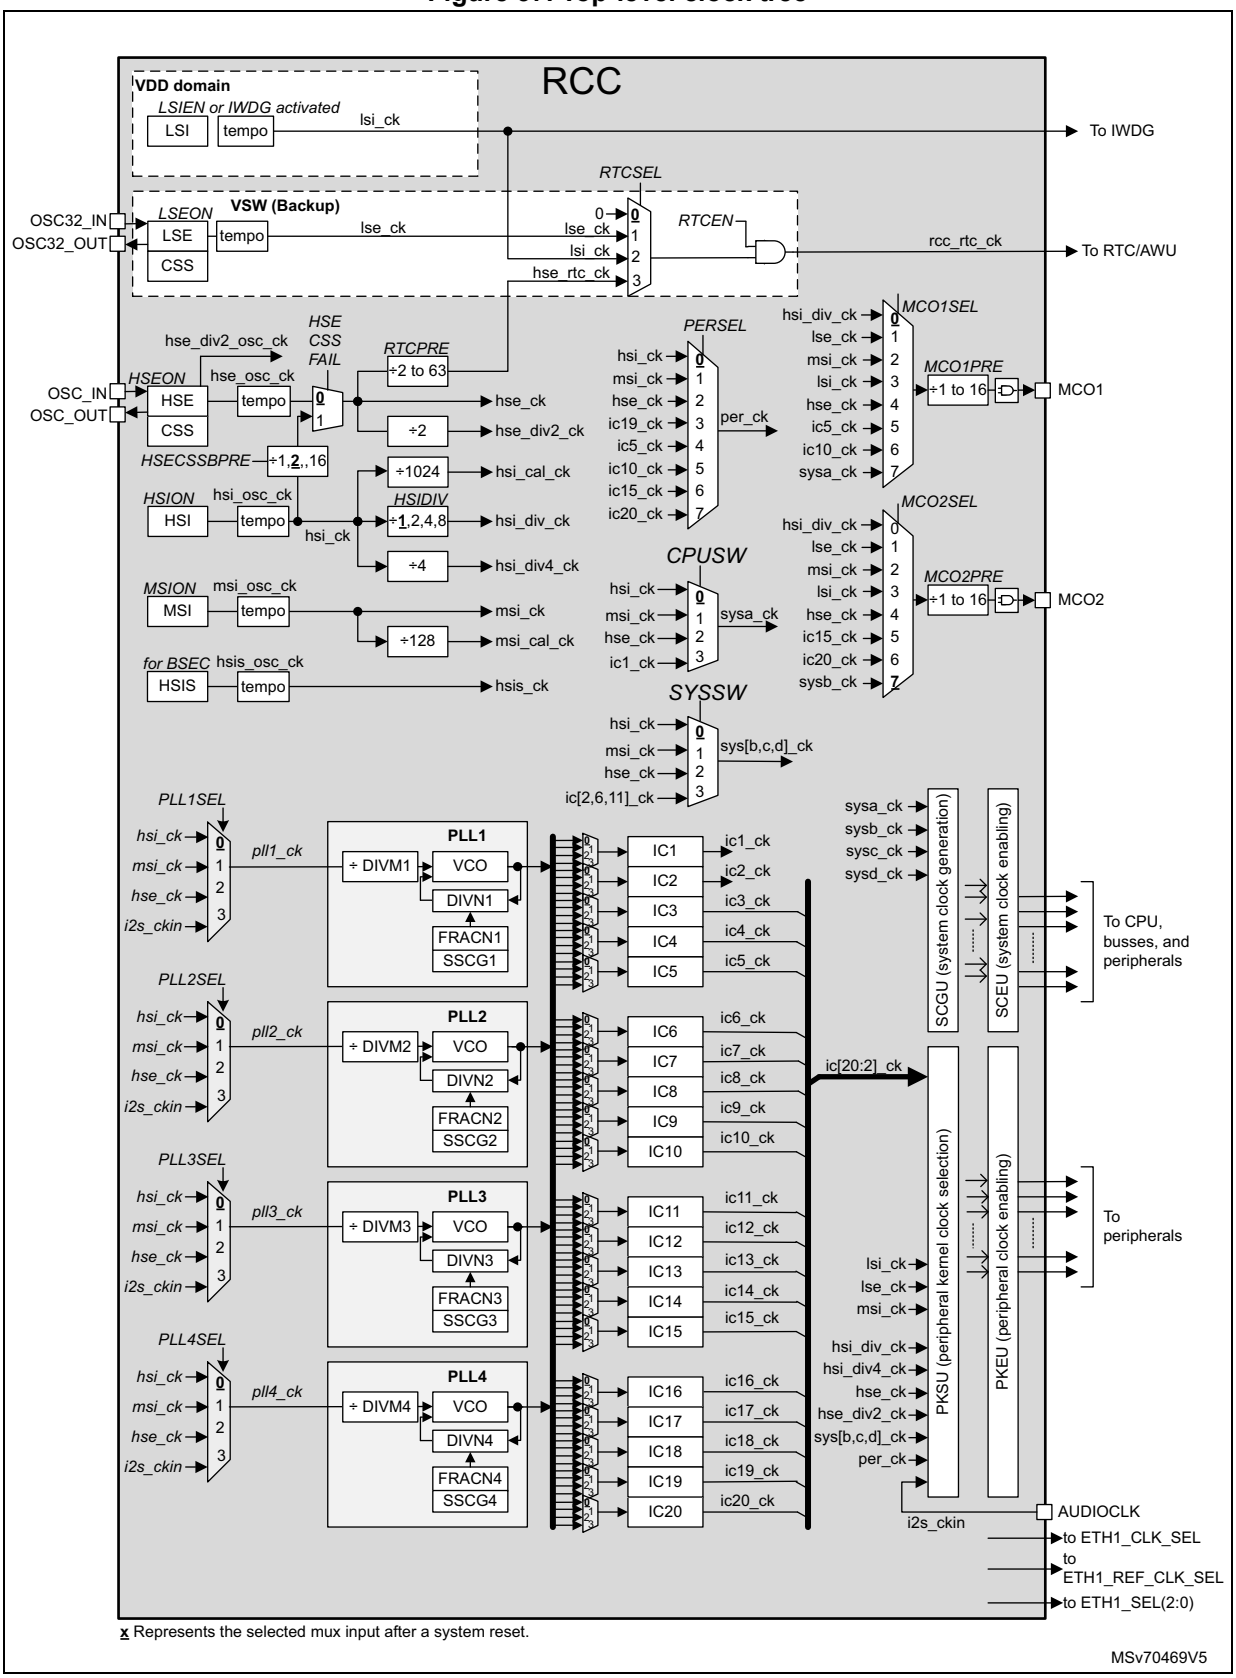
As shown in the *Figure 37*, the RCC offers two clock outputs (MCO1 and MCO2), with flexibility on the clock selection and frequency adjustment.

The SCGU (system clock generation unit) contains several prescalers to configure the CPU and bus matrix clock frequencies.

The PKSU (peripheral kernel clock selection unit) provides several dynamic switches, which give a large choice of kernel clock distribution to peripherals.

The PKEU (peripheral kernel clock enable unit) performs the peripheral kernel clock gating. The SCEU (system clock enable unit) performs the clock gating for the bus interface, cores, and the bus matrix.

Figure 37. Top-level clock tree



14.6.1 Clock naming convention

The RCC provides clocks to the complete circuit. To avoid misunderstandings, the following terms are used in this document:

- Peripheral clocks provided by the RCC to the peripherals

  Two kinds of clock are available:

  – bus interface clocks

  – kernel clocks

  A peripheral receives from the RCC a bus interface clock to access its registers, and thus control the peripheral operation. This clock is generally the AHB, APB, or AXI clock, depending on which bus the peripheral is connected to. Some peripherals need only a bus interface clock.

  Some peripherals require also a dedicated clock (named kernel clock) to handle the interface function. As an example, SAI must generate specific and accurate master clock frequencies, which require dedicated kernel clock frequencies.

  An advantage of decoupling the bus interface clock from the kernel clock is that the bus clock can be changed without reprogramming the peripheral.
- CPU clock: derived from a dedicated system clock (sysa_ck), is asynchronous to the bus clocks.
- Bus matrix clocks: provided to the different bridges (APB, AHB, AXI, or NoC), are derived from a system clock (sysb_ck).
- NPU and NPU AXI clocks: the NPU clock is derived from a dedicated system clock, sysc_ck, also used for the AXI matrix close to the NPU.
- AXISRAM1/2 clocks: derived from sysb_ck.
- AXISRAM3/4/5/6 clocks: derived from sysd_ck.

14.6.2 Oscillator description

Table 69 shows the oscillator states versus system modes, when the oscillators are enabled via registers. Available means that the resource can be used if activated via registers.

Table 69. Oscillator states versus system modes

System modes	V_{DDCORE} domain				V_{DD} domain	V_{SW} domain
	HSIS	HSE	HSI	MSI	LSI	LSE
Exit from system reset	On	Off	On	Off	Available	Available
Exit from system stop	On	Off	On(1)	On(2)	Available	Available
In Run/Sleep mode	On	Available	Available	Available	Available	Available
In Stop mode	Off	Off	Available(3)	Available(4)	Available	Available
In Standby mode	Off	Off	Off	Off	Available	Available
In V_{BAT} mode	Off	Off	Off	Off	Off	Available

1. If STOPWUCK = 0.
2. If STOPWUCK = 1.
3. HSI can remain activated in Stop mode if HSISTOPEN = 1, or if a peripheral selecting HSI generates a kernel clock request. **Caution**: HSI must be off if the PWR is programmed to use SVOS low.
4. MSI can remain activated in Stop mode if MSISTOPEN = 1, or if the peripheral selecting MSI generates a kernel clock request. **Caution**: MSI must be off if the PWR is programmed to use SVOS low.

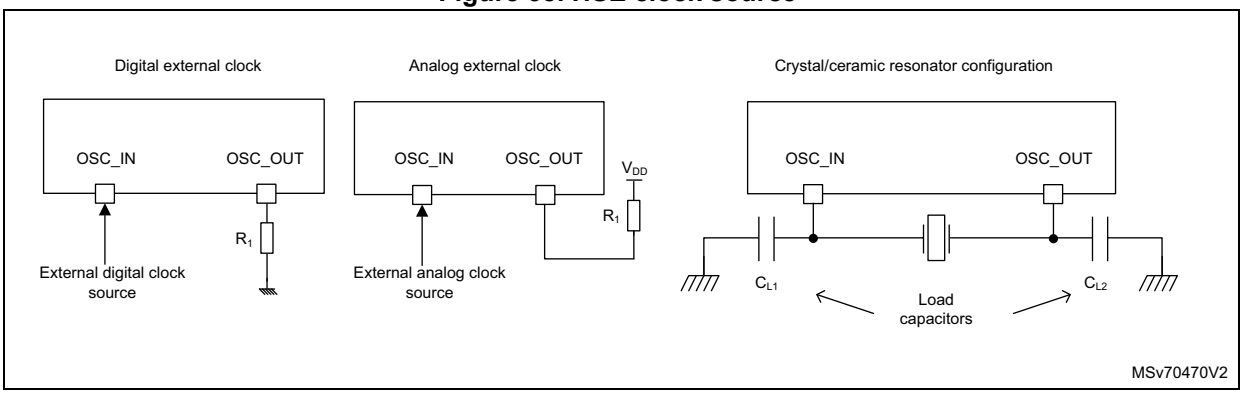
HSE oscillator

The HSE allows the application to provide a very accurate high-speed clock for the device. The HSE can generate an internal clock from two sources:

- external clock source (analog or digital)
- external crystal/ceramic resonator

Refer to the datasheet for the values of CL1, CL2, and R1.

Figure 38. HSE clock source



External clock source (HSE bypass)

In this mode, the oscillator is not used, and an external clock source must be provided to the OSC_IN pin. The external clock can be low swing (analog) or digital.

In order to allow the boot ROM to detect in which configuration the HSE is used, a resistor (R1) must be connected to GND or V_{DD} (see *Figure 38*).

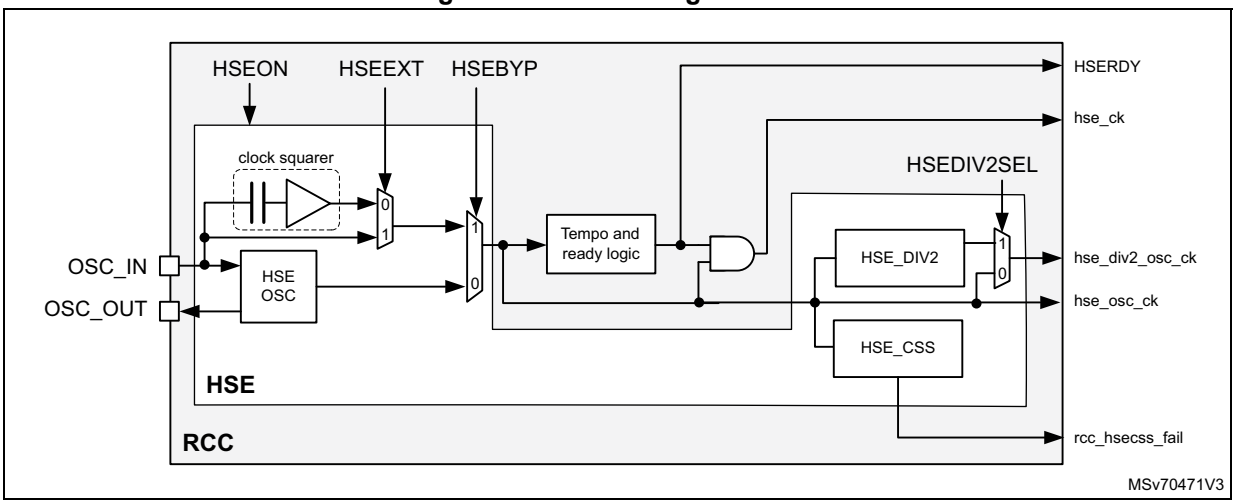
The resistor must be connected to GND when the HSE uses an external digital clock, and to V_{DD} when the HSE is using an external analog clock. The resistor must be removed if a crystal or ceramic resonator is used.

The external clock signal can be digital or analog (square, sinus, or triangle). An analog clock signal with a reduced amplitude is supported thanks to an internal clock squarer.

The input signal must have a duty cycle close to 50% (refer to the datasheet for additional information).

This mode is selected when HSEBYP = 1 in RCC_HSECFGR and HSEON = 1 in RCC_CR. In case of an analog clock input (low swing) HSEEXT must be set to 0 in RCC_HSECFGR. For a digital clock input, HSEEXT must be set to 1.

Figure 39. HSE clock generation



External crystal/ceramic resonator

A crystal/resonator can be connected as shown in *Figure 38*: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize the output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is enabled by setting HSEBYP = 0 and HSEON = 1.

HSE ready logic

The HSERDY flag indicates when a valid clock is available at HSE output (hse_ck). When the HSE is enabled (HSEON = 1), the HSERDY flag goes to 1 when 1024 valid cycles of HSE have been detected. The hse_ck clock is not released until HSERDY goes to 1.

An interrupt can be generated if enabled in RCC_CIER.

HSE controls

The HSE can be switched on and off through HSEON.

The HSE is automatically disabled by hardware when the system enters Stop or Standby mode (see *Table 69*).

The HSE clock can also be driven to MCO1 and MCO2 outputs, and used as clock source for other application components.

HSE programming sequence

In order to initialize the HSE, the application must follow this sequence:

1. Make sure the HSE is not directly or indirectly used as system clock. If it is, switch to the HSI or MSI as clock source for system clock.
2. Disable the HSE by writing 0 to HSEON.
3. Check that the HSE is disabled by waiting HSERDY = 0.
4. If the oscillator mode is needed, select the oscillator mode with HSEBYP = 0.
5. If an external clock is connected to OSC_IN:
   – Select the bypass mode by setting HSEBYP = 1.

– If the input clock is a full-swing digital signal, set HSEEXT = 1.
– If the input clock is a low-swing signal, set HSEEXT = 0.

6. Enable again the HSE by writing 1 to HSEON.
7. Wait for HSERDY = 1, then the HSE is ready for use.

LSE oscillator

The LSE allows the application to provide a very accurate low-frequency clock for the device. The LSE can generate an internal clock from two possible sources:

- external user clock
- external crystal/ceramic resonator

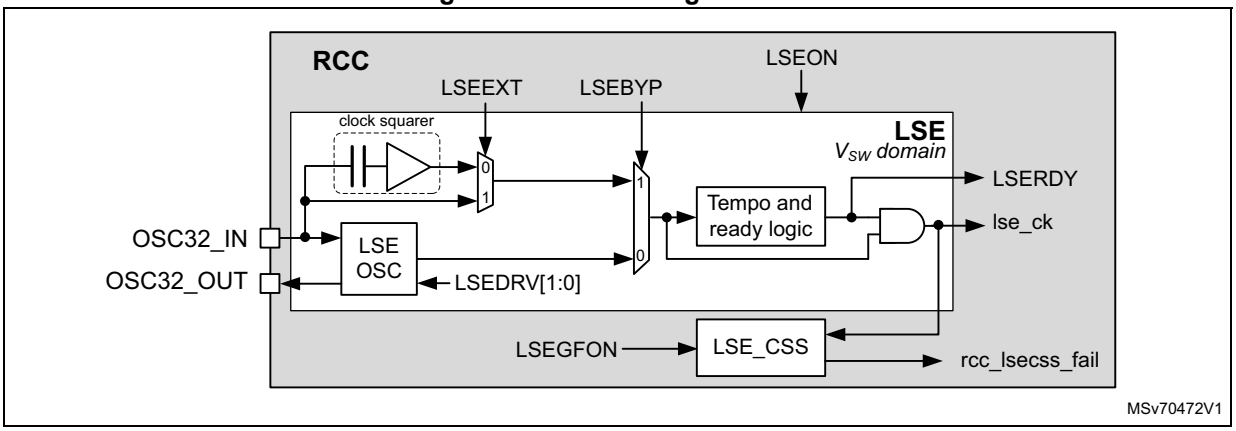
External clock source (LSE bypass)

In this mode, the oscillator is not used, and an external clock source must be provided to the OSC32_IN pin. The OSC32_OUT pin must be left high-Z.

The external clock signal can have a frequency up to 32.768 kHz, and can be digital or analog (square, sinus, or triangle). An analog clock signal with a reduced amplitude is supported thanks to an internal clock squarer. The input signal must have a duty cycle close to 50%. Refer to the datasheet for additional information.

This mode is selected by setting LSEBYP = 1 in RCC_LSECFGR, and LSEON = 1 in RCC_CR. In case of an analog clock input (low swing), LSEEXT must be set to 0 in RCC_LSECFGR. For a digital clock input, LSEEXT must be set to 1.

Figure 40. LSE clock generation



External crystal/ceramic resonator source (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It provides a low-power highly accurate clock source to the RTC for clock/calendar, or other timing functions. A crystal/resonator can be connected as shown in *Figure 38*. The crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is selected by setting LSEBYP bit to 0 and LSEON bit to 1.

The LSE offers a programmable driving capability (LSEDRV in RCC_LSECFGR) to modulate the amplifier driving capability. This driving capability is chosen according to the external crystal/ceramic component requirement to ensure a stable oscillation.

The driving capability must be set before enabling the LSE oscillator.

Warning: The driving capability must not be changed when the LSE is enabled. The LSE behavior is not guaranteed in that case.

LSE ready logic

The LSE offers an LSERDY flag, which indicates whether the LSE clock is available or not. When the LSE is enabled (LSEON = 1), LSERDY goes to 1 in RCC_SR when a certain number of valid LSE clock cycles has been detected. The lse_ck clock is not released until LSERDY goes to 1.

When LSEBYP = 0, the RCC waits 4096 clocks cycles before activating the LSERDY flag. When LSEBYP = 1, the RCC waits 16 clocks cycles.

An interrupt can be generated if enabled in RCC_CIER.

LSE controls

LSEBYP, LSEEXT, LSEDRV, and LSEON are write-protected by DBP in PWR_DBPCR. In order to modify the bits, DBP must be set 1.

The LSE oscillator is switched on and off using the LSEON bit.

The LSE remains enabled when the system enters Stop, Standby, or V_{BAT} mode (see *Table 69*).

The LSE clock can also be driven to MCOx outputs, and used as clock source for external components.

LSE programming sequence

To initialize the LSE, the application must follow the sequence hereafter:

1. Set DBP = 1 in PWR_DBPCR in order to allow write access.
2. Disable the LSE by writing to 0 to LSEON.
3. Check that the LSE is disabled by waiting LSERDY = 0.
4. If the oscillator mode is needed:
   - Select the oscillator mode by setting LSEBYP = 0.
   - Configure LSEDRV (if needed).
5. If an external clock is connected to OSC32_IN:
   - Select the bypass mode by setting LSEBYP = 1.
   - If the input clock is a full-swing digital signal, set LSEEXT = 1.
   - If the input clock is a low-swing signal, set LSEEXT = 0.
6. enable again the LSE by writing 1 to LSEON.
7. Wait for LSERDY = 1, then the LSE is ready for use.
8. If no further changes are needed, set DBP = 0 in PWR_DBPCR to write-protect the settings.

If the RTC is used, the LSE bypass must not be configured in digital mode, but in low-swing analog mode (default value after reset).

HSI oscillator

The HSI block provides the default clock to the device. It is a high-speed internal RC oscillator that can be used directly as system clock, peripheral clock, or as PLL input. A predivider allows the application to select an HSI output frequency of 8, 16, 32, or 64 MHz. This predivider is controlled by the HSIDIV in RCC_HSICFGR.

The HSI advantages are the following:

- low-cost clock source (no external crystals required)
- faster startup time than HSE (a few microseconds)
- reduced power consumption

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

HSI controls

The HSI can be switched on and off using HSION in RCC_CR. The HSIRDY flag in RCC_SR indicates if the HSI is stable or not. At startup, the HSI output clock is not released until HSIRDY is set to 1 by hardware.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (see *CSS on HSE*).

The HSI can be disabled or not when the system enters Stop mode (see *Table 69*).

The HSI clock can also be driven to MCOx outputs, and used as clock source for other application components.

Care must be taken when the HSI is used as kernel clock for communication peripherals. The application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request, and the moment where the clock is really available
- the frequency accuracy

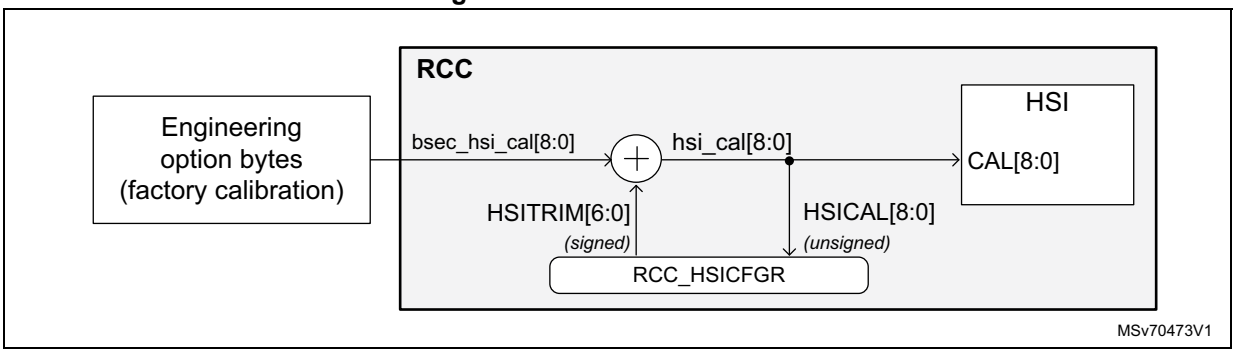
HSI calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an ACC_{HSI} accuracy (refer to the product datasheet for more information).

After a power-on reset or pin reset, the factory calibration value is loaded in HSICAL[8:0] in RCC_HSICFGR.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using HSITRIM[6:0] in RCC_HSICFGR.

Figure 41. HSI calibration flow



Note: The HSI clock divided by eight is also used for PAD compensation mechanism, and must be enabled if the PAD compensation mechanism is activated. Refer to Section 16: System configuration controller (SYSCFG) for additional details.

MSI oscillator

The MSI is a low-power RC oscillator that can be used directly as system clock, peripheral clock, or PLL input.

However, the following point must be considered: If the MSI clock is currently used as kernel clock for some peripherals, the application must ensure that the MSI frequency change does not disturb these peripherals.

The MSI advantages are the following:

- low-cost clock source (no external crystals required)
- faster startup time than HSE (a few microseconds)
- very low-power consumption

The MSI provides a clock frequency of 4 MHz (default MSIFREQSEL) or 16 MHz, while the HSI is able to provide a clock up to 64 MHz.

The MSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

MSI controls

The MSI can be switched on and off through the MSION in RCC_CR. The MSIRDY flag in RCC_SR indicates whether the MSI is stable or not. At startup, the MSI output clock is not released until MSIRDY is set by hardware.

The MSI can be disabled or not when the system enters Stop mode (see *Table 69*).

The MSI clock can also be driven to MCOx outputs, and used as clock source for other application components.

Even if the MSI settling time is faster than the HSI, care must be taken when the MSI is used as kernel clock for communication peripherals: the application must take into account the following parameters:

- the interval between the moment when the peripheral generates a kernel clock request, and the moment when the clock is really available
- the frequency precision

MSI calibration

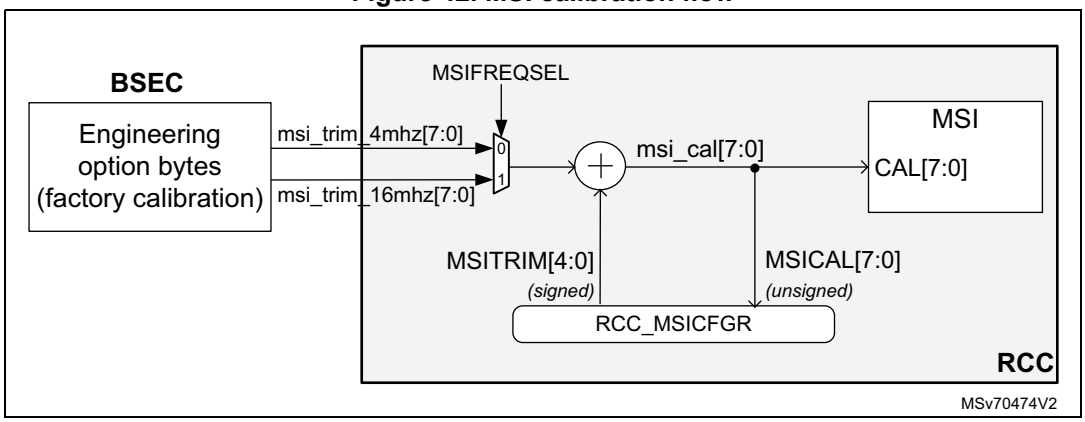
RC oscillator frequencies can vary because of manufacturing process variations. Each device is factory calibrated by ST to achieve the specified ACC_{MSI} accuracy (refer to the product datasheet for more information).

After a power-on or pin reset, the factory calibration value for 4 MHz is loaded in MSICAL[7:0] in RCC_MSICFGR.

If MSIFREQSEL is set to 16 MHz in RCC_MSICFGR, a different calibration value is provided by the BSEC.

Voltage or temperature variations can affect the RC oscillator frequency. The user application can trim the MSI frequency using MSITRIM[4:0] in RCC_MSICFGR.

Figure 42. MSI calibration flow



HSIS oscillator

The HSIS is a 64 MHz RC oscillator to clock only the BSEC. It is always activated after pwr_por_rstn or app_rstn reset.

When the system goes into Stop or Standby mode, the HSIS clock is disabled by hardware. Refer to *Section 14.6.7* for additional information.

HSIS calibration

RC oscillator frequencies can vary from one device to another, due to manufacturing process variations. To compensate for this, there is an HSISCAL[8:0] input on the oscillator.

The BSEC provides two calibration values (ambient and not ambient). The RCC selects between these two values using a select signal from the BSEC.

After a power-on reset, or pad reset, the factory calibration value is loaded in HSISCAL[8:0].

LSI oscillator

The LSI acts as a very low-power clock source that can be kept running when the system is in Stop or Standby mode for the IWDG and the auto-wake-up unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched on and off using LSION. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced on, and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode (see *Table 69*).

At LSI startup, the clock is not provided until the hardware sets LSIRDY. An interrupt can be generated if enabled in RCC_CIER.

Te LSI clock can also be driven to MCOx outputs, and used as a clock source for other application components.

14.6.3 Clock security system (CSS)

The CSS can detect a failure of either (or both) LSE and HSE oscillators. There are signals that can be connected to the TAMP (rcc_lsecss_fail and rcc_hsecss_fail), and signals for the interrupt controller (rcc_lsecss_it, rcc_hsecss_it, and rcc_it).

CSS on HSE

The CSS can be enabled by software via HSECSSON. This bit can be enabled even when HSEON = 0.

The CSS on HSE is activated when the HSE is enabled and ready, and when the software sets HSECSSON = 1. The CSS on HSE does no longer work when the HSE is disabled. For example, this function does not work when the system is in Stop mode.

HSECSSON cannot be cleared directly by software. It is cleared by hardware when a system reset occurs, or when the system enters Standby mode (see *Section 14.5.2*).

On an HSE failure, an HSI injection feature can automatically inject a divided HSI clock in replacement at the root of the HSE tree. Users of the failed HSE keep running, but potentially at a slightly lower frequency. The HSI injected clock is adapted to the HSE frequency by an integer division. The PLLs relocks, but at the same or lower speed.

To enable the automatic HSI injection, first configure HSECSSBPRE in RCC_HSECFGR, then set HSECSSBYP = 1.

The HSI division ratio is configured with HSECSSBPRE. For instance, with the HSI at 64 MHz and an HSE at 48 MHz, the division ratio must be configured to 2x (HSECSSBPRE = 1): a failed HSE is replaced by a clock at 64 / 2 = 32 MHz.

When the CSS on HSE is enabled, the following actions are done by the RCC if a failure is detected:

- If the HSI injection feature is enabled, the HSI oscillator is forced active, and the HSE clock is replaced by hsi_css_ck.
- rcc_hsecss_fail is asserted.
- The clock failure event (rcc_hsecss_fail) is also sent to the break inputs of advanced-control timers (TIM1/8/15/16/17).
- An NMI interrupt is generated to inform the software about the failure (rcc_hsecss_it). This allows the MCU to perform rescue operations. The NMI interrupt is asserted until HSECSSF = 0 in RCC_CICR. The HSECSSF flag can be cleared by setting HSECSSC = 1.
- A tamper event can also be triggered to clear content of backup registers and BKPSRAM.

CSS on LSE

A CSS on the LSE oscillator can be enabled by software by programming LSECSSON. This bit is disabled by hardware if one of the following conditions is met:

- after a V_{SW} hardware reset (pwr_vsw_rst)
- after a V_{SW} software reset via VSWRST bit

The software can also disable the CSS after an LSE failure detection.

The CSS on LSE works in all modes (Run, Stop, and Standby modes) including V_{BAT} mode.

The LSECSS provides a re-arm feature, offering the possibility to the software to re-arm the LSECSS, and to re-enable the LSE clock when a failure has been detected. This feature allows the application to decide if the LSE must be provided again to the RTC even if a failure occurred, or if another action must be performed. For example, the application can decide to reset the V_{SW} domain only if a certain number of consecutive LSE failures occurred, within a time window.

The LSECSS offers two flag signals:

- the LSECSSD able to retain an LSE failure even in V_{BAT} mode
- the LSECSSF used to generate an interrupt in case of LSE failure (flag not affected by a failure detected when the product is in V_{BAT} mode)

The sequence hereafter describes the LSE that enables sequence with the CSS enabled:

1. Follow the LSE enable procedure given in *LSE programming sequence*, except the last step.
2. Select the LSE clock via RTCSEL[1:0].
3. Set the LSECSSON bit to 1.
4. If no further changes are needed, clear DBP to 0 in PWR_DBPCR to write-protect accesses.

Note: The LSECSSON bit must be enabled after the LSE is enabled (LSEON set by software) and ready (LSERDY set by hardware), and after the RTC clock has been selected through RTCSEL.

If a failure is detected on the LSE, the hardware does the following:

- The LSE clock is no more delivered to the RTC.
- RTCSEL, LSECSSON, and LSEON are not changed by the hardware.
- A failure event is generated (rcc_lsecss_fail). This event allows the system to wake up from Standby mode, but also to protect the backup registers and BKPSRAM via TAMP. This event is also generated in V_{BAT} mode.
- The LSECSSF is activated (except in V_{BAT} mode) in order to generate an interrupt (rcc_lsecss_it, enabled by LSECSSIE).
- The LSECSSD is activated as well, retaining the first LSE failure even in V_{BAT} mode.

On the software side, different actions can be taken according to the application requirements. Three different cases are described hereafter in order to illustrate the hardware behavior, they can also be combined. The application can also decide to handle LSE failure differently.

Case A

The application no longer wants to use LSE when a failure is detected:

1. Unlock registers by setting DBP in PWR_DBPCR to 1.

2. Disable the CSS function (this step is mandatory):
   a) Clear LSECSSF if the interrupt was enabled for this event.
   b) Clear LSECSSON to 0.
   c) Clear LSEON to 0 in order to disable the LSE.
3. Change the clock source for the RTC if needed:
   a) Clear RTCEN to 0 to disable the RTC clock.
   b) Enable the new clock source for the RTC.
   c) Set RTCPRE if HSE is a new clock source.
   d) Select the proper clock source via RTCSEL.
   e) Set RTCEN to 1 to enable the RTC clock.
4. The application must perform specific actions for TAMP events if enabled (see *Section 4: Boot and security control (BSEC)* and *Section 61: Real-time clock (RTC)*).

- Lock registers by clearing DBP to 0 in PWR_DBPCR

Case B

The application wants to re-initialize the V_{SW} domain:

1. Unlock registers by setting the DBP bit of PWR_DBPCR to 1
2. Perform a VSW reset by setting VSWRST bit to 1, then back to 0.
3. The application must perform specific actions for TAMP events if enabled (see *Section 4: Boot and security control (BSEC)* and *Section 61: Real-time clock (RTC)*).
4. Re-initialize all components of the V_{SW} domain.
5. Lock registers by clearing DBP to 0 in PWR_DBPCR.

Case C

The application tries to reuse LSE when a failure is detected:

1. If the number of failures in a given time window is higher than a given threshold then go to case A or B. Otherwise, continue to next step.
2. Unlock registers by setting DBP to 1 in PWR_DBPCR.
3. Clear LSECSSF if interrupt was enabled for this event.
4. The application must perform specific actions for TAMP events if enabled (see *Section 4: Boot and security control (BSEC)* and *Section 61: Real-time clock (RTC)*).
5. Clear LSECSSON to 0.
6. Rearm the LSECSS function by writing 1 to LSECSSRA, then back to 0.
7. Wait for LSERDY = 1. The LSERDY flag must go to 1 after the oscillator settling time delay plus, 4096 periods of LSE clock. If it is not the case, it probably means that the LSE failure is permanent. LSECSSON cannot be set to 1. It is recommended to execute case A or B.
8. Set LSECSSON to 1.
9. When LSECSSON = 1, the LSE is enabled, and protected by LSECSS.
10. Lock registers by clearing DBP to 0 in PWR_DBPCR.

14.6.4 Clock output generation (MCO1/MCO2)

There are two MCO1 and MCO2 microcontroller clock output pins. A clock source can be selected for each output.The selected clock can be divided thanks to a configurable prescaler (refer to *Figure 37* for additional information on signal selection).

MCO1 and MCO2 are enabled using MCO1EN and MCO2EN in RCC_MISCENR.

The GPIO port corresponding to each MCO pin must be programmed in alternate function mode.

MCO1 and MCO2 are controlled via MCO1PRE[3:0], MCO1SEL[2:0], MCO2PRE[3:0], and MCO2SEL[2:0] located in RCC_CCIPR5.

MCO1PRE and MCO2PRE dividers provide a clock with a duty cycle of 50% for even divisions values, and around 53% for odd division values.

Note: MCO1 and MCO2 are available in Run, Stop, and Sleep modes.

Caution: The clock provided to the MCOx outputs must not exceed the maximum pin speed (refer to the product datasheet for information about the supported pin speed).

Table 70 shows the signals available on each MCO output.

Table 70. Clock output selection

MCO1SEL		MCO2SEL	
Position	**Clock source**	**Position**	**Clock source**
0	hsi_div_ck	0	hsi_div_ck
1	lse_ck	1	lse_ck

7	sysa_ck	7	sysb_ck

14.6.5 PLL description

The RCC features four PLLs with the same features.

A typical allocation is:

- PLL1, clocks to the CPU, buses, and storage (XSPI, SDMMC)
- PLL2, clocks to NPU and audio peripherals
- PLL3, clocks to CACHEAXI RAM and Ethernet
- PLL4, clocks to display, camera, FDCAN, and other peripherals

Each PLL has the following features:

- FREF frequency range:
  - 5 to 1200 MHz in integer mode
  - 10 to 1200 MHz in fractional mode
- VCO frequency range from 800 to 3200 MHz
- Three working modes:

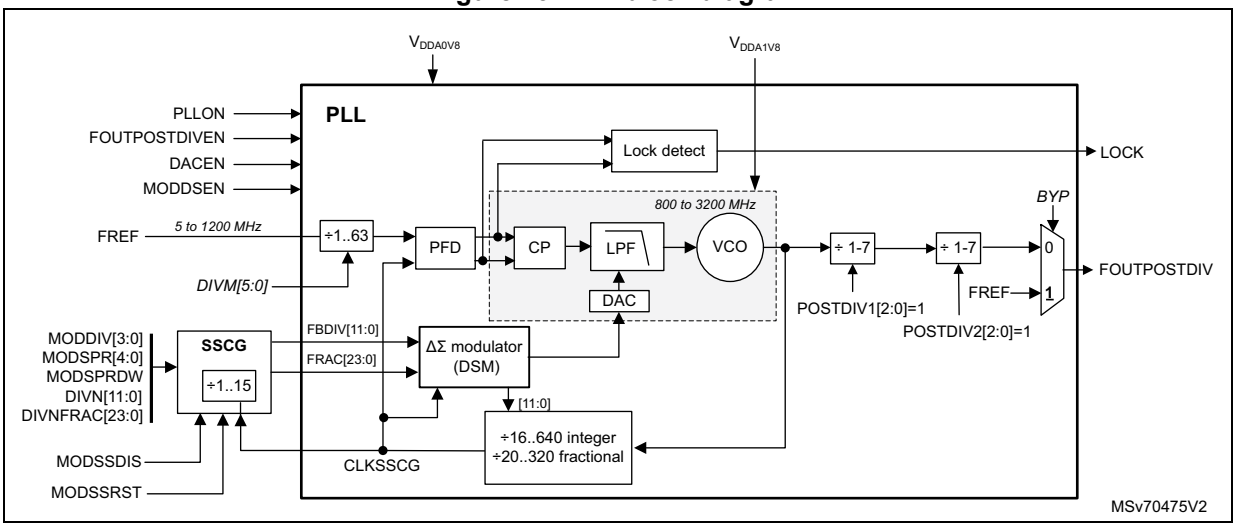
– fractional mode, using a 24-bit delta-sigma modulator (DSM)
– integer mode
– spread spectrum mode to reduce EMI. The fully digital spread spectrum clock generator (SSCG) is used in that case.

The internal post-dividers (POSTDIV1, POSTDIV2) are powered-off by default. They must be powered-on when the PLL is in use (PLLxPDIVEN).

The active post-dividers (ICx) are outside the PLL design. Each post-divider has a 4-way multiplexer before it, which can select any PLL output as input.

The DIVMx divider in RCC_PLLxCFGR1 must be properly programmed to keep the PFD input frequency below 50 MHz.

Figure 43. PLL block diagram



The PLL is enabled by setting PLLxON to 1 in RCC_CR. PLLxRDY in RCC_SR indicates that the PLL is ready (locked).

The DIVNx loop divider must be programmed to achieve the expected VCO output frequency before enabling the PLL. Changing the value on-the-fly can result in a spike on the VCO output proportional to the PFD frequency step. A frequency step of more than 0.01% per PFD clock period must be avoided. The SSCG typically steps the frequency by less than 0.005% per PFD clock period, so does not generate spikes.

The VCO output range must be respected.

The clock from FOUTPOSTDIV has a 50% duty-cycle (± 3%).

The ICx post-dividers provide clocks with 50% duty-cycle when dividing by an even value.

If an ICx post-divider enable is set to 0, its value can be changed without disabling any PLL.

The PLLs are disabled by hardware when the system enters Stop or Standby mode.

PLLs using HSE as reference clock are also disabled by hardware if an HSE failure is detected.

PLL programming recommendations

- Before enabling the PLLs, the user must ensure that the reference frequency (FREF) provided to the PLL is stable and in the correct range.
- POSTDIV1 and POSTDIV2 must be set to 1.
- PLLxPDIVEN must be set to 1 to output the clock FOUTPOSTDIV.
- When a PLL output is used, PLLxON and PLLxRDY must be set to 1. The application can then set any connected post-divider enable bits to 1 (in RCC_DIVEN).
- When a PLL output is not used, PLLxON must be cleared to 0. The application must also set any connected post-divider enable bits to 0 (in RCC_DIVEN).

Caution: The 4 MHz setting for the MSI oscillator cannot be used as FREF.

The PLLs can work in three different modes:

- integer
- fractional
- spread spectrum

Using PLLs in integer mode

The PLLx works in integer mode when the delta-sigma modulator (DSM) is loaded with a 0 value, and PLLxMODSSDIS = 1.

To load 0 into the DSM and to set DIVN, use the following sequence:

1. Clear PLLxON to 0.
2. Set DIVN value (valid range 16 to 640).
3. Clear DIVNFRAC (in RCC_PLLxCFGR2) and PLLxMODDSEN to 0.
4. Set PLLxMODSSRST to 1.
5. Set PLLxON to 1.

Caution: Do not update DIVN after the PLL has been enabled.

The VCO frequency (F_{VCO}) and output frequency expressions are the following:

$$F_{VCO} = F_{REF} \times \frac{DIVN}{DIVM}$$

$$F_{OUTPOSTDIV} = \frac{F_{VCO}}{POSTDIV1 \times POSTDIV2}$$

Using the PLLs in fractional mode

This mode is enabled when DSM ≠ 0, PLLxMODDSEN = 1, and PLLxMODSSDIS = 1.

To load the value into the DSM perform the following sequence:

1. Clear PLLxON to 0.
2. Set DIVN value (valid range 20 to 320).
3. Set DIVNFRAC (in RCC_PLLxCFGR2) to the required value, and set PLLxMODDSEN = DACEN 1.
4. Set PLLxMODSSRST to 1.
5. Set PLLxON to 1.

Caution: Do not update DIVN and DIVNFRAC after the PLL has been enabled.
The minimum FREF is 10 MHz in fractional mode.

The VCO frequency (F_{VCO}) and output frequency expressions are the following:

$$F_{VCO} = F_{REF} \times \frac{\left(DIVN + \frac{DIVNFRAC}{2^{24}}\right)}{DIVM}$$

$$F_{OUTPOSTDIV} = \frac{F_{VCO}}{POSTDIV1 \times POSTDIV2}$$

Using PLLs in spread spectrum mode

The spread spectrum mode is activated when the DSM is loaded with 0, and PLLxMODSSDIS is cleared to 0. This feature is available for all PLLs.

The spread spectrum method is to modulate the VCO frequency with a low-frequency triangular signal, in order to spread the clock energy into a wider frequency band. The amount of emitted EMI is then reduced.

The spread spectrum modulation is adjusted using the following fields:

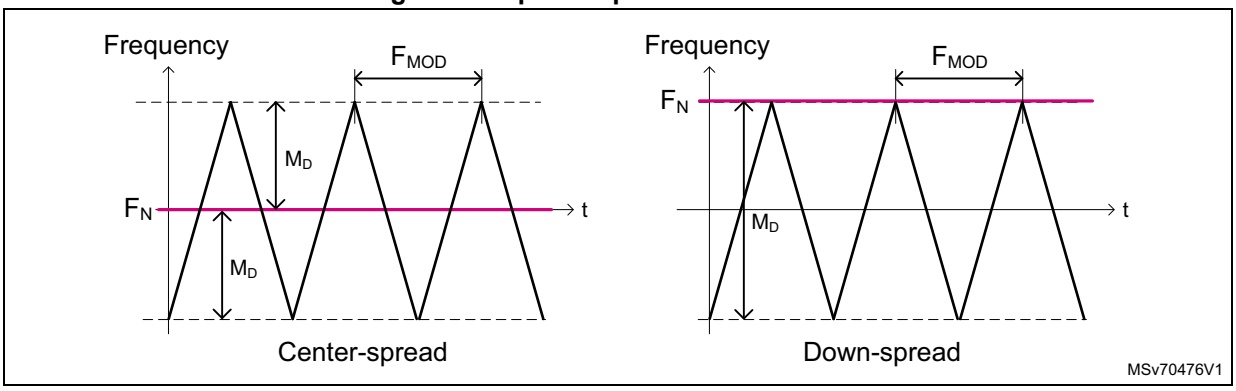
- MODDIV[3:0] to adjust the modulation frequency
- MODSPR[4:0] to adjust the modulation depth (or modulation index)
- MODSPRDW to define if the modulation is centered around the VCO frequency (center-spread), or lowered with respect to VCO frequency (down-spread)

MODDIV[3:0], MODSPR[4:0] and MODSPRDW are in RCC_PLLxCFGR3.

Figure 44 shows the SSCG modulating the nominal frequency (F_N), when MODSPRDW = 0 (center-spread), and MODSPRDW = 1 (down-spread). The nominal frequency is that output by the PLL in integer mode, when no clock spreading is applied.

Down-spread guarantees that the PLL output frequency does not exceed the programmed frequency value when SSCG is enabled.

Figure 44. Spread spectrum modulation



The peak modulation depth (in percentage) is given by the formula M_D (%) = MODSPR /10.

Note: Modulation is turned off when MODSPR = 0.

The modulation frequency (F_{MOD}) is given by:

$$F_{MOD} = \frac{F_{CLKSSCG}}{128 \times MODDIV}$$

where 128 is the number of points in the internal wave table.

Note: When the PLL is locked, $F_{CLKSSCG} = F_{PFD}$. The upper limit of the frequency of modulation (F_{MOD}) is set by the PLL bandwidth. The PLL bandwidth limits the maximum modulation to $F_{CLKSSCG}$ / 200, where $F_{CLKSSCG} = F_{REF}$ / DIVM or 50 MHz, whichever is lower.

To use the spread spectrum feature, to do the following:

1. Program the PLL to the nominal frequency (F_N) using the $F_{OUTPOSTDIV}$ formula from *Using PLLs in integer mode*
2. Compute the MODDIV value according to the desired modulation frequency (F_{MOD}):

$$MODDIV = ROUND\left(\frac{F_{CLKSSCG}}{128 \times F_{MOD}}\right)$$

3. Compute the MODSPR value according to the desired modulation depth (M_D).
4. Set the MODSPRDW value according to the desired modulation type (center-spread or down-spread).
5. Compute DIVN accordingly (DIVNFRAC=0):

$$DIVN = ROUND\left(\frac{F_N \times DIVM}{F_{REF}}\right)$$

6. Clear PLLxMODSSDIS, PLLxMODDSEN, and DACEN to 0.
7. Set PLLxMODSSRST to 1, and clear PLLxON to 0. PLLxON must be held at 0 for 1 µs to make sure the PLL is fully reset.
8. Set PLLxON, PLLxMODDSEN, and DACEN to 1 (see *Note:*).
9. Wait until the first edge of CLKSSCG, and then clear PLLxMODSSRST to 0 (this can be done before or after the PLL is locked).

Note: The spread spectrum accuracy relies on the PLL fractional-N capability, so MODDSEN and DACEN must be set to 1.

The user can check F_{MIN}, F_{MAX} as follows:

- Calculate F_N as above.
- If MODSPRDW = 0 (center-spread):

  $F_{MIN} = F_N \times (1 - M_D / 100)$ and $F_{MAX} = F_N \times (1 + M_D / 100)$
- If MODSPRDW = 1 (down-spread):

  $F_{MIN} = F_N \times (1 - M_D / 100)$ and $F_{MAX} = F_N$

Programming sequence for spread spectrum mode

The programming sequence to enable SSCG and the PLL is:

1. Deassert PLLxMODSSRST.
2. Set PLLxDIVN, PLLxDIVNFRAC, and PLLxMODSSDIS to 0.

3. Assert PLLxMODDSEN and PLLxDACEN.
4. Assert PLLxMODSSRST and deassert PLLxON.
5. PLLxON must be deasserted for 1µs to make sure PLL is fully reset. Then assert PLLxON.
6. Wait until PLLxRDY is asserted, then deassert PLLxMODSSRST.

14.6.6 System clocks

System clock selection

After a system reset, the HSI is selected as system clock (sys[a,b,c,d]_ck), and all PLLs are switched off.

The system clock can be stopped by hardware when the system enters Stop or Standby mode.

When the system runs, the user can select system clocks (sys[a,b,c,d]_ck) from the four following sources:

- HSE
- HSI
- MSI
- ic[1,2,6,11]_ck

This function is controlled by programming RCC_CFGR1. A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready.

The SYSSW only selects the ic[2,6,11]_ck if all three IC dividers are enabled.

SWS bits in RCC_CFGR1 indicate which clock sources are currently selected. Other status bits in RCC_CR indicate which clock(s) is (are) ready.

System clock generation

Figure 45 shows a simplified view of the clock distribution for the CPU and buses. All the dividers shown in the block diagram can be changed on-the-fly, without generating timing violations. This feature is a very simple solution to adapt bus frequencies to application needs, thus optimizing the power consumption.

The AXI sys_bus_ck is divided by HPRE to generate the AHB clock. HPRE is controlled by RCC_CFGR2.

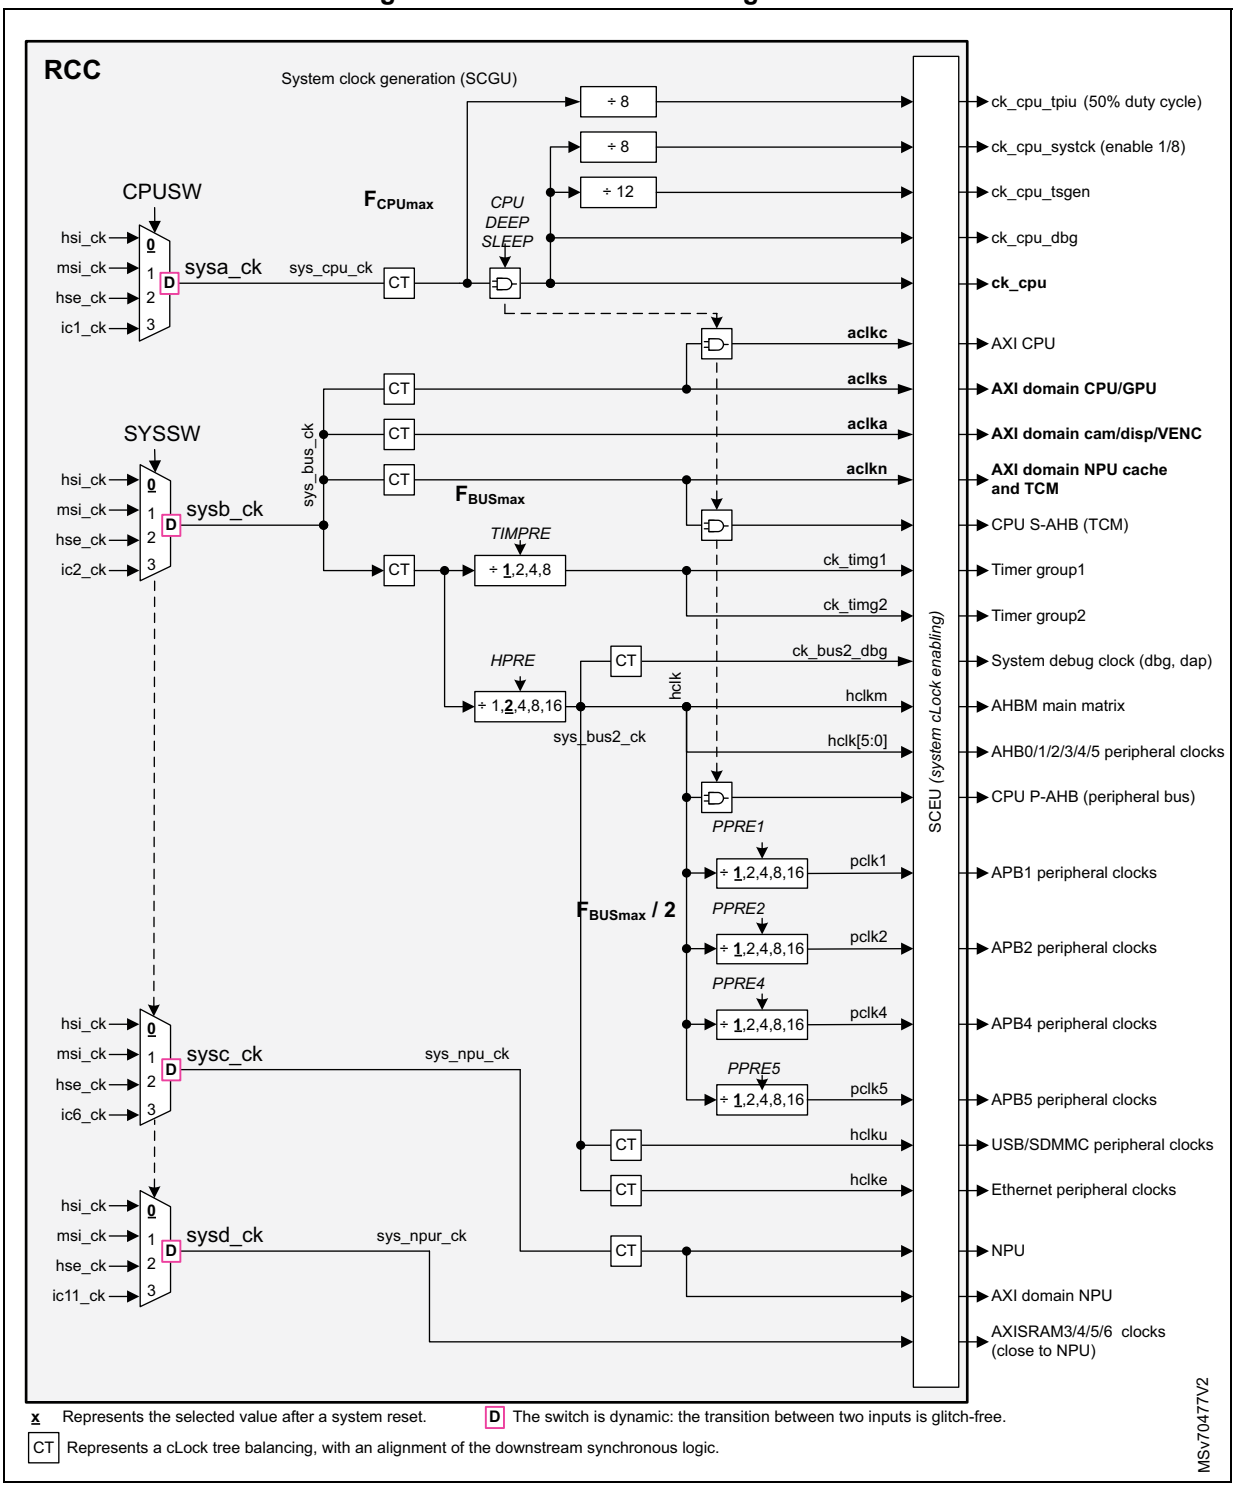
In addition to the divide values shown, PPRE1, PPRE2, PPRE4, and PPRE5 can divide by 32, 64, and 128.

There is almost no clock protection, so the software must avoid configurations that can block the system.

Note: The application must respect the maximum allowed frequencies: F_{CPUmax} and F_{BUSmax}. F_{BUS} represents the maximum allowed frequency for AHB and AXI buses (refer to the datasheet for the maximum values).

The trace clock (ck_cpu_tpiu) is generated from sys_cpu_ck clock, divided by eight. For additional information, refer to Clock distribution for trace and debug.

Figure 45. Core and bus clock generation



1. Dividers values can be changed on-the-fly. All dividers have 50% duty-cycles.

14.6.7 Clock generation in Stop and Standby modes

When the system enters Stop mode, all clocks (system and kernel) are stopped, and the following clock sources are disabled as well:

- MSI, HSI
- HSE
- PLL1, PLL2, PLL3, PLL4

Note: The MSI and HSI stay active based on xxxSTOPEN bits in RCC_STOPCR.

HSIS is also disabled.

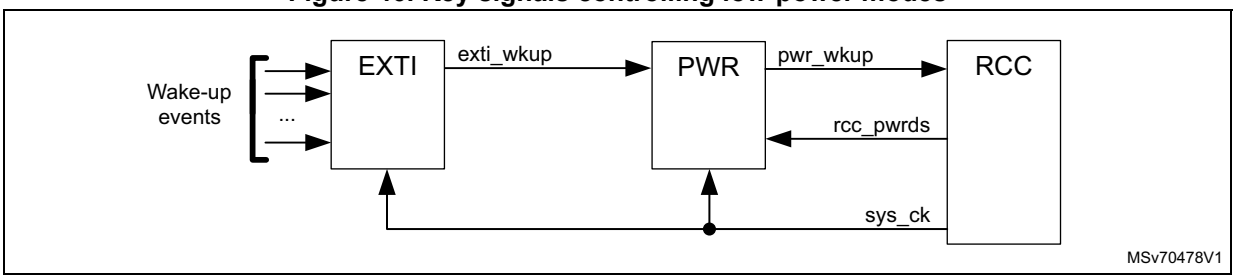
The content of the RCC registers is not altered, except CPUSW and SYSSW, forced to HSI or MSI (depending on STOPWUCK value), and PLLxON and HSEON, set to 0.

HSION and MSION are also modified, depending on STOPWUCK (see *Table 71*).

When the CPU requests to go in Stop mode, the RCC first stops all requested clocks, and informs the PWR that all clocks have been properly stopped. As shown in *Figure 46*, three main signals are used to control power transitions:

- rcc_pwrds: used to indicate to the PWR that the RCC stopped all clocks. The PWR can then go to Stop or Standby mode.
- pwr_wkup is used to indicate to the RCC to re-enable the clocks.
- The exti_wkup is used to indicate to the PWR that an event requests to exit the system from Stop mode.

Figure 46. Key signals controlling low-power modes



Exiting Stop mode

When the device exits system Stop mode via a wake-up event, HSIS is started automatically.

Note: sys_rst is only deasserted after HSIS has successfully started.

The application can select which other oscillator (HSI and/or MSI) is used to restart the system. STOPWUCK in RCC_CFGR1 selects the oscillator used as system clock. *Table 71* describes their behavior.

Table 71. STOPWUCK description

STOPWUCK	-	Activated oscillator when system exits Stop mode	Distributed clocks when system exits Stop mode	
			System clock	Kernel clock
0	→	HSI	HSI	HSI
1	→	MSI	MSI	MSI

During Stop mode

There are two specific cases where the HSI or MSI can be enabled during system Stop mode:

- When a dedicated peripheral requests the kernel clock, the peripheral receives the HSI or MSI according to the kernel clock source selected for this peripheral (via PERxSEL).
- When HSISTOPEN or MSISTOPEN are set in RCC_STOPCR, the HSI and MSI are kept running during Stop mode but the outputs are gated. The clock is then available immediately when the system exits Stop mode, or when a peripheral requests the kernel clock (see *Table 72* for details).

Caution: HSI and MSI are always off in Stop mode when the PWR is set to SVOS low.

Table 72. HSISTOPEN and MSISTOPEN behavior

HSISTOPEN (MSISTOPEN)	-	HSI (MSI) state during Stop mode	HSI (MSI) setting time
0	→	Off	$t_{su(HSI)}$ ($t_{su(MSI)}$) (1)
1	→	Running and gated	Immediate

1. $t_{su(HSI)}$ and $t_{su(MSI)}$ are the startup times of the HSI and MSI oscillators (see the datasheet for their values).

When the microcontroller exits Standby mode, the HSI is selected as system and kernel clock. RCC registers are reset to their initial values except for the backup domain configurations (LSE in RCC_CR/RCC_LSECFGR, RTC in RCC_CCIPR7, RCC_BDCR), and the reset cause (RCC_RSR, RCC_HWRSR).

Caution: When leaving Stop mode without reset (but not from Standby mode), the RCC returns in the same state as before, except for the software that has been forced to select the STOPWUCK source. When leaving Standby mode, the application can restore previous CPU clock settings, if needed.

Caution: If the system clock switch selection (SYSSW) is HSI or MSI oscillator, STOPWUCK (system clock selection after a wake-up from system Stop) must select the same oscillator.

14.6.8 Peripheral clock distribution

Some peripherals are designed to work with two different clock domains, operating asynchronously:

- a domain synchronous with the register and bus interface (ckg_bus_perx clock)
- a domain generally synchronous with the peripheral (kernel clock)

Other peripherals only need a bus interface clock, hence the user application has more freedom to choose an optimized clock frequency for the CPU, bus matrix, and for the kernel part of the peripheral. The user can change the bus frequency without reprogramming peripherals (example: an ongoing transfer with UART is not disturbed if its APB clock is changed on-the-fly).

Table 73 summarizes the clocks from RCC to the peripherals. The clock named per_ck is the output of a mux (see *Figure 37*).

Table 73. Peripheral clock distribution summary

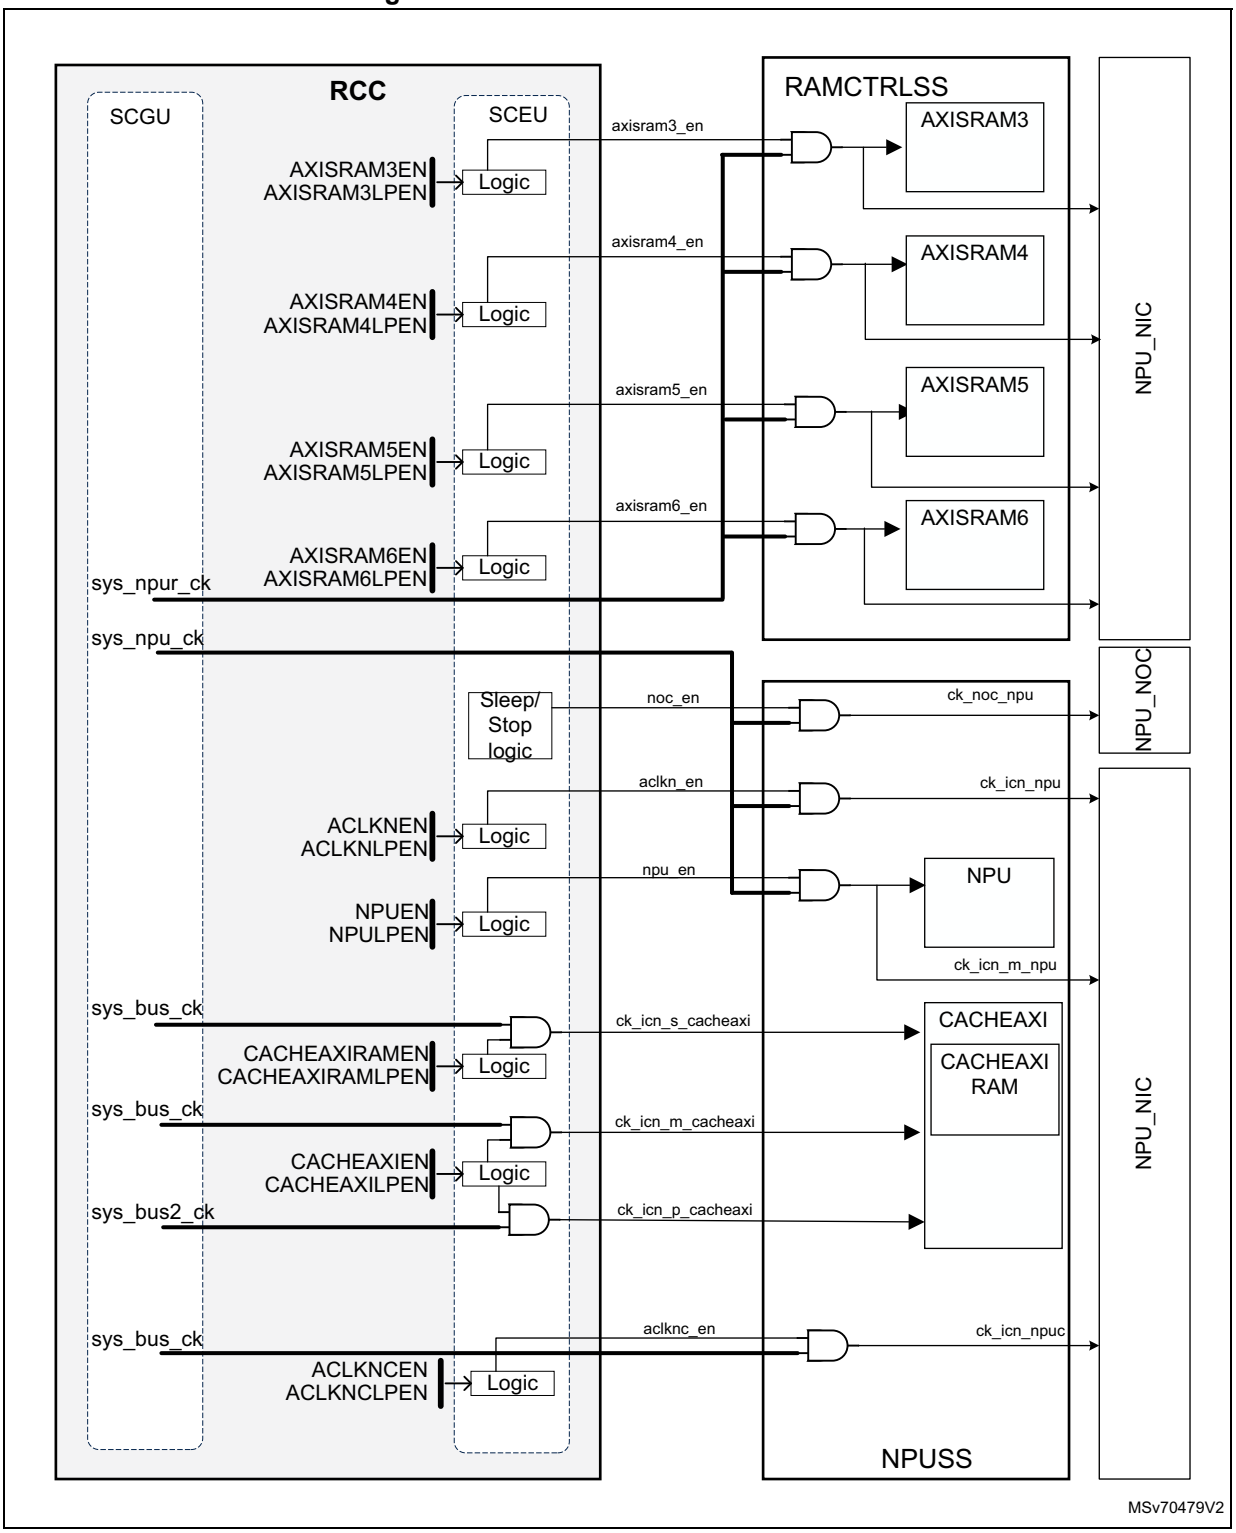
Clock distribution for the NPU

Figure 47. Clock distribution for the NPU



Clock distribution for graphic blocks (GPU, LTDC, DCMIPP, and PSSI)

Figure 48. Clock distribution for PSSI, CSI, and DCMIPP

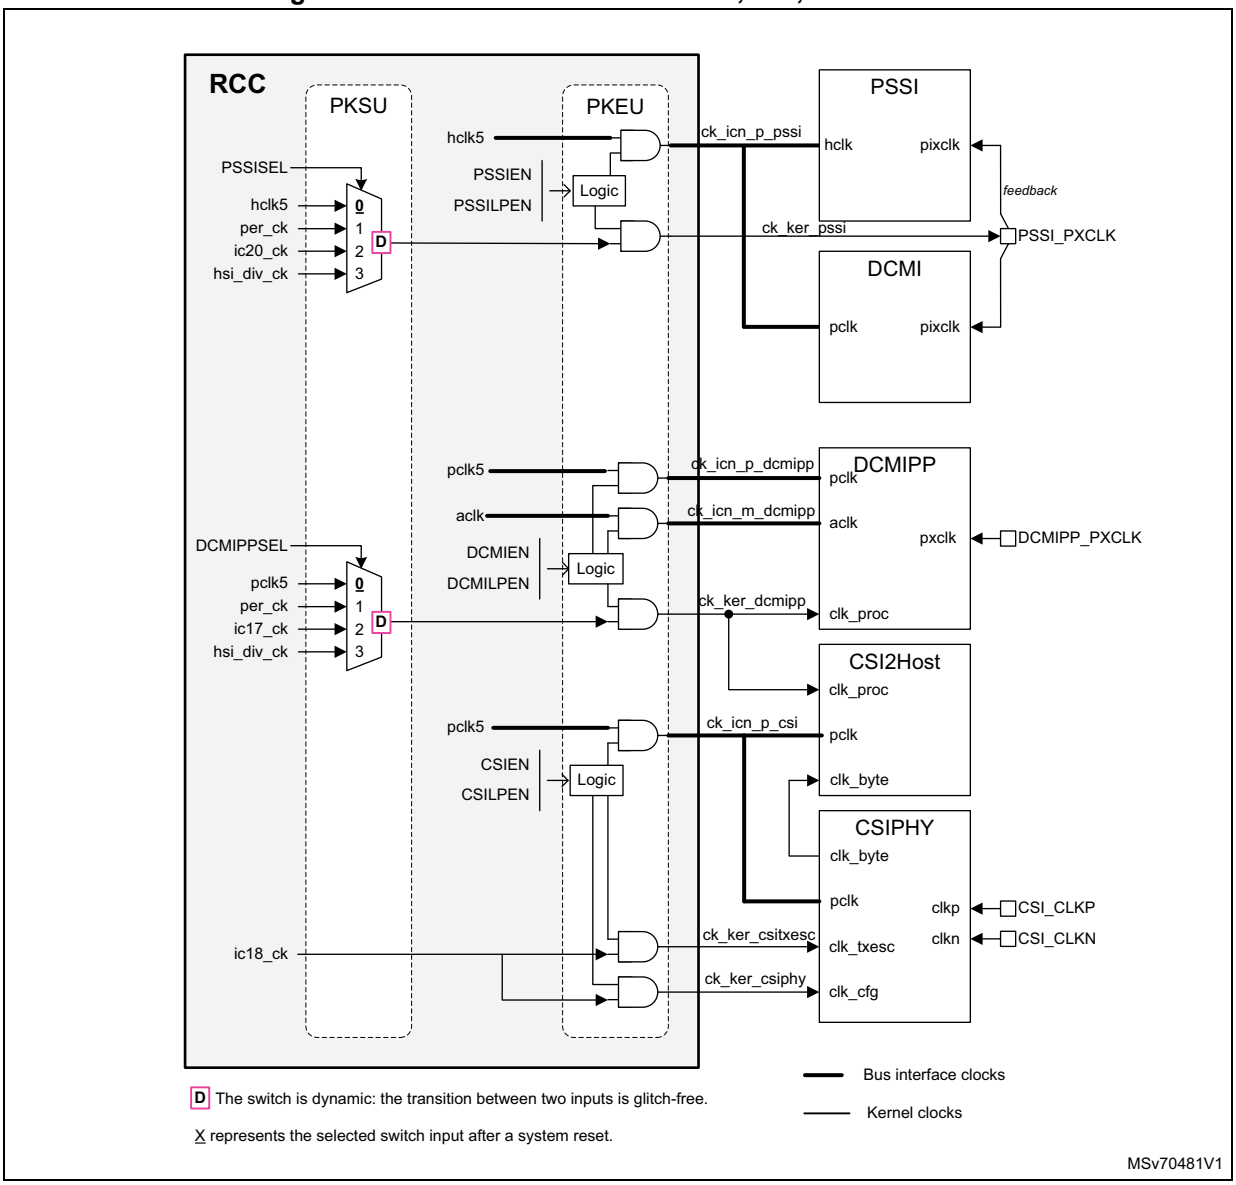


Figure 49. Clock distribution for GPU, ICACHE, and GFXMMU

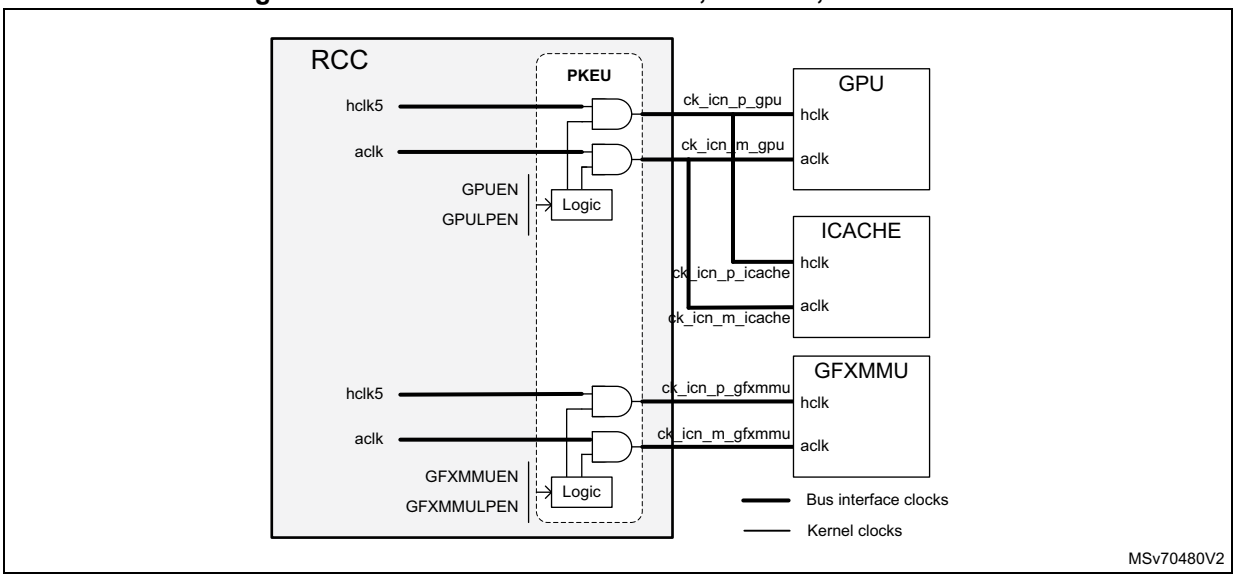

The PSSI receives an AHB clock and a kernel clock (pxclk). The pxclk can be provided either by an external device via PSSI_PIXCK pin, or by the RCC.

Note: The clock generated by the RCC is provided to pxclk input by the feedback path of the PSSI_PIXCK pin. The drive of the PSSI_PIXCK is controlled by the PSSI.

Figure 50. Clock distribution for LTDC

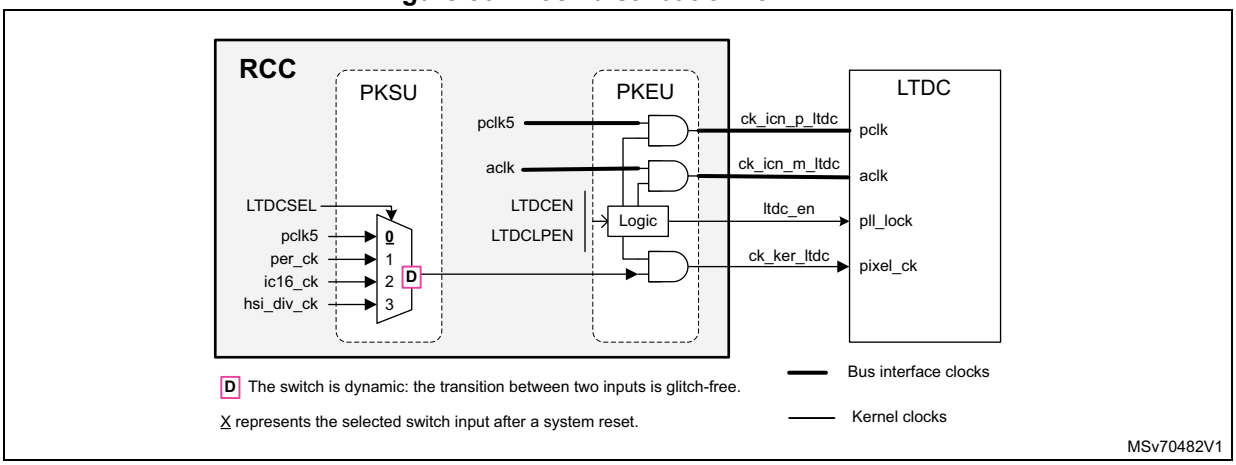

Figure 51. Clock distribution for VENC

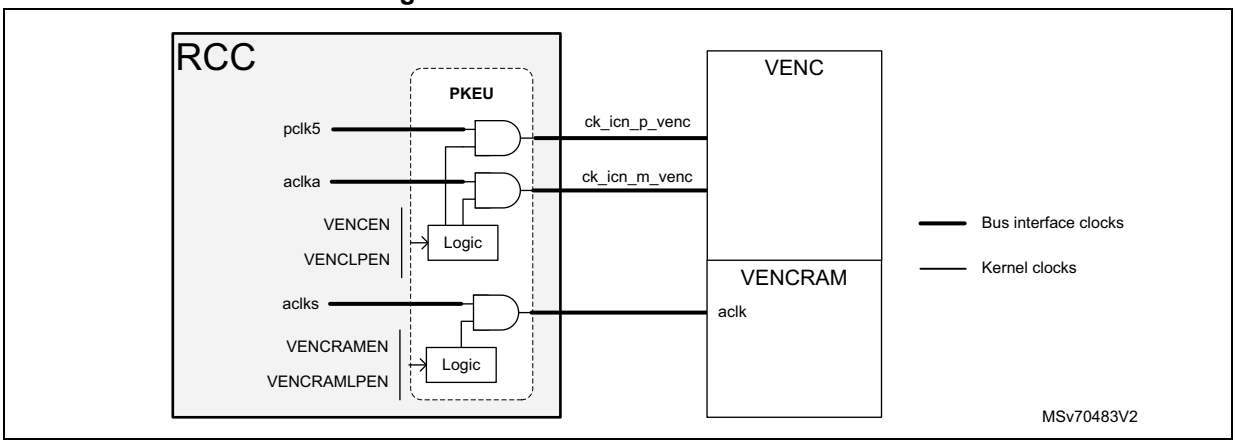


Clock distribution for OTG1, OTG2, and UCPD1

Figure 52 shows the clock distribution for:

- USB Type-C Power Delivery block (UCPD1): uses ucpd1_ker_ck as kernel clock. ucpd1_ker_ck is directly generated from the HSI output divided by four.
- OTGPHYx: embeds a PLL that accepts a reference input frequency of 19.2, 20, or 24 MHz. The reference clock can be selected among one of the following:
  - hse_div2_osc_ck
  - hse_div2_ck
  - ic15_ck
  - per_ck

  hse_div2_osc_ck is direct from the HSE oscillator, without the tempo delay. It can be selected to be HSE or HSE/2.

  The OTGPHYx provides a 60 MHz clock (phyclock) to the OTGx.
- OTGx: uses the phyclock when working in HS or FS mode.

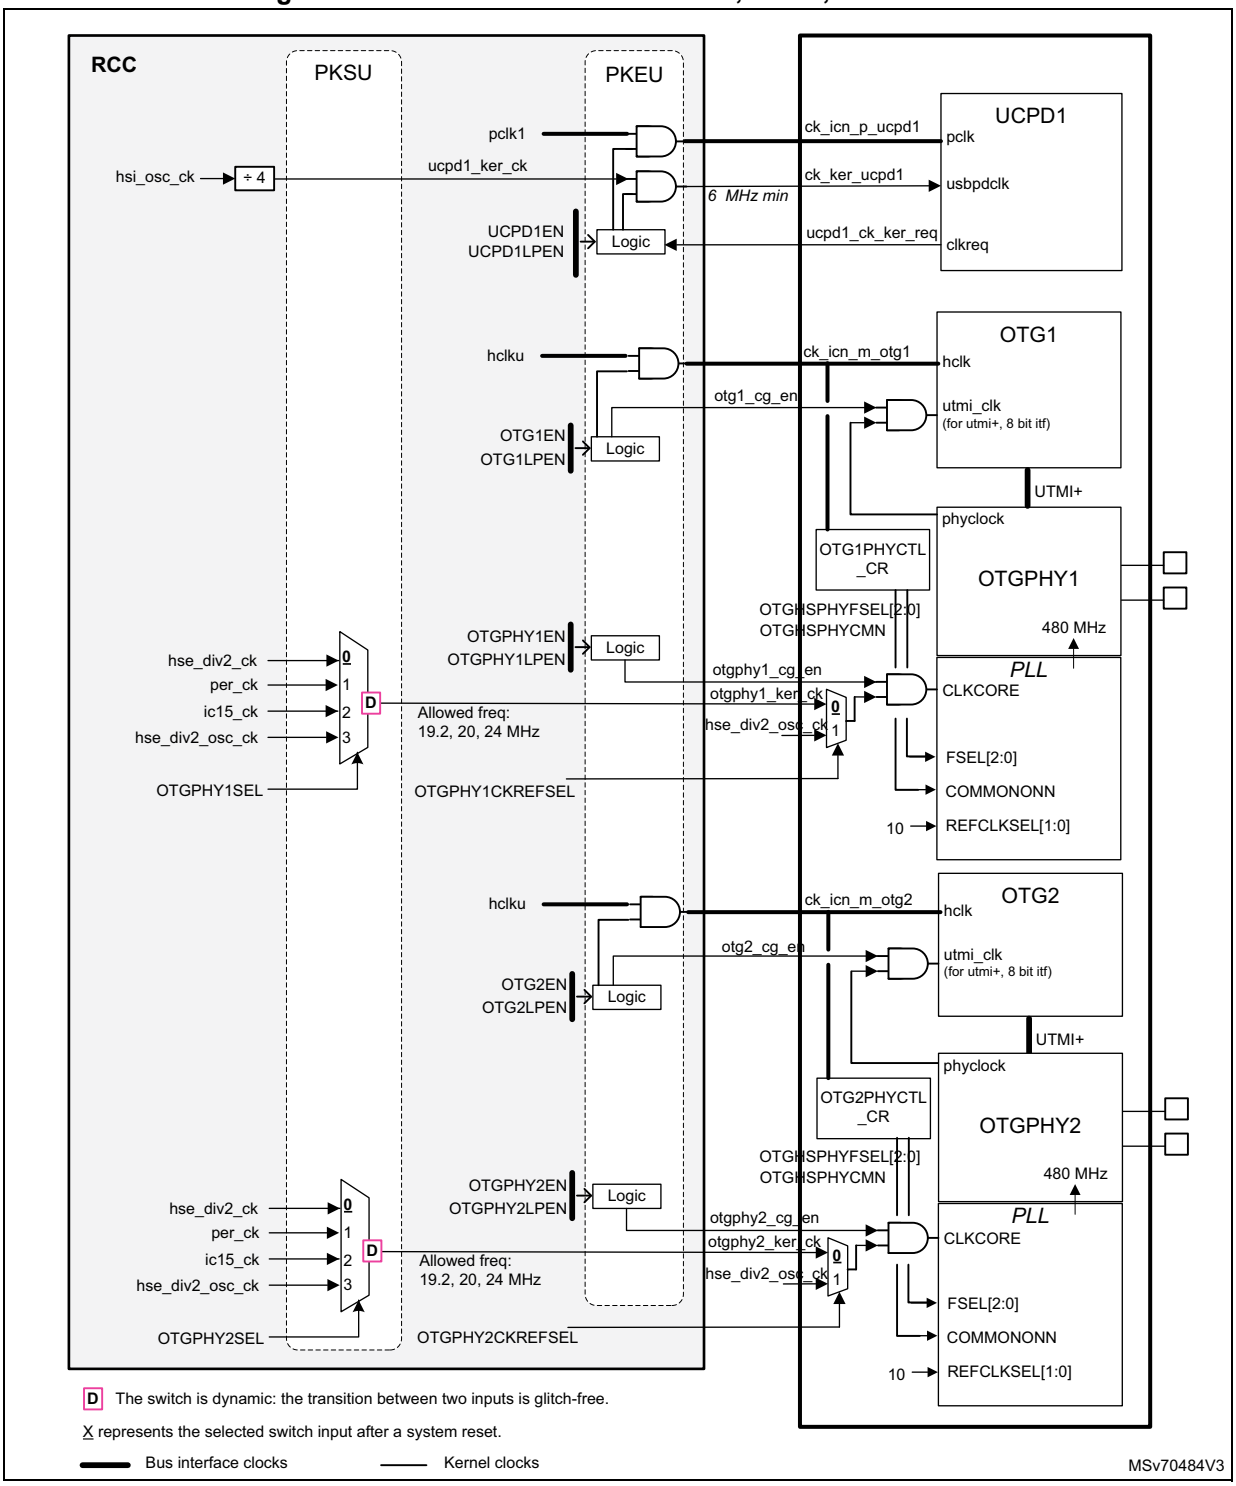
The reference clock selection for the OTGPHYx is performed by a simple multiplexer. To change the clock source, the application must use the following sequence:

1. Disable the OTGPHYx clock by clearing OTGPHYxEN to 0.
2. Change the clock source selector (OTGPHYxSEL) to the desired value.
3. Enable the OTGPHYx clock by setting OTGPHYxEN to 1.

Clocks provided by the RCC are controlled by enable bits in RCC_AHB5ENR.

Note: Before programming OTG1PHYCTL_CR, OTG1EN must be asserted (the OTG1PHYCTL_CR logic requires the clock enabled by OTG1EN).

Figure 52. Clock distribution for OTG1, OTG2, and UCPD1

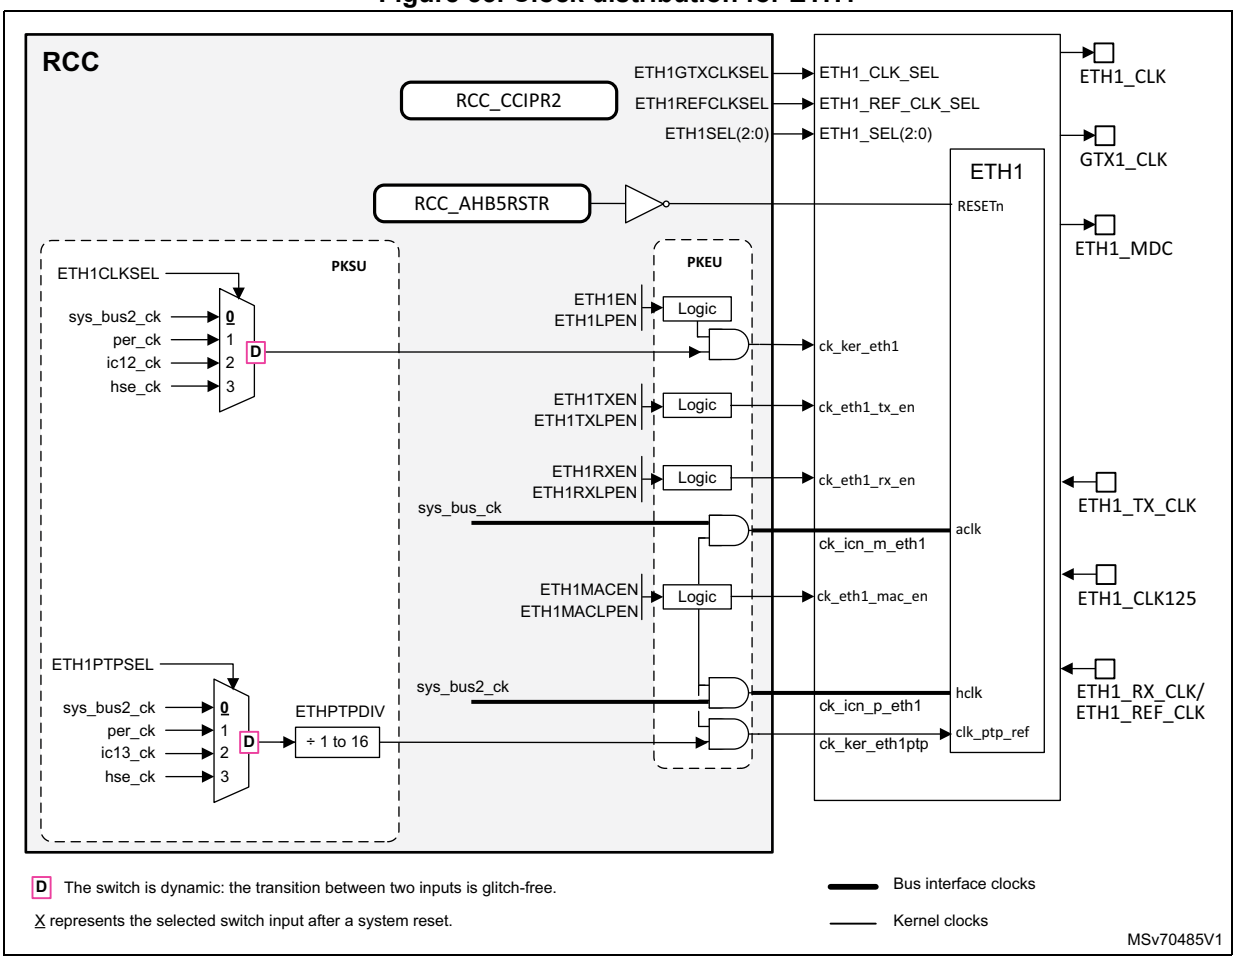


Clock distribution for ETH1

Kernel Ethernet clocks are provided by the RCC, who provides also clock selectors (CLK_SEL, REF_CLK_SEL, SEL), and clock enables for TX and RX used in the ETHSS.

Note: Bus and PTP clocks are gated via ETH1MACEN and ETH1MACLPEN bits.

Figure 53. Clock distribution for ETH1

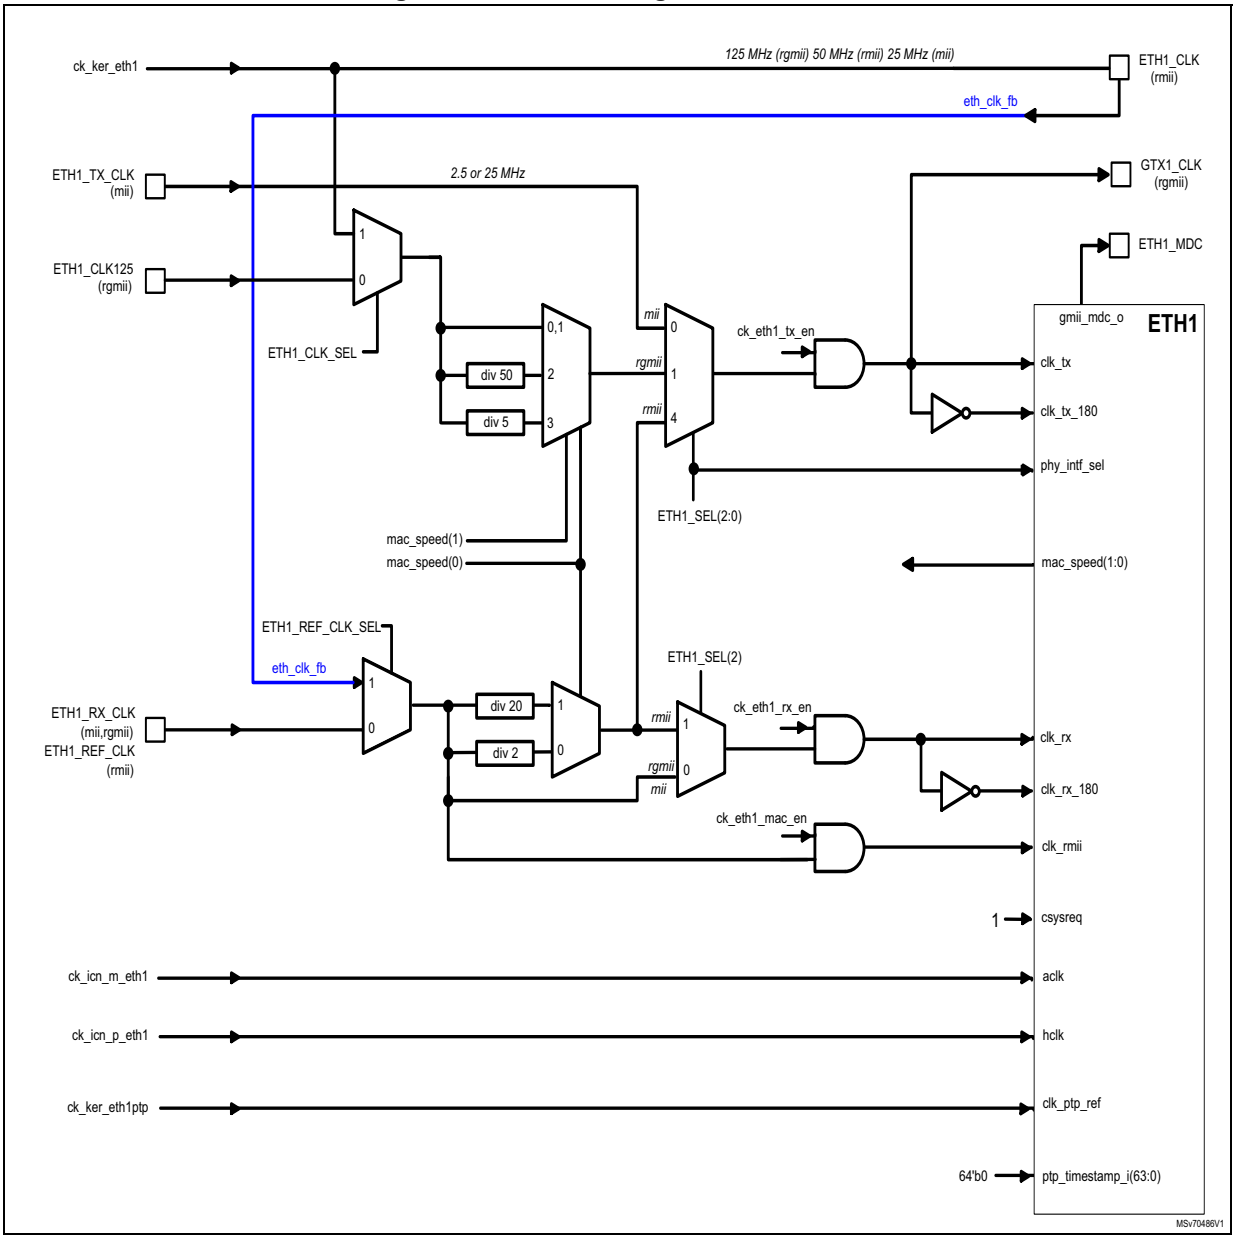


The ETH1 can generate a reference clock to the external PHY via the ETH1_CLK pin. The ETH1_CLK is generated only if all the following conditions are met:

- ETH1EN is enabled.
- The system is in Run or Sleep mode.
- The clock source for ck_ker_eth1 is available.

The clock management for ETH is very flexible and based on the PHY interface mode (MII, RMII, or RGMII). All clock signals (enables, selection, and pins) are shown in *Figure 54*.

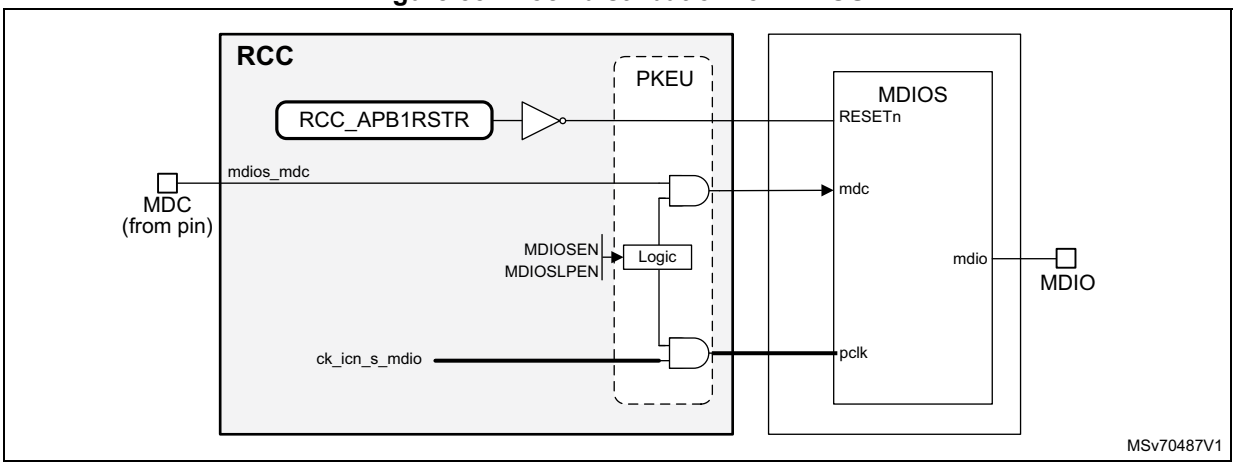
Figure 54. Clock management for ETH1



Clock distribution for MDIOS

MDIOS (MDIO slave) clocks are provided by the RCC.

Figure 55. Clock distribution for MDIOS



Clock distribution for FMC, XSPIs, and SDMMCs

The FMC kernel clock can be chosen between four different sources. For each XSPI, a clock switch can be used to select between four different sources. Each XSPI can be enabled independently.

The following steps are needed to correctly configure XSPI switches:

1. Switch on the desired clock source.
2. Ensure the clock source is ready, and conditions described above are met.
3. Set XSPIxSEL to the desired position.
4. Enable the XSPI clock (XSPIxEN = 1).

The XSPIs provide a clock to the external memory with a duty-cycle distortion lower than 5%. To this end, the kernel clock provided to the XSPIs has a typical duty cycle of 50%. In addition, the XSPIs embed a prescaler allowing clock division by even ratios.

Figure 56. Clock distribution for FMC and MCE4

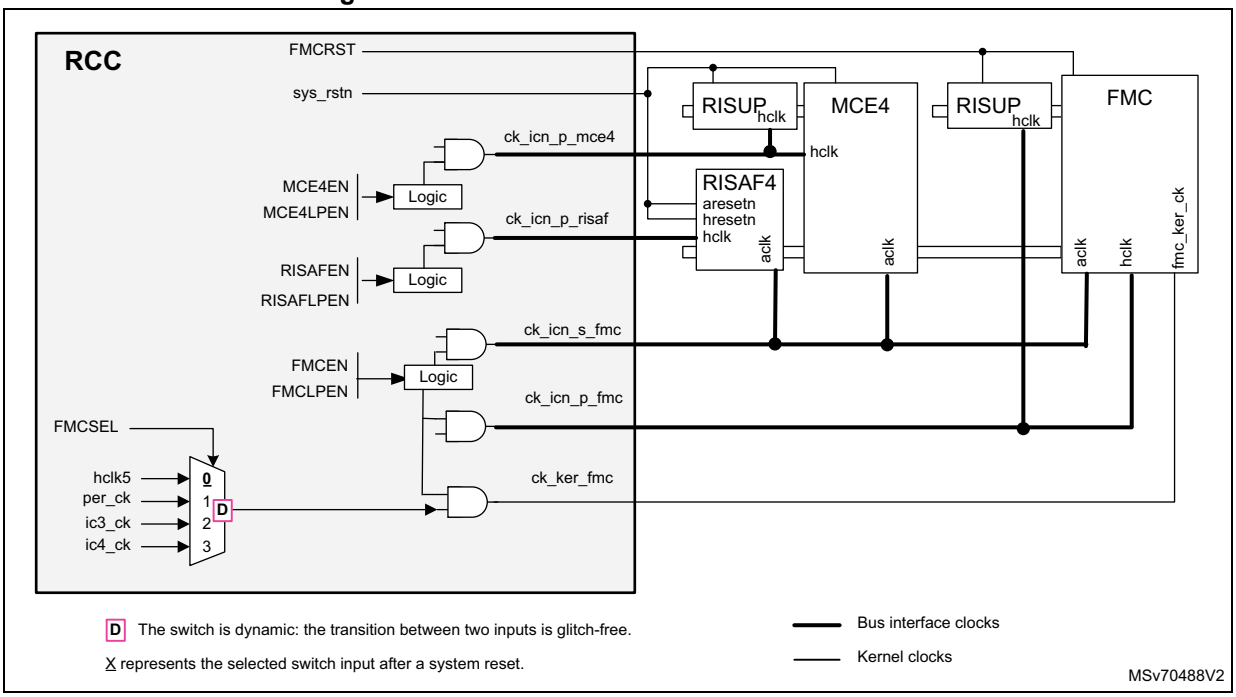


Figure 57. Clock distribution for XSPIs and MCE1/2/3

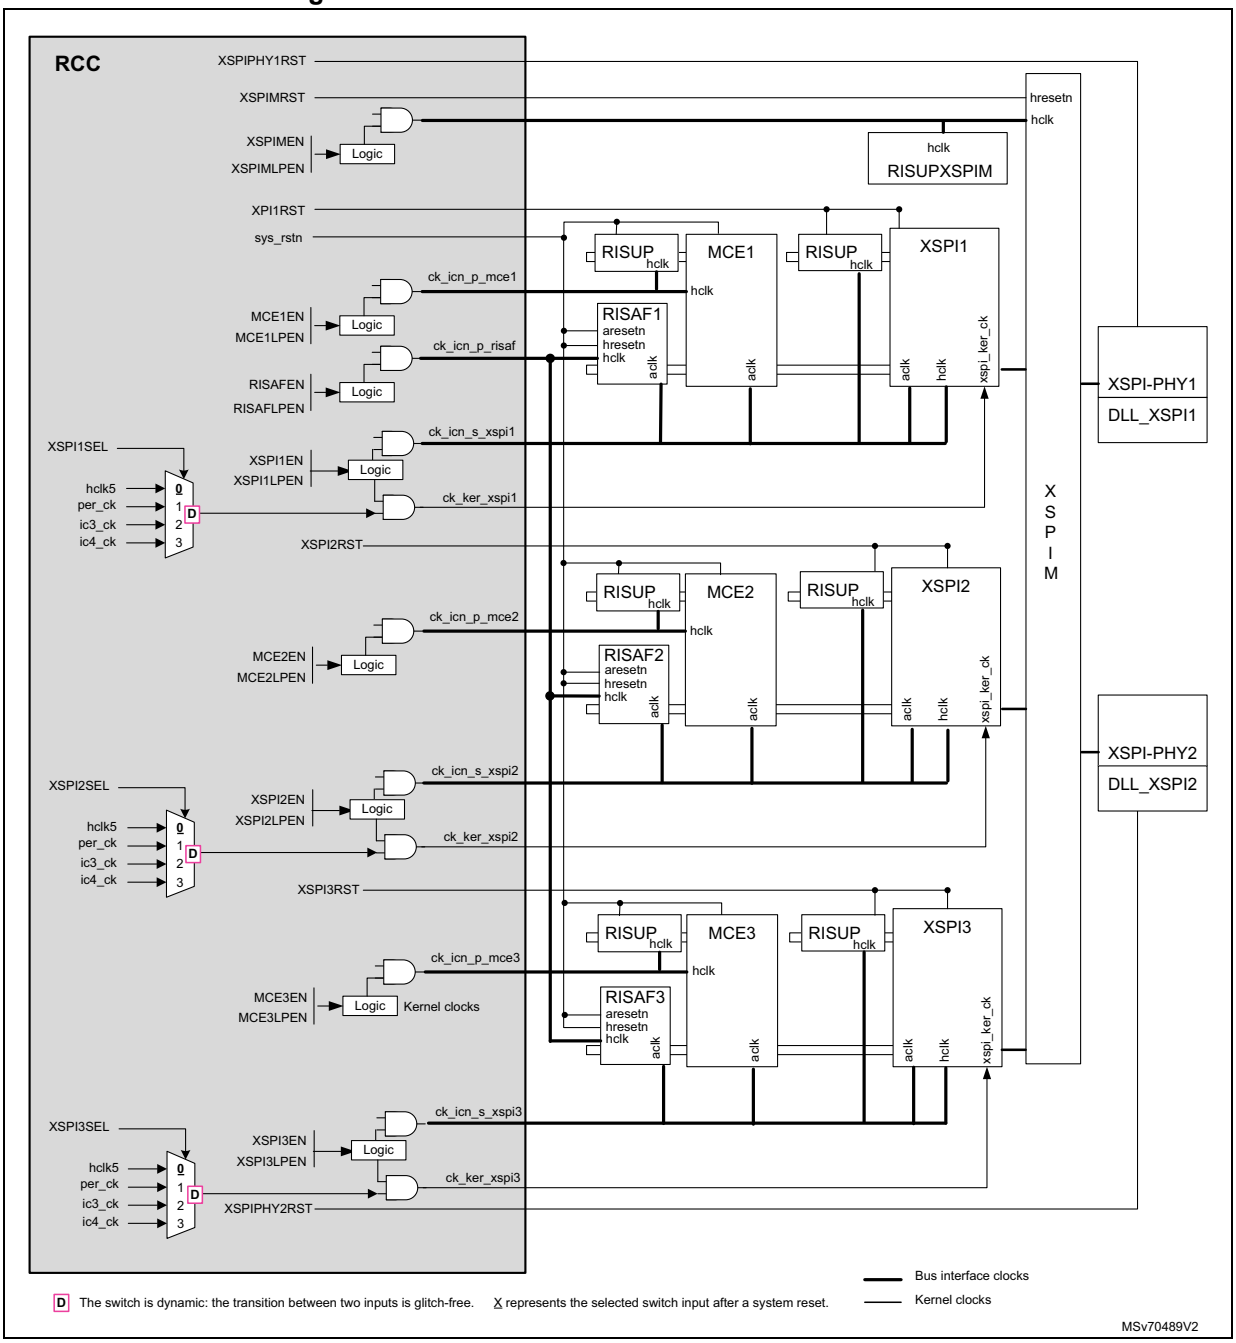


The SDMMC1 and SDMMC2 have separate kernel clocks. A clock switch allows the selection between four different sources. Each SDMMC can be enabled independently.

When an SDMMC is enabled via its SDMMCxEN bit, the associated SDMMC_SYSCONF is also enabled.

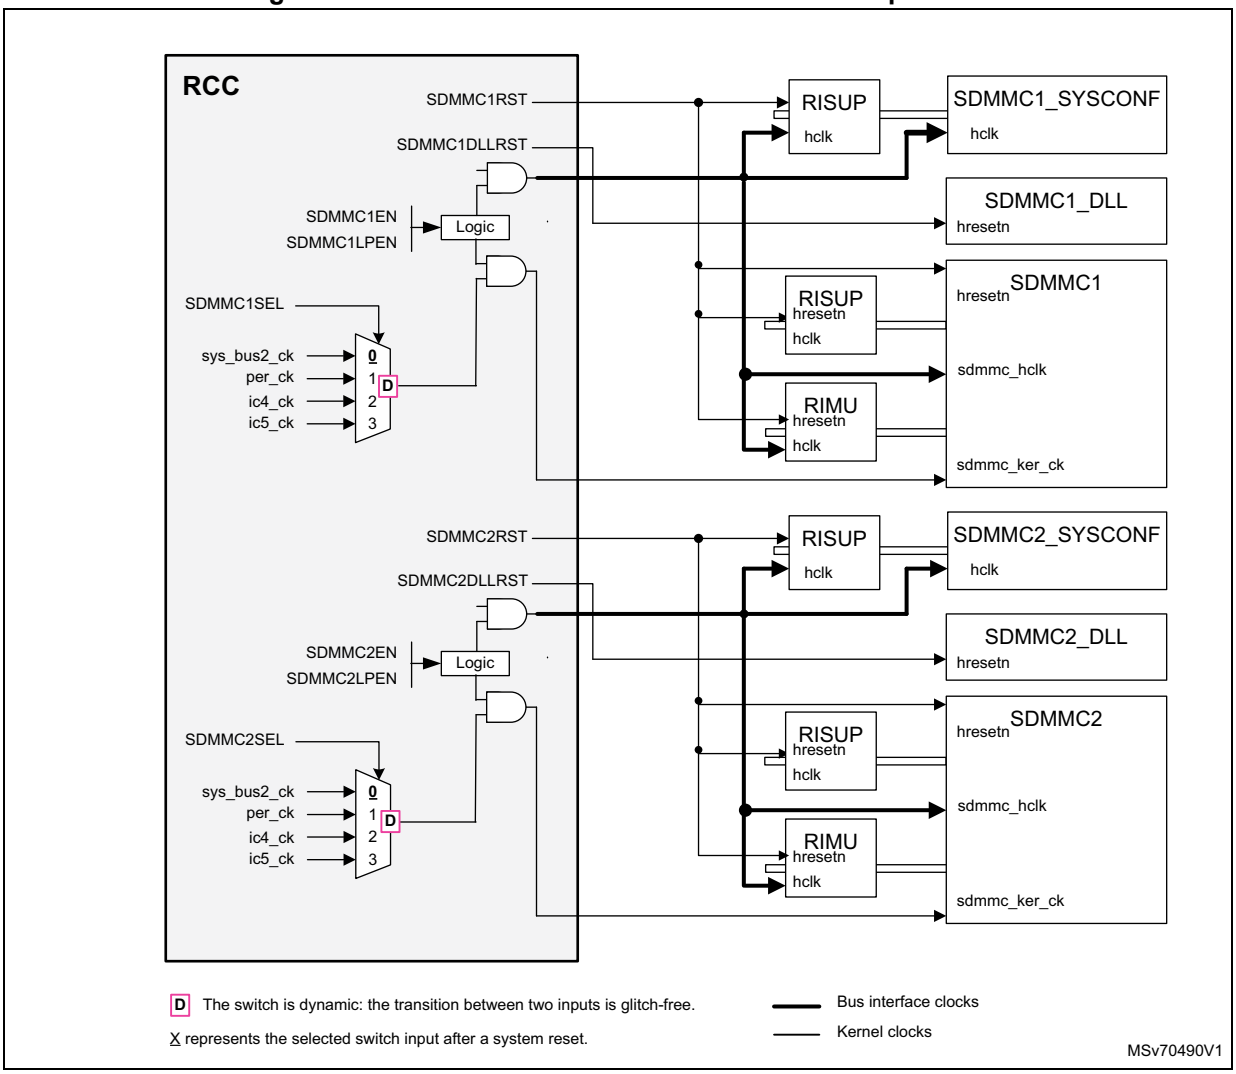
The application must configure the SDMMC to match the duty-cycle constraint of the interface clock.

Table 74. SDMMC interface clock constraints

SDMMC mode	Mode name	Interface clock frequency	Duty cycle constraint
SDIO	SDR12	25 MHz or less	30 - 70%
	SDR25	50 MHz or less	30 - 70%
	DDR50	50 MHz or less	45 - 55%
	SDR50	100 MHz or less	30 - 70%
e.MMC	Backward compatible	26 MHz or less	30 - 70%
	High-speed SDR	52 MHz or less	30 - 70%
	High-speed DDR	52 MHz or less	45 - 55%

For example, if the SDMMC works in SDR50, a kernel clock of 50 MHz, with a duty cycle better than 30-70% is enough. If the SDMMC works in DDR50, it is recommended to provide a kernel clock of 100 MHz, and to divide the frequency of the kernel clock by two, using the SDMMC divider, to ensure a duty-cycle very close to 50% for the SDMMC_CK.

Figure 58. Clock distribution for SDMMCx and companions



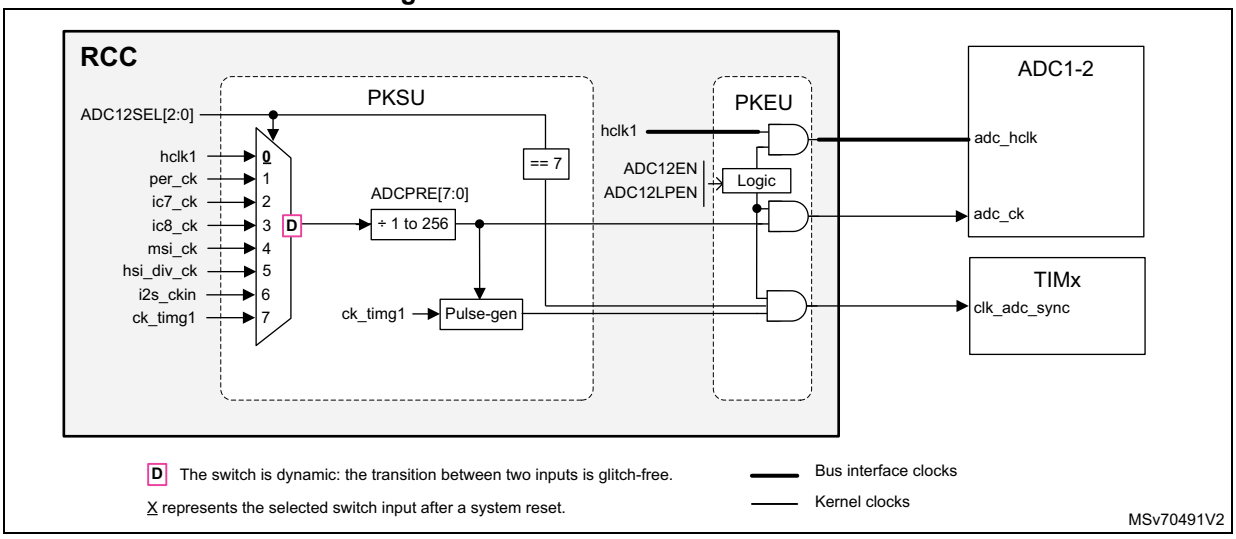
Clock distribution for ADC1/2

If the application requires that the ADC is precisely triggered by a TIMx timer without any uncertainty (fixed trigger latency), ck_timg1 must be selected as the kernel clock source. The other clock sources are asynchronous to TIMx, which results in an uncertain trigger instant due to the resynchronization between the two clock domains. The LPTIMx timers are also asynchronous.

The ADCPRE[7:0] divide value is set in RCC_CCIPR1.

clk_adc_sync is generated by Pulse-gen, one ck_timg1 cycle before the adc_ck rising edge.

Figure 59. Clock distribution for ADCs



Clock distribution for RTC/AWU clock

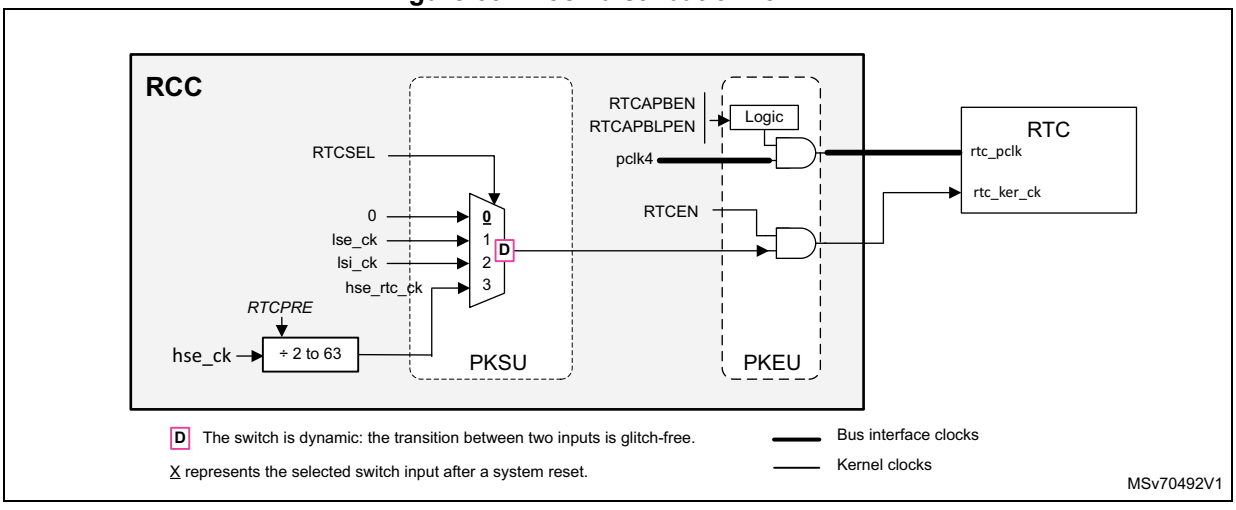
The rtc_ck clock source can be one of the following:

- hse_rtc_ck (hse_ker_ck divided by a programmable prescaler)
- lse_ck
- lsi_ck clock

The source clock is selected by programming RTCSEL and RTCPRE in RCC_CCIPR7. RTCSEL and RTCPRE are write-protected by DBP bit in PWR_DBPCR. In order to modify the bits, DBP must be set 1.

This selection cannot be modified without resetting the backup domain.

Figure 60. Clock distribution for RTC



If the LSE is selected as RTC clock, the RTC works normally even if the backup or the V_{DD} supply disappears.

The LSE clock is in the backup domain, whereas the other oscillators are not, with the following consequences:

- If LSE is selected as RTC clock, the RTC continues to work even if the V_{DD} supply is switched off, provided the V_{BAT} supply is maintained.
- If LSI is selected as the RTC clock, the AWU state is not guaranteed if the V_{DD} supply is powered off.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the V_{DD} supply is powered off, or if the $V_{VDDCORE}$ supply is powered off. In addition, the HSE is not available if the system goes to Stop mode.

rtc_ker_ck is enabled through RTCEN in RCC_APB4ENR.

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN in RCC_APB4ENR, and RTCAPBLPEN in RCC_APB4LLPENR.

Note: To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency ($F_{APB} < 7 \times F_{RTCLCK}$), the software must read the calendar time and date registers twice. Data are correct if the second read access to RTC_TR gives the same result of the first one. Otherwise, a third read access must be performed.

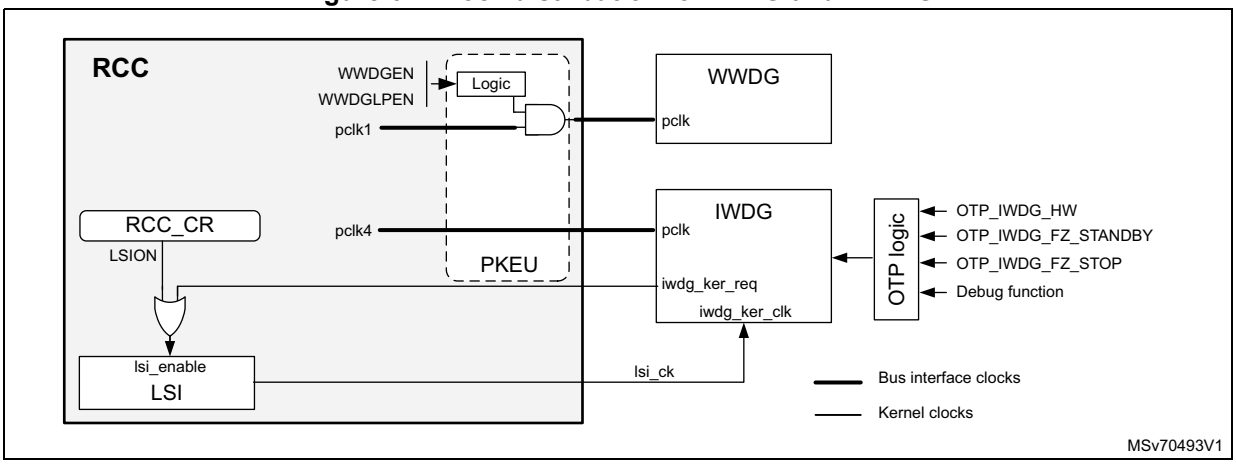
Clock distribution for watchdogs

The RCC provides the clock for the two watchdogs: the independent watchdog (IWDG), connected to the LSI, and the window watchdog (WWDG), connected to the APB clock.

If an IWDG is started by either hardware option or software access, the LSI is forced on, and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDG.

The WWDG clock (pclk1) can be enabled by setting WWDGEN in RCC_APB1LENR. The software cannot stop WWDG down-counting by clearing WWDGEN to 0. The WWDG is frozen when the device goes to Stop mode.

Figure 61. Clock distribution for IWDG and WWDG



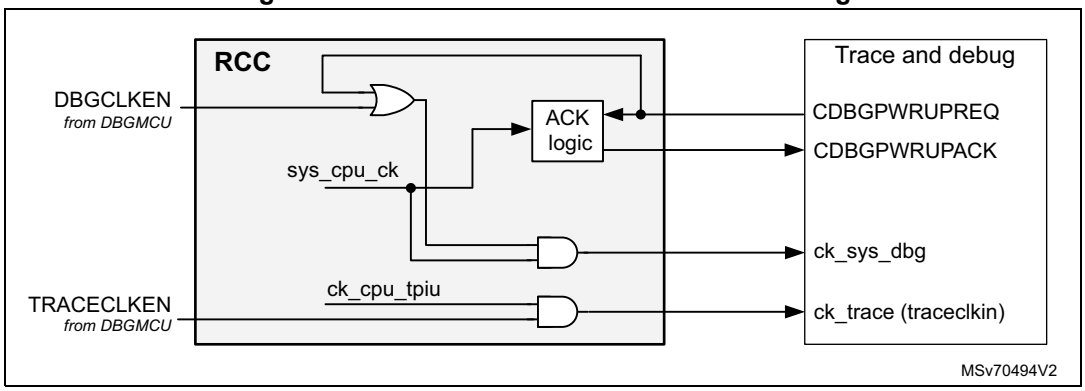
Clock distribution for trace and debug

The clock generation for the trace and debug is controlled by the DBGMCU.

DBGCLKEN in DBGMCU_CR allows the application to provide a clock to the debug components. This clock can also be enabled via the debug access port.

The trace clock generation is controlled via TRACECLKEN in DBGMCU_CR.

Figure 62. Clock distribution for trace and debug



14.6.9 General clock concept overview

The RCC handles the distribution of the CPU, bus interface, and peripheral clocks for the system, according to the CPU operating mode (refer to *Section 14.6.1* for details on clock definitions).

For each peripheral, the application can control the activation/deactivation of its kernel and bus interface clocks. Before using a peripheral, the CPU must enable it (by setting PERxEN to 1), and define if it remains active in Sleep mode (by setting PERxLPEN to 1). This is called allocation of a peripheral by the CPU (refer to *Section 14.6.10* for more details).

The peripheral allocation is used:

- by the RCC to automatically control the clock gating according to the CPU modes
- by the PWR to control V_{DDCORE} supply voltages

Memory handling

The CPU can access all memory areas available in the device:

- AXISRAM1 to AXISRAM6, CACHEAXI RAM, and FLEXRAM
- AHBSRAM1 and AHBSRAM2
- BKPSRAM

CACHEAXI RAM, and VENCRAM are disabled by default, see *RCC embedded memories enable register (RCC_MEMENR)*. The CPU must enable them before using these memories.

Read or write accesses to a peripheral register or memory, without the clocks enabled in the RCC registers, result in a system freeze. A system reset is required to unlock this.

If the access is performed by a debug interface (as an example, from a debug session inside an IDE), then a power-on reset is required to unlock the device, as the debug interface is not affected by a system reset.

Note: The memory interface clocks (flash memory and RAM interfaces) can be stopped by software during Sleep mode (via SRAMyLPEN bits).

Refer to *Section 14.6.11* and *Section 14.6.12* for details on clock enabling.

14.6.10 Peripheral allocation

The CPU can allocate a peripheral (and hence control its kernel and bus interface clock) by setting the dedicated PERxEN bit to 1. The CPU can control the peripheral clock gating when it is in Sleep mode via PERxLPEN bits.

The peripheral allocation bits (PERxEN bits) are used by the hardware to provide the kernel and bus interface clocks to the peripherals. Theses bits are also used to link peripherals to the CPU. The hardware can then safely gate peripheral clocks and bus matrix clocks, according to CPU states.

Clock switches and gating

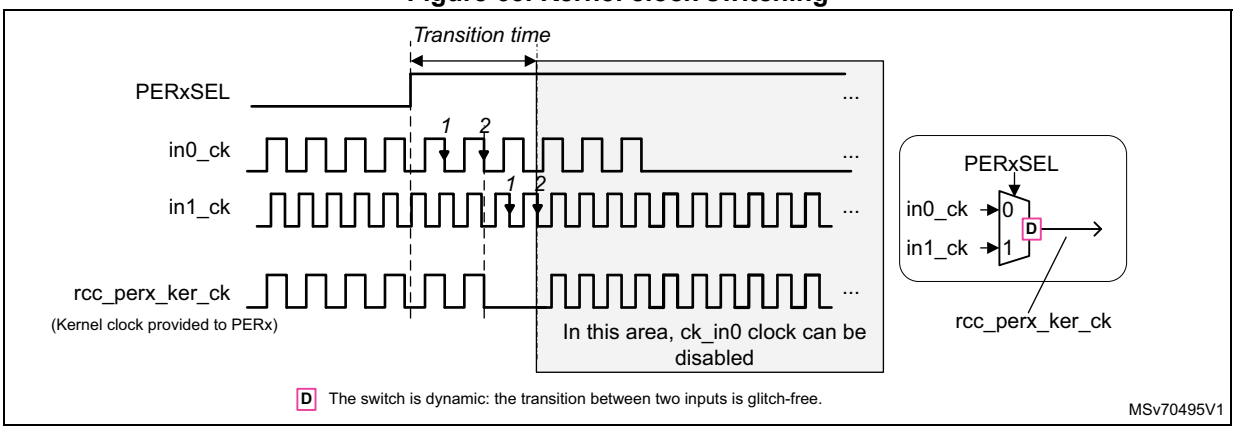
- Clock switching delays

  The input selected by the clock switches can be changed dynamically without generating spurs or timing violation. For example, if PERxSEL (in *Figure 63*) goes from 0 to 1, the switch first disables the clock output using the currently selected clock (in0_ck), and enables again the clock output using the new selected clock (in1_ck). Disable and enable commands are re-synchronized to their respective clocks. If one of the two clocks are not present, the sequence cannot be completed, and no clock is output. To recover from this situation, the user must either provide a valid clock to in1_ck input, or set back PERxSEL to 0.

  During the transition from one input to another, the kernel clock provided to the peripheral is gated, in the worst case, during two or three clock cycles of the new selected clock.

  As shown in *Figure 63*, both input clocks must be present during transition time.

Figure 63. Kernel clock switching



- Clock enabling delays

  In the same way, the clock gating logic synchronizes the enable command (coming generally from a kernel clock request, or PERxEN bits) with the selected clock, in order to avoid generation of spurious:

  – A maximum delay of two periods of the enabled clock can occur between the enable command and the first rising edge of the clock. The enable command can

be the rising edge of PERxEN in RCC_xxxxENR, or a kernel clock request asserted by a peripheral.

– A maximum delay of 1.5 periods of the disabled clock can occur between the disable command and the last falling edge of the clock. The disable command can be the falling edge of PERxEN in RCC_xxxxENR, or a kernel clock request released by a peripheral.

Note: Both kernel and bus interface clocks are affected by this re-synchronization delay.

14.6.11 Peripheral clock-gating control

As mentioned previously, each peripheral requires one or several bus interface clocks, named rcc_perx_bus_ck (for peripheral 'x'). These clocks can be an APB, AHB, or AXI clock, according to which bus(ses) the peripheral is connected.

The clocks used as bus interface for peripherals can be aclk[s,a,n], hclk[m,u,e], hclk[5:1], pclk[5:4], pclk[2:1], or ck_timg[1,2], depending on the bus connected to each peripheral.

Some peripherals also require dedicated clocks for their communication interface. These clocks are generally asynchronous with respect to the bus interface clock. They are named kernel clocks (perx_ker_ck). Both bus interface and kernel clocks can be gated according to several conditions detailed hereafter.

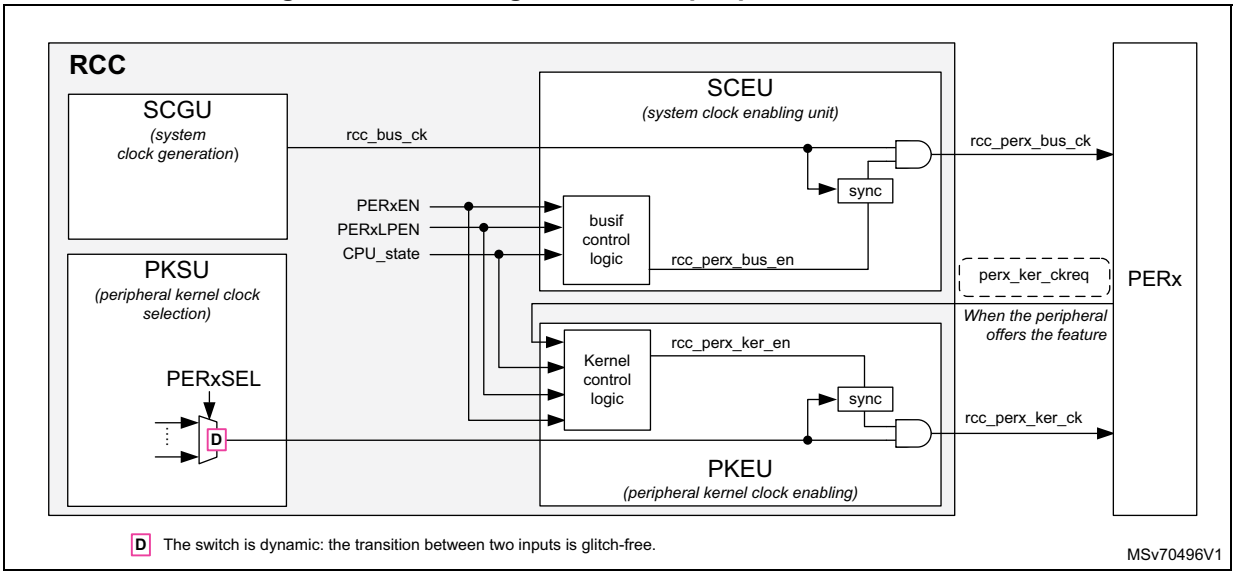
As shown in *Figure 64*, enabling kernel and bus interface clocks of each peripheral depends on several input signals:

- PERxEN and PERxLPEN bits

  PERxEN represents the peripheral enable (allocation) bit for the CPU. The CPU can write these bits to 1 via RCC_xxxxENR.
- CPU state (cpu_sleep and cpu_deepsleep signals)
- kernel clock request (perx_ker_ckreq) of the peripheral itself, when the feature is available

Refer to *Section 14.6.10* for more details.

Figure 64. Enable logic details for peripheral kernel clock



The clocks for all AHB and APB buses (AHBM, AHB1/2/3/4/5, APB1/2/4/5) are automatically enabled when a dependent peripheral is active. This may induce a chain: a peripheral activation activates the APB that activates the AHB, and activates the AHBM.

For instance, the manual UART4 activation induces the automatic APB1 activation (APB1 is used to configure the UART4). This induces the automatic AHB1 bus activation (AHB1 is needed to drive the APB1). This induces the activation of the central AHBM matrix (AHBM is needed to drive the AHB1).

High-bandwidth interconnect

The NoC and the two NPU AXI bus clocks (ck_icn_npu and ck_icn_npuc, see *Figure 47*) are permanently enabled in Run and Sleep modes, and permanently disabled in Stop and Standby modes.

An internal automatic clock-gating optimizes the NoC power consumption: when no transaction is ongoing in a bus section, an automatic clock-gating clocks and gates this bus.

The NPU interconnect clock (ck_icn_npu) can be disabled by setting ACLKNEN = 0 (disabled in Run and Sleep modes), or ACLKNLPEN = 0 (disabled in Sleep mode only). If the clock is disabled, the NPU cannot work (no interconnect downstream), and the CPU cannot access AXISRAM3/4/5/6, the CACHEAXI RAM, or the FLEXRAM.

The clock of the NPU interconnect (ck_icn_npuc) can be disabled by setting ACLKNCEN = 0 (disabled in Run and Sleep modes), or ACLKNCLPEN = 0 (disabled in Sleep mode only). If the clock is disabled, neither the CPU or NPU can access AXISRAM3/4/5/6, the CACHEAXI, the CACHEAXI RAM, or the FLEXRAM.

Table 75 gives a detailed description of the enabling logic of the peripheral clocks for peripherals located in the CPU domain and allocated by the CPU.

Table 75. Peripheral clock enabling

PERxEN	PERxLPEN	PERxSEL	perx_ker_ckreq	CPU state	rcc_perx_ker_ck	rcc_perx_bus_ck	Comments
0	X	X	X	X	-	-	No clock provided to the peripheral (PERxEN = 0)
1	X	X	X	Run	CK	CK	Kernel and bus interface clocks are provided to the peripheral (CPU in Run mode, and PERxEN = 1)
1	0	X	X	Sleep	-	-	No clock provided to the peripheral (CPU is in Sleep mode and PERxLPEN = 0)
1	1				CK	CK	Kernel and bus interface clocks are provided to the peripheral (CPU in Sleep mode and PERxLPEN = 1)

Table 75. Peripheral clock enabling (continued)

PERxEN	PERxLPEN	PERxSEL	perx_ker_ckreq	CPU state	rcc_perx_ker_ck	rcc_perx_bus_ck	Comments
1	0	X	X	Stop	-	-	No clock provided to the peripheral (PERxLPEN = 0)
1	1	no lsi_ck and no lse_ck and no hsi_ker_ck and no msi_ker_ck	X		-	-	No clock provided to the peripheral (CPU in Stop mode, and lse_ck or lsi_ck or hsi_ker_ck or msi_ker_ck not selected as kernel clock)
1	1	lsi_ck or lse_ck	X		CK	-	Kernel clock provided to the peripheral (PERxEN = PERxLPEN = 1, and lsi_ck or lse_ck selected and enabled) Bus interface clock not provided as the CPU is in Stop mode
1	1	hsi_ker_ck or msi_ker_ck	1		CK	-	Kernel clock provided to the peripheral (req_ker_perx = 1, PERxEN = PERxLPEN = 1, and hsi_ker_ck or msi_ker_ck selected and enabled) Bus interface clock not provided as the CPU is in Stop mode
1	1	hsi_ker_ck or msi_ker_ck	0		-	-	No clock provided to the peripheral (CPU in Stop mode, and no kernel clock request pending)

The kernel clock is provided to the peripherals when one of the following conditions is met:

1. The CPU is in Run mode and the peripheral is enabled.
2. The CPU is in Sleep mode and the peripheral is enabled with PERxLPEN = 1.
3. The CPU is in Stop mode, the peripheral is enabled with PERxLPEN = 1, the peripheral generates a kernel clock request, and the selected clock is hsi_ker_ck or msi_ker_ck.
4. The CPU is in Stop mode, the peripheral is enabled with PERxLPEN = 1, and the kernel source clock of the peripheral is lse_ck or lsi_ck.

The bus interface clock is provided to the peripherals only when conditions *1* or *2* are met.

14.6.12 CPU and bus matrix clock-gating control

The clocks of the CPU, AHB/AXI bridges, and APB buses are enabled as follows:

- The CPU clock (rcc_cpu_ck) is enabled when the CPU is in Run or Sleep mode.
- The AXI bridge clock is enabled when the CPU is in Run or Sleep mode.
- The AHB bus matrix clock is enabled if one of the following conditions is met:
  - The CPU is in Run mode.
  - The CPU is in Sleep mode, and at least one peripheral connected to this bridge has both its PERxEN and PERxLPEN set to 1.
  - The CPU is in Sleep mode, and AHB1, 2, 3, 4, or 5 has its clock enabled.
- The clocks of AHB1/2/3/4/5 bridges are enabled when one of the following conditions is met:

  - The CPU is in Run mode.
  - The CPU is in Sleep mode, and at least one peripheral connected to this bus has both its PERxEN and PERxLPEN set to 1.
  - The CPU is in Sleep mode, and the APB bus connected to the AHB bridge has its clock enabled.
- The APB1/2/4/5 clock buses are enabled when one of the following conditions is met:
  - The CPU is in Run mode.
  - The CPU is in Sleep mode, and at least one peripheral connected to this bus has both its PERxEN and PERxLPEN set to 1.

Refer to *Section 14.6.11* for details on the automatic clock-gating for AHBMEN, and all AHB/APB buses.

14.6.13 Low-power emulation modes

To ease the device debug, the RCC is able to handle an emulation mode for Stop and Standby modes.

Sleep emulation mode

The Sleep emulation mode is controlled by DBGSLEEP in DBGMCU_CR. When the processor goes to Sleep mode with DBGSLEEP = 1, the processor clock, the clocks of all enabled peripherals, debug parts, and interconnect are maintained activated.

Stop emulation mode

The Stop emulation mode is controlled by DBGSTOP in DBGMCU_CR. When the processor goes to Stop mode with DBGSTOP = 1:

- The processor, peripheral, and interconnect clocks remain active.
- The debug clock is active (ck_bus2_dbg, see *Figure 45*), and all debug parts remain clocked. All PLLs and OSCs remain active.

When a wake-up event occurs:

- The peripheral waking up the system sends the interrupt to the NVIC via the EXTI.
- If the PWR asserts the pwr_wkup signal, the RCC exits Stop mode. The RCC selects HSI or MSI as system clock, depending on STOPWUCK. The CPU exits Stop mode.

Standby emulation mode

The Standby emulation mode is controlled by DBGSTBY in DBGMCU_CR.

When the system goes to Standby mode with DBGSTBY = 1 and dbg_stdby_rstn = 0:

- the V_{DDCORE} voltage is not switched-off
- all CPU, interconnect, and peripherals are under reset except the debug part
- all PLLs and OSCs remain active
- the debug part is clocked
- peripherals on V_{SW} or V_{DD} domains are not reset

The system exits Standby mode when dbg_stdby_rstn is deasserted:

- the RCC deasserts the rcc_pwrds signal
- all peripherals are removed from reset
- the RCC enters Run state

14.7 RCC interrupts

The RCC provides the following interrupt lines:

- rcc_it: general interrupt line that provides events when PLLs or oscillators are ready (for nonsecure bits)
- rcc_s_it: general interrupt line that provides events when PLLs or oscillators are ready (for secure bits)
- rcc_hsecss_it: interrupt line dedicated to the failure detection of the HSE CSS
- rcc_lsecss_it: interrupt line dedicated to the failure detection of the LSE CSS

The interrupt enable is controlled via RCC_CIER, except for the HSE CSS failure. When the HSE CSS feature is enabled, the interrupt generation cannot be masked.

The interrupt flags can be checked via RCC_CIFR, and these flags can be cleared via RCC_CICR.

Note: The interrupt flags are not relevant if the corresponding interrupt enable bit is not set.

Table 76 gives a summary of the interrupt sources and the way to control them.

Table 76. Interrupt sources and control

Interrupt source	Description	Interrupt enable	Action to clear interrupt	Interrupt line
LSIRDYF	LSI ready	LSIRDYIE	Set LSIRDYC to 1	rcc_it, rcc_s_it
LSERDYF	LSE ready	LSERDYIE	Set LSERDYC to 1	
HSIDRYF	HSI ready	HSIDRYIE	Set HSIRDYC to 1	
HSERDYF	HSE ready	HSERDYIE	Set HSERDYC to 1	
MSIRDYF	MSI ready	MSIRDYIE	Set MSIRDYC to 1	
PLL1RDYF	PLL1 ready	PLL1RDYIE	Set PLL1RDYC to 1	
PLL2RDYF	PLL2 ready	PLL2RDYIE	Set PLL2RDYC to 1	
PLL3RDYF	PLL3 ready	PLL3RDYIE	Set PLL3RDYC to 1	
PLL4RDYF	PLL4 ready	PLL4RDYIE	Set PLL4RDYC to 1	
LSECSSF	LSE CSS failure	LSECSSIE (1)	Set LSECSSC to 1	rcc_lsecss_it
HSECSSF	HSE CSS failure	- (2)	Set HSECSSC to 1	rcc_hsecss_it

1. The security system feature must be enabled (LSECSSON = 1) to generate interrupts.
2. This interrupt cannot be masked when the security system feature is enabled (HSECSSON = 1).

14.8 RCC application information

14.8.1 HSE crystal auto-detection

The software can detect the frequency of the crystal connected to the HSE. The crystal choices are 19.2, 20.0, 24.0, 38.4, 40.0, 48.0 MHz. The closest crystal frequencies are 19.2 and 20 MHz (differing ~4%).

Measurement uses a timer clocked by a fast clock, triggered by the slower clock. Using the PWM input mode of input capture, it is possible to measure the full period of the slow clock.

LSE reference

If available, the LSE can trigger TIM16 to count hse_ck ticks. This is crystal accurate (better than using HSI).

Configure a PLL to generate (HSE * 8) MHz. Then set SYSSW to select ic2_ck for sysb_ck = ck_timg (TIMPRE = 1). This means sys_bus_ck relates to the HSE frequency.

LSE is connected to TIM16 - TI1_2.

Example: the multiplication by eight of hse_ck gives
(40 × 1000 × 8) / 32.768 = 9765 counts, and (38.4 × 1000 × 8) / 32.768 = 9375 counts.

19.2, 20, 24, 38.4, 40, 48 = 4687, 4882, 5859, 9375, 9765, 11718 counts

sys_bus_ck = 153.6, 160, 192, 307.2, 320, 384 MHz

HSI reference

HSI can be used when LSE is not available. A trimmed HSI can vary by ±4% (at 3 σ) across the full temperature range. This means that 19.2 and 20 MHz cannot be differentiated reliably.

If the DTS is available, the user can measure the temperature to compensate for the HSI drift.

The RCC generates an hse_cal_ck signal, which is HSE divided by 1024. This signal is connected to TIM17 - TI1_2.

hse_cal_ck has an expected frequency between 19.2 to 50 kHz. The HSI is about 64 MHz. To get 300 MHz, select HSI as input to a PLL, then ic2_ck for sysb_ck = ck_timg (TIMPRE = 1).

Example: The division by 1024 of hse_ck gives 300 × 1024 / 40 = 7680 counts, and 300 × 1024 / 38.4 = 8000 counts.

19.2, 20, 24, 38.4, 40, 48 = 16000, 15360, 12800, 8000, 7680, 6400 counts

A less accurate method is to use hse_ck output on MCO divided by 16. This gives, for example: 300 × 16 / 40 = 120 counts, and 300 × 16 / 38.4 = 125 counts.

19.2, 20, 24, 38.4, 40, 48 = 250, 240, 200, 125, 120, 100 counts

14.8.2 Calibration and clock frequency measurement using TIMx

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

Calibrating HSI or MSI with the LSE

The main purpose of connecting the LSE to a TIMx input capture is to accurately measure the HSI or MSI. This requires to use the HSI or MSI as sys_bus_ck either directly, or via a PLL. The number of system clock counts between consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm), the user can determine the internal clock frequency with the same resolution, and trim the source to compensate for variations due to manufacturing, temperature, or voltage.

The ratio between the two clock frequencies affects the measurement precision. The greater the ratio, the more accurate the calculation.

HSI and MSI oscillators have dedicated user-accessible calibration bits for this purpose (see RCC_HSICFGR and RCC_MSICFGR). When the HSI or MSI is used via a PLL, it is also possible to fine-tune the sys_bus_ck using the fractional divider of the PLL.

Calibrating LSI with HSI

The LSI frequency can also be measured. This is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process variation. The LSI clock frequency can be measured using the more precise HSI clock source. Using this measurement, the user can obtain a more accurate RTC timebase timeout (when LSI is used as RTC clock source), and/or a more accurate IWDG timeout.

14.8.3 Clock monitoring

Monitoring HSI with LSE

The purpose is to assist the software calibration procedure when the HSI frequency drifts out of a predefined range because of environmental variation (for example, temperature).

This monitoring can be enabled in all system modes where HSI is used, except Standby and V_{BAT} modes. When enabled, the number of HSI clock ticks between consecutive edges of the LSE clock is counted.

The HSI monitoring control is based on RCC_HSIMCR and RCC_HSIMSR.

The following steps can be used to enable the monitoring:

1. Enable LSE signal:
   a) Set DBP = 1 in PWR_DBPCR.
   b) Write 1 to LSEON.
   c) Wait for LSERDY = 1.
   d) Set DBP = 0 in PWR_DBPCR.
2. Set up HSI clock period monitoring:
   a) Write 1 to HSIMONEN in RCC_HSIMCR to start the monitoring.

14.8.4 Clock frequency limits

The maximum frequencies that can be set for each peripheral are detailed in *Table 77*.

Table 77. Maximum peripheral clock frequencies

Peripheral	Maximum kernel clock frequency (MHz)
PWR	200
RNG	64
RTC	4
SAES	200
SAI1	200
SAI2	200
SDMMC1	208
SDMMC2	208

Table 77. Maximum peripheral clock frequencies (continued)

Peripheral	Maximum kernel clock frequency (MHz)
SPDIFRX1	200
SPI1	200
SPI2	200
SPI3	200
SPI4	133
SPI5	133
SPI6	200
SYSCFG	200
TIMx	400
LPTIMx	200
DTS	10
USART1	100
USART2	100
USART3	100
UART4	100
UART5	100
USART6	100
UART7	100
UART8	100
UART9	100
USART10	100
LPUART1	100
UCPD1	25
VENC	400
VREFBUF	200
WWDG	200
MREPAIR	64

As an example, the PLL configuration to achieve these frequencies would use HSI as reference clock (64 MHz), and program the VCO of PLL1, 2, 3, and 4, to respectively, 800, 993.52, 875, and 514.5 MHz.

14.9 RCC security

The system RIF protects bus accesses to the RCC and peripheral registers.

The RIFSC indicates if an access to the RCC or other peripherals is secure and/or privileged. Signals are connected from the RIFSC to the RCC to communicate this information. The notation for these signals is S, P.

The RCC is able to protect register bits from being modified by nonsecure and unprivileged accesses.

If a peripheral RISUP is programmed as secure (or privileged), the peripheral clock and reset bits become secure (or privileged).

If the peripheral is TrustZone-aware, the peripheral clock and reset bits become secure (or privileged) as soon as at least one function is configured as secure (or privileged) by RIFSC.

Peripheral configuration registers inside the RCC can be also be made secure (or privileged) via a global override bit (PERSEC in RCC_SECCFGR3, PERPRIV in RCC_PRIVCFGR3).

After an application reset or system reset, the RCC does not filter any access until the trusted agent has configured the system.

14.9.1 Internal register protection

The following can be made secure and/or privileged (via RCC_SECCFGRx and RCC_PRIVCFGRx):

- internal and external oscillators (HSE, LSE, HSI, MSI, LSI)
- PLLs and AHB prescalers
- system clock-source selection
- MCO clock outputs
- reset flags
- automatic internal oscillator wake-up configuration

There are four access controls for RCC registers:

- SEC (secure)
- PRIV (privileged)
- LOCK (locked SEC and PRIV)
- PUB (public)

SEC (in RCC_SECCFGRx)

xxxSEC defines the secure status required for a write to the xxx configuration registers (for example, HSISEC for the HSI oscillator). When this bit is set, configuration register bits are writable by secure software only. This bit can be locked (cannot be changed) with the xxxLOCK bit, and is readable by all. Write access to RCC_SECCFGRx is controlled by S, P.

PRIV (in RCC_PRIVCFGRx)

xxxPRIV defines the privileged status required for a write to the xxx configuration registers (such as HSIPRIV for the HSI oscillator). When this bit is set, the configuration register bits are writable only by privileged software. This bit can be locked (cannot be changed) with the xxxLOCK bit, and is readable by all. Write access to RCC_PRIVCFGRx is controlled by xxxSEC, P. xxxPRIV can be set/cleared by write to 1 registers.

LOCK (in RCC_LOCKCFGRx)

xxxLOCK, when set, locks definitively xxxSEC and xxxPRIV settings: xxxLOCK is readable by all. Write access to RCC_LOCKCFGRx is controlled by S, P. xxxLOCK is a set-once bit.

PUB (in RCC_PUBCFGRx)

xxxPUB grants read access to configuration/status bits, regardless of security or privilege.

For example, if HSIPUB bit is set, any software can read the HSI oscillator configuration and status. If not set then normal access controls are enforced.

xxxPUB is readable by all. Write access to RCC_PUBCFGRx is controlled by xxxSEC and xxxPRIV. xxxPUB can be set/cleared by write-to-1 registers.

14.9.2 Internal register write-protection

There are different controls for write-protecting a register bit.

- xxxLOCK bits (described above)
- other internal protection logic (controlled from internal or external signals)

Only protection logic using the pwr_lock_backup signal is implemented.

14.10 RCC registers

14.10.1 RCC control register (RCC_CR)

Address offset: 0x0

Reset value: 0x0000 0008

This register is used to enable the RCC oscillators and PLLs in Run or Sleep mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PLL4 ON	PLL3 ON	PLL2 ON	PLL1 ON	Res.	Res.	Res.	HSE ON	HSI ON	MSI ON	LSE ON	LSI ON
				rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **PLL4ON**: PLL4 enable

This bit is reset by int_sys_rstn. It is security-protected by PLL4SEC or PLL4PRIV, and is publicly readable if PLL4PUB = 1. It can be set with PLL4ONS, and cleared with PLL4ONC. This bit is set and reset by software. It cannot be cleared if PLL4 is currently used to generate the CPU or system clock.

0: PLL4 is OFF (default after reset)

1: PLL4 is ON

Bit 10 **PLL3ON**: PLL3 enable

This bit is reset by int_sys_rstn. It is security-protected by PLL3SEC or PLL3PRIV, and is publicly readable if PLL3PUB = 1. It can be set with PLL3ONS, and cleared with PLL3ONC. This bit is set and reset by software. It cannot be cleared if PLL3 is currently used to generate the CPU or system clock.

0: PLL3 is OFF (default after reset)

1: PLL3 is ON

Bit 9 **PLL2ON**: PLL2 enable

This bit is reset by int_sys_rstn. It is security-protected by PLL2SEC or PLL2PRIV, and is publicly readable if PLL2PUB = 1. It can be set with PLL2ONS, and cleared with PLL2ONC. This bit is set and reset by software. It cannot be cleared if PLL2 is currently used to generate the CPU or system clock.

0: PLL2 is OFF (default after reset)

1: PLL2 is ON

Bit 8 **PLL1ON**: PLL1 enable

This bit is reset by int_sys_rstn. It is security-protected by PLL1SEC or PLL1PRIV, and is publicly readable if PLL1PUB = 1. It can be set with PLL1ONS, and cleared with PLL1ONC. This bit is set and reset by software. It cannot be cleared if PLL1 is currently used to generate the CPU or system clock.

0: PLL1 is OFF (default after reset)

1: PLL1 is ON

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **HSEON**: HSE oscillator enable

This bit is reset by int_sys_rstn. It is security-protected by HSESEC or HSEPRIV, and is publicly readable if HSEPUB = 1. It can be set with HSEONS, and cleared with HSEONC. This bit is set and reset by software.

0: HSE is OFF (default after reset)

1: HSE is ON

Bit 3 **HSION**: HSI oscillator enable

This bit is reset by int_sys_rstn. It is security-protected by HSISEC or HSIPRIV, and is publicly readable if HSIPUB = 1. It can be set with HSIONS, and cleared with HSIONC. This bit is set and reset by software.

0: HSI is OFF

1: HSI is ON (default after reset)

Bit 2 **MSION**: MSI oscillator enable

This bit is reset by int_sys_rstn. It is security-protected by MSISEC or MSIPRIV, and is publicly readable if MSIPUB = 1. It can be set with MSIONS, and cleared with MSIONC. This bit is set and reset by software.

0: MSI is OFF (default after reset)

1: MSI is ON

Bit 1 **LSEON**: LSE oscillator enable

This bit is reset by rcc_vsw_rstn. It is in the V_{BKP} voltage domain. It is write-protected by the pwr_lock_backup_n signal. It is security-protected by LSESEC, LSEPRIV, and is publicly readable if LSEPUB = 1. It can be set with LSEONS, and cleared with LSEONC. This bit is set and reset by software.

0: LSE is OFF (default after reset)

1: LSE is ON

Bit 0 **LSION**: LSI oscillator enable

This bit is reset by nreset_rstn. It is in the V_{RET} voltage domain. This bit is security-protected by LSISEC or LSIPRIV, and is publicly readable if LSIPUB = 1. It can be set with LSIONS, and cleared with LSIONC. This bit is set and reset by software.

0: LSI is OFF (default after reset)

1: LSI is ON

14.10.2 RCC status register (RCC_SR)

Address offset: 0x4

Reset value: 0x0000 0000

This register is used to retrieve the status the RCC oscillators and PLLs.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PLL4 RDY	PLL3 RDY	PLL2 RDY	PLL1 RDY	Res.	Res.	Res.	HSE RDY	HSI RDY	MSI RDY	LSE RDY	LSI RDY
				r	r	r	r				r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **PLL4RDY**: PLL4 clock ready flag

This bit is security-protected by PLL4SEC or PLL4PRIV, and is publicly readable if PLL4PUB = 1. It is set by hardware to indicate that the PLL4 is locked.

0: PLL4 unlocked (default after reset)

1: PLL4 locked

Bit 10 **PLL3RDY**: PLL3 clock ready flag

This bit is security-protected by PLL3SEC or PLL3PRIV, and is publicly readable if PLL3PUB = 1. It is set by hardware to indicate that the PLL3 is locked.

0: PLL3 unlocked (default after reset)

1: PLL3 locked

Bit 9 **PLL2RDY**: PLL2 clock ready flag

This bit is security-protected by PLL2SEC or PLL2PRIV, and is publicly readable if PLL2PUB = 1. it is set by hardware to indicate that the PLL2 is locked.

0: PLL2 unlocked (default after reset)

1: PLL2 locked

Bit 8 **PLL1RDY**: PLL1 clock ready flag

This bit is security-protected by PLL1SEC or PLL1PRIV, and is publicly readable if PLL1PUB = 1. It is set by hardware to indicate that the PLL1 is locked.

0: PLL1 unlocked (default after reset)

1: PLL1 locked

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **HSERDY**: HSE clock ready flag

This bit is security-protected by HSESEC or HSEPRIV, and is publicly readable if HSEPUB = 1.

It is set by hardware to indicate that the HSE oscillator is stable.

0: HSE not ready (default after reset)

1: HSE ready

Bit 3 **HSIRDY**: HSI clock ready flag

This bit is security-protected by HSISEC or HSIPRIV, and is publicly readable if HSIPUB = 1.

It is set by hardware to indicate that the HSI oscillator is stable.

0: HSI not ready (default after reset)

1: HSI ready

Bit 2 **MSIRDY**: MSI clock ready flag

This bit is security-protected by MSISEC or MSIPRIV, and is publicly readable if MSIPUB = 1.

It is set and reset by hardware to indicate that the MSI oscillator is stable.

0: MSI not ready (default after reset)

1: MSI ready

Bit 1 **LSERDY**: LSE clock ready flag

This bit is security-protected by LSESEC or LSEPRIV, and is publicly readable if LSEPUB = 1. It is set and reset by hardware to indicate that the LSE oscillator is stable. This bit requires 6 cycles of lse_ck before it is deasserted.

0: LSE not ready (default after reset)

1: LSE ready

Bit 0 **LSIRDY**: LSI clock ready flag

This bit is security-protected by LSISEC or LSIPRIV, and is publicly readable if LSIPUB = 1. It is set by hardware to indicate that the LSI oscillator is stable.

0: LSI not ready (default after reset)

1: LSI ready

14.10.3 RCC Stop mode control register (RCC_STOPCR)

Address offset: 0x8

Reset value: 0x0000 0002

This register is used to enable the RCC oscillators in Stop mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **HSISTOPEN**: HSI oscillator enable

This bit is reset by int_sys_rstn. It is security-protected by HSISEC or HSIPRIV, and is publicly readable if HSIPUB = 1. It can be set with HSISTOPENS, and cleared with HSISTOPENC. This bit is set and reset by software.

0: HSI is OFF

1: HSI is ON (default after reset)

Bit 0 **MSISTOPEN**: MSI oscillator enable

This bit is reset by int_sys_rstn. It is security-protected by MSISEC or MSIPRIV, and is publicly readable if MSIPUB = 1. It can be set with MSISTOPENS, and cleared with MSISTOPENC. This bit is set and reset by software.

0: MSI is OFF (default after reset)

1: MSI is ON

14.10.4 RCC configuration register 1 (RCC_CFGR1)

Address offset: 0x20

Reset value: 0x0000 0000

This register controls the selection of the CPU and system clocks, and their status (see *Figure 45* for various SYSSW inputs). The register is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **SYSSWS[1:0]**: System clock switch status

This bitfield is security-protected by SYSSEC, SYSPRIV, and is publicly readable if SYSPUB = 1. It is set and reset by hardware to show the source of the system bus clocks (sys_bus_ck).

00: hsi_ck selected as sysb_ck, sysc_ck, sysd_ck system clocks (default after reset)

01: msi_ck selected as sysb_ck, sysc_ck, sysd_ck system clocks

10: hse_ck selected as sysb_ck, sysc_ck, sysd_ck system clocks

11: ic2_ck selected as sysb_ck, ic6_ck selected as sysc_ck, ic11_ck as sysd_ck system clocks

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:24 **SYSSW[1:0]**: System clock switch selection

This bitfield is security-protected by SYSSEC, SYSPRIV, and is publicly readable if SYSPUB = 1. It is set by the software to select the source of the system bus clocks (sys_bus_ck).

00: hsi_ck selected as system clock (default after reset)

01: msi_ck selected as system clock

10: hse_ck selected as system clock

11: ic2_ck selected as system clock

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **CPUSWS[1:0]**: CPU clock switch status
This bitfield is security-protected by SYSSEC, SYSPRIV, and is publicly readable if SYSPUB = 1. It is set and reset by hardware to show the source of the CPU clock (sys_cpu_ck).
00: hsi_ck selected as system clock (default after reset)
01: msi_ck selected as system clock
10: hse_ck selected as system clock
11: ic1_ck selected as system clock

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **CPUSW[1:0]**: CPU clock switch selection
This bitfield is security-protected by SYSSEC, SYSPRIV, and is publicly readable if SYSPUB = 1. It is set by the software to select the source of the CPU clock (sys_cpu_ck).
00: hsi_ck selected as system clock (default after reset)
01: msi_ck selected as system clock
10: hse_ck selected as system clock
11: ic1_ck selected as system clock

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **STOPWUCK**: System clock selection after a wake up from system stop
This bit is security-protected by SYSSEC, SYSPRIV, and is publicly readable if SYSPUB = 1. It is set and reset by software to select the system wake-up clock from system stop.
0: HSI selected as wake-up clock from system stop (default after reset)
1: MSI selected as wake-up clock from system stop

14.10.5 RCC configuration register 2 (RCC_CFGR2)

Address offset: 0x24

Reset value: 0x0010 0000

This register controls the division factors of the central clocks: AHB, APB, and timer. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw						rw	rw	rw		rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **TIMPRE[1:0]**: Timer clock prescaler selection
This bitfield is security-protected by a SEC signal from RIFSC, the SYSSEC bit, a PRIV signal from RIFSC, or the SYSPRIV bit, and is publicly readable if SYSPUB = 1. It is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domains.
00: timg_ck = sys_bus_ck (default after reset)
01: timg_ck = sys_bus_ck / 2
10: timg_ck = sys_bus_ck / 4
11: timg_ck = sys_bus_ck / 8

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **HPRE[2:0]**: AHB clock prescaler

This bitfield is security-protected by SYSSEC or SYSPRIV, and is publicly readable if SYSPUB = 1. It is set and reset by software to control the division factor of the clocks between the system AXI bus and the configuration AHB bus. The AXI sys_bus_ck source clock is divided in function of HPRE, to generate the AHB clock.

The division ratio is as follows:

000: sys_bus2_ck= sys_bus_ck

001: sys_bus2_ck = sys_bus_ck / 2 (default after reset)

010: sys_bus2_ck= sys_bus_ck / 4

011: sys_bus2_ck = sys_bus_ck / 8

100: sys_bus2_ck = sys_bus_ck / 16

101: sys_bus2_ck = sys_bus_ck / 32

110: sys_bus2_ck = sys_bus_ck / 64

111: sys_bus2_ck = sys_bus_ck / 128

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **PPRE5[2:0]**: CPU domain APB5 prescaler

This bitfield is security-protected by SYSSEC or SYSPRIV, and is publicly readable if SYSPUB = 1. It is set and reset by software to control the division factor of rcc_pclk5.

000: rcc_pclk5 = sys_bus2_ck (default after reset)

001: rcc_pclk5 = sys_bus2_ck / 2

010: rcc_pclk5 = sys_bus2_ck / 4

011: rcc_pclk5 = sys_bus2_ck / 8

100: rcc_pclk5 = sys_bus2_ck / 16

101: rcc_pclk5 = sys_bus2_ck / 32

110: rcc_pclk5 = sys_bus2_ck / 64

111: rcc_pclk5 = sys_bus2_ck / 128

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **PPRE4[2:0]**: CPU domain APB4 prescaler

This bitfield is security-protected by SYSSEC or SYSPRIV, and is publicly readable if SYSPUB = 1. It is set and reset by software to control the division factor of rcc_pclk4.

000: rcc_pclk4 = sys_bus2_ck (default after reset)

001: rcc_pclk4 = sys_bus2_ck / 2

010: rcc_pclk4 = sys_bus2_ck / 4

011: rcc_pclk4 = sys_bus2_ck / 8

100: rcc_pclk4 = sys_bus2_ck / 16

101: rcc_pclk4 = sys_bus2_ck / 32

110: rcc_pclk4 = sys_bus2_ck / 64

111: rcc_pclk4 = sys_bus2_ck / 128

Bits 11:7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE2[2:0]**: CPU domain APB2 prescaler

This bitfield is security-protected by SYSSEC or SYSPRIV, and is publicly readable if SYSPUB = 1. It is set and reset by software to control the division factor of rcc_pclk2.

000: rcc_pclk2 = sys_bus2_ck (default after reset)
001: rcc_pclk2 = sys_bus2_ck / 2
010: rcc_pclk2 = sys_bus2_ck / 4
011: rcc_pclk2 = sys_bus2_ck / 8
100: rcc_pclk2 = sys_bus2_ck / 16
101: rcc_pclk2 = sys_bus2_ck / 32
110: rcc_pclk2 = sys_bus2_ck / 64
111: rcc_pclk2 = sys_bus2_ck / 128

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **PPRE1[2:0]**: CPU domain APB1 prescaler

This bitfield is security-protected by SYSSEC or SYSPRIV, and is publicly readable if SYSPUB = 1. Is it set and reset by software to control the division factor of rcc_pclk1.

000: rcc_pclk1 = sys_bus2_ck (default after reset)
001: rcc_pclk1 = sys_bus2_ck / 2
010: rcc_pclk1 = sys_bus2_ck / 4
011: rcc_pclk1 = sys_bus2_ck / 8
100: rcc_pclk1 = sys_bus2_ck / 16
101: rcc_pclk1 = sys_bus2_ck / 32
110: rcc_pclk1 = sys_bus2_ck / 64
111: rcc_pclk1 = sys_bus2_ck / 128

14.10.6 RCC backup domain protection register (RCC_BDCR)

Address offset: 0x2C

Reset value: 0x0000 0000

This register controls the reset of the backup domain. It is reset by pwr_vsw_rstn, and is in the V_{BKP} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VSW RST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 **VSWRST**: V_{switch} (V_{SW}) domain software reset.

This bit is write-protected by the pwr_lock_backup_n signal. It is security-protected by a SEC signal from RIFSC, the RSTSEC bit, a PRIV signal from RIFSC, or the RSTPRIV bit, and is publicly readable if RSTPUB = 1. Writing 1 to this VSWRST bit by software generates a pulse that resets the V_{SW} domain.

0: V_{SW} domain not reset (default after reset)
1: V_{SW} domain reset

Bits 30:0 Reserved, must be kept at reset value.

14.10.7 RCC reset status register for hardware (RCC_HWRSR)

Address offset: 0x30

Reset value: 0x00A0 0000

This register is used to monitor the resets that occurred. It is reset by pwr_por_rstn, and is in the V_{BKP} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **LPWRRSTF**: Illegal Stop or Standby flag

This bit is set by hardware when the CPU goes erroneously in Stop or Standby mode. It is reset by software by writing HWRMVF.

0: No illegal reset occurred (default after power-on reset)

1: Illegal Stop or Standby reset occurred

Bit 29 Reserved, must be kept at reset value.

Bit 28 **WWDGRSTF**: Window watchdog reset flag

This bit is set by hardware when a window watchdog reset occurs. it is reset by software by writing HWRMVF.

0: No window watchdog reset occurred from WWDG (default after power-on reset)

1: Window watchdog reset occurred from WWDG

Bit 27 Reserved, must be kept at reset value.

Bit 26 **IWDGRSTF**: Independent watchdog reset flag

This bit is set by hardware when an independent watchdog reset occurs. It is reset by software by writing HWRMVF.

0: No independent watchdog reset occurred (default after power-on reset)

1: Independent watchdog reset occurred

Bit 25 Reserved, must be kept at reset value.

Bit 24 **SFTRSTF**: Software system reset flag

This bit is set by hardware when the software system reset is due to the CPU.The CPU can generate a software system reset by writing SYSRESETREQ in AIRCR register of the CPU. This bit is reset by software by writing HWRMVF.

0: No software system reset occurred (default after power-on reset)

1: A software system reset has been generated by the CPU.

Bit 23 **PORRSTF**: POR/PDR reset flag

This bit is set by hardware when a POR/PDR occurs. it is reset by software by writing HWRMVF.

0: No POR/PDR occurred

1: POR/PDR occurred (default after power-on reset)

Bit 22 **PINRSTF**: Pin reset flag (NRST)

This bit is set by hardware when a reset from pin occurs. it is reset by software by writing HWRMVF.

0: No reset from pin occurred

1: Reset from pin occurred (default after power-on reset)

Bit 21 **BORRSTF**: BOR reset flag

This bit is set by hardware when a BOR occurs (pwr_bor_rst). it is reset by software by writing HWRMVF.

0: No BOR occurred

1: BOR occurred (default after power-on reset)

Bits 20:18 Reserved, must be kept at reset value.

Bit 17 **LCKRSTF**: CPU lockup reset flag

This bit is set by hardware when a reset from a CPU lockup occurs. Is it reset by software by writing RMVF.

0: No reset from CPU lockup occurred

1: Reset from CPU lockup occurred

Bit 16 **RMVF**: Remove reset flag

This bit is write-protected by the security bit. It is security-protected by a SEC signal from RIFSC, the RSTSEC bit, a PRIV signal from RIFSC, or the RSTPRIV bit, and is publicly readable if RSTPUB = 1. This bit is written by software to clear the value of the reset flags in this register.

0: Clear of the reset flags not activated (default after power-on reset)

1: Clear the value of the reset flags

Bits 15:0 Reserved, must be kept at reset value.

14.10.8 RCC reset register (RCC_RSR)

Address offset: 0x34

Reset value: 0x00A0 0000

This register is used to monitor the resets that occurred. It is reset by pwr_por_rstn, and is in the V_{BKP} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **LPWRRSTF**: Illegal Stop or Standby flag

This bit is set by hardware when the CPU goes erroneously in Stop or Standby mode. It is reset by software by writing RMVF.

0: No illegal reset occurred (default after power-on reset)

1: Illegal Stop or Standby reset occurred

Bit 29 Reserved, must be kept at reset value.

Bit 28 **WWDGRSTF**: Window watchdog reset flag

This bit is set by hardware when a window watchdog reset occurs. It is reset by software by writing RMVF.

0: No window watchdog reset occurred from WWDG (default after power-on reset)

1: Window watchdog reset occurred from WWDG

Bit 27 Reserved, must be kept at reset value.

Bit 26 **IWDGRSTF**: Independent watchdog reset flag

This bit is set by hardware when an independent watchdog reset occurs. It is reset by software by writing RMVF.

0: No independent watchdog reset occurred (default after power-on reset)

1: Independent watchdog reset occurred

Bit 25 Reserved, must be kept at reset value.

Bit 24 **SFTRSTF**: Software system reset flag

This bit is set by hardware when the software system reset is due to the CPU.The CPU can generate a software system reset by writing SYSRESETREQ in AIRCR register of the CPU. This bit is reset by software by writing RMVF.

0: No software system reset occurred (default after power-on reset)

1: A software system reset has been generated by the CPU.

Bit 23 **PORRSTF**: POR/PDR reset flag

This bit is set by hardware when a POR/PDR occurs. It is reset by software by writing RMVF.

0: No POR/PDR occurred

1: POR/PDR occurred (default after power-on reset)

Bit 22 **PINRSTF**: Pin reset flag (NRST)

This bit is set by hardware when a reset from pin occurs. It is reset by software by writing RMVF.

0: No reset from pin occurred

1: Reset from pin occurred (default after power-on reset)

Bit 21 **BORRSTF**: BOR reset flag

This bit is set by hardware when a BOR occurs (pwr_bor_rst). It is reset by software by writing RMVF.

0: No BOR occurred

1: BOR occurred (default after power-on reset)

Bits 20:18 Reserved, must be kept at reset value.

Bit 17 **LCKRSTF**: CPU lockup reset flag

This bit is set by hardware when a reset from a CPU lockup occurs. it is reset by software by writing RMVF.

0: No reset from CPU lockup occurred

1: Reset from CPU lockup occurred

Bit 16 **RMVF**: Remove reset flag

This bit is write-protected by the security bit. It is security-protected by a SEC signal from RIFSC, the SYSSEC bit, a PRIV signal from RIFSC, or the SYSPRIV bit, and is publicly readable if SYSPUB = 1. This bit is written by software to clear the value of the reset flags in this register.

0: Clear of the reset flags not activated (default after power-on reset)

1: Clear the value of the reset flags

Bits 15:0 Reserved, must be kept at reset value.

14.10.9 RCC LSE configuration register (RCC_LSECFGR)

Address offset: 0x40

Reset value: 0x0000 0000

This register is used to configure the LSE oscillator. It is reset by rcc_vsw_rstn, and is in the V_{BKP} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw						r	rw	w							

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 **LSEDRV[1:0]**: LSE oscillator driving capability

This bitfield is write-protected by the pwr_lock_backup_n signal. It is security-protected by LSESEC or LSEPRIV, and is publicly readable if LSEPUB = 1. it is set by software to select the driving capability of the LSE oscillator.

00: Lowest drive (default after reset)

01: Medium-high drive

10: Medium-low drive

11: Highest drive

Bit 17 **LSEGFON**: LSE clock glitch filter enable

This bit is write-protected by the pwr_lock_backup_n signal. It is security-protected by LSESEC or LSEPRIV, and is publicly readable if LSEPUB = 1. This bit is set and cleared by software to enable the LSE clock glitch filter. it t can be written only when LSE is disabled (LSE ACT = 0).

0: LSE clock glitch filter disabled (default after reset)

1: LSE clock glitch filter enabled

Bit 16 **LSEEXT**: LSE clock type in bypass mode

This bit is write-protected by the pwr_lock_backup_n signal. It is security-protected by LSESEC or LSEPRIV, and is publicly readable if LSEPUB = 1. This bit is set and reset by software to select the external clock type (analog or digital).

The external clock must be enabled with the LSE enable bit to be used by the device.

This LSEEXT bit can be written only if the LSE oscillator is disabled.

0: LSE in analog mode (default after reset)

1: LSE in digital mode

Bit 15 **LSEBYP**: LSE clock bypass

This bit is write-protected by the pwr_lock_backup_n signal. It is security-protected by LSESEC or LSEPRIV, and is publicly readable if LSEPUB = 1. This bit is set and cleared by software to bypass the oscillator with an external clock.

The external clock must be enabled with the LSE enable bit to be used by the device.

This LSEBYP bit can be written even if the LSE oscillator is disabled.

0: LSE oscillator not bypassed (default after reset)

1: LSE oscillator bypassed with an external clock

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **LSECSSD**: LSE clock security system (CSS) failure detection

This bit is set by hardware to indicate when a failure has been detected by the CSS on the external LSE oscillator.

0: No failure detected on the oscillator (default after reset)

1: Failure detected on the oscillator

Bit 8 **LSECSSRA**: LSE clock security system (CSS) rearm function

This bit is write-protected by the pwr_lock_backup_n signal. It is security-protected by LSESEC or LSEPRIV, and is publicly readable if LSEPUB = 1. This bit is set by software. After an LSE failure detection, the software can re-enable the LSECSS by writing this bit to 1. Reading this bit returns the written value. Prior to set this bit to 1, LSECSSON must be set to 0. Refer to *CSS on LSE* for details.

0: Writing 0 has no effect (default after reset).

1: Writing 1 generates a rearm pulse for the LSECSS function.

Bit 7 **LSECSSON**: LSE clock security system (CSS) enable

This bit is write-protected by the pwr_lock_backup_n signal. It is security-protected by LSESEC or LSEPRIV, and is publicly readable if LSEPUB = 1. This bit is set by software to enable the CSS on the LSE oscillator. Refer to *LSE oscillator* for details on the activation and deactivation sequences. Once this LSECSSON bit is enabled, it cannot be disabled, except after an LSE failure detection (LSECSSD = 1).

0: CSS on the LSE oscillator OFF (default after reset)

1: CSS on the LSE oscillator ON

Bits 6:0 Reserved, must be kept at reset value.

14.10.10 RCC MSI configuration register (RCC_MSICFGR)

Address offset: 0x44

Reset value: 0x0000 0000

This register is used to configure the MSI oscillator. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						MSIFREQSEL									
						rw									

Bit 31 Reserved, must be kept at reset value.

Bits 30:23 **MSICAL[7:0]**: MSI clock calibration

This bitfield is set by hardware by option-byte loading during a system reset. It is adjusted by software through MSITRIM bitfield. This MSICAL bitfield represents the sum of the engineering-option-byte calibration value and MSITRIM[4:0] value.

Bits 22:21 Reserved, must be kept at reset value.

Bits 20:16 **MSITRIM[4:0]**: MSI clock trimming
This bitfield is set by software to adjust calibration. It is added to the engineering option bytes (CAL_BSEC_Fuse[7:0]) loaded during the reset phase (bsec_msi_cal[7:0]), to form the calibration trimming value.
MSICAL[7:0] = MSITRIM[4:0] + CAL_BSEC_Fuse[7:0].

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **MSIFREQSEL**: MSI oscillator frequency selection
This bit is set and cleared by software.
0: MSI oscillator frequency is 4 MHz (default after backup domain reset).
1: MSI oscillator frequency is 16 MHz.

Bits 8:0 Reserved, must be kept at reset value.

14.10.11 RCC HSI configuration register (RCC_HSICFGR)

Address offset: 0x48

Reset value: 0x0000 0000

This register is used to configure the HSI oscillator. It is reset by pwr_okin_vcore_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:23 **HSICAL[8:0]**: HSI clock calibration
This bitfield is set by hardware by option-byte loading during a system reset. It is adjusted by software through HSITRIM bitfield. This HSICAL bitfield represents the sum of the engineering option byte calibration value and HSITRIM[6:0] value.

Bits 22:16 **HSITRIM[6:0]**: HSI clock trimming
This bitfield is set by software to adjust calibration. It represents a signed value, added to the engineering option bytes (bsec_hsi_cal[8:0]) loaded during the reset phase (bsec_hsi_cal), to form the calibration trimming value: HSICAL[8:0] = HSITRIM[6:0] + bsec_hsi_cal[8:0].
0x1-0x3F: bsec_hsi_cal[8:0] + {V}
0x40-0x7F: bsec_hsi_cal[8:0] - 128 + {v}
0x00: bsec_hsi_cal[8:0] (default after reset)

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:7 **HSIDIV[1:0]**: HSI clock divider
This bitfield is set and reset by software to control the hsi_ck frequency (see *Figure 37*).
00: hsi_div_ck = hsi_ck (default after reset)
01: hsi_div_ck = hsi_ck / 2
10: hsi_div_ck = hsi_ck / 4
11: hsi_div_ck = hsi_ck / 8

Bits 6:0 Reserved, must be kept at reset value.

14.10.12 RCC HSI monitor control register (RCC_HSIMCR)

Address offset: 0x4C

Reset value: 0x001F 07A1

This register is used to monitor and trim of the HSI oscillator. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	HSIREF[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **HSIMONEN**: HSI clock period monitor enable
This bit is set and cleared by software.
0: Writing 0 disables the HSI clock period monitoring. Reading 0 means that the HSI clock period monitoring is disabled.
1: Writing 1 enables the HSI clock period monitoring. Reading 1 means that the HSI clock period monitoring is enabled.

Bits 30:22 Reserved, must be kept at reset value.

Bits 21:16 **HSIDEV[5:0]**: HSI clock count deviation value
This bitfield is set and cleared by software.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **HSIREF[10:0]**: HSI clock-cycle counter reference value.
This bit contains the number of HSI clock cycles expected between two consecutive rising edges of the LSE signal. It is set by hardware.

14.10.13 RCC HSI monitor status register (RCC_HSIMSR)

Address offset: 0x50

Reset value: 0x0000 0000

This register is used to monitor and trim of the HSI oscillator. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **HSIVAL[10:0]**: HSI clock-cycle counter measured value
This bitfield contains the number of HSI clock cycles measured between consecutive rising edges of the LSE signal. it is set by hardware.

14.10.14 RCC HSE configuration register (RCC_HSECFGR)

Address offset: 0x54

Reset value: 0x0000 0800

This register is used to configure the HSE oscillator. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSE EXT
															rw

rw	rw	rw	rw	rw	rw	r		rs	rw						

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **HSEEXT**: HSE clock type in bypass mode

This bit is set and reset by software to select the external clock type (analog or digital). The external clock must be enabled with the HSE enable bit to be used by the device. This HSEEXT bit can be written only if the HSE oscillator is disabled.

0: HSE in analog mode (default after reset)

1: HSE in digital mode

Bit 15 **HSEBYP**: HSE clock bypass

This bit is set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSE enable bit to be used by the device. This HSEBYP bit can be written even if the HSE oscillator is disabled.

0: HSE oscillator not bypassed (default after reset)

1: HSE oscillator bypassed with an external clock

Bits 14:11 **HSECSSBPRE[3:0]**: HSE CSS bypass divider

This bitfield is set and reset by software to divide the replacement internal HSI oscillator that bypasses the HSE oscillator when a failure is detected. Refer to *HSE oscillator* for details on the activation and deactivation sequences.

0000: HSI clock divided by 1
0001: HSI clock divided by 2
0010: HSI clock divided by 3
0011: HSI clock divided by 4
0100: HSI clock divided by 5
0101: HSI clock divided by 6
0110: HSI clock divided by 7
0111: HSI clock divided by 8
1000: HSI clock divided by 9
1001: HSI clock divided by 10
1010: HSI clock divided by 11
1011: HSI clock divided by 12
1100: HSI clock divided by 13
1101: HSI clock divided by 14
1110: HSI clock divided by 15
1111: HSI clock divided by 16

Bit 10 **HSECSSBYP**: HSE CSS bypass enable

This bit is set and reset by software to enable the CSS to bypass the HSE oscillator when a failure is detected, and to get a clock from the HSI oscillator. Refer to *HSE oscillator* for details on the activation and deactivation sequences.

0: CSS bypass of the HSE oscillator OFF (default after reset)

1: CSS bypass on the HSE oscillator ON

Bit 9 **HSECSSD**: HSE CSS failure detection

This bit is set by hardware to indicate when a failure has been detected by the CSS on the external HSE oscillator.

0: No failure detected on the oscillator (default after reset)

1: Failure detected on the oscillator

Bit 8 Reserved, must be kept at reset value.

Bit 7 **HSECSSON**: HSE CSS enable

This bit is set by software to enable the CSS on the HSE oscillator. Refer to *HSE oscillator* for details on the activation and deactivation sequences. Once this HSECSSON bit is enabled, it cannot be disabled, except after an HSE failure detection (HSECSSD = 1).

0: CSS on the HSE oscillator OFF (default after reset)

1: CSS on the HSE oscillator ON

Bit 6 **HSEDIV2SEL**: HSE div2 clock source select

This bit is set and reset by software to select the source of the div2 output clock.

0: HSE: hse_div2_osc_ck = hse_osc_ck (default after reset)

1: HSE: hse_div2_osc_ck = hse_osc_ck/2

Bits 5:0 Reserved, must be kept at reset value.

14.10.15 RCC PLL1 configuration register 1 (RCC_PLL1CFGR1)

Address offset: 0x80

Reset value: 0x0820 2500

This register is used to configure the main features of PLL1. It is reset by int_sys_rst,n and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	PLL1SEL[2:0]			PLL1BYP	Res.	PLL1DIVM[5:0]						PLL1DIVN[11:8]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PLL1DIVN[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLL1SEL[2:0]**: PLL1 source selection of the reference clock

This bitfield is set and reset by software to select system clock source (sys_ck).

000: hsi_ck selected as reference clock

001: msi_ck selected as reference clock

010: hse_ck selected as reference clock

011: I2S_CKIN selected as reference clock

Bit 27 **PLL1BYP**: PLL1 bypass
This bit is set and cleared by software to bypass the VCO, and to feed the output with the PLL reference clock.
0: PLL output is driven by the VCO, via the optional POSTDIV division.
1: PLL output is bypassed and driven by the PLL reference clock (default after reset).

Bit 26 Reserved, must be kept at reset value.

Bits 25:20 **PLL1DIVM[5:0]**: PLL1 reference input clock divide frequency ratio
This bitfield is set and cleared by software.
0x00: Not applicable when the PLL is enabled
0x01: Reference clock divided by 1 (min value)
0x2-0x3F: Reference clock divided by {v}. It is recommended to configure the maximum divided reference clock frequency close to FVCO / 16.

Bits 19:8 **PLL1DIVN[11:0]**: PLL1 integer part for the VCO multiplication factor
This bitfield is set and cleared by software to control the multiplication factor of the VCO.
VCO output frequency = reference clock * DIVN / DIVM when FRACV = 0.
In integer mode, this value must be set between 0x10 (16) and 0x280 (640).
In fractional mode, this value must be set between 0x14 (20) and 0x140 (320).

Bits 7:0 Reserved, must be kept at reset value.

14.10.16 RCC PLL1 configuration register 2 (RCC_PLL1CFGR2)

Address offset: 0x84

Reset value: 0x0080 0000

This register is used to configure the optional fractional feedback division of PLL1. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PLL1DIVNFRAC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **PLL1DIVNFRAC[23:0]**: PLL1 fractional part of the VCO multiplication factor
This bitfield is set and cleared by software to control the VCO fractional multiplication factor.
VCO output frequency = reference clock * (DIVN + DIVNFRAC / 2^{24}) / DIVM.

14.10.17 RCC PLL1 configuration register 3 (RCC_PLL1CFGR3)

Address offset: 0x88

Reset value: 0x4900 000D

This register is used to configure the SSCG and optional inner features of PLL1. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw	rw	rw	rw				rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **PLL1PDIVEN**: PLL1 post divider POSTDIV1, POSTDIV2, and PLL clock output enable
This bit is set and cleared by software to enable the post divider.
0: POSTDIV1 and POSTDIV2 powered down
1: POSTDIV1 and POSTDIV2 active (default after reset)

Bits 29:27 **PLL1PDIV1[2:0]**: PLL1 VCO frequency divider level 1
This bitfield is set and cleared by software to divide the VCO frequency output.
000: Not applicable
001: VCO output divided by 1 (minimum value) (default after reset)
010: VCO output divided by 2
011: VCO output divided by 3
100: VCO output divided by 4
101: VCO output divided by 5
110: VCO output divided by 6
111: VCO output divided by 7

Bits 26:24 **PLL1PDIV2[2:0]**: PLL1 VCO frequency divider level 2
This bitfield is set and cleared by software to divide the VCO frequency output.
000: Not applicable
001: VCO output divided by 1 (minimum value) (default after reset)
010: VCO output divided by 2
011: VCO output divided by 3
100: VCO output divided by 4
101: VCO output divided by 5
110: VCO output divided by 6
111: VCO output divided by 7

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **PLL1MODSPR[4:0]**: PLL1 modulation spread depth adjustment
This bitfield is set and cleared by software to adjust the modulation depth of the clock spreading generator.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **PLL1MODDIV[3:0]**: PLL1 modulation division frequency adjustment
This bitfield is set and cleared by software to adjust the modulation frequency of the clock spreading generator. Corresponds to DIVVAL in *Figure 43*).

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL1MODSPRDW**: PLL1 modulation spread spectrum down
This bit is set and cleared by software to select the clock spreading mode of PLL1.
0: Center-spread modulation selected (default after reset)
1: Down-spread modulation selected

Bit 3 **PLL1MODDSEN**: PLL1 modulation spread spectrum (and fractional divide) enable
This bit is set and cleared by software to enable the delta-sigma modulator.
0: Modulation spread spectrum and fractional divide not active
1: Modulation spread spectrum and fractional divide active (default after reset)

Bit 2 **PLL1MODSSDIS**: PLL1 modulation spread spectrum disable
This bit is set and cleared by software to enable the clock spreading generator of PLL1.
0: Modulation spread spectrum active (and fractional divide inactive)
1: Fractional divide active (and modulation spread spectrum inactive) (default after reset)

Bit 1 **PLL1DACEN**: PLL1 noise canceling DAC enable in fractional mode
This bit is set and cleared by software to enable the noise cancellation in fractional mode.
0: DAC not active (default after reset)
1: DAC active

Bit 0 **PLL1MODSSRST**: PLL1 modulation spread spectrum reset
This bit is set and cleared by software.
0: PLL1 modulation spread spectrum reset module released
1: PLL1 modulation spread spectrum reset module asserted (default after reset)

14.10.18 RCC PLL2 configuration register 1 (RCC_PLL2CFGR1)

Address offset: 0x90

Reset value: 0x0800 0000

This register is used to configure the main features of PLL2. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw								

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLL2SEL[2:0]**: PLL2 source selection of the reference clock
This bitfield is set and reset by software to select system clock source (sys_ck).
000: hsi_ck selected as reference clock
001: msi_ck selected as reference clock
010: hse_ck selected as reference clock
011: I2S_CKIN selected as reference clock

Bit 27 **PLL2BYP**: PLL2 bypass

This bit is set and cleared by software to bypass the VC,O and to feed the output with the PLL reference clock.

0: PLL output is driven by the VCO, via the optional POSTDIV division.

1: PLL output is bypassed and driven by the PLL reference clock (default after reset).

Bit 26 Reserved, must be kept at reset value.

Bits 25:20 **PLL2DIVM[5:0]**: PLL2 reference input clock divide frequency ratio

This bitfield is set and cleared by software.

0x2-0x3F: Reference clock is divided by {v}. The maximum divided reference clock frequency must be close to FVCO/16.

0x00: Not applicable when PLL is enabled

0x01: Reference clock is divided by 1 (min value).

Bits 19:8 **PLL2DIVN[11:0]**: PLL2 integer part for the VCO multiplication factor

This bitfield is set and cleared by software to control the multiplication factor of the VCO.

VCO output frequency = reference clock * DIVN / DIVM when FRACV = 0.

In integer mode, this value must be set between 0x10 (16) and 0x280 (640).

In fractional mode, this value must be set between 0x14 (20) and 0x140 (320).

Bits 7:0 Reserved, must be kept at reset value.

14.10.19 RCC PLL2 configuration register 2 (RCC_PLL2CFGR2)

Address offset: 0x94

Reset value: 0x0000 0000

This register is used to configure the optional fractional feedback division of PLL2. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **PLL2DIVNFRAC[23:0]**: PLL2 fractional part of the VCO multiplication factor

This bitfield is set and cleared by software to control the VCO fractional multiplication factor.

VCO output frequency = reference clock * (DIVN + DIVNFRAC / 2^{24}) / DIVM.

14.10.20 RCC PLL2 configuration register 3 (RCC_PLL2CFGR3)

Address offset: 0x98

Reset value: 0x4900 0005

This register is used to configure the SSCG and optional inner features of PLL2. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **PLL2PDIVEN**: PLL2 post divider POSTDIV1, POSTDIV2, and PLL clock output enable
This bit is set and cleared by software to enable the post divider.
0: POSTDIV1 and POSTDIV2 powered down
1: POSTDIV1 and POSTDIV2 active (default after reset)

Bits 29:27 **PLL2PDIV1[2:0]**: PLL2 VCO frequency divider level 1
This bitfield is set and cleared by software to divide the VCO frequency output.
000: Not applicable
001: VCO output divided by 1 (minimum value) (default after reset)
010: VCO output divided by 2
011: VCO output divided by 3
100: VCO output divided by 4
101: VCO output divided by 5
110: VCO output divided by 6
111: VCO output divided by 7

Bits 26:24 **PLL2PDIV2[2:0]**: PLL2 VCO frequency divider level 2
This bitfield is set and cleared by software to divide the VCO frequency output.
000: Not applicable
001: VCO output divided by 1 (minimum value) (default after reset)
010: VCO output divided by 2
011: VCO output divided by 3
100: VCO output divided by 4
101: VCO output divided by 5
110: VCO output divided by 6
111: VCO output divided by 7

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **PLL2MODSPR[4:0]**: PLL2 modulation spread depth adjustment
This bitfield is set and cleared by software to adjust the modulation depth of the clock spreading generator.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **PLL2MODDIV[3:0]**: PLL2 modulation division frequency adjustment
This bitfield is set and cleared by software to adjust the modulation frequency of the clock spreading generator. It corresponds to DIVVAL in *Figure 43*.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL2MODSPRDW**: PLL2 modulation down spread
This bit is set and cleared by software to select the clock spreading mode of PLL2.
0: Center-spread modulation selected (default after reset)
1: Down-spread modulation selected

Bit 3 **PLL2MODDSEN**: PLL2 modulation spread spectrum (and fractional divide) enable
This bit is set and cleared by software to enable the delta-sigma modulator.
0: Modulation spread spectrum and fractional divide not active (default after reset)
1: Modulation spread spectrum and fractional divide active

Bit 2 **PLL2MODSSDIS**: PLL2 modulation spread spectrum disable
This bit is set and cleared by software to enable the clock spreading generator of PLL2.
0: Modulation spread spectrum active (and fractional divide inactive)
1: Fractional divide active (and the Modulation spread spectrum inactive) (default after reset)

Bit 1 **PLL2DACEN**: PLL2 noise canceling DAC enable in fractional mode
This bit is set and cleared by software to enable the noise cancellation in fractional mode.
0: DAC not active (default after reset)
1: DAC active

Bit 0 **PLL2MODSSRST**: PLL2 modulation spread spectrum reset
This bit is set and cleared by software.
0: PLL2 modulation spread spectrum reset module released
1: PLL2 modulation spread spectrum reset module asserted (default after reset)

14.10.21 RCC PLL3 configuration register 1 (RCC_PLL3CFGR1)

Address offset: 0xA0

Reset value: 0x0800 0000

This register is used to configure the main features of PLL3. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw								

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLL3SEL[2:0]**: PLL3 source selection of the reference clock
This bitfield is set and reset by software to select system clock source (sys_ck).
000: hsi_ck selected as reference clock
001: msi_ck selected as reference clock
010: hse_ck selected as reference clock
011: I2S_CKIN selected as reference clock

Bit 27 **PLL3BYP**: PLL3 bypass
This bit is set and cleared by software to bypass the VCO and feed the output with the PLL reference clock.
0: PLL output is driven by the VCO, via the optional POSTDIV division.
1: PLL output is bypassed and driven by the PLL reference clock (default after reset).

Bit 26 Reserved, must be kept at reset value.

Bits 25:20 **PLL3DIVM[5:0]**: PLL3 reference input clock divide frequency ratio
This bitfield is set and cleared by software.
0x2-0x3F: Reference clock is divided by {v}. The maximum divided reference clock frequency must be close to FVCO/16.
0x00: Not applicable when PLL is enabled
0x01: Reference clock is divided by 1 (min value)

Bits 19:8 **PLL3DIVN[11:0]**: PLL3 Integer part for the VCO multiplication factor
This bitfield is set and cleared by software to control the multiplication factor of the VCO.
VCO output frequency = reference clock * DIVN / DIVM when FRACV = 0.
In integer mode, this value must be set between 0x10 (16) and 0x280 (640).
In fractional mode, this value must be set between 0x14 (20) and 0x140 (320).

Bits 7:0 Reserved, must be kept at reset value.

14.10.22 RCC PLL3 configuration register 2 (RCC_PLL3CFGR2)

Address offset: 0xA4

Reset value: 0x0000 0000

This register is used to configure the optional fractional feedback division of PLL3. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **PLL3DIVNFRAC[23:0]**: PLL3 fractional part of the VCO multiplication factor
This bitfield is set and cleared by software to control the VCO fractional multiplication factor.
VCO output frequency = reference clock * (DIVN + DIVNFRAC / 2^{24}) / DIVM.

14.10.23 RCC PLL3 configuration register 3 (RCC_PLL3CFGR3)

Address offset: 0xA8

Reset value: 0x4900 0005

This register is used to configure the SSCG and optional inner features of PLL3. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

				rw	rw	rw	rw				rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **PLL3PDIVEN**: PLL3 post divider POSTDIV1, POSTDIV2, and PLL clock output enable
This bit is set and cleared by software to enable the post divider.
0: POSTDIV1 and POSTDIV2 powered down
1: POSTDIV1 and POSTDIV2 active (default after reset)

Bits 29:27 **PLL3PDIV1[2:0]**: PLL3 VCO frequency divider level 1
This bitfield is set and cleared by software to divide the VCO frequency output.
000: Not applicable
001: VCO output divided by 1 (minimum value) (default after reset)
010: VCO output divided by 2
011: VCO output divided by 3
100: VCO output divided by 4
101: VCO output divided by 5
110: VCO output divided by 6
111: VCO output divided by 7

Bits 26:24 **PLL3PDIV2[2:0]**: PLL3 VCO frequency divider level 2
This bitfield is set and cleared by software to divide the VCO frequency output.
000: Not applicable
001: VCO output divided by 1 (minimum value) (default after reset)
010: VCO output divided by 2
011: VCO output divided by 3
100: VCO output divided by 4
101: VCO output divided by 5
110: VCO output divided by 6
111: VCO output divided by 7

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **PLL3MODSPR[4:0]**: PLL3 modulation spread depth adjustment
This bitfield is set and cleared by software to adjust the modulation depth of the clock spreading generator.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **PLL3MODDIV[3:0]**: PLL3 modulation division frequency adjustment
This bitfield is set and cleared by software to adjust the modulation frequency of the clock spreading generator. It corresponds to DIVVAL in *Figure 43*.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL3MODSPRDW**: PLL3 modulation down spread
This bit is set and cleared by software to select the clock spreading mode of PLL3.
0: Center-spread modulation selected (default after reset)
1: Down-spread modulation selected

Bit 3 **PLL3MODDSEN**: PLL3 modulation spread spectrum (and fractional divide) enable
This bit is set and cleared by software to enable the delta-sigma modulator.
0: Modulation spread spectrum and fractional divide not active (default after reset)
1: Modulation spread spectrum and fractional divide active

Bit 2 **PLL3MODSSDIS**: PLL3 modulation spread spectrum disable
This bit is set and cleared by software to enable the clock spreading generator of PLL3.
0: Modulation spread spectrum active (and fractional divide inactive)
1: Fractional divide active (and the modulation spread spectrum inactive) (default after reset)

Bit 1 **PLL3DACEN**: PLL3 noise canceling DAC enable in fractional mode
This bit is set and cleared by software to enable the noise cancellation in fractional mode.
0: DAC not active (default after reset)
1: DAC active

Bit 0 **PLL3MODSSRST**: PLL3 modulation spread spectrum reset
This bit is set and cleared by software.
0: PLL3 modulation spread spectrum reset module released
1: PLL3 modulation spread spectrum reset module asserted (default after reset)

14.10.24 RCC PLL4 configuration register 1 (RCC_PLL4CFGR1)

Address offset: 0xB0

Reset value: 0x0800 0000

This register is used to configure the main features of PLL4. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	PLL4SEL[2:0]			PLL4BYP	Res.	PLL4DIVM[5:0]						PLL4DIVN[11:8]

PLL4DIVN[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLL4SEL[2:0]**: PLL4 source selection of the reference clock
This bitfield is set and reset by software to select system clock source (sys_ck).
000: hsi_ck selected as reference clock
001: msi_ck selected as reference clock
010: hse_ck selected as reference clock
011: I2S_CKIN selected as reference clock

Bit 27 **PLL4BYP**: PLL4 bypass
This bit is set and cleared by software to bypass the VCO, and to feed the output with the PLL reference clock.
0: PLL output is driven by the VCO, via the optional POSTDIV division.
1: PLL output is bypassed and driven by the PLL reference clock (default after reset).

Bit 26 Reserved, must be kept at reset value.

Bits 25:20 **PLL4DIVM[5:0]**: PLL4 reference input clock divide frequency ratio
This bitfield is set and cleared by software.
0x2-0x3F: Reference clock is divided by {v}. The maximum divided reference clock frequency must be close to FVCO/16.
0x00: Not applicable when PLL is enabled
0x01: Reference clock is divided by 1 (min value).

Bits 19:8 **PLL4DIVN[11:0]**: PLL4 integer part for the VCO multiplication factor
This bitfield is set and cleared by software to control the multiplication factor of the VCO.
VCO output frequency = reference clock * DIVN / DIVM when FRACV = 0.
In integer mode, this value must be set between 0x10 (16) and 0x280 (640).
In fractional mode, this value must be set between 0x14 (20) and 0x140 (320).

Bits 7:0 Reserved, must be kept at reset value.

14.10.25 RCC PLL4 configuration register 2 (RCC_PLL4CFGR2)

Address offset: 0xB4

Reset value: 0x0000 0000

This register is used to configure the optional fractional feedback division of PLL4. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **PLL4DIVNFRAC[23:0]**: PLL4 fractional part of the VCO multiplication factor
This bitfield is set and cleared by software to control the VCO fractional multiplication factor.
VCO output frequency = reference clock * (DIVN + DIVNFRAC / 2^{24}) / DIVM.

14.10.26 RCC PLL4 configuration register 3 (RCC_PLL4CFGR3)

Address offset: 0xB8

Reset value: 0x4900 0005

This register is used to configure the SSCG and optional inner features of PLL4. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **PLL4PDIVEN**: PLL4 post divider POSTDIV1, POSTDIV2, and PLL clock output enable
This bit is set and cleared by software to enable the post divider.
0: POSTDIV1 and POSTDIV2 powered down
1: POSTDIV1 and POSTDIV2 active (default after reset)

Bits 29:27 **PLL4PDIV1[2:0]**: PLL4 VCO frequency divider level 1
This bitfield is set and cleared by software to divide the VCO frequency output.
000: Not applicable
001: VCO output divided by 1 (minimum value) (default after reset)
010: VCO output divided by 2
011: VCO output divided by 3
100: VCO output divided by 4
101: VCO output divided by 5
110: VCO output divided by 6
111: VCO output divided by 7

Bits 26:24 **PLL4PDIV2[2:0]**: PLL4 VCO frequency divider level 2
This bitfield is set and cleared by software to divide the VCO frequency output.
000: Not applicable
001: VCO output divided by 1 (minimum value) (default after reset)
010: VCO output divided by 2
011: VCO output divided by 3
100: VCO output divided by 4
101: VCO output divided by 5
110: VCO output divided by 6
111: VCO output divided by 7

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **PLL4MODSPR[4:0]**: PLL4 modulation spread depth adjustment
This bitfield is set and cleared by software to adjust the modulation depth of the clock spreading generator.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **PLL4MODDIV[3:0]**: PLL4 modulation division frequency adjustment
This bitfield is set and cleared by software to adjust the modulation frequency of the clock spreading generator. It corresponds to DIVVAL in *Figure 43*.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL4MODSPRDW**: PLL4 modulation down spread
This bit is set and cleared by software to select the clock spreading mode of PLL4.
0: Center-spread modulation selected (default after reset)
1: Down-spread modulation selected

Bit 3 **PLL4MODDSEN**: PLL4 modulation spread spectrum (and fractional divide) enable
This bitfield is set and cleared by software to enable the delta-sigma modulator.
0: Modulation spread spectrum and fractional divide not active (default after reset)
1: Modulation spread spectrum and fractional divide active

Bit 2 **PLL4MODSSDIS**: PLL4 modulation spread spectrum disable
This bit is set and cleared by software to enable the clock spreading generator of PLL4.
0: Modulation spread spectrum active (and fractional divide inactive)
1: Fractional divide active (and modulation spread spectrum inactive) (default after reset)

Bit 1 **PLL4DACEN**: PLL4 noise canceling DAC enable in fractional mode
This bit is set and cleared by software to enable the noise cancellation in fractional mode.
0: DAC not active (default after reset)
1: DAC active

Bit 0 **PLL4MODSSRST**: PLL4 modulation spread spectrum reset
This bit is set and cleared by software.
0: PLL4 modulation spread spectrum reset module released
1: PLL4 modulation spread spectrum reset module asserted (default after reset)

14.10.27 RCC IC1 configuration register (RCC_IC1CFGR)

Address offset: 0xC4

Reset value: 0x0002 0000

This register is used to configure the IC1 divider. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **IC1SEL[1:0]**: Divider IC1 source selection
This bitfield is set and reset by software to select the PLL output to feed for the channel IC1.
00: pll1_ck selected (default after reset)
01: pll2_ck selected
10: pll3_ck selected
11: pll4_ck selected

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:16 **IC1INT[7:0]**: Divider IC1 integer division factor

This bitfield is set and reset by software to control the frequency of the IC1 clock. The frequency is divided by the value IC1INT + 1: {v}: IC1 = pllx_ck / {v + 1}.

0x00: IC1 = pllx_ck

0x01: IC1 = pllx_ck / 2

0x02: IC1 = pllx_ck / 3 (default after reset)

0x03: IC1 = pllx_ck / 4

...

0xFF: IC1 = pllx_ck / 256

Bits 15:0 Reserved, must be kept at reset value.

14.10.28 RCC IC2 configuration register (RCC_IC2CFGR)

Address offset: 0xC8

Reset value: 0x0003 0000

This register is used to configure the IC2 divider. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **IC2SEL[1:0]**: Divider IC2 source selection

This bitfield is set and reset by software to select the PLL output to feed for the channel IC2.

00: pll1_ck selected (default after reset)

01: pll2_ck selected

10: pll3_ck selected

11: pll4_ck selected

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:16 **IC2INT[7:0]**: Divider IC2 integer division factor

This bitfield is set and reset by software to control the frequency of the IC2 clock. The frequency is divided by the value IC2INT + 1: {v}: IC2 = pllx_ck / {v + 1}.

0x00: IC2 = pllx_ck

0x01: IC2 = pllx_ck / 2

0x02: IC2 = pllx_ck / 3

0x03: IC2 = pllx_ck / 4 (default after reset)

...

0xFF: IC2 = pllx_ck / 256

Bits 15:0 Reserved, must be kept at reset value.

14.10.29 RCC IC3 configuration register (RCC_IC3CFGR)

Address offset: 0xCC

Reset value: 0x0000 0000

This register is used to configure the IC3 divider. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **IC7SEL[1:0]**: Divider IC7 source selection

This bitfield is set and reset by software to select the PLL output to feed for the channel IC7.
00: pll1_ck selected
01: pll2_ck selected (default after reset)
10: pll3_ck selected
11: pll4_ck selected

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:16 **IC7INT[7:0]**: Divider IC7 integer division factor

This bitfield is set and reset by software to control the frequency of the IC7 clock. The frequency is divided by the value IC7INT + 1: {v}: IC7 = pllx_ck / {v + 1}.
0x00: IC7 = pllx_ck (default after reset)
0x01: IC7 = pllx_ck / 2
0x02: IC7 = pllx_ck / 3
0x03: IC7 = pllx_ck / 4
...
0xFF: IC7 = pllx_ck / 256

Bits 15:0 Reserved, must be kept at reset value.

14.10.34 RCC IC8 configuration register (RCC_IC8CFGR)

Address offset: 0xE0

Reset value: 0x1000 0000

This register is used to configure the IC8 divider. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **IC12SEL[1:0]**: Divider IC12 source selection
This bitfield is set and reset by software to select the PLL output to feed for the channel IC12.
00: pll1_ck selected
01: pll2_ck selected
10: pll3_ck selected (default after reset)
11: pll4_ck selected

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:16 **IC12INT[7:0]**: Divider IC12 integer division factor
This bitfield is set and reset by software to control the frequency of the IC12 clock. The frequency is divided by the value IC12INT + 1: {v}: IC12 = pllx_ck / {v + 1}.
0x00: IC12 = pllx_ck (default after reset)
0x01: IC12 = pllx_ck / 2
0x02: IC12 = pllx_ck / 3
0x03: IC12 = pllx_ck / 4
...
0xFF: IC12 = pllx_ck / 256

Bits 15:0 Reserved, must be kept at reset value.

14.10.39 RCC IC13 configuration register (RCC_IC13CFGR)

Address offset: 0xF4

Reset value: 0x2000 0000

This register is used to configure the IC13 divider. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

This bitfield is set and reset by software to select the PLL output to feed for the channel IC20.
00: pll1_ck selected
01: pll2_ck selected
10: pll3_ck selected
11: pll4_ck selected (default after reset)

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:16 **IC20INT[7:0]**: Divider IC20 integer division factor

This bitfield is set and reset by software to control the frequency of the IC20 clock. The frequency is divided by the value IC20INT + 1. {v}: IC20 = pllx_ck / {v + 1}.
0x00: IC20 = pllx_ck (default after reset)
0x01: IC20 = pllx_ck / 2
0x02: IC20 = pllx_ck / 3
0x03: IC20 = pllx_ck / 4

Bits 15:0 Reserved, must be kept at reset value.

14.10.47 RCC clock-source interrupt enable register (RCC_CIER)

Address offset: 0x124

Reset value: 0x0002 0000

This register controls the enabling (unmasking) of the interrupts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **WKUPIE**: CPU wake-up from Stop interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by CPU wake-up from Stop mode.

0: Wake-up interrupt disabled (default after reset)

1: Wake-up interrupt enabled

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **HSECSSIE**: HSE CSS interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the CSS on external 32 kHz oscillator.

0: HSE CSS interrupt disabled

1: HSE CSS interrupt enabled (default after reset)

Bit 16 **LSECSSIE**: LSE CSS interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the CSS on external 32 kHz oscillator.

0: LSE CSS interrupt disabled (default after reset)

1: LSE CSS interrupt enabled

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **PLL4RDYIE**: PLL4 ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by PLL4 lock.

0: PLL4 lock interrupt disabled (default after reset)

1: PLL4 lock interrupt enabled

Bit 10 **PLL3RDYIE**: PLL3 ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by PLL3 lock.

0: PLL3 lock interrupt disabled (default after reset)

1: PLL3 lock interrupt enabled

Bit 9 **PLL2RDYIE**: PLL2 ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by PLL2 lock.

0: PLL2 lock interrupt disabled (default after reset)

1: PLL2 lock interrupt enabled

Bit 8 **PLL1RDYIE**: PLL1 ready interrupt enable
This bit is set and reset by software to enable/disable interrupt caused by PLL1 lock.
0: PLL1 lock interrupt disabled (default after reset)
1: PLL1 lock interrupt enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **HSERDYIE**: HSE ready interrupt enable
This bit is set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled (default after reset)
1: HSE ready interrupt enabled

Bit 3 **HSIRDYIE**: HSI ready interrupt enable
This bit is set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.
0: HSI ready interrupt disabled (default after reset)
1: HSI ready interrupt enabled

Bit 2 **MSIRDYIE**: MSI ready interrupt enable
This bit is set and reset by software to enable/disable interrupt caused by the MSI oscillator stabilization.
0: MSI ready interrupt disabled (default after reset)
1: MSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable
This bit is set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled (default after reset)
1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable
This bit is set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.
0: LSI ready interrupt disabled (default after reset)
1: LSI ready interrupt enabled

14.10.48 RCC clock-source interrupt flag register (RCC_CIFR)

Address offset: 0x128

Reset value: 0x0000 0000

This register returns the triggered interrupts. It is reset by sys_rstn.

				r	r	r	r				r	r	r	r	r

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **WKUPF**: CPU wake-up from Stop interrupt flag
This bit is reset by software by writing the WKUPFC bit. It is set by hardware when the CPU needs to exit Stop mode.
0: No wake-up interrupt caused by the PWR (default after reset)
1: Wake-up interrupt caused by the PWR

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **HSECSSF**: HSE ready interrupt flag
This bit is reset by software by writing the HSECSSC bit. It is set by hardware when the HSE clock becomes stable and HSECSSIE is set.
0: No clock ready interrupt caused by the HSE (default after reset)
1: Clock ready interrupt caused by the HSE

Bit 16 **LSECSSF**: LSE ready interrupt flag
This bit is reset by software by writing the LSECSSC bit. It is set by hardware when the LSE clock becomes stable and LSECSSIE is set.
0: No clock ready interrupt caused by the LSE (default after reset)
1: Clock ready interrupt caused by the LSE

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **PLL4RDYF**: PLL4 ready interrupt flag
This bit is reset by software by writing the PLL4RDYC bit. It is set by hardware when the PLL4 clock becomes stable and PLL4RDYIE is set.
0: No clock ready interrupt caused by the PLL4 (default after reset)
1: Clock ready interrupt caused by the PLL4

Bit 10 **PLL3RDYF**: PLL3 ready interrupt flag
This bit is reset by software by writing the PLL3RDYC bit. It is set by hardware when the PLL3 clock becomes stable and PLL3RDYIE is set.
0: No clock ready interrupt caused by the PLL3 (default after reset)
1: Clock ready interrupt caused by the PLL3

Bit 9 **PLL2RDYF**: PLL2 ready interrupt flag
This bit is reset by software by writing the PLL2RDYC bit. it is set by hardware when the PLL2 clock becomes stable and PLL2RDYIE is set.
0: No clock ready interrupt caused by the PLL2 (default after reset)
1: Clock ready interrupt caused by the PLL2

Bit 8 **PLL1RDYF**: PLL1 ready interrupt flag
This bit is reset by software by writing the PLL1RDYC bit. It is set by hardware when the PLL1 clock becomes stable and PLL1RDYIE is set.
0: No clock ready interrupt caused by the PLL1 (default after reset)
1: Clock ready interrupt caused by the PLL1

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **HSERDYF**: HSE ready interrupt flag
This bit is reset by software by writing the HSERDYC bit. It is set by hardware when the HSE clock becomes stable and HSERDYIE is set.
0: No clock ready interrupt caused by the HSE (default after reset)
1: Clock ready interrupt caused by the HSE

Bit 3 **HSIRDYF**: HSI ready interrupt flag

This bit is reset by software by writing the HSIRDYC bit. It is set by hardware when the HSI clock becomes stable and HSIRDYIE is set.

0: No clock ready interrupt caused by the HSI (default after reset)

1: Clock ready interrupt caused by the HSI

Bit 2 **MSIRDYF**: MSI ready interrupt flag

This bit is reset by software by writing the MSIRDYC bit. It is set by hardware when the MSI clock becomes stable and MSIRDYIE is set.

0: No clock ready interrupt caused by the MSI (default after reset)

1: Clock ready interrupt caused by the MSI

Bit 1 **LSERDYF**: LSE ready interrupt flag

This bit is reset by software by writing the LSERDYC bit. It is set by hardware when the LSE clock becomes stable and LSERDYIE is set.

0: No clock ready interrupt caused by the LSE (default after reset)

1: Clock ready interrupt caused by the LSE

Bit 0 **LSIRDYF**: LSI ready interrupt flag

This bit is reset by software by writing the LSIRDYC bit. It is set by hardware when the LSI clock becomes stable and LSIRDYIE is set.

0: No clock ready interrupt caused by the LSI (default after reset)

1: Clock ready interrupt caused by the LSI

14.10.49 RCC clock-source interrupt clear register (RCC_CICR)

Address offset: 0x12C

Reset value: 0x0000 0000

This register clears the interrupts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	WKUPFC	Res.	Res.	Res.	Res.	Res.	Res.	HSECSSC	LSECSSC

				w	w	w	w				w	w	w	w	w

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **WKUPFC**: CPU wake-up ready interrupt clear

This bit is set by software to clear WKUPF. It is reset by hardware when clear done.

0: WKUPF not modified (default after reset)

1: WKUPF cleared

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **HSECSSC**: HSE ready interrupt clear

This bit is set by software to clear HSECSSF. it is reset by hardware when clear done.

0: HSECSSF not modified (default after reset)

1: HSECSSF cleared

Bit 16 **LSECSSC**: LSE ready interrupt clear
This bit is set by software to clear LSECSSF. It is reset by hardware when clear done.
0: LSECSSF not modified (default after reset)
1: LSECSSF cleared

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **PLL4RDYC**: PLL4 ready interrupt clear
This bit is set by software to clear PLL4RDYF. It is reset by hardware when clear done.
0: PLL4RDYF not modified (default after reset)
1: PLL4RDYF cleared

Bit 10 **PLL3RDYC**: PLL3 ready interrupt clear
This bit is set by software to clear PLL3RDYF. it is reset by hardware when clear done.
0: PLL3RDYF not modified (default after reset)
1: PLL3RDYF cleared

Bit 9 **PLL2RDYC**: PLL2 ready interrupt clear
This bit is set by software to clear PLL2RDYF. It is reset by hardware when clear done.
0: PLL2RDYF not modified (default after reset)
1: PLL2RDYF cleared

Bit 8 **PLL1RDYC**: PLL1 ready interrupt clear
This bit is set by software to clear PLL1RDYF. It is reset by hardware when clear done.
0: PLL1RDYF not modified (default after reset)
1: PLL1RDYF cleared

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **HSERDYC**: HSE ready interrupt clear
This bit is set by software to clear HSERDYF. It is reset by hardware when clear done.
0: HSERDYF not modified (default after reset)
1: HSERDYF cleared

Bit 3 **HSIRDYC**: HSI ready interrupt clear
This bit is set by software to clear HSIRDYF. It is reset by hardware when clear done.
0: HSIRDYF not modified (default after reset)
1: HSIRDYF cleared

Bit 2 **MSIRDYC**: MSI ready interrupt clear
This bit is set by software to clear MSIRDYF. It is reset by hardware when clear done.
0: MSIRDYF not modified (default after reset)
1: MSIRDYF cleared

Bit 1 **LSERDYC**: LSE ready interrupt clear
This bit is set by software to clear LSERDYF. it is reset by hardware when clear done.
0: LSERDYF not modified (default after reset)
1: LSERDYF cleared

Bit 0 **LSIRDYC**: LSI ready interrupt clear
This bit is set by software to clear LSIRDYF. It is reset by hardware when clear done.
0: LSIRDYF not modified (default after reset)
1: LSIRDYF cleared

14.10.50 RCC clock configuration for independent peripheral register 1 (RCC_CCIPR1)

Address offset: 0x144

Reset value: 0x0000 0000

This register is used to configure various clocks. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **DCMIPPSEL[1:0]**: Source selection for the DCMIPP kernel clock
This bitfield is set and reset by software.
00: pclk5 selected as reference clock
01: per_ck selected as reference clock
10: ic17_ck selected as reference clock
11: hsi_div_ck selected as reference clock

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:8 **ADCPRE[7:0]**: ADC12 kernel clock divider selection (for clock ck_ker_adc12)
This bitfield is set and reset by software. The division ratio is linear: {v}: ck_ker_adc12 / {v+1}.
0x00: ck_ker_adc12 divided by 1
0x01: ck_ker_adc12 divided by 2

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ADC12SEL[2:0]**: Source selection for the ADC12 kernel clock
This bitfield is set and reset by software.
000: hclk1 selected as reference clock
001: per_ck selected as reference clock
010: ic7_ck selected as reference clock
011: ic8_ck selected as reference clock
100: msi_ck selected as reference clock
101: hsi_div_ck selected as reference clock
110: I2S_CKIN selected as reference clock
111: timg_ck selected as reference clock

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **ADF1SEL[2:0]**: Source selection for the ADF1 kernel clock
This bitfield is set and reset by software.
000: hclk2 selected as reference clock
001: per_ck selected as reference clock
010: ic7_ck selected as reference clock
011: ic8_ck selected as reference clock
100: msi_ck selected as reference clock
101: hsi_div_ck selected as reference clock
110: I2S_CKIN selected as reference clock
111: timg_ck selected as reference clock

14.10.51 RCC clock configuration for independent peripheral register 2 (RCC_CCIPR2)

Address offset: 0x148

Reset value: 0x0000 0000

This register is used to configure various clocks. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ETH1GTXCLKSEL**: Ethernet 1 reference Tx RGMII 125 MHz clock selection
This bit is set and reset by software.
0: External clock (ETH1_CLK125) is used. Need to program AFmux.
1: Internal clock from the RCC is used.

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **ETH1REFCLKSEL**: Ethernet 1 reference Rx clock selection
This bit is set and reset by software.
0: External clock (ETH_RX/REF_CLK) is used. This is RX clock for an RGMII or MII PHY, or REF clock for an RMII PHY. Need to program AFmux.
1: Internal clock (ck_ker_eth1 from RCC) is used. To be used when the RMII 50 MHz (pad ETH1_CLK) is generated to the RMII PHY.

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **ETH1SEL[2:0]**: Ethernet 1 PHY interface selection
This bitfield is set and reset by software.
Note: Apply this configuration while the ETH1 is under reset, before enabling the ETH1 clocks.
000: MII
001: RGMII
100: RMII
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ETH1CLKSEL[1:0]**: Source selection for the ETH1 kernel clock
This bitfield is set and reset by software.
00: hclke selected as reference clock
01: per_ck selected as reference clock
10: ic12_ck selected as reference clock
11: hse_ck selected as reference clock

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **ETH1PWRDOWNACK**: Ethernet 1 Power-down status
This bit is set and reset by software. It is asserted when the power-down sequence start has been acknowledged.
0: Power-down sequence start not yet acknowledged
1: Power-down sequence start acknowledged

Bits 7:4 **ETH1PTPDIV[3:0]**: ETH1 kernel clock divider selection (for clock ck_ker_eth1ptp)
This bitfield is set and reset by software. The division ratio is linear.
0000: ck_ker_eth1ptp divided by 1
0001: ck_ker_eth1ptp divided by 2
0010: ck_ker_eth1ptp divided by 3
0011: ck_ker_eth1ptp divided by 4
0100: ck_ker_eth1ptp divided by 5
0101: ck_ker_eth1ptp divided by 6
0110: ck_ker_eth1ptp divided by 7
0111: ck_ker_eth1ptp divided by 8
1000: ck_ker_eth1ptp divided by 9
1001: ck_ker_eth1ptp divided by 10
1010: ck_ker_eth1ptp divided by 11
1011: ck_ker_eth1ptp divided by 12
1100: ck_ker_eth1ptp divided by 13
1101: ck_ker_eth1ptp divided by 14
1110: ck_ker_eth1ptp divided by 15
1111: ck_ker_eth1ptp divided by 16

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **ETH1PTPSEL[1:0]**: Source selection for the ETH1 kernel clock
This bitfield is set and reset by software.
00: hclke selected as reference clock
01: per_ck selected as reference clock
10: ic13_ck selected as reference clock
11: hse_ck selected as reference clock

14.10.52 RCC clock configuration for independent peripheral register 3 (RCC_CCIPR3)

Address offset: 0x14C

Reset value: 0x0000 0003

This register is used to configure various clocks. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MDF1SEL[2:0]**: Source selection for the MDF1 kernel clock
This bitfield is set and reset by software.
000: hclk2 selected as reference clock
001: per_ck selected as reference clock
010: ic7_ck selected as reference clock
011: ic8_ck selected as reference clock
100: msi_ck selected as reference clock
101: hsi_div_ck selected as reference clock
110: I2S_CKIN selected as reference clock
111: timg_ck selected as reference clock

Bits 15:12 **MCO2PRE[3:0]**: MCO2 Kernel clock divider selection (for clock MCO2)
This bitfield is set and reset by software. The division ratio is linear.
0000: MCO2 divided by 1
0001: MCO2 divided by 2
0010: MCO2 divided by 3
0011: MCO2 divided by 4
0100: MCO2 divided by 5
0101: MCO2 divided by 6

1101: MCO2 divided by 14
1110: MCO2 divided by 15
1111: MCO2 divided by 16

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **MCO2SEL[2:0]**: Source selection for the MCO2 kernel clock
This bitfield is set and reset by software.
000: hsi_div_ck selected as reference clock (default after reset)
001: lse_ck selected as reference clock
010: msi_ck selected as reference clock
011: lsi_ck selected as reference clock
100: hse_ck selected as reference clock
101: ic15_ck selected as reference clock
110: ic20_ck selected as reference clock
111: sysb_ck selected as reference clock

Bits 7:4 **MCO1PRE[3:0]**: MCO1 Kernel clock divider selection (for clock MCO1)
This bitfield is set and reset by software. The division ratio is linear.
0000: MCO1 divided by 1
0001: MCO1 divided by 2
0010: MCO1 divided by 3
0011: MCO1 divided by 4
0100: MCO1 divided by 5
0101: MCO1 divided by 6
0110: MCO1 divided by 7
0111: MCO1 divided by 8
1000: MCO1 divided by 9
1001: MCO1 divided by 10
1010: MCO1 divided by 11
1011: MCO1 divided by 12
1100: MCO1 divided by 13
1101: MCO1 divided by 14
1110: MCO1 divided by 15
1111: MCO1 divided by 16

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **MCO1SEL[2:0]**: Source selection for the MCO1 kernel clock
This bitfield is set and reset by software.
000: hsi_div_ck selected as reference clock (default after reset)
001: lse_ck selected as reference clock
010: msi_ck selected as reference clock
011: lsi_ck selected as reference clock
100: hse_ck selected as reference clock
101: ic5_ck selected as reference clock
110: ic10_ck selected as reference clock
111: sysa_ck selected as reference clock

14.10.55 RCC clock configuration for independent peripheral register 6 (RCC_CCIPR6)

Address offset: 0x158

Reset value: 0x0000 0000

This register is used to configure various clocks. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

11: hse_div2_osc_ck selected as reference clock
Others: Reserved, no clock provided as reference clock

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **XSPI3SEL[1:0]**: Source selection for the XSPI3 kernel clock
This bitfield is set and reset by software.
00: hclk5 selected as reference clock
01: per_ck selected as reference clock
10: ic3_ck selected as reference clock
11: ic4_ck selected as reference clock
Others: Reserved, no clock provided as reference clock

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **XSPI2SEL[1:0]**: Source selection for the XSPI2 kernel clock
This bitfield is set and reset by software.
00: hclk5 selected as reference clock
01: per_ck selected as reference clock
10: ic3_ck selected as reference clock
11: ic4_ck selected as reference clock
Others: Reserved, no clock provided as reference clock

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **XSPI1SEL[1:0]**: Source selection for the XSPI1 kernel clock
This bitfield is set and reset by software.
00: hclk5 selected as reference clock
01: per_ck selected as reference clock
10: ic3_ck selected as reference clock
11: ic4_ck selected as reference clock
Others: Reserved, no clock provided as reference clock

14.10.56 RCC clock configuration for independent peripheral register 7 (RCC_CCIPR7)

Address offset: 0x15C

Reset value: 0x0000 0200

This register is used to configure various clocks. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

100: msi_ck selected as reference clock
101: hsi_div_ck selected as reference clock
110: I2S_CKIN selected as reference clock
111: spdif_symb_ck selected as reference clock

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:12 **RTCPRE[5:0]**: RTC OSC clock divider selection (for clock hse_ck)
This bitfield is set and reset by software. The division ratio is linear: {v}: hse_ck / {v+1}.
0x00: hse_ck divided by 1
0x01: hse_ck divided by 2

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**: Source selection for the RTC kernel clock
This bitfield is write-protected by the pwr_lock_backup_n signal. It is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit.
This bitfield is set and reset by software.
01: lse_ck selected as reference clock
10: lsi_ck selected as reference clock
11: hse_rtc_ck selected as reference clock
Others: Reserved, no clock provided as reference clock

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **PSSISEL[1:0]**: Source selection for the PSSI kernel clock
This bitfield is set and reset by software.
00: hclk5 selected as reference clock
01: per_ck selected as reference clock
10: ic20_ck selected as reference clock
11: hsi_div_ck selected as reference clock
Others: Reserved, no clock provided as reference clock

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **PERSEL[2:0]**: Source selection for the PER kernel clock
This bitfield is set and reset by software.
000: hsi_ck selected as reference clock
001: msi_ck selected as reference clock
010: hse_ck selected as reference clock
011: ic19_ck selected as reference clock
100: ic5_ck selected as reference clock

							rw	rw		rw	rw				rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC2DLLRST**: SDMMC2DLL reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SDMMC2DLLRSTS, and cleared with SDMMC2DLLRSTC. This bit is set and reset by software.
0: SDMMC2DLL not under reset (default after reset)
1: SDMMC2DLL under reset

Bit 7 **SDMMC1DLLRST**: SDMMC1DLL reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SDMMC1DLLRSTS, and cleared with SDMMC1DLLRSTC. This bit is set and reset by software.
0: SDMMC1DLL not under reset (default after reset)
1: SDMMC1DLL under reset

Bit 6 Reserved, must be kept at reset value.

Bit 5 **XSPIPHY2RST**: XSPIPHY2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPIPHY2RST,S and cleared with XSPIPHY2RSTC. This bit is set and reset by software.
0: XSPIPHY2 not under reset (default after reset)
1: XSPIPHY2 under reset

Bit 4 **XSPIPHY1RST**: XSPIPHY1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPIPHY1RSTS, and cleared with XSPIPHY1RSTC. This bit is set and reset by software.

0: XSPIPHY1 not under reset (default after reset)

1: XSPIPHY1 under reset

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DBGRST**: DBG reset

This bit is always security-protected. It can be set with DBGRSTS, and cleared with DBGRSTC. This bit is set and reset by software.

0: DBG not under reset (default after reset)

1: DBG under reset

14.10.63 RCC embedded memories reset register (RCC_MEMRSTR)

Address offset: 0x20C

Reset value: 0x0000 0000

This register is used to reset the embedded memories. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **BOOTROMRST**: BootROM reset

This bit is always security-protected. It can be set with BOOTROMRSTS, and cleared with BOOTROMRSTC. This bit is set and reset by software.

0: BootROM not under reset (default after reset)

1: BootROM under reset

Bit 11 **VENCRAMRST**: VENCRAM reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if VENCRAMPUB = 1. It can be set with VENCRAMRSTS, and cleared with VENCRAMRSTC. This bit is set and reset by software.

0: VENCRAM not under reset (default after reset)

1: VENCRAM under reset

Bit 10 **CACHEAXIRAMRST**: CACHEAXIRAM reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if CACHEAXIRAMPUB = 1. It can be set with CACHEAXIRAMRSTS, and cleared with CACHEAXIRAMRSTC. This bit is set and reset by software.

0: CACHEAXIRAM not under reset (default after reset)

1: CACHEAXIRAM under reset

Bit 9 **FLEXRAMRST**: FLEXRAM reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if FLEXRAMPUB = 1. It can be set with FLEXRAMRSTS, and cleared with FLEXRAMRSTC. This bit is set and reset by software.

0: FLEXRAM not under reset (default after reset)

1: FLEXRAM under reset

Bit 8 **AXISRAM2RST**: AXISRAM2 reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM2PUB = 1. it can be set with AXISRAM2RSTS, and cleared with AXISRAM2RSTC. This bit is set and reset by software.

0: AXISRAM2 s not under reset (default after reset)

1: AXISRAM2 under reset

Bit 7 **AXISRAM1RST**: AXISRAM1 reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM1PUB = 1. It can be set with AXISRAM1RSTS, and cleared with AXISRAM1RSTC. This bit is set and reset by software.

0: AXISRAM1 not under reset (default after reset)

1: AXISRAM1 under reset

Bit 6 Reserved, must be kept at reset value.

Bit 5 **AHBSRAM2RST**: AHBSRAM2 reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AHBSRAM2PUB = 1. It can be set with AHBSRAM2RSTS, and cleared with AHBSRAM2RSTC. This bit is set and reset by software.

0: AHBSRAM2 not under reset (default after reset)

1: AHBSRAM2 under reset

Bit 4 **AHBSRAM1RST**: AHBSRAM1 reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AHBSRAM1PUB = 1. It can be set with AHBSRAM1RSTS, and cleared with AHBSRAM1RSTC. This bit is set and reset by software.

0: AHBSRAM1 not under reset (default after reset)

1: AHBSRAM1 under reset

Bit 3 **AXISRAM6RST**: AXISRAM6 reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM6PUB = 1. It can be set with AXISRAM6RSTS, and cleared with AXISRAM6RSTC. This bit is set and reset by software.

0: AXISRAM6 not under reset (default after reset)

1: AXISRAM6 under reset

Bit 2 **AXISRAM5RST**: AXISRAM5 reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM5PUB = 1. It can be set with AXISRAM5RSTS, and cleared with AXISRAM5RSTC. This bit is set and reset by software.

0: AXISRAM5 not under reset (default after reset)

1: AXISRAM5 under reset

Bit 1 **AXISRAM4RST**: AXISRAM4 reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM4PUB = 1. It can be set with AXISRAM4RSTS, and cleared with AXISRAM4RSTC. This bit is set and reset by software.

0: AXISRAM4 not under reset (default after reset)

1: AXISRAM4 under reset

Bit 0 **AXISRAM3RST**: AXISRAM3 reset

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM3PUB = 1. It can be set with AXISRAM3RSTS, and cleared with AXISRAM3RSTC. This bit is set and reset by software.

0: AXISRAM3 not under reset (default after reset)

1: AXISRAM3 under reset

14.10.64 RCC AHB1 reset register (RCC_AHB1RSTR)

Address offset: 0x210

Reset value: 0x0000 0000

This register is used to reset the AHB1. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

										rw	rw				

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **ADC12RST**: ADC12 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with ADC12RSTS and cleared with ADC12RSTC. This bit is set and reset by software.

0: ADC12 not under reset (default after reset)

1: ADC12 under reset

Bit 4 **GPDMA1RST**: GPDMA1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPDMA1RSTS and cleared with GPDMA1RSTC. This bit is set and reset by software.

0: GPDMA1 not under reset (default after reset)

1: GPDMA1 under reset

Bits 3:0 Reserved, must be kept at reset value.

14.10.65 RCC AHB2 reset register (RCC_AHB2RSTR)

Address offset: 0x214

Reset value: 0x0000 0000

This register is used to reset the AHB2. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **ADF1RST**: ADF1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ADF1RSTS and cleared with ADF1RSTC. This bit is set and reset by software.

0: ADF1 not under reset (default after reset)

1: ADF1 under reset

Bit 16 **MDF1RST**: MDF1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MDF1RSTS and cleared with MDF1RSTC. This bit is set and reset by software.

0: MDF1 not under reset (default after reset)

1: MDF1 under reset

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **RAMCFGRST**: RAMCFG reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with RAMCFGRSTS and cleared with RAMCFGRSTC. This bit is set and reset by software.

0: RAMCFG not under reset (default after reset)

1: RAMCFG under reset

Bits 11:0 Reserved, must be kept at reset value.

14.10.66 RCC AHB3 reset register (RCC_AHB3RSTR)

Address offset: 0x218

Reset value: 0x0000 0000

This register is used to reset the AHB3. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw		rw				rw		rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **IACRST**: IAC reset

This bit is always security-protected. It can be set with IACRSTS, and cleared with IACRSTC. This bit is set and reset by software.

0: IAC not under reset (default after reset)

1: IAC under reset

Bit 9 Reserved, must be kept at reset value.

Bit 8 **PKARST**: PKA reset

This bit is security-protected by the SYSSEC bit, the SYSPRIV bit. It can be set with PKARSTS, and cleared with PKARSTC. This bit is set and reset by software.

0: PKA not under reset (default after reset)

1: PKA under reset

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SAESRST**: SAES reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SAESRSTS, and cleared with SAESRSTC. This bit is set and reset by software.

0: SAES not under reset (default after reset)

1: SAES under reset

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPRST**: CRYP reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CRYPRSTS, and cleared with CRYPRSTC. This bit is set and reset by software.

0: CRYP not under reset (default after reset)

1: CRYP under reset

Bit 1 **HASHRST**: HASH reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with HASHRSTS, and cleared with HASHRSTC. This bit is set and reset by software.

0: HASH not under reset (default after reset)

1: HASH under reset

Bit 0 **RNGRST**: RNG reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with RNGRSTS, and cleared with RNGRSTC. This bit is set and reset by software.

0: RNG not under reset (default after reset)

1: RNG under reset

14.10.67 RCC AHB4 reset register (RCC_AHB4RSTR)

Address offset: 0x21C

Reset value: 0x0000 0000

This register is used to reset the AHB4. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw						rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CRCRST**: CRC reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CRCRST,S and cleared with CRCRSTC.This bit is set and reset by software.

0: CRC not under reset (default after reset)

1: CRC under reset

Bit 18 **PWRRST**: PWR reset

This bit is always security-protected. It can be set with PWRRSTS, and cleared with PWRRSTC. This bit is set and reset by software.

0: PWR not under reset (default after reset)

1: PWR under reset

Bit 17 Reserved, must be kept at reset value.

Bit 16 **GPIOQRST**: GPIO Q reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOQRSTS, and cleared with GPIOQRSTC. This bit is set and reset by software.

0: GPIO Q not under reset (default after reset)

1: GPIO Q under reset

Bit 15 **GPIOPRST**: GPIO P reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOPRSTS, and cleared with GPIOPRSTC. This bit is set and reset by software.

0: GPIO P not under reset (default after reset)

1: GPIO P under reset

Bit 14 **GPIOORST**: GPIO O reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOORSTS, and cleared with GPIOORSTC. This bit is set and reset by software.

0: GPIO O not under reset (default after reset)

1: GPIO O under reset

Bit 13 **GPIONRST**: GPIO N reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIONRSTS, and cleared with GPIONRSTC. This bit is set and reset by software.

0: GPIO N not under reset (default after reset)

1: GPIO N under reset

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHRST**: GPIO H reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOHRSTS, and cleared with GPIOHRSTC. This bit is set and reset by software.

0: GPIO H not under reset (default after reset)

1: GPIO H under reset

Bit 6 **GPIOGRST**: GPIO G reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOGRSTS, and cleared with GPIOGRSTC. This bit is set and reset by software.

0: GPIO G not under reset (default after reset)

1: GPIO G under reset

Bit 5 **GPIOFRST**: GPIO F reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOFRSTS, and cleared with GPIOFRSTC. This bit is set and reset by software.

0: GPIO F not under reset (default after reset)

1: GPIO F under reset

Bit 4 **GPIOERST**: GPIO E reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOERSTS, and cleared with GPIOERSTC. This bit is set and reset by software.

0: GPIO E not under reset (default after reset)

1: GPIO E under reset

Bit 3 **GPIODRST**: GPIO D reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIODRSTS, and cleared with GPIODRSTC. This bit is set and reset by software.

0: GPIO D not under reset (default after reset)

1: GPIO D under reset

Bit 2 **GPIOCRST**: GPIO C reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOCRSTS, and cleared with GPIOCRSTC. This bit is set and reset by software.

0: GPIO C not under reset (default after reset)

1: GPIO C under reset

Bit 1 **GPIOBRST**: GPIO B reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOBRSTS, and cleared with GPIOBRSTC. This bit is set and reset by software.

0: GPIO B not under reset (default after reset)

1: GPIO B under reset

Bit 0 **GPIOARST**: GPIO A reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOARSTS, and cleared with GPIOARSTC. This bit is set and reset by software.

0: GPIO A not under reset (default after reset)

1: GPIO A under reset

14.10.68 RCC AHB5 reset register (RCC_AHB5RSTR)

Address offset: 0x220

Reset value: 0x0000 0000

This register is used to reset the AHB5. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 **NPURST**: NPU reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with NPURSTS, and cleared with NPURSTC. This bit is set and reset by software.

0: NPU not under reset (default after reset)

1: NPU under reset

Bit 30 **CACHEAXIRST**: CACHEAXI reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CACHEAXIRSTS, and cleared with CACHEAXIRSTC. This bit is set and reset by software.

0: CACHEAXI not under reset (default after reset)

1: CACHEAXI under reset

Bit 29 **OTG2RST**: OTG2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTG2RSTS, and cleared with OTG2RSTC. This bit is set and reset by software.

0: OTG2 not under reset (default after reset)

1: OTG2 under reset

Bit 28 **OTGPHY2RST**: OTGPHY2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTGPHY2RSTS, and cleared with OTGPHY2RSTC. This bit is set and reset by software.

0: OTGPHY2 not under reset (default after reset)

1: OTGPHY2 under reset

Bit 27 **OTGPHY1RST**: OTGPHY1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTGPHY1RSTS, and cleared with OTGPHY1RSTC. This bit is set and reset by software.

0: OTGPHY1 not under reset (default after reset)

1: OTGPHY1 under reset

Bit 26 **OTG1RST**: OTG1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTG1RSTS, and cleared with OTG1RSTC. This bit is set and reset by software.

0: OTG1 not under reset (default after reset)

1: OTG1 under reset

Bit 25 **ETH1RST**: ETH1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ETH1RSTS, and cleared with ETH1RSTC. This bit is set and reset by software.

0: ETH1 not under reset (default after reset)

1: ETH1 under reset

Bit 24 **OTG2PHYCTLRST**: OTG2PHYCTL reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTG2PHYCTLRSTS, and cleared with OTG2PHYCTLRSTC. This bit is set and reset by software.

0: OTG2PHYCTL not under reset (default after reset)

1: OTG2PHYCTL under reset

Bit 23 **OTG1PHYCTLRST**: OTG1PHYCTL reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTG1PHYCTLRSTS, and cleared with OTG1PHYCTLRSTC. This bit is set and reset by software.

0: OTG1PHYCTL not under reset (default after reset)

1: OTG1PHYCTL under reset

Bits 22:21 Reserved, must be kept at reset value.

Bit 20 **GPU2DRST**: GPU2D reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPURSTS, and cleared with GPURSTC. This bit is set and reset by software.

0: GPU2D not under reset (default after reset)

1: GPU2D under reset

Bit 19 **GFXMMURST**: GFXMMU reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GFXMMURSTS, and cleared with GFXMMURSTC. This bit is set and reset by software.

0: GFXMMU not under reset (default after reset)

1: GFXMMU under reset

Bit 18 Reserved, must be kept at reset value.

Bit 17 **XSPI3RST**: XSPI3 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI3RSTS, and cleared with XSPI3RSTC. This bit is set and reset by software.

0: XSPI3 not under reset (default after reset)

1: XSPI3 under reset

Bits 16:14 Reserved, must be kept at reset value.

Bit 13 **XSPIMRST**: XSPIM reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPIMRSTS, and cleared with XSPIMRSTC. This bit is set and reset by software.

0: XSPIM not under reset (default after reset)

1: XSPIM under reset

Bit 12 **XSPI2RST**: XSPI2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI2RSTS, and cleared with XSPI2RSTC. This bit is set and reset by software.

0: XSPI2 not under reset (default after reset)

1: XSPI2 under reset

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1RST**: SDMMC1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SDMMC1RSTS, and cleared with SDMMC1RSTC. This bit is set and reset by software.

0: SDMMC1 not under reset (default after reset)

1: SDMMC1 under reset

Bit 7 **SDMMC2RST**: SDMMC2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SDMMC2RSTS, and cleared with SDMMC2RSTC. This bit is set and reset by software.

0: SDMMC2 not under reset (default after reset)

1: SDMMC2 under reset

Bit 6 **PSSIRST**: PSSI reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with PSSIRSTS, and cleared with PSSIRSTC. This bit is set and reset by software.

0: PSSI not under reset (default after reset)

1: PSSI under reset

Bit 5 **XSPI1RST**: XSPI1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI1RSTS, and cleared with XSPI1RSTC. This bit is set and reset by software.

0: XSPI1 not under reset (default after reset)

1: XSPI1 under reset

Bit 4 **FMCRST**: FMC reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with FMCRSTS and cleared with FMCRSTC. This bit is set and reset by software.

0: FMC not under reset (default after reset)

1: FMC under reset

Bit 3 **JPEGRST**: JPEG reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with JPEGRSTS, and cleared with JPEGRSTC. This bit is set and reset by software.

0: JPEG not under reset (default after reset)

1: JPEG under reset

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DRST**: DMA2D reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with DMA2DRSTS, and cleared with DMA2DRSTC. This bit is set and reset by software.

0: DMA2D not under reset (default after reset)

1: DMA2D under reset

Bit 0 **HPDMA1RST**: HPDMA1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with HPDMA1RSTS, and cleared with HPDMA1RSTC. This bit is set and reset by software.

0: HPDMA1 not under reset (default after reset)

1: HPDMA1 under reset

14.10.69 RCC APB1L reset register (RCC_APB1LRSTR)

Address offset: 0x224

Reset value: 0x0000 0000

This register is used to reset the APB1L. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **UART8RST**: UART8 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART8RSTS, and cleared with UART8RSTC. This bit is set and reset by software.

0: UART8 not under reset (default after reset)

1: UART8 under reset

Bit 30 **UART7RST**: UART7 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART7RSTS, and cleared with UART7RSTC. This bit is set and reset by software.

0: UART7 not under reset (default after reset)

1: UART7 under reset

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **I3C2RST**: I3C2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I3C2RSTS, and cleared with I3C2RSTC. This bit is set and reset by software.

0: I3C2 not under reset (default after reset)

1: I3C2 i under reset

Bit 24 **I3C1RST**: I3C1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I3C1RSTS, and cleared with I3C1RSTC. This bit is set and reset by software.

0: I3C1 not under reset (default after reset)

1: I3C1 under reset

Bit 23 **I2C3RST**: I2C3 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C3RSTS, and cleared with I2C3RSTC. This bit is set and reset by software.

0: I2C3 not under reset (default after reset)

1: I2C3 under reset

Bit 22 **I2C2RST**: I2C2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C2RSTS, and cleared with I2C2RSTC. This bit is set and reset by software.

0: I2C2 not under reset (default after reset)

1: I2C2 under reset

Bit 21 **I2C1RST**: I2C1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C1RST, S and cleared with I2C1RSTC. This bit is set and reset by software.

0: I2C1 not under reset (default after reset)

1: I2C1 under reset

Bit 20 **UART5RST**: UART5 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART5RSTS, and cleared with UART5RSTC. This bit is set and reset by software.

0: UART5 not under reset (default after reset)

1: UART5 under reset

Bit 19 **UART4RST**: UART4 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART4RSTS, and cleared with UART4RSTC. This bit is set and reset by software.

0: UART4 not under reset (default after reset)

1: UART4 under reset

Bit 18 **USART3RST**: USART3 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART3RSTS, and cleared with USART3RSTC.
This bit is set and reset by software.
0: USART3 not under reset (default after reset)
1: USART3 under reset

Bit 17 **USART2RST**: USART2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART2RSTS, and cleared with USART2RSTC.
This bit is set and reset by software.
0: USART2 not under reset (default after reset)
1: USART2 under reset

Bit 16 **SPDIFRX1RST**: SPDIFRX1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with SPDIFRX1RSTS, and cleared with SPDIFRX1RSTC. This bit is set and reset by software.
0: SPDIFRX1 not under reset (default after reset)
1: SPDIFRX1 under reset

Bit 15 **SPI3RST**: SPI3 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with SPI3RSTS, and cleared with SPI3RSTC. This bit is set and reset by software.
0: SPI3 not under reset (default after reset)
1: SPI3 under reset

Bit 14 **SPI2RST**: SPI2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI2RSTS, and cleared with SPI2RSTC. This bit is set and reset by software.
0: SPI2 not under reset (default after reset)
1: SPI2 under reset

Bit 13 **TIM11RST**: TIM11 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM11RSTS, and cleared with TIM11RSTC. This bit is set and reset by software.
0: TIM11 not under reset (default after reset)
1: TIM11 under reset

Bit 12 **TIM10RST**: TIM10 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. IT can be set with TIM10RSTS, and cleared with TIM10RSTC. This bit is set and reset by software.
0: TIM10 not under reset (default after reset)
1: TIM10 under reset

Bit 11 **WWDGRST**: WWDG reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with WWDGRSTS, and cleared with WWDGRSTC. This bit is set and reset by software.
0: WWDG not under reset (default after reset)
1: WWDG under reset

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1RST**: LPTIM1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM1RSTS, and cleared with LPTIM1RSTC. This bit is set and reset by software.

0: LPTIM1 not under reset (default after reset)

1: LPTIM1 under reset

Bit 8 **TIM14RST**: TIM14 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM14RSTS, and cleared with TIM14RSTC. This bit is set and reset by software.

0: TIM14 not under reset (default after reset)

1: TIM14 under reset

Bit 7 **TIM13RST**: TIM13 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM13RSTS, and cleared with TIM13RSTC. This bit is set and reset by software.

0: TIM13 not under reset (default after reset)

1: TIM13 under reset

Bit 6 **TIM12RST**: TIM12 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM12RSTS, and cleared with TIM12RSTC. This bit is set and reset by software.

0: TIM12 not under reset (default after reset)

1: TIM12 under reset

Bit 5 **TIM7RST**: TIM7 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM7RSTS, and cleared with TIM7RSTC. This bit is set and reset by software.

0: TIM7 not under reset (default after reset)

1: TIM7 under reset

Bit 4 **TIM6RST**: TIM6 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM6RSTS, and cleared with TIM6RSTC. This bit is set and reset by software.

0: TIM6 not under reset (default after reset)

1: TIM6 under reset

Bit 3 **TIM5RST**: TIM5 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM5RSTS, and cleared with TIM5RSTC. This bit is set and reset by software.

0: TIM5 not under reset (default after reset)

1: TIM5 under reset

Bit 2 **TIM4RST**: TIM4 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM4RSTS, and cleared with TIM4RSTC. This bit is set and reset by software.

0: TIM4 not under reset (default after reset)

1: TIM4 under reset

Bit 1 **TIM3RST**: TIM3 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM3RSTS, and cleared with TIM3RSTC. This bit is set and reset by software.

0: TIM3 not under reset (default after reset)

1: TIM3 under reset

Bit 0 **TIM2RST**: TIM2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM2RSTS, and cleared with TIM2RSTC. This bit is set and reset by software.

0: TIM2 not under reset (default after reset)

1: TIM2 under reset

14.10.70 RCC APB1H reset register (RCC_APB1HRSTR)

Address offset: 0x228

Reset value: 0x0000 0000

This register is used to reset the APB1H. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

							rw			rw					

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **UCPD1RST**: UCPD1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with UCPD1RSTS, and cleared with UCPD1RSTC. This bit is set and reset by software.

0: UCPD1 not under reset (default after reset)

1: UCPD1 under reset

Bits 17:9 Reserved, must be kept at reset value.

Bit 8 **FDCANRST**: FDCAN reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with FDCANRSTS, and cleared with FDCANRSTC. This bit is set and reset by software.

0: FDCAN not under reset (default after reset)

1: FDCAN under reset

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSRST**: MDIOS reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MDIOSRSTS, and cleared with MDIOSRSTC. This bit is set and reset by software.

0: MDIOS not under reset (default after reset)

1: MDIOS under reset

Bits 4:0 Reserved, must be kept at reset value.

14.10.71 RCC APB2 reset register (RCC_APB2RSTR)

Address offset: 0x22C

Reset value: 0x0000 0000

This register is used to reset the APB2. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SAI2RST**: SAI2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SAI2RSTS, and cleared with SAI2RSTC. This bit is set and reset by software.

0: SAI2 not under reset (default after reset)

1: SAI2 under reset

Bit 21 **SAI1RST**: SAI1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SAI1RSTS, and cleared with SAI1RSTC. This bit is set and reset by software.

0: SAI1 not under reset (default after reset)

1: SAI1 under reset

Bit 20 **SPI5RST**: SPI5 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with SPI5RSTS, and cleared with SPI5RSTC. This bit is set and reset by software.

0: SPI5 not under reset (default after reset)

1: SPI5 under reset

Bit 19 **TIM9RST**: TIM9 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM9RSTS, and cleared with TIM9RSTC. This bit is set and reset by software.

0: TIM9 not under reset (default after reset)

1: TIM9 under reset

Bit 18 **TIM17RST**: TIM17 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM17RSTS, and cleared with TIM17RSTC. This bit is set and reset by software.

0: TIM17 not under reset (default after reset)

1: TIM17 under reset

Bit 17 **TIM16RST**: TIM16 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM16RSTS, and cleared with TIM16RSTC. This bit is set and reset by software.

0: TIM16 not under reset (default after reset)

1: TIM16 under reset

Bit 16 **TIM15RST**: TIM15 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM15RSTS, and cleared with TIM15RSTC. This bit is set and reset by software.

0: TIM15 not under reset (default after reset)

1: TIM15 under reset

Bit 15 **TIM18RST**: TIM18 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM18RSTS, and cleared with TIM18RSTC. This bit is set and reset by software.

0: TIM18 not under reset (default after reset)

1: TIM18 under reset

Bit 14 Reserved, must be kept at reset value.

Bit 13 **SPI4RST**: SPI4 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI4RSTS, and cleared with SPI4RSTC. This bit is set and reset by software.

0: SPI4 not under reset (default after reset)

1: SPI4 under reset

Bit 12 **SPI1RST**: SPI1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI1RSTS, and cleared with SPI1RSTC. This bit is set and reset by software.

0: SPI1 not under reset (default after reset)

1: SPI1 under reset

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10RST**: USART10 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART10RSTS, and cleared with USART10RSTC. This bit is set and reset by software.

0: USART10 not under reset (default after reset)

1: USART10 under reset

Bit 6 **UART9RST**: UART9 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART9RSTS, and cleared with UART9RSTC. This bit is set and reset by software.

0: UART9 not under reset (default after reset)

1: UART9 under reset

Bit 5 **USART6RST**: USART6 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART6RSTS, and cleared with USART6RSTC. This bit is set and reset by software.

0: USART6 not under reset (default after reset)

1: USART6 under reset

Bit 4 **USART1RST**: USART1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART1RSTS, and cleared with USART1RSTC. This bit is set and reset by software.

0: USART1 not under reset (default after reset)

1: USART1 under reset

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8RST**: TIM8 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM8RSTS, and cleared with TIM8RSTC. This bit is set and reset by software.

0: TIM8 not under reset (default after reset)

1: TIM8 under reset

Bit 0 **TIM1RST**: TIM1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with TIM1RSTS, and cleared with TIM1RSTC. This bit is set and reset by software.

0: TIM1 not under reset (default after reset)

1: TIM1 under reset

14.10.72 RCC APB4L reset register (RCC_APB4LRSTR)

Address offset: 0x234

Reset value: 0x0000 0000

This register is used to reset the APB4L. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

rw			rw	rw	rw	rw		rw		rw		rw	rw		

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RTCRST**: RTC reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with RTCRSTS, and cleared with RTCRSTC. This bit is set and reset by software.

0: RTC not under reset (default after reset)

1: RTC under reset

Bit 15 **VREFBUFRST**: VREFBUF reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with VREFBUFRSTS, and cleared with VREFBUFRSTC. This bit is set and reset by software.

0: VREFBUF not under reset (default after reset)

1: VREFBUF under reset

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5RST**: LPTIM5 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with LPTIM5RSTS, and cleared with LPTIM5RSTC. This bit is set and reset by software.

0: LPTIM5 not under reset (default after reset)

1: LPTIM5 under reset

Bit 11 **LPTIM4RST**: LPTIM4 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with LPTIM4RSTS, and cleared with LPTIM4RSTC. This bit is set and reset by software.

0: LPTIM4 not under reset (default after reset)

1: LPTIM4 under reset

Bit 10 **LPTIM3RST**: LPTIM3 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with LPTIM3RSTS, and cleared with LPTIM3RSTC. This bit is set and reset by software.

0: LPTIM3 not under reset (default after reset)

1: LPTIM3 under reset

Bit 9 **LPTIM2RST**: LPTIM2 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with LPTIM2RSTS, and cleared with LPTIM2RSTC. This bit is set and reset by software.

0: LPTIM2 not under reset (default after reset)

1: LPTIM2 under reset

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4RST**: I2C4 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with I2C4RSTS, and cleared with I2C4RSTC. This bit is set and reset by software.

0: I2C4 not under reset (default after reset)

1: I2C4 under reset

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6RST**: SPI6 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with SPI6RSTS, and cleared with SPI6RSTC. This bit is set and reset by software.

0: SPI6 not under reset (default after reset)

1: SPI6 under reset

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1RST**: LPUART1 reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with LPUART1RST, S and cleared with LPUART1RSTC. This bit is set and reset by software.

0: LPUART1 not under reset (default after reset)

1: LPUART1 under reset

Bit 2 **HDPRST**: HDP reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with HDPRSTS, and cleared with HDPRSTC. This bit is set and reset by software.

0: HDP not under reset (default after reset)

1: HDP under reset

Bits 1:0 Reserved, must be kept at reset value.

14.10.73 RCC APB4H reset register (RCC_APB4HRSTR)

Address offset: 0x238

Reset value: 0x0000 0000

This register is used to reset the APB4H. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTSRST	Res.	SYSCFGRST
													rw		rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DTSRST**: DTS reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with DTSRSTS, and cleared with DTSRSTC. This bit is set and reset by software.

0: DTS not under reset (default after reset)

1: DTS under reset

Bit 1 Reserved, must be kept at reset value.

Bit 0 **SYSCFGRST**: SYSCFG reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with SYSCFGRSTS, and cleared with SYSCFGRSTC. This bit is set and reset by software.

0: SYSCFG not under reset (default after reset)

1: SYSCFG under reset

14.10.74 RCC APB5 reset register (RCC_APB5RSTR)

Address offset: 0x23C

Reset value: 0x0000 0000

This register is used to reset the APB5. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

									rw	rw	rw		rw	rw	

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CSIRST**: CSI reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with CSIRSTS, and cleared with CSIRSTC. This bit is set and reset by software.

0: CSI not under reset (default after reset)

1: CSI under reset

Bit 5 **VENCRST**: VENC reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with VENCRSTS, and cleared with VENCRSTC. This bit is set and reset by software.

0: VENC not under reset (default after reset)

1: VENC under reset

Bit 4 **GFXTIMRST**: GFXTIM reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with GFXTIMRSTS, and cleared with GFXTIMRSTC.

This bit is set and reset by software.

0: GFXTIM not under reset (default after reset)

1: GFXTIM under reset

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPRST**: DCMIPP reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with DCMIPPRSTS, and cleared with DCMIPPRSTC.
This bit is set and reset by software.
0: DCMIPP not under reset (default after reset)
1: DCMIPP under reset

Bit 1 **LTDCRST**: LTDC reset

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LTDCRST, S and cleared with LTDCRSTC. This bit is set and reset by software.
0: LTDC not under reset (default after reset)
1: LTDC under reset

Bit 0 Reserved, must be kept at reset value.

14.10.75 RCC IC dividers enable register (RCC_DIVENR)

Address offset: 0x240

Reset value: 0x0000 0000

This register is used to enable the IC dividers in Run, Sleep, and Stop modes. It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **IC20EN**: IC20 enable

This bit is security-protected by IC20SEC or IC20PRIV, and is publicly readable if IC20PUB = 1. It can be set with IC20ENS, and cleared with IC20ENC. This bit is set and reset by software.
0: IC20 disabled (default after reset)
1: IC20 enabled

Bit 18 **IC19EN**: IC19 enable

This bit is security-protected by IC19SEC or IC19PRIV, and is publicly readable if IC19PUB = 1. It can be set with IC19ENS, and cleared with IC19ENC. This bit is set and reset by software.
0: IC19 disabled (default after reset)
1: IC19 enabled

Bit 17 **IC18EN**: IC18 enable

This bit is security-protected by IC18SEC or IC18PRIV, and is publicly readable if IC18PUB = 1. It can be set with IC18ENS, and cleared with IC18ENC. This bit is set and reset by software.
0: IC18 disabled (default after reset)
1: IC18 enabled

Bit 16 **IC17EN**: IC17 enable

This bit is security-protected by IC17SEC or IC17PRIV, and is publicly readable if IC17PUB = 1. It can be set with IC17ENS, and cleared with IC17ENC. This bit is set and reset by software.

0: IC17 disabled (default after reset)

1: IC17 enabled

Bit 15 **IC16EN**: IC16 enable

This bit is security-protected by IC16SEC or IC16PRIV, and is publicly readable if IC16PUB = 1. It can be set with IC16ENS, and cleared with IC16ENC. This bit is set and reset by software.

0: IC16 disabled (default after reset)

1: IC16 enabled

Bit 14 **IC15EN**: IC15 enable

This bit is security-protected by IC15SEC or IC15PRIV, and is publicly readable if IC15PUB = 1. It can be set with IC15ENS, and cleared with IC15ENC. This bit is set and reset by software.

0: IC15 disabled (default after reset)

1: IC15 enabled

Bit 13 **IC14EN**: IC14 enable

This bit is security-protected by IC14SEC or IC14PRIV, and is publicly readable if IC14PUB = 1. It can be set with IC14ENS, and cleared with IC14ENC. This bit is set and reset by software.

0: IC14 disabled (default after reset)

1: IC14 enabled

Bit 12 **IC13EN**: IC13 enable

This bit is security-protected by IC13SEC or IC13PRIV, and is publicly readable if IC13PUB = 1. It can be set with IC13ENS, and cleared with IC13ENC. This bit is set and reset by software.

0: IC13 disabled (default after reset)

1: IC13 enabled

Bit 11 **IC12EN**: IC12 enable

This bit is security-protected by IC12SEC or IC12PRIV, and is publicly readable if IC12PUB = 1. It can be set with IC12ENS, and cleared with IC12ENC. This bit is set and reset by software.

0: IC12 disabled (default after reset)

1: IC12 enabled

Bit 10 **IC11EN**: IC11 enable

This bit is security-protected by IC11SEC or IC11PRIV, and is publicly readable if IC11PUB = 1. It can be set with IC11ENS, and cleared with IC11ENC. This bit is set and reset by software.

0: IC11 disabled (default after reset)

1: IC11 enabled

Bit 9 **IC10EN**: IC10 enable

This bit is security-protected by IC10SEC or IC10PRIV, and is publicly readable if IC10PUB = 1. It can be set with IC10ENS, and cleared with IC10ENC. This bit is set and reset by software.

0: IC10 disabled (default after reset)

1: IC10 enabled

Bit 8 **IC9EN**: IC9 enable
This bit is security-protected by IC9SEC or IC9PRIV, and is publicly readable if IC9PUB = 1. It can be set with IC9ENS, and cleared with IC9ENC. This bit is set and reset by software.
0: IC9 disabled (default after reset)
1: IC9 enabled

Bit 7 **IC8EN**: IC8 enable
This bit is security-protected by IC8SEC or IC8PRIV, and is publicly readable if IC8PUB = 1. It can be set with IC8ENS, and cleared with IC8ENC. This bit is set and reset by software.
0: IC8 disabled (default after reset)
1: IC8 enabled

Bit 6 **IC7EN**: IC7 enable
This bit is security-protected by IC7SEC or IC7PRIV, and is publicly readable if IC7PUB = 1. It can be set with IC7ENS, and cleared with IC7ENC. This bit is set and reset by software.
0: IC7 disabled (default after reset)
1: IC7 enabled

Bit 5 **IC6EN**: IC6 enable
This bit is security-protected by IC6SEC or IC6PRIV, and is publicly readable if IC6PUB = 1. It can be set with IC6ENS, and cleared with IC6ENC. This bit is set and reset by software.
0: IC6 disabled (default after reset)
1: IC6 enabled

Bit 4 **IC5EN**: IC5 enable
This bit is security-protected by IC5SEC or IC5PRIV, and is publicly readable if IC5PUB = 1. It can be set with IC5ENS, and cleared with IC5ENC. This bit is Set and reset by software.
0: IC5 disabled (default after reset)
1: IC5 enabled

Bit 3 **IC4EN**: IC4 enable
This bit is security-protected by IC4SEC or IC4PRIV, and is publicly readable if IC4PUB = 1. It can be set with IC4ENS, and cleared with IC4ENC. This bit is set and reset by software.
0: IC4 disabled (default after reset)
1: IC4 enabled

Bit 2 **IC3EN**: IC3 enable
This bit is security-protected by IC3SEC or IC3PRIV, and is publicly readable if IC3PUB = 1. It can be set with IC3ENS, and cleared with IC3ENC. This bit is set and reset by software.
0: IC3 disabled (default after reset)
1: IC3 enabled

Bit 1 **IC2EN**: IC2 enable
This bit is security-protected by IC2SEC or IC2PRIV, and is publicly readable if IC2PUB = 1. It can be set with IC2ENS, and cleared with IC2ENC. This bit is set and reset by software.
0: IC2 disabled (default after reset)
1: IC2 enabled

Bit 0 **IC1EN**: IC1 enable
This bit is security-protected by IC1SEC or IC1PRIV, and is publicly readable if IC1PUB = 1. It can be set with IC1ENS, and cleared with IC1ENC. This bit is set and reset by software.
0: IC1 disabled (default after reset)
1: IC1 enabled

14.10.76 RCC embedded buses enable register (RCC_BUSENR)

Address offset: 0x244

Reset value: 0x0000 0003

This register is used to enable the embedded buses in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rst, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **APB5EN**: APB5 enable

This bit is security-protected by the APB5SEC bit, the APB5PV bit, and is publicly readable if APB5PUB = 1. It can be set with APB5ENS, and cleared with APB5ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: APB5 disabled (default after reset)

1: APB5 enabled

Bit 11 **APB4EN**: APB4 enable

The bit field is security-protected by the APB4SEC bit, the APB4PV bit, and is publicly readable if APB4PUB=1. The bit can be set with APB4ENS and cleared with APB4ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: APB4 disabled (default after reset)

1: APB4 enabled

Bit 10 **APB3EN**: APB3 enable

The bit field is security-protected by the APB3SEC bit, the APB3PV bit, and is publicly readable if APB3PUB=1. The bit can be set with APB3ENS and cleared with APB3ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: APB3 disabled (default after reset)

1: APB3 enabled

Bit 9 **APB2EN**: APB2 enable

The bit field is security-protected by the APB2SEC bit, the APB2PV bit, and is publicly readable if APB2PUB=1. The bit can be set with APB2ENS and cleared with APB2ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: APB2 is disabled (default after reset)

1: APB2 is enabled

Bit 8 **APB1EN**: APB1 enable

The bit field is security-protected by the APB1SEC bit, the APB1PV bit, and is publicly readable if APB1PUB=1. The bit can be set with APB1ENS and cleared with APB1ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: APB1 is disabled (default after reset)

1: APB1 is enabled

Bit 7 **AHB5EN**: AHB5 enable

The bit field is security-protected by the AHB5SEC bit, the AHB5PV bit, and is publicly readable if AHB5PUB=1. The bit can be set with AHB5ENS and cleared with AHB5ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: AHB5 is disabled (default after reset)

1: AHB5 is enabled

Bit 6 **AHB4EN**: AHB4 enable

The bit field is security-protected by the AHB4SEC bit, the AHB4PV bit, and is publicly readable if AHB4PUB=1. The bit can be set with AHB4ENS and cleared with AHB4ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: AHB4 is disabled (default after reset)

1: AHB4 is enabled

Bit 5 **AHB3EN**: AHB3 enable

The bit field is security-protected by the AHB3SEC bit, the AHB3PV bit, and is publicly readable if AHB3PUB=1. The bit can be set with AHB3ENS and cleared with AHB3ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: AHB3 is disabled (default after reset)

1: AHB3 is enabled

Bit 4 **AHB2EN**: AHB2 enable

The bit field is security-protected by the AHB2SEC bit, the AHB2PV bit, and is publicly readable if AHB2PUB=1. The bit can be set with AHB2ENS and cleared with AHB2ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: AHB2 is disabled (default after reset)

1: AHB2 is enabled

Bit 3 **AHB1EN**: AHB1 enable

The bit field is security-protected by the AHB1SEC bit, the AHB1PV bit, and is publicly readable if AHB1PUB=1. The bit can be set with AHB1ENS and cleared with AHB1ENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: AHB1 is disabled (default after reset)

1: AHB1 is enabled

Bit 2 **AHBMEN**: AHBM enable

The bit field is security-protected by the AHBMSEC bit, the AHBMPV bit, and is publicly readable if AHBMPUB = 1. The bit can be set with AHBMENS and cleared with AHBMENC. The bit field is non-user. Set and reset by software. Debug field, must be kept at reset value.

0: AHBM is disabled (default after reset)

1: AHBM is enabled

Bit 1 **ACLKNCEN**: ACLKNC enable

This bit is security-protected by ACLKNCSEC or ACLKNCPRIV, and is publicly readable if ACLKNCPUB = 1. It can be set with ACLKNCENS, and cleared with ACLKNCENC. This bit is set and reset by software.

0: ACLKNC disabled

1: ACLKNC enabled (default after reset)

Bit 0 **ACLKNEN**: ACLKN enable

This bit is security-protected by ACLKNSEC or ACLKNPRIV, and is publicly readable if ACLKNPUB = 1. It can be set with ACLKNENS, and cleared with ACLKNENC. This bit is set and reset by software.

0: ACLKN disabled

1: ACLKN enabled (default after reset)

14.10.77 RCC miscellaneous configurations enable register (RCC_MISCENR)

Address offset: 0x248

Reset value: 0x0000 0000

This register is used to enable the miscellaneous configurations in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by int_sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw			rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PEREN**: PER enable

This bit is security-protected by PERSEC or PERPRIV. it can be set with PERENS, and cleared with PERENC. This bit is set and reset by software.

0: PER disabled (default after reset)

1: PER enabled

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **XSPIPHYCOMPEN**: XSPIPHYCOMP enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with XSPIPHYCOMPENS, and cleared with XSPIPHYCOMPENC. This bit is set and reset by software.

0: XSPIPHYCOMP disabled (default after reset)

1: XSPIPHYCOMP enabled

Bit 2 **MCO2EN**: MCO2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with MCO2ENS, and cleared with MCO2ENC. This bit is set and reset by software.

0: MCO2 disabled (default after reset)

1: MCO2 enabled

Bit 1 **MCO1EN**: MCO1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with MCO1ENS, and cleared with MCO1ENC. This bit is set and reset by software.

0: MCO1 disabled (default after reset)

1: MCO1 enabled

Bit 0 **DBGEN**: DBG enable

This bit is always security-protected. It can be set with DBGENS, and cleared with DBGENC.This bit is set and reset by software.

0: DBG disabled (default after reset)

1: DBG enabled

14.10.78 RCC embedded memories enable register (RCC_MEMENR)

Address offset: 0x24C

Reset value: 0x0000 13F0

This register is used to enable the embedded memories in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **BOOTROMEN**: BootROM enable

This bit is always security-protected. It can be set with BOOTROMENS, and cleared with BOOTROMENC. This bit is set and reset by software.

0: BootROM disabled

1: BootROM enabled (default after reset)

Bit 11 **VENCRAMEN**: VENCRAM enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if VENCRAMPUB = 1. It can be set with VENCRAMENS, and cleared with VENCRAMENC. This bit is set and reset by software.

0: VENCRAM disabled (default after reset)

1: VENCRAM enabled

Bit 10 **CACHEAXIRAMEN**: CACHEAXIRAM enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if CACHEAXIRAMPUB = 1. It can be set with CACHEAXIRAMENS, and cleared with CACHEAXIRAMENC. This bit is set and reset by software.

0: CACHEAXIRAM disabled (default after reset)

1: CACHEAXIRAM enabled

Bit 9 **FLEXRAMEN**: FLEXRAM enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if FLEXRAMPUB = 1. It can be set with FLEXRAMENS, and cleared with FLEXRAMENC. This bit is set and reset by software.

0: FLEXRAM disabled

1: FLEXRAM enabled (default after reset)

Bit 8 **AXISRAM2EN**: AXISRAM2 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM2PUB = 1. It can be set with AXISRAM2ENS, and cleared with AXISRAM2ENC. This bit is set and reset by software.

0: AXISRAM2 disabled

1: AXISRAM2 enabled (default after reset)

Bit 7 **AXISRAM1EN**: AXISRAM1 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM1PUB = 1. It can be set with AXISRAM1ENS, and cleared with AXISRAM1ENC. This bit is set and reset by software.

0: AXISRAM1 disabled

1: AXISRAM1 enabled (default after reset)

Bit 6 **BKPSRAMEN**: BKPSRAM enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if BKPSRAMPUB = 1. It can be set with BKPSRAMENS, and cleared with BKPSRAMENC. This bit is set and reset by software.

0: BKPSRAM disabled

1: BKPSRAM enabled (default after reset)

Bit 5 **AHBSRAM2EN**: AHBSRAM2 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AHBSRAM2PUB = 1. It can be set with AHBSRAM2ENS, and cleared with AHBSRAM2ENC. This bit is set and reset by software.

0: AHBSRAM2 disabled

1: AHBSRAM2 enabled (default after reset)

Bit 4 **AHBSRAM1EN**: AHBSRAM1 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AHBSRAM1PUB = 1. It can be set with AHBSRAM1ENS, and cleared with AHBSRAM1ENC. This bit is set and reset by software.

0: AHBSRAM1 disabled

1: AHBSRAM1 enabled (default after reset)

Bit 3 **AXISRAM6EN**: AXISRAM6 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM6PUB = 1. It can be set with AXISRAM6ENS, and cleared with AXISRAM6ENC. This bit is set and reset by software.

0: AXISRAM6 disabled (default after reset)

1: AXISRAM6 enabled

Bit 2 **AXISRAM5EN**: AXISRAM5 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM5PUB = 1. It can be set with AXISRAM5ENS, and cleared with AXISRAM5ENC. This bit is set and reset by software.

0: AXISRAM5 disabled (default after reset)

1: AXISRAM5 enabled

Bit 1 **AXISRAM4EN**: AXISRAM4 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM4PUB = 1. It can be set with AXISRAM4ENS, and cleared with AXISRAM4ENC. This bit is set and reset by software.

0: AXISRAM4 disabled (default after reset)

1: AXISRAM4 enabled

Bit 0 **AXISRAM3EN**: AXISRAM3 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM3PUB = 1. It can be set with AXISRAM3ENS, and cleared with AXISRAM3ENC. This bit is set and reset by software.

0: AXISRAM3 disabled (default after reset)

1: AXISRAM3 enabled

14.10.79 RCC AHB1 enable register (RCC_AHB1ENR)

Address offset: 0x250

Reset value: 0x0000 0000

This register is used to enable the AHB1 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADC12EN	GPDMA1EN	Res.	Res.	Res.	Res.
										rw	rw				

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **ADC12EN**: ADC12 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ADC12ENS, and cleared with ADC12ENC. This bit is set and reset by software.

0: ADC12 disabled (default after reset)

1: ADC12 enabled

Bit 4 **GPDMA1EN**: GPDMA1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPDMA1ENS, and cleared with GPDMA1ENC. This bit is set and reset by software.

0: GPDMA1 disabled (default after reset)

1: GPDMA1 enabled

Bits 3:0 Reserved, must be kept at reset value.

14.10.80 RCC AHB2 enable register (RCC_AHB2ENR)

Address offset: 0x254

Reset value: 0x0000 1000

This register is used to enable the AHB2 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

			rw												

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **ADF1EN**: ADF1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ADF1ENS, and cleared with ADF1ENC. This bit is set and reset by software.

0: ADF1 disabled (default after reset)

1: ADF1 enabled

Bit 16 **MDF1EN**: MDF1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MDF1ENS, and cleared with MDF1ENC. This bit is set and reset by software.

0: MDF1 disabled (default after reset)

1: MDF1 enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **RAMCFGEN**: RAMCFG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with RAMCFGENS, and cleared with RAMCFGENC. This bit is set and reset by software.

0: RAMCFG disabled

1: RAMCFG enabled (default after reset)

Bits 11:0 Reserved, must be kept at reset value.

14.10.81 RCC AHB3 enable register (RCC_AHB3ENR)

Address offset: 0x258

Reset value: 0x0000 4600

This register is used to enable the AHB3 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

	rw				rw	rw	rw				rw		rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **RISAFEN**: RISAF enable

This bit is always security-protected. It can be set with RISAFENS, and cleared with RISAFENC. This bit is set and reset by software.

0: RISAF disabled

1: RISAF enabled (default after reset)

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **IACEN**: IAC enable
This bit is always security-protected. It can be set with IACENS, and cleared with IACENC. This bit is set and reset by software.
0: IAC disabled
1: IAC enabled (default after reset)

Bit 9 **RIFSCEN**: RIFSC enable
This bit is always security-protected. It can be set with RIFSCENS, and cleared with RIFSCENC. This bit is set and reset by software.
0: RIFSC disabled
1: RIFSC enabled (default after reset)

Bit 8 **PKAEN**: PKA enable
This bit is security-protected by SYSSEC or SYSPRIV. It can be set with PKAENS, and cleared with PKAENC. This bit is set and reset by software.
0: PKA disabled (default after reset)
1: PKA enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SAESEN**: SAES enable
This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with SAESENS, and cleared with SAESENC. This bit is set and reset by software.
0: SAES disabled (default after reset)
1: SAES enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPEN**: CRYP enable
This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CRYPENS, and cleared with CRYPENC. This bit is set and reset by software.
0: CRYP disabled (default after reset)
1: CRYP enabled

Bit 1 **HASHEN**: HASH enable
This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with HASHENS, and cleared with HASHENC. This bit is set and reset by software.
0: HASH disabled (default after reset)
1: HASH enabled

Bit 0 **RNGEN**: RNG enable
This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with RNGENS, and cleared with RNGENC. This bit is set and reset by software.
0: RNG disabled (default after reset)
1: RNG enabled

14.10.82 RCC AHB4 enable register (RCC_AHB4ENR)

Address offset: 0x25C

Reset value: 0x0004 0000

This register is used to enable the AHB4 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw						rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CRCEN**: CRC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CRCENS, and cleared with CRCENC. This bit is set and reset by software.

0: CRC disabled (default after reset)

1: CRC enabled

Bit 18 **PWREN**: PWR enable

This bit is always security-protected. It can be set with PWRENS, and cleared with PWRENC. This bit is set and reset by software.

0: PWR disabled

1: PWR enabled (default after reset)

Bit 17 Reserved, must be kept at reset value.

Bit 16 **GPIOQEN**: GPIO Q enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOQENS, and cleared with GPIOQENC. This bit is set and reset by software.

0: GPIO Q disabled (default after reset)

1: GPIO Q enabled

Bit 15 **GPIOPEN**: GPIO P enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOPENS, and cleared with GPIOPENC. This bit is set and reset by software.

0: GPIO P disabled (default after reset)

1: GPIO P enabled

Bit 14 **GPIOOEN**: GPIO O enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOOENS, and cleared with GPIOOENC. This bit is set and reset by software.

0: GPIO O disabled (default after reset)

1: GPIO O enabled

Bit 13 **GPIONEN**: GPIO N enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIONENS, and cleared with GPIONENC. This bit is set and reset by software.

0: GPIO N disabled (default after reset)

1: GPIO N enabled

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHEN**: GPIO H enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOHENS, and cleared with GPIOHENC. This bit is set and reset by software.

0: GPIO H disabled (default after reset)

1: GPIO H enabled

Bit 6 **GPIOGEN**: GPIO G enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOGENS, and cleared with GPIOGENC. This bit is set and reset by software.

0: GPIO G disabled (default after reset)

1: GPIO G enabled

Bit 5 **GPIOFEN**: GPIO F enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. t can be set with GPIOFENS, and cleared with GPIOFENC. This bit is set and reset by software.

0: GPIO F disabled (default after reset)

1: GPIO F enabled

Bit 4 **GPIOEEN**: GPIO E enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOEENS, and cleared with GPIOEENC. This bit is set and reset by software.

0: GPIO E disabled (default after reset)

1: GPIO E enabled

Bit 3 **GPIODEN**: GPIO D enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIODENS, and cleared with GPIODENC. This bit is set and reset by software.

0: GPIO D disabled (default after reset)

1: GPIO D enabled

Bit 2 **GPIOCEN**: GPIO C enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOCENS, and cleared with GPIOCENC. This bit is set and reset by software.

0: GPIO C disabled (default after reset)

1: GPIO C enabled

Bit 1 **GPIOBEN**: GPIO B enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOBENS, and cleared with GPIOBENC. This bit is set and reset by software.

0: GPIO B disabled (default after reset)

1: GPIO B enabled

Bit 0 **GPIOAEN**: GPIO A enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOAENS, and cleared with GPIOAENC. This bit is set and reset by software.

0: GPIO A disabled (default after reset)

1: GPIO A enabled

14.10.83 RCC AHB5 enable register (RCC_AHB5ENR)

Address offset: 0x260

Reset value: 0x0000 0000

This register is used to enable the AHB5 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 **NPUEN**: NPU enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with NPUENS, and cleared with NPUENC. This bit is set and reset by software.

0: NPU disabled (default after reset)

1: NPU enabled

Bit 30 **CACHEAXIEN**: CACHEAXI enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CACHEAXIENS and cleared with CACHEAXIENC. This bit is set and reset by software.

0: CACHEAXI disabled (default after reset)

1: CACHEAXI enabled

Bit 29 **OTG2EN**: OTG2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTG2ENS, and cleared with OTG2ENC. This bit is set and reset by software.

0: OTG2 i disabled (default after reset)

1: OTG2 enabled

Bit 28 **OTGPHY2EN**: OTGPHY2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTGPHY2ENS, and cleared with OTGPHY2ENC. This bit is set and reset by software.

0: OTGPHY2 disabled (default after reset)

1: OTGPHY2 enabled

Bit 27 **OTGPHY1EN**: OTGPHY1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, tor he PERPRIV bit. It can be set with OTGPHY1ENS, and cleared with OTGPHY1ENC. This bit is set and reset by software.

0: OTGPHY1 disabled (default after reset)

1: OTGPHY1 enabled

Bit 26 **OTG1EN**: OTG1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTG1ENS, and cleared with OTG1ENC. This bit is set and reset by software.

0: OTG1 disabled (default after reset)

1: OTG1 enabled

Bit 25 **ETH1EN**: ETH1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ETH1ENS, and cleared with ETH1ENC. This bit is set and reset by software.

0: ETH1 disabled (default after reset)

1: ETH1 enabled

Bit 24 **ETH1RXEN**: ETH1RX enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ETH1RXENS, and cleared with ETH1RXENC. This bit is set and reset by software.

0: ETH1RX disabled (default after reset)

1: ETH1RX enabled

Bit 23 **ETH1TXEN**: ETH1TX enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ETH1TXENS, and cleared with ETH1TXENC. This bit is set and reset by software.

0: ETH1TX disabled (default after reset)

1: ETH1TX enabled

Bit 22 **ETH1MACEN**: ETH1MAC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ETH1MACENS, and cleared with ETH1MACENC. This bit is set and reset by software.

0: ETH1MAC disabled (default after reset)

1: ETH1MAC enabled

Bit 21 Reserved, must be kept at reset value.

Bit 20 **GPU2DEN**: GPU2D enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPU2DENS, and cleared with GPU2DENC. This bit is set and reset by software.

0: GP2DU2D disabled (default after reset)

1: GPU enabled

Bit 19 **GFXMMUEN**: GFXMMU enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GFXMMUENS, and cleared with GFXMMUENC. This bit is set and reset by software.

0: GFXMMU disabled (default after reset)

1: GFXMMU enabled

Bit 18 **MCE4EN**: MCE4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MCE4ENS, and cleared with MCE4ENC. This bit is set and reset by software.

0: MCE4 disabled (default after reset)

1: MCE4 enabled

Bit 17 **XSPI3EN**: XSPI3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI3ENS, and cleared with XSPI3ENC. This bit is set and reset by software.

0: XSPI3 disabled (default after reset)

1: XSPI3 enabled

Bit 16 **MCE3EN**: MCE3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MCE3ENS, and cleared with MCE3ENC. This bit is set and reset by software.

0: MCE3 disabled (default after reset)

1: MCE3 enabled

Bit 15 **MCE2EN**: MCE2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MCE2ENS, and cleared with MCE2ENC. This bit is set and reset by software.

0: MCE2 disabled (default after reset)

1: MCE2 enabled

Bit 14 **MCE1EN**: MCE1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MCE1ENS, and cleared with MCE1ENC. This bit is set and reset by software.

0: MCE1 disabled (default after reset)

1: MCE1 enabled

Bit 13 **XSPIMEN**: XSPIM enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPIMENS, and cleared with XSPIMENC. This bit is set and reset by software.

0: XSPIM disabled (default after reset)

1: XSPIM enabled

Bit 12 **XSPI2EN**: XSPI2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI2ENS, and cleared with XSPI2ENC. This bit is set and reset by software.

0: XSPI2 disabled (default after reset)

1: XSPI2 enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1EN**: SDMMC1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SDMMC1ENS, and cleared with SDMMC1ENC. This bit is set and reset by software.

0: SDMMC1 disabled (default after reset)

1: SDMMC1 enabled

Bit 7 **SDMMC2EN**: SDMMC2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SDMMC2ENS, and cleared with SDMMC2ENC. This bit is set and reset by software.

0: SDMMC2 disabled (default after reset)

1: SDMMC2 enabled

Bit 6 **PSSIEN**: PSSI enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with PSSIENS, and cleared with PSSIENC. This bit is set and reset by software.

0: PSSI disabled (default after reset)

1: PSSI enabled

Bit 5 **XSPI1EN**: XSPI1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI1ENS, and cleared with XSPI1ENC. This bit is set and reset by software.

0: XSPI1 disabled (default after reset)

1: XSPI1 enabled

Bit 4 **FMCEN**: FMC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with FMCENS, and cleared with FMCENC. This bit is set and reset by software.

0: FMC disabled (default after reset)

1: FMC enabled

Bit 3 **JPEGEN**: JPEG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with JPEGENS, and cleared with JPEGENC. This bit is set and reset by software.

0: JPEG disabled (default after reset)

1: JPEG enabled

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DEN**: DMA2D enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with DMA2DENS, and cleared with DMA2DENC. This bit is set and reset by software.

0: DMA2D disabled (default after reset)

1: DMA2D enabled

Bit 0 **HPDMA1EN**: HPDMA1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with HPDMA1ENS, and cleared with HPDMA1ENC. This bit is set and reset by software.

0: HPDMA1 disabled (default after reset)

1: HPDMA1 enabled

14.10.84 RCC APB1L enable register (RCC_APB1LENR)

Address offset: 0x264

Reset value: 0x0000 0000

This register is used to enable the APB1L in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 **UART8EN**: UART8 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART8ENS, and cleared with UART8ENC. This bit is set and reset by software.

0: UART8 disabled (default after reset)

1: UART8 enabled

Bit 30 **UART7EN**: UART7 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART7ENS, and cleared with UART7ENC. This bit is set and reset by software.

0: UART7 disabled (default after reset)

1: UART7 enabled

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **I3C2EN**: I3C2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I3C2ENS, and cleared with I3C2ENC. This bit is set and reset by software.

0: I3C2 disabled (default after reset)

1: I3C2 enabled

Bit 24 **I3C1EN**: I3C1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I3C1ENS, and cleared with I3C1ENC. This bit is set and reset by software.

0: I3C1 disabled (default after reset)

1: I3C1 enabled

Bit 23 **I2C3EN**: I2C3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C3ENS, and cleared with I2C3ENC. This bit is set and reset by software.

0: I2C3 disabled (default after reset)

1: I2C3 enabled

Bit 22 **I2C2EN**: I2C2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C2ENS, and cleared with I2C2ENC. This bit is set and reset by software.

0: I2C2 disabled (default after reset)

1: I2C2 enabled

Bit 21 **I2C1EN**: I2C1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C1ENS, and cleared with I2C1ENC. This bit is set and reset by software.

0: I2C1 disabled (default after reset)

1: I2C1 enabled

Bit 20 **UART5EN**: UART5 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit,. It can be set with UART5ENS, and cleared with UART5ENC. This bit is set and reset by software.

0: UART5 disabled (default after reset)

1: UART5 enabled

Bit 19 **UART4EN**: UART4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART4ENS, and cleared with UART4ENC. This bit is set and reset by software.

0: UART4 disabled (default after reset)

1: UART4 enabled

Bit 18 **USART3EN**: USART3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART3ENS, and cleared with USART3ENC. This bit is set and reset by software.

0: USART3 disabled (default after reset)

1: USART3 enabled

Bit 17 **USART2EN**: USART2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART2ENS, and cleared with USART2ENC. This bit is set and reset by software.

0: USART2 disabled (default after reset)

1: USART2 enabled

Bit 16 **SPDIFRX1EN**: SPDIFRX1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPDIFRX1ENS, and cleared with SPDIFRX1ENC. This bit is set and reset by software.

0: SPDIFRX1 disabled (default after reset)

1: SPDIFRX1 enabled

Bit 15 **SPI3EN**: SPI3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI3ENS, and cleared with SPI3ENC. This bit is set and reset by software.

0: SPI3 disabled (default after reset)

1: SPI3 enabled

Bit 14 **SPI2EN**: SPI2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI2ENS, and cleared with SPI2ENC. This bit is set and reset by software.

0: SPI2 disabled (default after reset)

1: SPI2 enabled

Bit 13 **TIM11EN**: TIM11 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM11ENS, and cleared with TIM11ENC. This bit is set and reset by software.

0: TIM11 disabled (default after reset)

1: TIM11 enabled

Bit 12 **TIM10EN**: TIM10 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM10ENS, and cleared with TIM10ENC. This bit is set and reset by software.

0: TIM10 disabled (default after reset)

1: TIM10 enabled

Bit 11 **WWDGEN**: WWDG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with WWDGENS. This bit is set and reset by software.

0: WWDG is disabled (default after reset)

1: WWDG is enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1EN**: LPTIM1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM1ENS, and cleared with LPTIM1ENC. This bit is set and reset by software.

0: LPTIM1 is disabled (default after reset)

1: LPTIM1 is enabled

Bit 8 **TIM14EN**: TIM14 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM14ENS, and cleared with TIM14ENC. This bit is set and reset by software.

0: TIM14 is disabled (default after reset)

1: TIM14 is enabled

Bit 7 **TIM13EN**: TIM13 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with TIM13ENS, and cleared with TIM13ENC. This bit is set and reset by software.

0: TIM13 disabled (default after reset)

1: TIM13 enabled

Bit 6 **TIM12EN**: TIM12 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM12ENS, and cleared with TIM12ENC. This bit is set and reset by software.

0: TIM12 disabled (default after reset)

1: TIM12 enabled

Bit 5 **TIM7EN**: TIM7 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM7ENS, and cleared with TIM7ENC. This bit is set and reset by software.

0: TIM7 disabled (default after reset)

1: TIM7 enabled

Bit 4 **TIM6EN**: TIM6 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM6ENS, and cleared with TIM6ENC. This bit is set and reset by software.

0: TIM6 disabled (default after reset)

1: TIM6 enabled

Bit 3 **TIM5EN**: TIM5 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM5ENS, and cleared with TIM5ENC. This bit is set and reset by software.

0: TIM5 disabled (default after reset)

1: TIM5 enabled

Bit 2 **TIM4EN**: TIM4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM4ENS, and cleared with TIM4ENC. This bit is set and reset by software.

0: TIM4 disabled (default after reset)

1: TIM4 enabled

Bit 1 **TIM3EN**: TIM3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM3ENS, and cleared with TIM3ENC. This bit is set and reset by software.

0: TIM3 disabled (default after reset)

1: TIM3 enabled

Bit 0 **TIM2EN**: TIM2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM2ENS, and cleared with TIM2ENC. This bit is set and reset by software.

0: TIM2 disabled (default after reset)

1: TIM2 enabled

14.10.85 RCC APB1H enable register (RCC_APB1HENR)

Address offset: 0x268

Reset value: 0x0000 0000

This register is used to enable the APB1H in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **UCPD1EN**: UCPD1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UCPD1ENS, and cleared with UCPD1ENC. This bit is set and reset by software.

0: UCPD1 disabled (default after reset)

1: UCPD1 enabled

Bits 17:9 Reserved, must be kept at reset value.

Bit 8 **FDCANEN**: FDCAN enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with FDCANENS, and cleared with FDCANENC. This bit is set and reset by software.

0: FDCAN disabled (default after reset)

1: FDCAN enabled

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSEN**: MDIOS enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MDIOSENS, and cleared with MDIOSENC. This bit is set and reset by software.

0: MDIOS disabled (default after reset)

1: MDIOS enabled

Bits 4:0 Reserved, must be kept at reset value.

14.10.86 RCC APB2 enable register (RCC_APB2ENR)

Address offset: 0x26C

Reset value: 0x0000 0000

This register is used to enable the APB2 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SAI2EN**: SAI2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SAI2ENS, and cleared with SAI2ENC. This bit is set and reset by software.

0: SAI2 disabled (default after reset)

1: SAI2 enabled

Bit 21 **SAI1EN**: SAI1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SAI1EN, and cleared with SAI1ENC. This bit is set and reset by software.

0: SAI1 disabled (default after reset)

1: SAI1 enabled

Bit 20 **SPI5EN**: SPI5 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI5ENS, and cleared with SPI5ENC.This bit is set and reset by software.

0: SPI5 disabled (default after reset)

1: SPI5 enabled

Bit 19 **TIM9EN**: TIM9 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM9ENS, and cleared with TIM9ENC. This bit is set and reset by software.

0: TIM9 disabled (default after reset)

1: TIM9 enabled

Bit 18 **TIM17EN**: TIM17 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM17ENS, and cleared with TIM17ENC. This bit is set and reset by software.

0: TIM17 disabled (default after reset)

1: TIM17 enabled

Bit 17 **TIM16EN**: TIM16 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM16ENS, and cleared with TIM16ENC. This bit is set and reset by software.

0: TIM16 disabled (default after reset)

1: TIM16 enabled

Bit 16 **TIM15EN**: TIM15 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit,. It can be set with TIM15ENS, and cleared with TIM15ENC. This bit is set and reset by software.

0: TIM15 disabled (default after reset)

1: TIM15 enabled

Bit 15 **TIM18EN**: TIM18 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM18ENS, and cleared with TIM18ENC. This bit is set and reset by software.

0: TIM18 disabled (default after reset)

1: TIM18 enabled

Bit 14 Reserved, must be kept at reset value.

Bit 13 **SPI4EN**: SPI4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI4ENS, and cleared with SPI4ENC. This bit is set and reset by software.

0: SPI4 disabled (default after reset)

1: SPI4 enabled

Bit 12 **SPI1EN**: SPI1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI1ENS, and cleared with SPI1ENC. This bit is set and reset by software.

0: SPI1 disabled (default after reset)

1: SPI1 enabled

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10EN**: USART10 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART10ENS, and cleared with USART10ENC. This bit is set and reset by software.

0: USART10 disabled (default after reset)

1: USART10 enabled

Bit 6 **UART9EN**: UART9 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART9ENS, and cleared with UART9ENC. This bit is set and reset by software.

0: UART9 disabled (default after reset)

1: UART9 enabled

Bit 5 **USART6EN**: USART6 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART6ENS, and cleared with USART6ENC. This bit is set and reset by software.

0: USART6 disabled (default after reset)

1: USART6 enabled

Bit 4 **USART1EN**: USART1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART1EN,S and cleared with USART1ENC. This bit is set and reset by software.

0: USART1 disabled (default after reset)

1: USART1 enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8EN**: TIM8 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM8ENS, and cleared with TIM8ENC. This bit is set and reset by software.

0: TIM8 disabled (default after reset)

1: TIM8 enabled

Bit 0 **TIM1EN**: TIM1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM1ENS, and cleared with TIM1ENC. This bit is set and reset by software.

0: TIM1 disabled (default after reset)

1: TIM1 enabled

14.10.87 RCC APB3 enable register (RCC_APB3ENR)

Address offset: 0x270

Reset value: 0x0000 0000

This register is used to enable the APB3 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DFTEN**: DFT enable

This bit is security-protected by DFTSEC or DFTPRIV. It can be set with DFTENS, and cleared with DFTENC. This bit is set and reset by software.

0: DFT disabled (default after reset)

1: DFT enabled

Bits 1:0 Reserved, must be kept at reset value.

14.10.88 RCC APB4L enable register (RCC_APB4LENR)

Address offset: 0x274

Reset value: 0x0000 0000

This register is used to enable the APB4L in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

rw			rw	rw	rw	rw		rw		rw		rw	rw		

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RTCAPBEN**: RTCAPB enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with RTCAPBENS, and cleared with RTCAPBENC. This bit is set and reset by software.

0: RTCAPB disabled (default after reset)

1: RTCAPB enabled

Bit 16 **RTCEN**: RTC enable

This bit is write-protected by the pwr_lock_backup_n signal. It is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. This bit can be set with RTCENS, and cleared with RTCENC.

0: RTC disabled (default after reset)

1: RTC enabled

Bit 15 **VREFBUFEN**: VREFBUF enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with VREFBUFENS, and cleared with VREFBUFENC. This bit is set and reset by software.

0: VREFBUF disabled (default after reset)

1: VREFBUF enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5EN**: LPTIM5 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM5ENS, and cleared with LPTIM5ENC. This bit is set and reset by software.

0: LPTIM5 disabled (default after reset)

1: LPTIM5 enabled

Bit 11 **LPTIM4EN**: LPTIM4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM4ENS, and cleared with LPTIM4ENC. This bit is set and reset by software.

0: LPTIM4 disabled (default after reset)

1: LPTIM4 enabled

Bit 10 **LPTIM3EN**: LPTIM3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM3ENS, and cleared with LPTIM3ENC. This bit is set and reset by software.

0: LPTIM3 disabled (default after reset)

1: LPTIM3 enabled

Bit 9 **LPTIM2EN**: LPTIM2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM2ENS, and cleared with LPTIM2ENC. This bit is set and reset by software.

0: LPTIM2 disabled (default after reset)

1: LPTIM2 enabled

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4EN**: I2C4 enable
This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C4ENS, and cleared with I2C4ENC. This bit is set and reset by software.
0: I2C4 disabled (default after reset)
1: I2C4 enabled

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6EN**: SPI6 enable
This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI6ENS, and cleared with SPI6ENC. This bit is set and reset by software.
0: SPI6 disabled (default after reset)
1: SPI6 enabled

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1EN**: LPUART1 enable
This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPUART1ENS, and cleared with LPUART1ENC. This bit is set and reset by software.
0: LPUART1 disabled (default after reset)
1: LPUART1 enabled

Bit 2 **HDPEN**: HDP enable
This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with HDPENS, and cleared with HDPENC. This bit is set and reset by software.
0: HDP disabled (default after reset)
1: HDP enabled

Bits 1:0 Reserved, must be kept at reset value.

14.10.89 RCC APB4H enable register (RCC_APB4HENR)

Address offset: 0x278

Reset value: 0x0000 0002

This register is used to enable the APB4H in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTSEN	BSECEN	SYSCFGEN
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DTSEN**: DTS enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with DTSENS, and cleared with DTSENC. This bit is set and reset by software.

0: DTS disabled (default after reset)

1: DTS enabled

Bit 1 **BSECEN**: BSEC enable

This bit is always security-protected. It can be set with BSECENS, and cleared with BSECENC. This bit is set and reset by software.

0: BSEC disabled

1: BSEC enabled (default after reset)

Bit 0 **SYSCFGEN**: SYSCFG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. IT can be set with SYSCFGENS, and cleared with SYSCFGENC. This bit is set and reset by software.

0: SYSCFG disabled (default after reset)

1: SYSCFG enabled

14.10.90 RCC APB5 enable register (RCC_APB5ENR)

Address offset: 0x27C

Reset value: 0x0000 0000

This register is used to enable the APB5 in boh Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

									rw	rw	rw		rw	rw	

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CSIEN**: CSI enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CSIENS, and cleared with CSIENC. This bit is set and reset by software.

0: CSI disabled (default after reset)

1: CSI enabled

Bit 5 **VENCEN**: VENC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with VENCENS, and cleared with VENCENC. This bit is set and reset by software.

0: VENC disabled (default after reset)

1: VENC enabled

Bit 4 **GFXTIMEN**: GFXTIM enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GFXTIMENS, and cleared with GFXTIMENC. This bit is set and reset by software.

0: GFXTIM disabled (default after reset)

1: GFXTIM enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPEN**: DCMIPP enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with DCMIPPENS, and cleared with DCMIPPENC. This bit is set and reset by software.

0: DCMIPP disabled (default after reset)

1: DCMIPP enabled

Bit 1 **LTDCEN**: LTDC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LTDCENS, and cleared with LTDCENC. This bit is set and reset by software.

0: LTDC disabled (default after reset)

1: LTDC enabled

Bit 0 Reserved, must be kept at reset value.

14.10.91 RCC embedded buses sleep enable register (RCC_BUSLPENR)

Address offset: 0x284

Reset value: 0x0000 0003

This register is used to enable the embedded buses in Sleep mode (each bit in this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACLKNCLPEN	ACLKNLPEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **ACLKNCLPEN**: ACLKNC enable

This bit is security-protected by ACLKNCSEC or ACLKNCPRIV, and is publicly readable if ACLKNCPUB = 1. It can be set with ACLKNCLPENS, and cleared with ACLKNCLPENC. This bit is set and reset by software.

0: ACLKNC disabled in Sleep mode

1: ACLKNC enabled in Sleep mode (default after reset)

Bit 0 **ACLKNLPEN**: ACLKN enable

This bit is security-protected by ACLKNSEC or ACLKNPRIV, and is publicly readable if ACLKNPUB = 1. It can be set with ACLKNLPENS, and cleared with ACLKNLPENC. This bit is set and reset by software.

0: ACLKN disabled in Sleep mode

1: ACLKN enabled in Sleep mode (default after reset)

14.10.92 RCC miscellaneous configurations sleep enable register (RCC_MISCLPENR)

Address offset: 0x288

Reset value: 0x0000 0000

This register is used to enable the miscellaneous configurations in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PERLPEN	Res.	Res.	XSPIPHYCOMPLPEN	Res.	Res.	DBGLPEN
									rw			rw			rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PERLPEN**: PER enable

This bit is security-protected by PERSEC or PERPRIV. It can be set with PERLPENS, and cleared with PERLPENC. This bit is set and reset by software.

0: PER disabled in Sleep mode (default after reset)

1: PER enabled in Sleep mode

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **XSPIPHYCOMPLPEN**: XSPIPHYCOMP enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPIPHYCOMPLPENS, and cleared with XSPIPHYCOMPLPENC. This bit is set and reset by software.

0: XSPIPHYCOMP disabled in Sleep mode (default after reset)

1: XSPIPHYCOMP enabled in Sleep mode

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **DBGLPEN**: DBG enable

This bit is always security-protected. It can be set with DBGLPENS, and cleared with DBGLPENC. This bit is set and reset by software.

0: DBG disabled in Sleep mode (default after reset)

1: DBG enabled in Sleep mode

14.10.93 RCC embedded memories sleep enable register (RCC_MEMLPENR)

Address offset: 0x28C

Reset value: 0x0000 0000

This register is used to enable the embedded memories in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **BOOTROMLPEN**: BootROM enable

This bit is always security-protected. It can be set with BOOTROMLPENS, and cleared with BOOTROMLPENC. This bit is set and reset by software.

0: BootROM disabled in Sleep mode (default after reset)

1: BootROM enabled in Sleep mode

Bit 11 **VENCRAMLPEN**: VENCRAM enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if VENCRAMPUB = 1. It can be set with VENCRAMLPENS, and cleared with VENCRAMLPENC. This bit is set and reset by software.

0: VENCRAM disabled in Sleep mode (default after reset)

1: VENCRAM enabled in Sleep mode

Bit 10 **CACHEAXIRAMLPEN**: CACHEAXIRAM enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if CACHEAXIRAMPUB = 1. It can be set with CACHEAXIRAMLPENS and cleared with CACHEAXIRAMLPENC. This bit is set and reset by software.

0: CACHEAXIRAM disabled in Sleep mode (default after reset)

1: CACHEAXIRAM enabled in Sleep mode

Bit 9 **FLEXRAMLPEN**: FLEXRAM enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if FLEXRAMPUB = 1. It can be set with FLEXRAMLPENS, and cleared with FLEXRAMLPENC. This bit is set and reset by software.

0: FLEXRAM disabled in Sleep mode (default after reset)

1: FLEXRAM enabled in Sleep mode

Bit 8 **AXISRAM2LPEN**: AXISRAM2 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM2PUB = 1. It can be set with AXISRAM2LPENS, and cleared with AXISRAM2LPENC.This bit is set and reset by software.

0: AXISRAM2 disabled in Sleep mode (default after reset)

1: AXISRAM2 enabled in Sleep mode

Bit 7 **AXISRAM1LPEN**: AXISRAM1 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM1PUB = 1. It can be set with AXISRAM1LPENS, and cleared with AXISRAM1LPENC.This bit is set and reset by software.

0: AXISRAM1 disabled in Sleep mode (default after reset)

1: AXISRAM1 enabled in Sleep mode

Bit 6 **BKPSRAMLPEN**: BKPSRAM enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if BKPSRAMPUB = 1. It can be set with BKPSRAMLPENS, and cleared with BKPSRAMLPENC. This bit is set and reset by software.

0: BKPSRAM disabled in Sleep mode (default after reset)

1: BKPSRAM enabled in Sleep mode

Bit 5 **AHBSRAM2LPEN**: AHBSRAM2 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AHBSRAM2PUB = 1. It can be set with AHBSRAM2LPENS, and cleared with AHBSRAM2LPENC. This bit is set and reset by software.

0: AHBSRAM2 disabled in Sleep mode (default after reset)

1: AHBSRAM2 enabled in Sleep mode

Bit 4 **AHBSRAM1LPEN**: AHBSRAM1 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AHBSRAM1PUB = 1. It can be set with AHBSRAM1LPENS, and cleared with AHBSRAM1LPENC. This bit is set and reset by software.

0: AHBSRAM1 disabled in Sleep mode (default after reset)

1: AHBSRAM1 enabled in Sleep mode

Bit 3 **AXISRAM6LPEN**: AXISRAM6 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM6PUB = 1. It can be set with AXISRAM6LPENS, and cleared with AXISRAM6LPENC. This bit is set and reset by software.

0: AXISRAM6 disabled in Sleep mode (default after reset)

1: AXISRAM6 enabled in Sleep mode

Bit 2 **AXISRAM5LPEN**: AXISRAM5 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM5PUB = 1. It can be set with AXISRAM5LPENS, and cleared with AXISRAM5LPENC. This bit is set and reset by software.

0: AXISRAM5 disabled in Sleep mode (default after reset)

1: AXISRAM5 enabled in Sleep mode

Bit 1 **AXISRAM4LPEN**: AXISRAM4 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM4PUB = 1. It can be set with AXISRAM4LPENS, and cleared with AXISRAM4LPENC. This bit is set and reset by software.

0: AXISRAM4 disabled in Sleep mode (default after reset)

1: AXISRAM4 enabled in Sleep mode

Bit 0 **AXISRAM3LPEN**: AXISRAM3 enable

This bit is security-protected by a SEC or a PRIV signal from RIFSC, and is publicly readable if AXISRAM3PUB = 1. It can be set with AXISRAM3LPENS, and cleared with AXISRAM3LPENC. This bit is set and reset by software.

0: AXISRAM3 disabled in Sleep mode (default after reset)

1: AXISRAM3 enabled in Sleep mode

14.10.94 RCC AHB1 sleep enable register (RCC_AHB1LPENR)

Address offset: 0x290

Reset value: 0x0000 0000

This register is used to enable the AHB1 in Sleep mode (each bit in this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADC12 LPEN	GPDMA1LPEN	Res.	Res.	Res.	Res.
										rw	rw				

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **ADC12LPEN**: ADC12 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ADC12LPENS, and cleared with ADC12LPENC. This bit is set and reset by software.

0: ADC12 disabled in Sleep mode (default after reset)

1: ADC12 enabled in Sleep mode

Bit 4 **GPDMA1LPEN**: GPDMA1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPDMA1LPENS, and cleared with GPDMA1LPENC. This bit is set and reset by software.

0: GPDMA1 disabled in Sleep mode (default after reset)

1: GPDMA1 enabled in Sleep mode

Bits 3:0 Reserved, must be kept at reset value.

14.10.95 RCC AHB2 sleep enable register (RCC_AHB2LPENR)

Address offset: 0x294

Reset value: 0x0000 0000

This register is used to enable the AHB2 in Sleep mode (each bit in this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw												

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **ADF1LPEN**: ADF1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ADF1LPENS, and cleared with ADF1LPENC. This bit is set and reset by software.

0: ADF1 disabled in Sleep mode (default after reset)

1: ADF1 enabled in Sleep mode

Bit 16 **MDF1LPEN**: MDF1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MDF1LPENS, and cleared with MDF1LPENC. This bit is set and reset by software.

0: MDF1 disabled in Sleep mode (default after reset)

1: MDF1 enabled in Sleep mode

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **RAMCFGLPEN**: RAMCFG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with RAMCFGLPENS, and cleared with RAMCFGLPENC. This bit is set and reset by software.

0: RAMCFG disabled in Sleep mode (default after reset)

1: RAMCFG enabled in Sleep mode

Bits 11:0 Reserved, must be kept at reset value.

14.10.96 RCC AHB3 sleep enable register (RCC_AHB3LPENR)

Address offset: 0x298

Reset value: 0x0000 0400

This register is used to enable the AHB3 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw				rw	rw	rw				rw		rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **RISAFLPEN**: RISAF enable

This bit is always security-protected. It can be set with RISAFLPENS, and cleared with RISAFLPENC. This bit is set and reset by software.

0: RISAF disabled in Sleep mode (default after reset)

1: RISAF enabled in Sleep mode

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **IACLPEN**: IAC enable

This bit is always security-protected. It can be set with IACLPENS, and cleared with IACLPENC. This bit is set and reset by software.

0: IAC disabled in Sleep mode

1: IAC enabled in Sleep mode (default after reset)

Bit 9 **RIFSCLPEN**: RIFSC enable

This bit is always security-protected. It can be set with RIFSCLPENS, and cleared with RIFSCLPENC. This bit is set and reset by software.

0: RIFSC disabled in Sleep mode (default after reset)

1: RIFSC enabled in Sleep mode

Bit 8 **PKALPEN**: PKA enable

This bit is security-protected by SYSSEC or SYSPRIV. It can be set with PKALPENS, and cleared with PKALPENC. This bit is set and reset by software.

0: PKA disabled in Sleep mode (default after reset)

1: PKA enabled in Sleep mode

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SAESLPEN**: SAES enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SAESLPENS, and cleared with SAESLPENC. This bit is set and reset by software.

0: SAES disabled in Sleep mode (default after reset)

1: SAES enabled in Sleep mode

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPLPEN**: CRYP enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CRYPLPENS, and cleared with CRYPLPENC. This bit is set and reset by software.

0: CRYP disabled in Sleep mode (default after reset)

1: CRYP enabled in Sleep mode

Bit 1 **HASHLPEN**: HASH enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with HASHLPENS, and cleared with HASHLPENC. This bit is set and reset by software.

0: HASH disabled in Sleep mode (default after reset)

1: HASH enabled in Sleep mode

Bit 0 **RNGLPEN**: RNG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with RNGLPENS, and cleared with RNGLPENC. This bit is set and reset by software.

0: RNG disabled in Sleep mode (default after reset)

1: RNG enabled in Sleep mode

14.10.97 RCC AHB4 sleep enable register (RCC_AHB4LPENR)

Address offset: 0x29C

Reset value: 0x0004 0000

This register is used to enable the AHB4 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

rw	rw	rw						rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CRCLPEN**: CRC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CRCLPENS, and cleared with CRCLPENC. This bit is set and reset by software.

0: CRC disabled in Sleep mode (default after reset)

1: CRC enabled in Sleep mode

Bit 18 **PWRLPEN**: PWR enable

This bit is always security-protected. It can be set with PWRLPENS, and cleared with PWRLPENC.This bit is set and reset by software.

0: PWR disabled in Sleep mode

1: PWR enabled in Sleep mode (default after reset)

Bit 17 Reserved, must be kept at reset value.

Bit 16 **GPIOQLPEN**: GPIO Q enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOQLPENS, and cleared with GPIOQLPENC. This bit is set and reset by software.

0: GPIO Q disabled in Sleep mode (default after reset)

1: GPIO Q enabled in Sleep mode

Bit 15 **GPIOPLPEN**: GPIO P enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOPLPENS, and cleared with GPIOPLPENC. This bit is set and reset by software.

0: GPIO P disabled in Sleep mode (default after reset)

1: GPIO P enabled in Sleep mode

Bit 14 **GPIOOLPEN**: GPIO O enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOOLPENS, and cleared with GPIOOLPENC. This bit is set and reset by software.

0: GPIO O disabled in Sleep mode (default after reset)/

1: GPIO O enabled in Sleep mode

Bit 13 **GPIONLPEN**: GPIO N enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIONLPENS, and cleared with GPIONLPENC. This bit is set and reset by software.

0: GPIO N disabled in Sleep mode (default after reset)

1: GPIO N enabled in Sleep mode

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHLPEN**: GPIO H enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOHLPENS, and cleared with GPIOHLPENC. This bit is set and reset by software.

0: GPIO H disabled in Sleep mode (default after reset)

1: GPIO H enabled in Sleep mode

Bit 6 **GPIOGLPEN**: GPIO G enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOGLPENS, and cleared with GPIOGLPENC. This bit is set and reset by software.

0: GPIO G disabled in Sleep mode (default after reset)

1: GPIO G enabled in Sleep mode

Bit 5 **GPIOFLPEN**: GPIO F enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOFLPENS, and cleared with GPIOFLPENC. This bit is set and reset by software.

0: GPIO F disabled in Sleep mode (default after reset)

1: GPIO F enabled in Sleep mode

Bit 4 **GPIOELPEN**: GPIO E enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOELPENS, and cleared with GPIOELPENC. This bit is set and reset by software.

0: GPIO E disabled in Sleep mode (default after reset)

1: GPIO E enabled in Sleep mode

Bit 3 **GPIODLPEN**: GPIO D enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with GPIODLPENS, and cleared with GPIODLPENC. This bit is set and reset by software.

0: GPIO D disabled in Sleep mode (default after reset)

1: GPIO D enabled in Sleep mode

Bit 2 **GPIOCLPEN**: GPIO C enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOCLPENS, and cleared with GPIOCLPENC. This bit is set and reset by software.

0: GPIO C disabled in Sleep mode (default after reset)

1: GPIO C enabled in Sleep mode

Bit 1 **GPIOBLPEN**: GPIO B enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOBLPENS, and cleared with GPIOBLPENC. This bit is set and reset by software.

0: GPIO B disabled in Sleep mode (default after reset)

1: GPIO B enabled in Sleep mode

Bit 0 **GPIOALPEN**: GPIO A enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GPIOALPENS, and cleared with GPIOALPENC. This bit is set and reset by software.

0: GPIO A disabled in Sleep mode (default after reset)

1: GPIO A enabled in Sleep mode

14.10.98 RCC AHB5 sleep enable register (RCC_AHB5LPENR)

Address offset: 0x2A0

Reset value: 0x0000 0000

This register is used to enable the AHB5 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 **NPULPEN**: NPU enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with NPULPENS, and cleared with NPULPENC. This bit is set and reset by software.

0: NPU disabled in Sleep mode (default after reset)

1: NPU enabled in Sleep mode

Bit 30 **CACHEAXILPEN**: CACHEAXI enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CACHEAXILPENS, and cleared with CACHEAXILPENC. This bit is set and reset by software.

0: CACHEAXI disabled in Sleep mode (default after reset)

1: CACHEAXI enabled in Sleep mode

Bit 29 **OTG2LPEN**: OTG2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTG2LPENS, and cleared with OTG2LPENC. This bit is set and reset by software.

0: OTG2 disabled in Sleep mode (default after reset)

1: OTG2 enabled in Sleep mode

Bit 28 **OTGPHY2LPEN**: OTGPHY2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTGPHY2LPENS, and cleared with OTGPHY2LPENC. This bit is set and reset by software.

0: OTGPHY2 disabled in Sleep mode (default after reset)

1: OTGPHY2 enabled in Sleep mode

Bit 27 **OTGPHY1LPEN**: OTGPHY1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTGPHY1LPENS, and cleared with OTGPHY1LPENC. This bit is set and reset by software.

0: OTGPHY1 disabled in Sleep mode (default after reset)

1: OTGPHY1 enabled in Sleep mode

Bit 26 **OTG1LPEN**: OTG1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with OTG1LPENS, and cleared with OTG1LPENC. This bit is set and reset by software.

0: OTG1 disabled in Sleep mode (default after reset)

1: OTG1 enabled in Sleep mode

Bit 25 **ETH1LPEN**: ETH1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ETH1LPENS, and cleared with ETH1LPENC. This bit is set and reset by software.

0: ETH1 disabled in Sleep mode (default after reset)

1: ETH1 enabled in Sleep mode

Bit 24 **ETH1RXLPEN**: ETH1RX enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with ETH1RXLPENS, and cleared with ETH1RXLPENC. This bit is set and reset by software.

0: ETH1RX disabled in Sleep mode (default after reset)

1: ETH1RX enabled in Sleep mode

Bit 23 **ETH1TXLPEN**: ETH1TX enable

This bit is security-protected by a SEC signal from RIFSC, th,e PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ETH1TXLPENS and cleared with ETH1TXLPENC. This bit is set and reset by software.

0: ETH1TX disabled in Sleep mode (default after reset)

1: ETH1TX enabled in Sleep mode

Bit 22 **ETH1MACLPEN**: ETH1MAC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with ETH1MACLPENS, and cleared with ETH1MACLPENC. This bit is set and reset by software.

0: ETH1MAC disabled in Sleep mode (default after reset)

1: ETH1MAC enabled in Sleep mode

Bit 21 Reserved, must be kept at reset value.

Bit 20 **GPU2DLPEN**: GPU2D enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with GPU2DLPENS, and cleared with GPU2DLPENC. This bit is set and reset by software.

0: GPU2D disabled in Sleep mode (default after reset)

1: GPU2D enabled in Sleep mode

Bit 19 **GFXMMULPEN**: GFXMMU enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with GFXMMULPENS, and cleared with GFXMMULPENC. This bit is set and reset by software.

0: GFXMMU disabled in Sleep mode (default after reset)

1: GFXMMU enabled in Sleep mode

Bit 18 **MCE4LPEN**: MCE4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with MCE4LPENS, and cleared with MCE4LPENC. This bit is set and reset by software.

0: MCE4 disabled in Sleep mode (default after reset)

1: MCE4 enabled in Sleep mode

Bit 17 **XSPI3LPEN**: XSPI3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI3LPENS, and cleared with XSPI3LPENC. This bit is set and reset by software.

0: XSPI3 disabled in Sleep mode (default after reset)

1: XSPI3 enabled in Sleep mode

Bit 16 **MCE3LPEN**: MCE3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with MCE3LPENS, and cleared with MCE3LPENC. This bit is set and reset by software.

0: MCE3 disabled in Sleep mode (default after reset)

1: MCE3 enabled in Sleep mode

Bit 15 **MCE2LPEN**: MCE2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MCE2LPENS, and cleared with MCE2LPENC. This bit is set and reset by software.

0: MCE2 disabled in Sleep mode (default after reset)

1: MCE2 enabled in Sleep mode

Bit 14 **MCE1LPEN**: MCE1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MCE1LPENS, and cleared with MCE1LPENC. This bit is set and reset by software.

0: MCE1 disabled in Sleep mode (default after reset)

1: MCE1 enabled in Sleep mode

Bit 13 **XSPIMLPEN**: XSPIM enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with XSPIMLPENS, and cleared with XSPIMLPENC.This bit is set and reset by software.

0: XSPIM disabled in Sleep mode (default after reset)

1: XSPIM enabled in sleep mode

Bit 12 **XSPI2LPEN**: XSPI2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI2LPENS, and cleared with XSPI2LPENC. This bit is set and reset by software.

0: XSPI2 disabled in Sleep mode (default after reset)

1: XSPI2 enabled in Sleep mode

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1LPEN**: SDMMC1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with SDMMC1LPENS, and cleared with SDMMC1LPENC. This bit is set and reset by software.

0: SDMMC1 disabled in Sleep mode (default after reset)

1: SDMMC1 enabled in Sleep mode

Bit 7 **SDMMC2LPEN**: SDMMC2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SDMMC2LPENS, and cleared with SDMMC2LPENC. This bit is set and reset by software.

0: SDMMC2 disabled in Sleep mode (default after reset)

1: SDMMC2 enabled in Sleep mode

Bit 6 **PSSILPEN**: PSSI enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with PSSILPENS, and cleared with PSSILPENC. This bit is set and reset by software.

0: PSSI disabled in Sleep mode (default after reset)

1: PSSI enabled in Sleep mode

Bit 5 **XSPI1LPEN**: XSPI1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with XSPI1LPENS, and cleared with XSPI1LPENC. This bit is set and reset by software.

0: XSPI1 disabled in Sleep mode (default after reset)

1: XSPI1 enabled in Sleep mode

Bit 4 **FMCLPEN**: FMC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with FMCLPENS, and cleared with FMCLPENC. This bit is set and reset by software.

0: FMC disabled in Sleep mode (default after reset)

1: FMC enabled in Sleep mode

Bit 3 **JPEGLPEN**: JPEG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with JPEGLPENS, and cleared with JPEGLPENC. This bit is set and reset by software.

0: JPEG disabled in Sleep mode (default after reset)

1: JPEG enabled in Sleep mode

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DLPEN**: DMA2D enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with DMA2DLPENS, and cleared with DMA2DLPENC. This bit is set and reset by software.

0: DMA2D disabled in Sleep mode (default after reset)

1: DMA2D enabled in Sleep mode

Bit 0 **HPDMA1LPEN**: HPDMA1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with HPDMA1LPENS, and cleared with HPDMA1LPENC. This bit is set and reset by software.

0: HPDMA1 disabled in Sleep mode (default after reset)

1: HPDMA1 enabled in Sleep mode

14.10.99 RCC APB1L sleep enable register (RCC_APB1LLPENR)

Address offset: 0x2A4

Reset value: 0x0000 0000

This register is used to enable the APB1L in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 **UART8LPEN**: UART8 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with UART8LPENS, and cleared with UART8LPENC. This bit is set and reset by software.

0: UART8 disabled in Sleep mode (default after reset)

1: UART8 enabled in Sleep mode

Bit 30 **UART7LPEN**: UART7 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with UART7LPENS, and cleared with UART7LPENC. This bit is set and reset by software.

0: UART7 disabled in Sleep mode (default after reset)

1: UART7 enabled in Sleep mode

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **I3C2LPEN**: I3C2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with I3C2LPENS, and cleared with I3C2LPENC. This bit is set and reset by software.

0: I3C2 disabled in Sleep mode (default after reset)

1: I3C2 enabled in Sleep mode

Bit 24 **I3C1LPEN**: I3C1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I3C1LPENS, and cleared with I3C1LPENC. This bit is set and reset by software.

0: I3C1 disabled in Sleep mode (default after reset)

1: I3C1 enabled in Sleep mode

Bit 23 **I2C3LPEN**: I2C3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C3LPENS, and cleared with I2C3LPENC. This bit is set and reset by software.

0: I2C3 disabled in Sleep mode (default after reset)

1: I2C3 enabled in Sleep mode

Bit 22 **I2C2LPEN**: I2C2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C2LPENS, and cleared with I2C2LPENC. This bit is set and reset by software.

0: I2C2 disabled in Sleep mode (default after reset)

1: I2C2 enabled in Sleep mode

Bit 21 **I2C1LPEN**: I2C1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C1LPENS, and cleared with I2C1LPENC. This bit is set and reset by software.

0: I2C1 disabled in Sleep mode (default after reset)

1: I2C1 enabled in Sleep mode

Bit 20 **UART5LPEN**: UART5 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART5LPENS, and cleared with UART5LPENC. This bit is set and reset by software.

0: UART5 disabled in Sleep mode (default after reset)

1: UART5 enabled in Sleep mode

Bit 19 **UART4LPEN**: UART4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART4LPENS, and cleared with UART4LPENC. This bit is set and reset by software.

0: UART4 disabled in Sleep mode (default after reset)

1: UART4 enabled in Sleep mode

Bit 18 **USART3LPEN**: USART3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART3LPENS, and cleared with USART3LPENC. This bit is set and reset by software.

0: USART3 disabled in Sleep mode (default after reset)

1: USART3 enabled in Sleep mode

Bit 17 **USART2LPEN**: USART2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART2LPENS, and cleared with USART2LPENC. This bit is set and reset by software.

0: USART2 disabled in Sleep mode (default after reset)

1: USART2 enabled in Sleep mode

Bit 16 **SPDIFRX1LPEN**: SPDIFRX1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPDIFRX1LPENS, and cleared with SPDIFRX1LPENC. This bit is set and reset by software.

0: SPDIFRX1 disabled in Sleep mode (default after reset)

1: SPDIFRX1 enabled in Sleep mode

Bit 15 **SPI3LPEN**: SPI3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI3LPENS, and cleared with SPI3LPENC. This bit is set and reset by software.

0: SPI3 disabled in Sleep mode (default after reset)

1: SPI3 enabled in Sleep mode

Bit 14 **SPI2LPEN**: SPI2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI2LPENS, and cleared with SPI2LPENC. This bit is set and reset by software.

0: SPI2 disabled in Sleep mode (default after reset)

1: SPI2 enabled in Sleep mode

Bit 13 **TIM11LPEN**: TIM11 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM11LPENS, and cleared with TIM11LPENC. This bit is set and reset by software.

0: TIM11 disabled in Sleep mode (default after reset)

1: TIM11 enabled in Sleep mode

Bit 12 **TIM10LPEN**: TIM10 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM10LPENS, and cleared with TIM10LPENC. This bit is set and reset by software.

0: TIM10 disabled in Sleep mode (default after reset)

1: TIM10 enabled in Sleep mode

Bit 11 **WWDGLPEN**: WWDG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with WWDGLPENS, and cleared with WWDGLPENC. This bit is set and reset by software.

0: WWDG disabled in Sleep mode (default after reset)

1: WWDG enabled in Sleep mode

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: LPTIM1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM1LPENS, and cleared with LPTIM1LPENC. This bit is set and reset by software.

0: LPTIM1 disabled in Sleep mode (default after reset)

1: LPTIM1 enabled in Sleep mode

Bit 8 **TIM14LPEN**: TIM14 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM14LPENS, and cleared with TIM14LPENC. This bit is set and reset by software.

0: TIM14 disabled in Sleep mode (default after reset)

1: TIM14 enabled in Sleep mode

Bit 7 **TIM13LPEN**: TIM13 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM13LPEN,S and cleared with TIM13LPENC. This bit is set and reset by software.

0: TIM13 disabled in Sleep mode (default after reset)

1: TIM13 enabled in Sleep mode

Bit 6 **TIM12LPEN**: TIM12 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM12LPENS, and cleared with TIM12LPENC. This bit is set and reset by software.

0: TIM12 disabled in Sleep mode (default after reset)

1: TIM12 enabled in Sleep mode

Bit 5 **TIM7LPEN**: TIM7 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM7LPENS, and cleared with TIM7LPENC. This bit is set and reset by software.

0: TIM7 disabled in Sleep mode (default after reset)

1: TIM7 enabled in Sleep mode

Bit 4 **TIM6LPEN**: TIM6 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM6LPENS, and cleared with TIM6LPENC. This bit is set and reset by software.

0: TIM6 disabled in Sleep mode (default after reset)

1: TIM6 enabled in Sleep mode

Bit 3 **TIM5LPEN**: TIM5 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM5LPENS, and cleared with TIM5LPENC. This bit is set and reset by software.

0: TIM5 disabled in Sleep mode (default after reset)

1: TIM5 enabled in Sleep mode

Bit 2 **TIM4LPEN**: TIM4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM4LPENS, and cleared with TIM4LPENC. This bit is set and reset by software.

0: TIM4 disabled in Sleep mode (default after reset)

1: TIM4 enabled in Sleep mode

Bit 1 **TIM3LPEN**: TIM3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM3LPENS, and cleared with TIM3LPENC. This bit is set and reset by software.

0: TIM3 disabled in Sleep mode (default after reset)

1: TIM3 enabled in Sleep mode

Bit 0 **TIM2LPEN**: TIM2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM2LPENS, and cleared with TIM2LPENC. This bit is set and reset by software.

0: TIM2 disabled in Sleep mode (default after reset)

1: TIM2 enabled in Sleep mode

14.10.100 RCC APB1H sleep enable register (RCC_APB1HLPENR)

Address offset: 0x2A8

Reset value: 0x0000 0000

This register is used to enable the APB1H in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **UCPD1LPEN**: UCPD1 enable in Sleep mode

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UCPD1LPENS, and cleared with UCPD1LPENC. This bit is set and reset by software.

0: UCPD1 disabled in Sleep mode (default after reset)

1: UCPD1 enabled in Sleep mode

Bits 17:9 Reserved, must be kept at reset value.

Bit 8 **FDCANLPEN**: FDCAN enablein Sleep mode

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with FDCANLPENS, and cleared with FDCANLPENC. This bit is set and reset by software.

0: FDCAN disabled in Sleep mode (default after reset)

1: FDCAN enabled in Sleep mode

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSLPEN**: MDIOS enable in Sleep mode

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with MDIOSLPENS, and cleared with MDIOSLPENC.This bit is set and reset by software.

0: MDIOS disabled in Sleep mode (default after reset)

1: MDIOS enabled in Sleep mode

Bits 4:0 Reserved, must be kept at reset value.

14.10.101 RCC APB2 sleep enable register (RCC_APB2LPENR)

Address offset: 0x2AC

Reset value: 0x0000 0000

This register is used to enable the APB2 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SAI2LPEN**: SAI2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with SAI2LPENS, and cleared with SAI2LPENC. This bit is set and reset by software.

0: SAI2 disabled in Sleep mode (default after reset)

1: SAI2 enabled in Sleep mode

Bit 21 **SAI1LPEN**: SAI1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SAI1LPENS, and cleared with SAI1LPENC. This bit is set and reset by software.

0: SAI1 disabled in Sleep mode (default after reset)

1: SAI1 enabled in Sleep mode

Bit 20 **SPI5LPEN**: SPI5 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI5LPENS, and cleared with SPI5LPENC. This bit is set and reset by software.

0: SPI5 disabled in Sleep mode (default after reset)

1: SPI5 enabled in Sleep mode

Bit 19 **TIM9LPEN**: TIM9 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM9LPENS, and cleared with TIM9LPENC. This bit is set and reset by software.

0: TIM9 disabled in Sleep mode (default after reset)

1: TIM9 enabled in Sleep mode

Bit 18 **TIM17LPEN**: TIM17 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM17LPENS, and cleared with TIM17LPENC. This bit is set and reset by software.

0: TIM17 disabled in Sleep mode (default after reset)

1: TIM17 enabled in Sleep mode

Bit 17 **TIM16LPEN**: TIM16 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM16LPENS, and cleared with TIM16LPENC. This bit is set and reset by software.

0: TIM16 disabled in Sleep mode (default after reset)

1: TIM16 enabled in Sleep mode

Bit 16 **TIM15LPEN**: TIM15 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM15LPENS, and cleared with TIM15LPENC. This bit is set and reset by software.

0: TIM15 disabled in Sleep mode (default after reset)

1: TIM15 enabled in Sleep mode

Bit 15 **TIM18LPEN**: TIM18 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM18LPENS, and cleared with TIM18LPENC. This bit is set and reset by software.

0: TIM18 disabled in Sleep mode (default after reset)

1: TIM18 enabled in Sleep mode

Bit 14 Reserved, must be kept at reset value.

Bit 13 **SPI4LPEN**: SPI4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI4LPENS, and cleared with SPI4LPENC. This bit is set and reset by software.

0: SPI4 disabled in Sleep mode (default after reset)

1: SPI4 enabled in Sleep mode

Bit 12 **SPI1LPEN**: SPI1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI1LPENS, and cleared with SPI1LPENC. This bit is set and reset by software.

0: SPI1 disabled in Sleep mode (default after reset)

1: SPI1 enabled in Sleep mode

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10LPEN**: USART10 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART10LPENS, and cleared with USART10LPENC. This bit is set and reset by software.

0: USART10 disabled in Sleep mode (default after reset)

1: USART10 enabled in Sleep mode

Bit 6 **UART9LPEN**: UART9 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with UART9LPENS, and cleared with UART9LPENC. This bit is set and reset by software.

0: UART9 disabled in Sleep mode (default after reset)

1: UART9 enabled in Sleep mode

Bit 5 **USART6LPEN**: USART6 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART6LPENS, and cleared with USART6LPENC. This bit is set and reset by software.

0: USART6 disabled in Sleep mode (default after reset)

1: USART6 enabled in Sleep mode

Bit 4 **USART1LPEN**: USART1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with USART1LPENS, and cleared with USART1LPENC. This bit is set and reset by software.

0: USART1 disabled in Sleep mode (default after reset)

1: USART1 enabled in Sleep mode

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8LPEN**: TIM8 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM8LPENS, and cleared with TIM8LPENC. This bit is set and reset by software.

0: TIM8 disabled in Sleep mode (default after reset)

1: TIM8 enabled in Sleep mode

Bit 0 **TIM1LPEN**: TIM1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with TIM1LPENS, and cleared with TIM1LPENC. This bit is set and reset by software.

0: TIM1 disabled in Sleep mode (default after reset)

1: TIM1 enabled in Sleep mode

14.10.102 RCC APB3 sleep enable register (RCC_APB3LPENR)

Address offset: 0x2B0

Reset value: 0x0000 0000

This register is used to enable the APB3 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw		

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DFTLPEN**: DFT enable

This bit is security-protected by DFTSEC or DFTPRIV. It can be set with DFTLPENS, and cleared with DFTLPENC. This bit is set and reset by software.

0: DFT disabled in Sleep mode (default after reset)

1: DFT enabled in Sleep mode

Bits 1:0 Reserved, must be kept at reset value.

14.10.103 RCC APB4L sleep enable register (RCC_APB4LLPENR)

Address offset: 0x2B4

Reset value: 0x0000 0000

This register is used to enable the APB4L in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw			rw	rw	rw	rw		rw		rw		rw	rw		

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RTCAPBLPEN**: RTCAPB enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with RTCAPBLPENS, and cleared with RTCAPBLPENC. This bit is set and reset by software.

0: RTCAPB disabled in Sleep mode (default after reset)

1: RTCAPB enabled in Sleep mode

Bit 16 **RTCLPEN**: RTC enable

This bit is write-protected by the pwr_lock_backup_n signal. It is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. This bit can be set with RTCLPENS, and cleared with RTCLPENC.

0: RTC disabled in Sleep mode (default after reset)

1: RTC enabled in Sleep mode

Bit 15 **VREFBUFLPEN**: VREFBUF enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with VREFBUFLPENS, and cleared with VREFBUFLPENC.This bit is set and reset by software.

0: VREFBUF disabled in Sleep mode (default after reset)

1: VREFBUF enabled in Sleep mode

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5LPEN**: LPTIM5 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM5LPENS, and cleared with LPTIM5LPENC. This bit is set and reset by software.

0: LPTIM5 disabled in Sleep mode (default after reset)

1: LPTIM5 enabled in Sleep mode

Bit 11 **LPTIM4LPEN**: LPTIM4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM4LPENS, and cleared with LPTIM4LPENC. This bit is set and reset by software.

0: LPTIM4 disabled in Sleep mode (default after reset)

1: LPTIM4 enabled in Sleep mode

Bit 10 **LPTIM3LPEN**: LPTIM3 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM3LPENS, and cleared with LPTIM3LPENC. This bit is set and reset by software.

0: LPTIM3 disabled in Sleep mode (default after reset)

1: LPTIM3 enabled in Sleep mode

Bit 9 **LPTIM2LPEN**: LPTIM2 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPTIM2LPENS, and cleared with LPTIM2LPENC. This bit is set and reset by software.

0: LPTIM2 disabled in Sleep mode (default after reset)

1: LPTIM2 enabled in Sleep mode

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4LPEN**: I2C4 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with I2C4LPENS, and cleared with I2C4LPENC. This bit is set and reset by software.

0: I2C4 disabled in Sleep mode (default after reset)

1: I2C4 enabled in Sleep mode

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6LPEN**: SPI6 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SPI6LPENS, and cleared with SPI6LPENC. This bit is set and reset by software.

0: SPI6 disabled in Sleep mode (default after reset)

1: SPI6 enabled in Sleep mode

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1LPEN**: LPUART1 enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LPUART1LPENS, and cleared with LPUART1LPENC. This bit is set and reset by software.

0: LPUART1 disabled in Sleep mode (default after reset)

1: LPUART1 enabled in Sleep mode

Bit 2 **HDPLPEN**: HDP enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with HDPLPENS, and cleared with HDPLPENC. This bit is set and reset by software.

0: HDP disabled in Sleep mode (default after reset)

1: HDP enabled in Sleep mode

Bits 1:0 Reserved, must be kept at reset value.

14.10.104 RCC APB4H sleep enable register (RCC_APB4HLPENR)

Address offset: 0x2B8

Reset value: 0x0000 0002

This register is used to enable the APB4H in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rst, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTSLPEN	BSECLPEN	SYSCFGLPEN
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DTSLPEN**: DTS enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. it can be set with DTSLPENS, and cleared with DTSLPENC. This bit is set and reset by software.

0: DTS disabled in Sleep mode (default after reset)

1: DTS enabled in Sleep mode

Bit 1 **BSECLPEN**: BSEC enable

This bit is always security-protected. it can be set with BSECLPENS, and cleared with BSECLPENC. This bit is set and reset by software.

0: BSEC disabled in Sleep mode

1: BSEC enabled in Sleep mode (default after reset)

Bit 0 **SYSCFGLPEN**: SYSCFG enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with SYSCFGLPENS, and cleared with SYSCFGLPENC. This bit IS Set and reset by software.

0: SYSCFG disabled in Sleep mode (default after reset)

1: SYSCFG enabled in Sleep mode

14.10.105 RCC APB5 sleep enable register (RCC_APB5LPENR)

Address offset: 0x2BC

Reset value: 0x0000 0000

This register is used to enable the APB5 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw	rw	rw		rw	rw	

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CSILPEN**: CSI enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with CSILPENS, and cleared with CSILPENC. This bit is set and reset by software.

0: CSI disabled in Sleep mode (default after reset)

1: CSI enabled in Sleep mode

Bit 5 **VENCLPEN**: VENC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with VENCLPENS, and cleared with VENCLPENC. This bit is set and reset by software.

0: VENC disabled in Sleep mode (default after reset)

1: VENC enabled in Sleep mode

Bit 4 **GFXTIMLPEN**: GFXTIM enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with GFXTIMLPENS, and cleared with GFXTIMLPENC. This bit is set and reset by software.

0: GFXTIM disabled in Sleep mode (default after reset)

1: GFXTIM enabled in Sleep mode

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPLPEN**: DCMIPP enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with DCMIPPLPENS, and cleared with DCMIPPLPENC. This bit is set and reset by software.

0: DCMIPP disabled in Sleep mode (default after reset)

1: DCMIPP enabled in Sleep mode

Bit 1 **LTDCLPEN**: LTDC enable

This bit is security-protected by a SEC signal from RIFSC, the PERSEC bit, a PRIV signal from RIFSC, or the PERPRIV bit. It can be set with LTDCLPENS, and cleared with LTDCLPENC. This bit is set and reset by software.

0: LTDC disabled in Sleep mode (default after reset)

1: LTDC enabled in Sleep mode

Bit 0 Reserved, must be kept at reset value.

14.10.106 RCC reset duration control register (RCC_RDCR)

Address offset: 0x44C

Reset value: 0x0600 0000

This register is used to control the minimum sys_rstn active duration. It is reset by pwr_por_rstn, and is in the V_{RET} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	EADLY[3:0]				Res.	Res.	Res.	MRD[4:0]				
				rw	rw	rw	rw				rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **EADLY[3:0]**: External access delay

The bit field is security-protected by the 1 bit. Set and reset by software.
Time to wait before the BOOTROM performs any external device access
0000: No extra delay added by the BOOTROM
0001: 100 µs
0010: 200 µs
0011: 500 µs
0100: 1 ms
0101: 2 ms
0110: 5 ms (default after reset)
0111: 10 ms
1000: 20 ms
1001: 50 ms
1010: 100 ms
1011: 200 ms
1100: 500 ms
1101: 1 s
1110: 2 s
1111: 5 s

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **MRD[4:0]**: Minimum reset duration

This bit is alway security-protected. It is set and reset by software. It defines the minimum guaranteed duration of the NRST assertion. The LSI oscillator is automatically enabled when needed by the RPCTL.
0x00: NRST duration is guaranteed by the pulse stretcher of the PAD. The RPCTL is bypassed (default after reset).
0x01: The guaranteed NRST duration is about 1 ms (1 x 32 lsi_ck cycles).
0x02: The guaranteed NRST duration is about 2 ms (2 x 32 lsi_ck cycles).
{v}: guaranteed NRST duration is about {v} ms ({v} x 32 lsi_ck cycles).

Bits 15:0 Reserved, must be kept at reset value.

14.10.107 RCC oscillator secure configuration register 0 (RCC_SECCFGR0)

Address offset: 0x780

Reset value: 0x0000 0000

This register is used to control the secure access rights to the configuration register of the oscillators. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxSEC bit defines the secure protection for the configuration registers of the oscillator: a write access is denied if the access is nonsecure while the respective bit is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSE SEC	HSI SEC	MSI SEC	LSE SEC	LSI SEC
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSESEC**: Secure protection of HSE oscillator configuration bits
This bit is set and reset by secure privileged software only. it can be read by any software.
0: HSE configuration bits are accessible by nonsecure software only (default after reset).
1: HSE configuration bits are accessible by secure software only.

Bit 3 **HSISEC**: Secure protection of HSI oscillator configuration bits
This bit it set and reset by secure privileged software only. It can be read by any software.
0: HSI configuration bits are accessible by nonsecure software only (default after reset).
1: HSI configuration bits are accessible by secure software only.

Bit 2 **MSISEC**: Secure protection of MSI oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: MSI configuration bits are accessible by nonsecure software only (default after reset).
1: MSI configuration bits are accessible by secure software only.

Bit 1 **LSESEC**: Secure protection of LSE oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: LSE configuration bits are accessible by nonsecure software only (default after reset).
1: LSE configuration bits are accessible by secure software only.

Bit 0 **LSISEC**: Secure protection of LSI oscillator configuration bits.
This bit is set and reset by secure privileged software only. it can be read by any software.
0: LSI configuration bits are accessible by nonsecure software only (default after reset).
1: LSI configuration bits are accessible by secure software only.

14.10.108 RCC oscillator privilege configuration register 0 (RCC_PRIVCFGR0)

Address offset: 0x784

Reset value: 0x0000 0000

This register is used to control the privilege access rights to the configuration register of the oscillators. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit

defines the privileged protection for the configuration registers of the oscillator: a write access is denied if the access is unprivileged while the respective bit is set.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSEPRIV	HSIPRIV	MSIPRIV	LSEPRIV	LSIPRIV
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSEPRIV**: Privileged protection of HSE oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: HSE configuration bits are accessible by unprivileged software only (default after reset).
1: HSE configuration bits are accessible by privileged software only.

Bit 3 **HSIPRIV**: Privileged protection of HSI oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: HSI configuration bits are accessible by unprivileged software only (default after reset).
1: HSI configuration bits are accessible by privileged software only.

Bit 2 **MSIPRIV**: Privileged protection of MSI oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: MSI configuration bits are accessible by unprivileged software only (default after reset).
1: MSI configuration bits are accessible by privileged software only.

Bit 1 **LSEPRIV**: Privileged protection of LSE oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: LSE configuration bits are accessible by unprivileged software only (default after reset).
1: LSE configuration bits are accessible by privileged software only.

Bit 0 **LSIPRIV**: Privileged protection of LSI oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: LSI configuration bits are accessible by unprivileged software only (default after reset.)
1: LSI configuration bits are accessible by privileged software only.

14.10.109 RCC oscillator lock configuration register 0 (RCC_LOCKCFGR0)

Address offset: 0x788

Reset value: 0x0000 0000

This register is used to control the locked access rights to the configuration register of the oscillators. It is reset by sys_rst, n and is in the V_{CORE} voltage domain.Each xxLOCK bit defines the lock protection for the configuration registers of the oscillator: a write access is denied if the access is unlocked while the respective bit is set.

											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSELOCK**: Locked protection of HSE oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: HSE configuration bits are accessible by unlocked software only (default after reset).
1: HSE configuration bits are accessible by locked software only.

Bit 3 **HSILOCK**: Locked protection of HSI oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: HSI configuration bits are accessible by unlocked software only (default after reset).
1: HSI configuration bits are accessible by locked software only.

Bit 2 **MSILOCK**: Locked protection of MSI oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: MSI configuration bits are accessible by unlocked software only (default after reset).
1: MSI configuration bits are accessible by locked software only.

Bit 1 **LSELOCK**: Locked protection of LSE oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: LSE configuration bits are accessible by unlocked software only (default after reset).
1: LSE configuration bits are accessible by locked software only.

Bit 0 **LSILOCK**: Locked protection of LSI oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: LSI configuration bits are accessible by unlocked software only (default after reset).
1: LSI configuration bits are accessible by locked software only.

14.10.110 RCC oscillator public configuration register 0 (RCC_PUBCFGR0)

Address offset: 0x78C

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the oscillators. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of the oscillator: a write access is denied if the access is non-public while the respective bit is set.

											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSEPUB**: Public protection of HSE oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: HSE configuration bits are accessible by non-public software only (default after reset).
1: HSE configuration bits are accessible by public software only.

Bit 3 **HSIPUB**: Public protection of HSI oscillator configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: HSI configuration bits are accessible by non-public software only (default after reset).
1: HSI configuration bits are accessible by public software only.

Bit 2 **MSIPUB**: Public protection of MSI oscillator configuration bits
This bit is set and reset by secure privileged software only. it can be read by any software.
0: MSI configuration bits are accessible by non-public software only (default after reset).
1: MSI configuration bits are accessible by public software only.

Bit 1 **LSEPUB**: Public protection of LSE oscillator configuration bits.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: LSE configuration bits are accessible by non-public software only (default after reset).
1: LSE configuration bits are accessible by public software only.

Bit 0 **LSIPUB**: Public protection of LSI oscillator configuration bits.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: LSI configuration bits are accessible by non-public software only (default after reset).
1: LSI configuration bits are accessible by public software only.

14.10.111 RCC PLL secure configuration register 1 (RCC_SECCFGR1)

Address offset: 0x790

Reset value: 0x0000 0000

This register is used to control the secure access rights to the configuration register of the PLLs. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxSEC bit defines the secure protection for the configuration registers of the PLL: a write access is denied if the access is nonsecure while the respective bit here is set.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PLL4 SEC	PLL3 SEC	PLL2 SEC	PLL1 SEC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **PLL4SEC**: Secure protection of PLL4 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL4 configuration bits are accessible by nonsecure software only (default after reset).
1: PLL4 configuration bits are accessible by secure software only.

Bit 2 **PLL3SEC**: Secure protection of PLL3 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL3 configuration bits are accessible by nonsecure software only (default after reset).
1: PLL3 configuration bits are accessible by secure software only.

Bit 1 **PLL2SEC**: Secure protection of PLL2 configuration bits
This bit is set and reset by secure privileged software only. It be read by any software.
0: PLL2 configuration bits are accessible by nonsecure software only (default after reset).
1: PLL2 configuration bits are accessible by secure software only.

Bit 0 **PLL1SEC**: Secure protection of PLL1 configuration bits.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL1 configuration bits are accessible by nonsecure software only (default after reset).
1: PLL1 configuration bits are accessible by secure software only.

14.10.112 RCC PLL privilege configuration register 1 (RCC_PRIVCFGR1)

Address offset: 0x794

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the PLLs. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV defines the privileged protection for the configuration registers of the PLL: a write access is denied if the access is unprivileged while the respective bit is set.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PLL4PRIV	PLL3PRIV	PLL2PRIV	PLL1PRIV
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **PLL4PRIV**: Privileged protection of PLL4 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL4 configuration bits are accessible by unprivileged software only (default after reset).
1: PLL4 configuration bits are accessible by privileged software only.

Bit 2 **PLL3PRIV**: Privileged protection of PLL3 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL3 configuration bits are accessible by unprivileged software only (default after reset).
1: PLL3 configuration bits are accessible by privileged software only.

Bit 1 **PLL2PRIV**: Privileged protection of PLL2 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL2 configuration bits are accessible by unprivileged software only (default after reset).
1: PLL2 configuration bits are accessible by privileged software only.

Bit 0 **PLL1PRIV**: Privileged protection of PLL1 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL1 configuration bits are accessible by unprivileged software only (default after reset).
1: PLL1 configuration bits are accessible by privileged software only.

14.10.113 RCC PLL lock configuration register 1 (RCC_LOCKCFGR1)

Address offset: 0x798

Reset value: 0x0000 0000

This register is used to control the locked access rights to the configuration register of the PLLs. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxLOCK bit defines the locked protection for the configuration registers of the PLL: a write access is denied if the access is unlocked while the respective bit is set.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PLL4 LOCK	PLL3 LOCK	PLL2 LOCK	PLL1 LOCK
												w	w	w	w

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **PLL4LOCK**: Locked protection of PLL4 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL4 configuration bits are accessible by unlocked software only (default after reset).
1: PLL4 configuration bits are accessible by locked software only.

Bit 2 **PLL3LOCK**: Locked protection of PLL3 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL3 configuration bits are accessible by unlocked software only (default after reset).
1: PLL3 configuration bits are accessible by locked software only.

Bit 1 **PLL2LOCK**: Locked protection of PLL2 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL2 configuration bits are accessible by unlocked software only (default after reset).
1: PLL2 configuration bits are accessible by locked software only.

Bit 0 **PLL1LOCK**: Locked protection of PLL1 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL1 configuration bits are accessible by unlocked software only (default after reset).
1: PLL1 configuration bits are accessible by locked software only.

14.10.114 RCC PLL public configuration register1 (RCC_PUBCFGR1)

Address offset: 0x79C

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the PLLs. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB defines the public protection for the configuration registers of the PLL: a write access is denied if the access is unlocked while the respective bit is set.

												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **PLL4PUB**: Public protection of PLL4 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL4 configuration bits are accessible by non-public software. only (default after reset).
1: PLL4 configuration bits are accessible by public software only.

Bit 2 **PLL3PUB**: Public protection of PLL3 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL3 configuration bits are accessible by non-public software only (default after reset).
1: PLL3 configuration bits are accessible by public software only.

Bit 1 **PLL2PUB**: Public protection of PLL2 configuration bits
This bit is set and reset by secure privileged software only. It can my be read by any software.
0: PLL2 configuration bits are accessible by non-public software only (default after reset).
1: PLL2 configuration bits are accessible by public software only.

Bit 0 **PLL1PUB**: Public protection of PLL1 configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PLL1 configuration bits are accessible by non-public software only (default after reset).
1: PLL1 configuration bits are accessible by public software only.

14.10.115 RCC divider secure configuration register 2 (RCC_SECCFGR2)

Address offset: 0x7A0

Reset value: 0x0000 0000

This register is used to control the secure access rights to the configuration register of the dividers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxSEC bit defines the secure protection for the configuration registers of the divider: a write access is denied if the access is nonsecure while the respective bit is set.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **IC20SEC**: Secure protection of IC20 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC20 configuration bits are accessible by nonsecure software only (default after reset).
1: IC20 configuration bits are accessible by secure software only.

Bit 18 **IC19SEC**: Secure protection of IC19 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC19 configuration bits are accessible by nonsecure software only (default after reset).
1: IC19 configuration bits are accessible by secure software only.

Bit 17 **IC18SEC**: Secure protection of IC18 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC18 configuration bits are accessible by nonsecure software only (default after reset).
1: IC18 configuration bits are accessible by secure software only.

Bit 16 **IC17SEC**: Secure protection of IC17 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC17 configuration bits are accessible by nonsecure software only (default after reset).
1: IC17 configuration bits are accessible by secure software only.

Bit 15 **IC16SEC**: Secure protection of IC16 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC16 configuration bits are accessible by nonsecure software only (default after reset).
1: IC16 configuration bits are accessible by secure software only.

Bit 14 **IC15SEC**: Secure protection of IC15 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC15 configuration bits are accessible by nonsecure software only (default after reset).
1: IC15 configuration bits are accessible by secure software only.

Bit 13 **IC14SEC**: Secure protection of IC14 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC14 configuration bits are accessible by nonsecure software only (default after reset).
1: IC14 configuration bits are accessible by secure software only.

Bit 12 **IC13SEC**: Secure protection of IC13 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC13 configuration bits are accessible by nonsecure software only (default after reset).
1: IC13 configuration bits are accessible by secure software only.

Bit 11 **IC12SEC**: Secure protection of IC12 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC12 configuration bits are accessible by nonsecure software only (default after reset).
1: IC12 configuration bits are accessible by secure software only.

Bit 10 **IC11SEC**: Secure protection of IC11 divider configuration bits
Set and reset by secure privileged software only. It can read by any software.
0: IC11 configuration bits are accessible by nonsecure software only (default after reset).
1: IC11 configuration bits are accessible by secure software only.

Bit 9 **IC10SEC**: Secure protection of IC10 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC10 configuration bits are accessible by nonsecure software only (default after reset)
1: IC10 configuration bits are accessible by secure software only

Bit 8 **IC9SEC**: Secure protection of IC9 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC9 configuration bits are accessible by nonsecure software only (default after reset).
1: IC9 configuration bits are accessible by secure software only.

Bit 7 **IC8SEC**: Secure protection of IC8 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC8 configuration bits are accessible by nonsecure software only (default after reset).
1: IC8 configuration bits are accessible by secure software only.

Bit 6 **IC7SEC**: Secure protection of IC7 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC7 configuration bits are accessible by nonsecure software only (default after reset).
1: IC7 configuration bits are accessible by secure software only.

Bit 5 **IC6SEC**: Secure protection of IC6 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC6 configuration bits are accessible by nonsecure software only (default after reset).
1: IC6 configuration bits are accessible by secure software only.

Bit 4 **IC5SEC**: Secure protection of IC5 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC5 configuration bits are accessible by nonsecure software only (default after reset)
1: IC5 configuration bits are accessible by secure software only

Bit 3 **IC4SEC**: Secure protection of IC4 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC4 configuration bits are accessible by nonsecure software only (default after reset).
1: IC4 configuration bits are accessible by secure software only.

Bit 2 **IC3SEC**: Secure protection of IC3 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC3 configuration bits are accessible by nonsecure software only (default after reset).
1: IC3 configuration bits are accessible by secure software only.

Bit 1 **IC2SEC**: Secure protection of IC2 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC2 configuration bits are accessible by nonsecure software only (default after reset).
1: IC2 configuration bits are accessible by secure software only.

Bit 0 **IC1SEC**: Secure protection of IC1 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC1 configuration bits are accessible by nonsecure software only (default after reset).
1: IC1 configuration bits are accessible by secure software only.

14.10.116 RCC divider privilege configuration register 2 (RCC_PRIVCFGR2)

Address offset: 0x7A4

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the dividers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privileged protection for the configuration registers of the divider: a write access is denied if the access is unprivileged while the respective bit is set.

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **IC20PRIV**: Privileged protection of IC20 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC20 configuration bits are accessible by unprivileged software only (default after reset).
1: IC20 configuration bits are accessible by privileged software only.

Bit 18 **IC19PRIV**: Privileged protection of IC19 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC19 configuration bits are accessible by unprivileged software only (default after reset).
1: IC19 configuration bits are accessible by privileged software only.

Bit 17 **IC18PRIV**: Privilege protection of IC18 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC18 configuration bits are accessible by unprivileged software only (default after reset).
1: IC18 configuration bits are accessible by privileged software only.

Bit 16 **IC17PRIV**: Privileges protection of IC17 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC17 configuration bits are accessible by unprivileged software only (default after reset).
1: IC17 configuration bits are accessible by privileged software only.

Bit 15 **IC16PRIV**: Privileged protection of IC16 divider configuration bits.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC16 configuration bits are accessible by unprivileged software only (default after reset).
1: IC16 configuration bits are accessible by privileged software only.

Bit 14 **IC15PRIV**: Privileged protection of IC15 divider configuration bits.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC15 configuration bits are accessible by unprivileged software only (default after reset).
1: IC15 configuration bits are accessible by privileged software only.

Bit 13 **IC14PRIV**: Privileged protection of IC14 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC14 configuration bits are accessible by unprivileged software only (default after reset).
1: IC14 configuration bits are accessible by privileged software only.

Bit 12 **IC13PRIV**: Privileged protection of IC13 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC13 configuration bits are accessible by unprivileged software only (default after reset).
1: IC13 configuration bits are accessible by privileged software only.

Bit 11 **IC12PRIV**: Privileged protection of IC12 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC12 configuration bits are accessible by unprivileged software only (default after reset).
1: IC12 configuration bits are accessible by privileged software only.

Bit 10 **IC11PRIV**: Privileged protection of IC11 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC11 configuration bits are accessible by unprivileged software only (default after reset).
1: IC11 configuration bits are accessible by privileged software only.

Bit 9 **IC10PRIV**: Privileged protection of IC10 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC10 configuration bits are accessible by unprivileged software only (default after reset).
1: IC10 configuration bits are accessible by privileged software only.

Bit 8 **IC9PRIV**: Privileged protection of IC9 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC9 configuration bits are accessible by unprivileged software only (default after reset).
1: IC9 configuration bits are accessible by privileged software only.

Bit 7 **IC8PRIV**: Privileged protection of IC8 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC8 configuration bits are accessible by unprivileged software only (default after reset).
1: IC8 configuration bits are accessible by privileged software only.

Bit 6 **IC7PRIV**: Privileged protection of IC7 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC7 configuration bits are accessible by unprivileged software only (default after reset).
1: IC7 configuration bits are accessible by privileged software only.

Bit 5 **IC6PRIV**: Privileged protection of IC6 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC6 configuration bits are accessible by unprivileged software only (default after reset).
1: IC6 configuration bits are accessible by privileged software only.

Bit 4 **IC5PRIV**: Privileged protection of IC5 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC5 configuration bits are accessible by unprivileged software only (default after reset).
1: IC5 configuration bits are accessible by privileged software only.

Bit 3 **IC4PRIV**: Privileged protection of IC4 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC4 configuration bits are accessible by unprivileged software only (default after reset).
1: IC4 configuration bits are accessible by privileged software only.

Bit 2 **IC3PRIV**: Privileged protection of IC3 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC3 configuration bits are accessible by unprivileged software only (default after reset).
1: IC3 configuration bits are accessible by privileged software only.

Bit 1 **IC2PRIV**: Privileged protection of IC2 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC2 configuration bits are accessible by unprivileged software only (default after reset).
1: IC2 configuration bits are accessible by privileged software only.

Bit 0 **IC1PRIV**: Privileged protection of IC1 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC1 configuration bits are accessible by unprivileged software only (default after reset).
1: IC1 configuration bits are accessible by privileged software only.

14.10.117 RCC divider lock configuration register 2 (RCC_LOCKCFGR2)

Address offset: 0x7A8

Reset value: 0x0000 0000

This register is used to control the locked access rights to the configuration register of the dividers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxLOCK bit defines the locked protection for the configuration registers of the divider: a write access is denied if the access is unlocked while the respective bit is set.

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **IC20LOCK**: Locked protection of IC20 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC20 configuration bits are accessible by unlocked software only (default after reset).
1: IC20 configuration bits are accessible by locked software only.

Bit 18 **IC19LOCK**: Locked protection of IC19 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC19 configuration bits are accessible by unlocked software only (default after reset).
1: IC19 configuration bits are accessible by locked software only.

Bit 17 **IC18LOCK**: Locked protection of IC18 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC18 configuration bits are accessible by unlocked software only (default after reset).
1: IC18 configuration bits are accessible by locked software only.

Bit 16 **IC17LOCK**: Locked protection of IC17 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC17 configuration bits are accessible by unlocked software only (default after reset).
1: IC17 configuration bits are accessible by locked software only.

Bit 15 **IC16LOCK**: Locked protection of IC16 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC16 configuration bits are accessible by unlocked software only (default after reset).
1: IC16 configuration bits are accessible by locked software only.

Bit 14 **IC15LOCK**: Locked protection of IC15 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC15 configuration bits are accessible by unlocked software only (default after reset).
1: IC15 configuration bits are accessible by locked software only.

Bit 13 **IC14LOCK**: Locked protection of IC14 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC14 configuration bits are accessible by unlocked software only (default after reset).
1: IC14 configuration bits are accessible by locked software only.

Bit 12 **IC13LOCK**: Locked protection of IC13 divider configuration bits.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC13 configuration bits are accessible by unlocked software only (default after reset).
1: IC13 configuration bits are accessible by locked software only.

Bit 11 **IC12LOCK**: Locked protection of IC12 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC12 configuration bits are accessible by unlocked software only (default after reset).
1: IC12 configuration bits are accessible by locked software only.

Bit 10 **IC11LOCK**: Locked protection of IC11 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC11 configuration bits are accessible by unlocked software only (default after reset).
1: IC11 configuration bits are accessible by locked software only.

Bit 9 **IC10LOCK**: Locked protection of IC10 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC10 configuration bits are accessible by unlocked software only (default after reset).
1: IC10 configuration bits are accessible by locked software only.

Bit 8 **IC9LOCK**: Locked protection of IC9 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC9 configuration bits are accessible by unlocked software only (default after reset).
1: IC9 configuration bits are accessible by locked software only.

Bit 7 **IC8LOCK**: Locked protection of IC8 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC8 configuration bits are accessible by unlocked software only (default after reset).
1: IC8 configuration bits are accessible by locked software only.

Bit 6 **IC7LOCK**: Locked protection of IC7 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC7 configuration bits are accessible by unlocked software only (default after reset).
1: IC7 configuration bits are accessible by locked software only.

Bit 5 **IC6LOCK**: Locked protection of IC6 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC6 configuration bits are accessible by unlocked software only (default after reset).
1: IC6 configuration bits are accessible by locked software only.

Bit 4 **IC5LOCK**: Locked protection of IC5 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC5 configuration bits are accessible by unlocked software only (default after reset).
1: IC5 configuration bits are accessible by locked software only.

Bit 3 **IC4LOCK**: Locked protection of IC4 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC4 configuration bits are accessible by unlocked software only (default after reset).
1: IC4 configuration bits are accessible by locked software only.

Bit 2 **IC3LOCK**: Locked protection of IC3 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC3 configuration bits are accessible by unlocked software only (default after reset).
1: IC3 configuration bits are accessible by locked software only.

Bit 1 **IC2LOCK**: Locked protection of IC2 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC2 configuration bits are accessible by unlocked software only (default after reset).
1: IC2 configuration bits are accessible by locked software only.

Bit 0 **IC1LOCK**: Locked protection of IC1 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC1 configuration bits are accessible by unlocked software only (default after reset).
1: IC1 configuration bits are accessible by locked software only.

14.10.118 RCC divider public configuration register 2 (RCC_PUBCFGR2)

Address offset: 0x7AC

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the dividers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of the divider: a write access is denied if the access is non-public while the respective bit here is set.

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **IC20PUB**: Public protection of IC20 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC20 configuration bits are accessible by non-public software only (default after reset).
1: IC20 configuration bits are accessible by public software only.

Bit 18 **IC19PUB**: Public protection of IC19 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC19 configuration bits are accessible by non-public software only (default after reset).
1: IC19 configuration bits are accessible by public software only.

Bit 17 **IC18PUB**: Public protection of IC18 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC18 configuration bits are accessible by non-public software only (default after reset).
1: IC18 configuration bits are accessible by public software only.

Bit 16 **IC17PUB**: Public protection of IC17 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC17 configuration bits are accessible by non-public software only (default after reset).
1: IC17 configuration bits are accessible by public software only.

Bit 15 **IC16PUB**: Public protection of IC16 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC16 configuration bits are accessible by non-public software only (default after reset).
1: IC16 configuration bits are accessible by public software only.

Bit 14 **IC15PUB**: Public protection of IC15 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC15 configuration bits are accessible by non-public software only (default after reset).
1: IC15 configuration bits are accessible by public software only.

Bit 13 **IC14PUB**: Public protection of IC14 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC14 configuration bits are accessible by non-public software only (default after reset).
1: IC14 configuration bits are accessible by public software only.

Bit 12 **IC13PUB**: Public protection of IC13 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC13 configuration bits are accessible by non-public software only (default after reset).
1: IC13 configuration bits are accessible by public software only.

Bit 11 **IC12PUB**: Public protection of IC12 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC12 configuration bits are accessible by non-public software only (default after reset).
1: IC12 configuration bits are accessible by public software only.

Bit 10 **IC11PUB**: Public protection of IC11 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC11 configuration bits are accessible by non-public software only (default after reset).
1: IC11 configuration bits are accessible by public software only.

Bit 9 **IC10PUB**: Public protection of IC10 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC10 configuration bits are accessible by non-public software only (default after reset).
1: IC10 configuration bits are accessible by public software only.

Bit 8 **IC9PUB**: Public protection of IC9 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC9 configuration bits are accessible by non-public software only (default after reset).
1: IC9 configuration bits are accessible by public software only.

Bit 7 **IC8PUB**: Public protection of IC8 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC8 configuration bits are accessible by non-public software only (default after reset).
1: IC8 configuration bits are accessible by public software only.

Bit 6 **IC7PUB**: Public protection of IC7 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC7 configuration bits are accessible by non-public software only (default after reset).
1: IC7 configuration bits are accessible by public software only.

Bit 5 **IC6PUB**: Public protection of IC6 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC6 configuration bits are accessible by non-public software only (default after reset).
1: IC6 configuration bits are accessible by public software only.

Bit 4 **IC5PUB**: Public protection of IC5 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC5 configuration bits are accessible by non-public software only (default after reset).
1: IC5 configuration bits are accessible by public software only.

Bit 3 **IC4PUB**: Public protection of IC4 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC4 configuration bits are accessible by non-public software only (default after reset).
1: IC4 configuration bits are accessible by public software only.

Bit 2 **IC3PUB**: Public protection of IC3 divider configuration bits.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC3 configuration bits are accessible by non-public software only (default after reset).
1: IC3 configuration bits are accessible by public software only.

Bit 1 **IC2PUB**: Public protection of IC2 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC2 configuration bits are accessible by non-public software only (default after reset).
1: IC2 configuration bits are accessible by public software only.

Bit 0 **IC1PUB**: Public protection of IC1 divider configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: IC1 configuration bits are accessible by non-public software only (default after reset).
1: IC1 configuration bits are accessible by public software only.

14.10.119 RCC system secure configuration register 3 (RCC_SECCFGR3)

Address offset: 0x7B0

Reset value: 0x0000 0000

This register is used to control the secure access rights to the system configuration registers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxSEC bit defines the secure protection for the configuration registers: a write access is denied if the access is nonsecure while the respective bit is set.

										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RSTSEC**: Secure protection of RST system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: RST configuration bits are accessible by nonsecure software only (default after reset).
1: RST configuration bits are accessible by secure software only.

Bit 4 **INTSEC**: Secure protection of INT system configuration bits.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: INT configuration bits are accessible by nonsecure software only (default after reset).
1: INT configuration bits are accessible by secure software only.

Bit 3 **PERSEC**: Secure protection of PER system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PER configuration bits are accessible by nonsecure software only (default after reset).
1: PER configuration bits are accessible by secure software only.

Bit 2 **BUSSEC**: Secure protection of BUS system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: BUS configuration bits are accessible by nonsecure software only (default after reset).
1: BUS configuration bits are accessible by secure software only.

Bit 1 **SYSSEC**: Secure protection of SYS system configuration bit.
This bit is set and reset by secure privileged software only. It can be read by any software.
0: SYS configuration bits are accessible by nonsecure software only (default after reset).
1: SYS configuration bits are accessible by secure software only.

Bit 0 **MODSEC**: Secure protection of MOD system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: MOD configuration bits are accessible by nonsecure software only (default after reset).
1: MOD configuration bits are accessible by secure software only.

14.10.120 RCC system privilege configuration register3 (RCC_PRIVCFGR3)

Address offset: 0x7B4

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the system configuration registers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privileged protection for the system configuration registers: a write access is denied if the access is unprivileged while the respective bit is set.

										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RSTPRIV**: Privileged protection of RST system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: RST configuration bits are accessible by unprivileged software only (default after reset).
1: RST configuration bits are accessible by privileged software only.

Bit 4 **INTPRIV**: Privileged protection of INT system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: INT configuration bits are accessible by unprivileged software only (default after reset).
1: INT configuration bits are accessible by privileged software only.

Bit 3 **PERPRIV**: Privileged protection of PER system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PER configuration bits are accessible by unprivileged software only (default after reset).
1: PER configuration bits are accessible by privileged software only.

Bit 2 **BUSPRIV**: Privileged protection of BUS system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: BUS configuration bits are accessible by unprivileged software only (default after reset.)
1: BUS configuration bits are accessible by privileged software only.

Bit 1 **SYSPRIV**: Privileged protection of SYS system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: SYS configuration bits are accessible by unprivileged software only (default after reset).
1: SYS configuration bits are accessible by privileged software only.

Bit 0 **MODPRIV**: Privileged protection of MOD system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: MOD configuration bits are accessible by unprivileged software only (default after reset).
1: MOD configuration bits are accessible by privileged software only.

14.10.121 RCC system lock configuration register 3 (RCC_LOCKCFGR3)

Address offset: 0x7B8

Reset value: 0x0000 0000

This register is used to control the locked access rights to the system configuration registers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxLOCK bit defines the locked protection for the system configuration registers: a write access is denied if the access is unlocked while the respective bit is set.

										w	w	w	w	w	w

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RSTLOCK**: Locked protection of RST system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: RST configuration bits are accessible by unlocked software only (default after reset).
1: RST configuration bits are accessible by locked software only.

Bit 4 **INTLOCK**: Locked protection of INT system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: INT configuration bits are accessible by unlocked software only (default after reset).
1: INT configuration bits are accessible by locked software only.

Bit 3 **PERLOCK**: Locked protection of PER system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PER configuration bits are accessible by unlocked software only (default after reset).
1: PER configuration bits are accessible by locked software only.

Bit 2 **BUSLOCK**: Locked protection of BUS system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: BUS configuration bits are accessible by unlocked software only (default after reset).
1: BUS configuration bits are accessible by locked software only.

Bit 1 **SYSLOCK**: Locked protection of SYS system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: SYS configuration bits are accessible by unlocked software only (default after reset).
1: SYS configuration bits are accessible by locked software only.

Bit 0 **MODLOCK**: Locked protection of MOD system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: MOD configuration bits are accessible by unlocked software only (default after reset).
1: MOD configuration bits are accessible by locked software only.

14.10.122 RCC system public configuration register 3 (RCC_PUBCFGR3)

Address offset: 0x7BC

Reset value: 0x0000 0000

This register is used to control the public access rights to the system configuration registers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB defines the public protection for the system configuration registers: a write access is denied if the access is non-public while the respective bit is set.

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RSTPUB**: Public protection of RST system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: RST configuration bits are accessible by non-public software only (default after reset).
1: RST configuration bits are accessible by public software only.

Bit 4 **INTPUB**: Public protection of INT system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: INT configuration bits are accessible by non-public software only (default after reset).
1: INT configuration bits are accessible by public software only.

Bit 3 **PERPUB**: Public protection of PER system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: PER configuration bits are accessible by non-public software only (default after reset).
1: PER configuration bits are accessible by public software only.

Bit 2 **BUSPUB**: Public protection of BUS system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: BUS configuration bits are accessible by non-public software only (default after reset).
1: BUS configuration bits are accessible by public software only.

Bit 1 **SYSPUB**: Public protection of SYS system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: SYS configuration bits are accessible by non-public software only (default after reset).
1: SYS configuration bits are accessible by public software only.

Bit 0 **MODPUB**: Public protection of MOD system configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: MOD configuration bits are accessible by non-public software only (default after reset).
1: MOD configuration bits are accessible by public software only.

14.10.123 RCC bus secure configuration register 4 (RCC_SECCFGR4)

Reset value: 0x0000 0000

Address offset: 0x7C0

This register is used to control the secure access rights to the configuration register of the buses. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxSEC pub defines the secure protection for the configuration registers of the bus: a write access is denied if the access is nonsecure while the respective bit is set.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NOCSEC**: Secure protection of NOC bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: NOC configuration bits are accessible by nonsecure software only (default after reset).
1: NOC configuration bits are accessible by secure software only.

Bit 12 **APB5SEC**: Secure protection of APB5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB5 configuration bits are accessible by nonsecure software only (default after reset).
1: APB5 configuration bits are accessible by secure software only.

Bit 11 **APB4SEC**: Secure protection of APB4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB4 configuration bits are accessible by nonsecure software only (default after reset).
1: APB4 configuration bits are accessible by secure software only.

Bit 10 **APB3SEC**: Secure protection of APB3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB3 configuration bits are accessible by nonsecure software only (default after reset).
1: APB3 configuration bits are accessible by secure software only.

Bit 9 **APB2SEC**: Secure protection of APB2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB2 configuration bits are accessible by nonsecure software only (default after reset).
1: APB2 configuration bits are accessible by secure software only.

Bit 8 **APB1SEC**: Secure protection of APB1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB1 configuration bits are accessible by nonsecure software only (default after reset).
1: APB1 configuration bits are accessible by secure software only.

Bit 7 **AHB5SEC**: Secure protection of AHB5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB5 configuration bits are accessible by nonsecure software only (default after reset).
1: AHB5 configuration bits are accessible by secure software only.

Bit 6 **AHB4SEC**: Secure protection of AHB4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB4 configuration bits are accessible by nonsecure software only (default after reset).
1: AHB4 configuration bits are accessible by secure software only.

Bit 5 **AHB3SEC**: Secure protection of AHB3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB3 configuration bits are accessible by nonsecure software only (default after reset).
1: AHB3 configuration bits are accessible by secure software only.

Bit 4 **AHB2SEC**: Secure protection of AHB2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB2 configuration bits are accessible by nonsecure software only (default after reset).
1: AHB2 configuration bits are accessible by secure software only.

Bit 3 **AHB1SEC**: Secure protection of AHB1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB1 configuration bits are accessible by nonsecure software only (default after reset).
1: AHB1 configuration bits are accessible by secure software only.

Bit 2 **AHBMSEC**: Secure protection of AHBM bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHBM configuration bits are accessible by nonsecure software only (default after reset).
1: AHBM configuration bits are accessible by secure software only.

Bit 1 **ACLKNCSEC**: Secure protection of ACLKNC bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: ACLKNC configuration bits are accessible by nonsecure software only (default after reset).
1: ACLKNC configuration bits are accessible by secure software only.

Bit 0 **ACLKNSEC**: Secure protection of ACLKN bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: ACLKN configuration bits are accessible by nonsecure software only (default after reset).
1: ACLKN configuration bits are accessible by secure software only.

14.10.124 RCC bus privilege configuration register 4 (RCC_PRIVCFGR4)

Address offset: 0x7C4

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the bus. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privileged protection for the configuration registers of the bus: a write access is denied if the access is unprivileges while the respective bit is set.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NOCPRIV**: Privileged protection of NOC bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: NOC configuration bits are accessible by unprivileged software only (default after reset).
1: NOC configuration bits are accessible by privileged software only.

Bit 12 **APB5PRIV**: Privileged protection of APB5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB5 configuration bits are accessible by unprivileged software only (default after reset).
1: APB5 configuration bits are accessible by privileged software only.

Bit 11 **APB4PRIV**: Privileged protection of APB4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB4 configuration bits are accessible by unprivileged software only (default after reset).
1: APB4 configuration bits are accessible by privileged software only.

Bit 10 **APB3PRIV**: Privileged protection of APB3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB3 configuration bits are accessible by unprivileged software only (default after reset).
1: APB3 configuration bits are accessible by privileged software only.

Bit 9 **APB2PRIV**: Privileged protection of APB2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB2 configuration bits are accessible by unprivileged software only (default after reset).
1: APB2 configuration bits are accessible by privileged software only.

Bit 8 **APB1PRIV**: Privileged protection of APB1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB1 configuration bits are accessible by unprivileged software only (default after reset).
1: APB1 configuration bits are accessible by privileged software only.

Bit 7 **AHB5PRIV**: Privileged protection of AHB5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB5 configuration bits are accessible by unprivileged software only (default after reset).
1: AHB5 configuration bits are accessible by privileged software only.

Bit 6 **AHB4PRIV**: Privileged protection of AHB4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB4 configuration bits are accessible by unprivileged software only (default after reset).
1: AHB4 configuration bits are accessible by privileged software only.

Bit 5 **AHB3PRIV**: Privileged protection of AHB3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB3 configuration bits are accessible by unprivileged software only (default after reset).
1: AHB3 configuration bits are accessible by privileged software only.

Bit 4 **AHB2PRIV**: Privileged protection of AHB2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB2 configuration bits are accessible by unprivileged software only (default after reset).
1: AHB2 configuration bits are accessible by privileged software only.

Bit 3 **AHB1PRIV**: Privileged protection of AHB1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB1 configuration bits are accessible by unprivileged software only (default after reset).
1: AHB1 configuration bits are accessible by privileged software only.

Bit 2 **AHBMPRIV**: Privileged protection of AHBM bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHBM configuration bits are accessible by unprivileged software only (default after reset).
1: AHBM configuration bits are accessible by privileged software only.

Bit 1 **ACLKNCPRIV**: Privileged protection of ACLKNC bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: ACLKNC configuration bits are accessible by unprivileged software only (default after reset).
1: ACLKNC configuration bits are accessible by privileged software only.

Bit 0 **ACLKNPRIV**: Privileged protection of ACLKN bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: ACLKN configuration bits are accessible by unprivileged software only (default after reset).
1: ACLKN configuration bits are accessible by privileged software only.

14.10.125 RCC bus lock configuration register 4 (RCC_LOCKCFGR4)

Address offset: 0x7C8

Reset value: 0x0000 0000

This register is used to control the locked access rights to the configuration register of the bus. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxLOCK defines the locked protection for the configuration registers of the bus: a write access is denied if the access is unlocked while the respective bit is set.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NOCLOCK**: Locked protection of NOC bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: NOC configuration bits are accessible by unlocked software only (default after reset).
1: NOC configuration bits are accessible by locked software only.

Bit 12 **APB5LOCK**: Locked protection of APB5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB5 configuration bits are accessible by unlocked software only (default after reset).
1: APB5 configuration bits are accessible by locked software only.

Bit 11 **APB4LOCK**: Locked protection of APB4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB4 configuration bits are accessible by unlocked software only (default after reset).
1: APB4 configuration bits are accessible by lock software only.

Bit 10 **APB3LOCK**: Locked protection of APB3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB3 configuration bits are accessible by unlocked software only (default after reset).
1: APB3 configuration bits are accessible by locked software only.

Bit 9 **APB2LOCK**: Locked protection of APB2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB2 configuration bits are accessible by unlocked software only (default after reset).
1: APB2 configuration bits are accessible by locked software only.

Bit 8 **APB1LOCK**: Locked protection of APB1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB1 configuration bits are accessible by unlocked software only (default after reset).
1: APB1 configuration bits are accessible by locked software only.

Bit 7 **AHB5LOCK**: Locked protection of AHB5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB5 configuration bits are accessible by unlocked software only (default after reset).
1: AHB5 configuration bits are accessible by locked software only.

Bit 6 **AHB4LOCK**: Locked protection of AHB4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB4 configuration bits are accessible by unlocked software only (default after reset).
1: AHB4 configuration bits are accessible by locked software only.

Bit 5 **AHB3LOCK**: Locked protection of AHB3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB3 configuration bits are accessible by unlocked software only (default after reset).
1: AHB3 configuration bits are accessible by locked software only.

Bit 4 **AHB2LOCK**: Locked protection of AHB2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB2 configuration bits are accessible by unlocked software only (default after reset).
1: AHB2 configuration bits are accessible by locked software only.

Bit 3 **AHB1LOCK**: Locked protection of AHB1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB1 configuration bits are accessible by unlocked software only (default after reset).
1: AHB1 configuration bits are accessible by locked software only.

Bit 2 **AHBMLOCK**: Locked protection of AHBM bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHBM configuration bits are accessible by unlocked software only (default after reset).
1: AHBM configuration bits are accessible by locked software only.

Bit 1 **ACLKNCLOCK**: Locked protection of ACLKNC bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: ACLKNC configuration bits are accessible by unlocked software only (default after reset).
1: ACLKNC configuration bits are accessible by locked software only.

Bit 0 **ACLKNLOCK**: Locked protection of ACLKN bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: ACLKN configuration bits are accessible by unlocked software only (default after reset).
1: ACLKN configuration bits are accessible by locked software only.

14.10.126 RCC bus public configuration register 4 (RCC_PUBCFGR4)

Address offset: 0x7CC

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the bus. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB defines the public protection for the configuration registers of the bus: a write access is denied if the access is non-public while the respective bit is set.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NOCPUB**: Public protection of NOC bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: NOC configuration bits are accessible by non-public software only (default after reset).
1: NOC configuration bits are accessible by public software only.

Bit 12 **APB5PUB**: Public protection of APB5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB5 configuration bits are accessible by non-public software only (default after reset)
1: APB5 configuration bits are accessible by public software only

Bit 11 **APB4PUB**: Public protection of APB4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB4 configuration bits are accessible by non-public software only (default after reset).
1: APB4 configuration bits are accessible by public software only.

Bit 10 **APB3PUB**: Public protection of APB3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB3 configuration bits are accessible by non-public software only (default after reset).
1: APB3 configuration bits are accessible by public software only.

Bit 9 **APB2PUB**: Public protection of APB2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB2 configuration bits are accessible by non-public software only (default after reset).
1: APB2 configuration bits are accessible by public software only.

Bit 8 **APB1PUB**: Public protection of APB1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: APB1 configuration bits are accessible by non-public software only (default after reset).
1: APB1 configuration bits are accessible by public software only.

Bit 7 **AHB5PUB**: Public protection of AHB5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB5 configuration bits are accessible by non-public software only (default after reset).
1: AHB5 configuration bits are accessible by public software only.

Bit 6 **AHB4PUB**: Public protection of AHB4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB4 configuration bits are accessible by non-public software only (default after reset).
1: AHB4 configuration bits are accessible by public software only.

Bit 5 **AHB3PUB**: Public protection of AHB3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB3 configuration bits are accessible by non-public software only (default after reset).
1: AHB3 configuration bits are accessible by public software only.

Bit 4 **AHB2PUB**: Public protection of AHB2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB2 configuration bits are accessible by non-public software only (default after reset).
1: AHB2 configuration bits are accessible by public software only.

Bit 3 **AHB1PUB**: Public protection of AHB1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHB1 configuration bits are accessible by non-public software only (default after reset).
1: AHB1 configuration bits are accessible by public software only.

Bit 2 **AHBMPUB**: Public protection of AHBM bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHBM configuration bits are accessible by non-public software only (default after reset).
1: AHBM configuration bits are accessible by public software only.

Bit 1 **ACLKNCPUB**: Public protection of ACLKNC bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: ACLKNC configuration bits are accessible by non-public software only (default after reset).
1: ACLKNC configuration bits are accessible by public software only.

Bit 0 **ACLKNPUB**: Public protection of the ACLKN bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: ACLKN configuration bits are accessible by non-public software only (default after reset).
1: ACLKN configuration bits are accessible by public software only.

14.10.127 RCC bus public configuration register 4 (RCC_PUBCFGR5)

Address offset: 0x7D0

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the bus. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of the bus: a write access is denied if the access is non-public while the respective bit is set.

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **VENCRAMPUB**: Public protection of VENCRAM bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: VENCRAM configuration bits are accessible by non-public software only (default after reset).
1: VENCRAM configuration bits are accessible by public software only.

Bit 10 **CACHEAXIRAMPUB**: Public protection of CACHEAXIRAM bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: CACHEAXIRAM configuration bits are accessible by non-public software only (default after reset).
1: CACHEAXIRAM configuration bits are accessible by public software only.

Bit 9 **FLEXRAMPUB**: Public protection of FLEXRAM bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: FLEXRAM configuration bits are accessible by non-public software only (default after reset).
1: FLEXRAM configuration bits are accessible by public software only.

Bit 8 **AXISRAM2PUB**: Public protection of AXISRAM2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AXISRAM2 configuration bits are accessible by non-public software only (default after reset).
1: AXISRAM2 configuration bits are accessible by public software only.

Bit 7 **AXISRAM1PUB**: Public protection of AXISRAM1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AXISRAM1 configuration bits are accessible by non-public software only (default after reset).
1: AXISRAM1 configuration bits are accessible by public software only.

Bit 6 **BKPSRAMPUB**: Public protection of BKPSRAM bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: BKPSRAM configuration bits are accessible by non-public software only (default after reset).
1: BKPSRAM configuration bits are accessible by public software only.

Bit 5 **AHBSRAM2PUB**: Public protection of AHBSRAM2 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHBSRAM2 configuration bits are accessible by non-public software only (default after reset).
1: AHBSRAM2 configuration bits are accessible by public software only.

Bit 4 **AHBSRAM1PUB**: Public protection of AHBSRAM1 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AHBSRAM1 configuration bits are accessible by non-public software only (default after reset).
1: AHBSRAM1 configuration bits are accessible by public software only.

Bit 3 **AXISRAM6PUB**: Public protection of AXISRAM6 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AXISRAM6 configuration bits are accessible by non-public software only (default after reset).
1: AXISRAM6 configuration bits are accessible by public software only.

Bit 2 **AXISRAM5PUB**: Public protection of AXISRAM5 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AXISRAM5 configuration bits are accessible by non-public software only (default after reset).
1: AXISRAM5 configuration bits are accessible by public software only.

Bit 1 **AXISRAM4PUB**: Public protection of AXISRAM4 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AXISRAM4 configuration bits are accessible by non-public software only (default after reset).
1: AXISRAM4 configuration bits are accessible by public software only.

Bit 0 **AXISRAM3PUB**: Public protection of AXISRAM3 bus configuration bits
This bit is set and reset by secure privileged software only. It can be read by any software.
0: AXISRAM3 configuration bits are accessible by non-public software only (default after reset).
1: AXISRAM3 configuration bits are accessible by public software only.

14.10.128 RCC control set register (RCC_CSR)

Address offset: 0x800

Reset value: 0x0000 0000

This register is used to enable the RCC oscillators and PLLs in Run or Sleep mode. It is reset by nreset_rstn, and is in the V_{CORE} voltage domain.

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **PLL4ONS**: PLL4 oscillator enable
Written at 1 to set PLL4ON.

Bit 10 **PLL3ONS**: PLL3 oscillator enable
Written at 1 to set PLL3ON.

Bit 9 **PLL2ONS**: PLL2 oscillator enable
Written at 1 to set PLL2ON.

Bit 8 **PLL1ONS**: PLL1 oscillator enable
Written at 1 to set PLL1ON.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **HSEONS**: HSE oscillator enable
Written at 1 to set HSEON.

Bit 3 **HSIONS**: HSI oscillator enable
Written at 1 to set HSION.

Bit 2 **MSIONS**: MSI oscillator enable
Written at 1 to set MSION.

Bit 1 **LSEONS**: LSE oscillator enable
Written at 1 to set LSEON.

Bit 0 **LSIONS**: LSI oscillator enable
Written at 1 to set LSION.

14.10.129 RCC Stop mode configuration set register (RCC_STOPCSR)

Address offset: 0x808

Reset value: 0x0000 0000

This register is used to enable the RCC oscillators and PLLs in Stop mode. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **HSISTOPENS**: HSI oscillator enable
Written at 1 to set HSISTOPEN.

Bit 0 **MSISTOPENS**: MSI oscillator enable
Written at 1 to set MSISTOPEN.

14.10.130 RCC miscellaneous reset register (RCC_MISCRSTSR)

Address offset: 0xA08

Reset value: 0x0000 0000

This register is used to reset the RCC miscellaneous. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							w	w		w	w				w

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC2DLLRSTS**: SDMMC2DLL reset
Written at 1 to set SDMMC2DLLRST.

Bit 7 **SDMMC1DLLRSTS**: SDMMC1DLL reset
Written at 1 to set SDMMC1DLLRST.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **XSPIPHY2RSTS**: XSPIPHY2 reset
Written at 1 to set XSPIPHY2RST.

Bit 4 **XSPIPHY1RSTS**: XSPIPHY1 reset
Written at 1 to set XSPIPHY1RST.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DBGRSTS**: DBG reset
Written at 1 to set DBGRST.

14.10.131 RCC memory reset register (RCC_MEMRSTSR)

Address offset: 0xA0C

Reset value: 0x0000 0000

This register is used to reset the RCC memories. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **BOOTROMRSTS**: BootROM reset
Written at 1 to set BOOTROMRST.

Bit 11 **VENCRAMRSTS**: VENCRAM reset
Written at 1 to set VENCRAMRST.

Bit 10 **CACHEAXIRAMRSTS**: CACHEAXIRAM reset
Written at 1 to set CACHEAXIRAM.

Bit 9 **FLEXRAMRSTS**: FLEXRAM reset
Written at 1 to set FLEXRAMRST.

Bit 8 **AXISRAM2RSTS**: AXISRAM2 reset
Written at 1 to set AXISRAM2RST.

Bit 7 **AXISRAM1RSTS**: AXISRAM1 reset
Written at 1 to set AXISRAM1RST.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **AHBSRAM2RSTS**: AHBSRAM2 reset
Written at 1 to set AHBSRAM2RST.

Bit 4 **AHBSRAM1RSTS**: AHBSRAM1 reset
Written at 1 to set AHBSRAM1RST.

Bit 3 **AXISRAM6RSTS**: AXISRAM6 reset
Written at 1 to set AXISRAM6RST.

Bit 2 **AXISRAM5RSTS**: AXISRAM5 reset
Written at 1 to set AXISRAM5RST.

Bit 1 **AXISRAM4RSTS**: AXISRAM4 reset
Written at 1 to set AXISRAM4RST.

Bit 0 **AXISRAM3RSTS**: AXISRAM3 reset
Written at 1 to set AXISRAM3RST.

14.10.132 RCC AHB1 reset register (RCC_AHB1RSTSR)

Address offset: 0xA10

Reset value: 0x0000 0000

This register is used to reset the RCC AHB1. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **ADF1RSTS**: ADF1 reset
Written at 1 to set ADF1RST.

Bit 16 **MDF1RSTS**: MDF1 reset
Written at 1 to set MDF1RST.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **RAMCFGRSTS**: RAMCFG reset
Written at 1 to set RAMCFGRST.

Bits 11:0 Reserved, must be kept at reset value.

14.10.134 RCC AHB3 reset register (RCC_AHB3RSTSR)

Address offset: 0xA18

Reset value: 0x0000 0000

This register is used to reset the RCC AHB3. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **IACRSTS**: IAC reset
Written at 1 to set IACRST.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **PKARSTS**: PKA reset
Written at 1 to set PKARST.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SAESRSTS**: SAES reset
Written at 1 to set SAESRST.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPRSTS**: CRYP reset
Written at 1 to set CRYPRST.

Bit 1 **HASHRSTS**: HASH reset
Written at 1 to set HASHRST.

Bit 0 **RNGRSTS**: RNG reset
Written at 1 to set RNGRST.

14.10.135 RCC AHB4 reset register (RCC_AHB4RSTSR)

Address offset: 0xA1C

Reset value: 0x0000 0000

This register is used to reset the RCC AHB4. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CRCRSTS**: CRC reset
Written at 1 to set CRCRST.

Bit 18 **PWRRSTS**: PWR reset
Written at 1 to set PWRRST.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **GPIOQRSTS**: GPIO Q reset
Written at 1 to set GPIOQRST.

Bit 15 **GPIOPRSTS**: GPIO P reset
Written at 1 to set GPIOPRST.

Bit 14 **GPIOORSTS**: GPIO O reset
Written at 1 to set GPIOORST.

Bit 13 **GPIONRSTS**: GPIO N reset
Written at 1 to set GPIONRST.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHRSTS**: GPIO H reset
Written at 1 to set GPIOHRST.

Bit 6 **GPIOGRSTS**: GPIO G reset
Written at 1 to set GPIOGRST.

Bit 5 **GPIOFRSTS**: GPIO F reset
Written at 1 to set GPIOFRST.

Bit 4 **GPIOERSTS**: GPIO E reset
Written at 1 to set GPIOERST.

Bit 3 **GPIODRSTS**: GPIO D reset
Written at 1 to set GPIODRST.

Bit 2 **GPIOCRSTS**: GPIO C reset
Written at 1 to set GPIOCRST.

Bit 1 **GPIOBRSTS**: GPIO B reset
Written at 1 to set GPIOBRST.

Bit 0 **GPIOARSTS**: GPIO A reset
Written at 1 to set GPIOARST.

14.10.136 RCC AHB5 reset register (RCC_AHB5RSTSR)

Address offset: 0xA20

Reset value: 0x0000 0000

This register is used to reset the RCC AHB5. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 **NPURSTS**: NPU reset
Written at 1 to set NPURST.

Bit 30 **CACHEAXIRSTS**: CACHEAXI reset
Written at 1 to set CACHEAXIRST.

Bit 29 **OTG2RSTS**: OTG2 reset
Written at 1 to set OTG2RST.

Bit 28 **OTGPHY2RSTS**: OTGPHY2 reset
Written at 1 to set OTGPHY2RST.

Bit 27 **OTGPHY1RSTS**: OTGPHY1 reset
Written at 1 to set OTGPHY1RST.

Bit 26 **OTG1RSTS**: OTG1 reset
Written at 1 to set OTG1RST.

Bit 25 **ETH1RSTS**: ETH1 reset
Written at 1 to set ETH1RST.

Bit 24 **OTG2PHYCTLRSTS**: OTG2PHYCTL reset
Written at 1 to set OTG2PHYCTLRST.

Bit 23 **OTG1PHYCTLRSTS**: OTG1PHYCTL reset
Written at 1 to set OTG1PHYCTLRST.

Bits 22:21 Reserved, must be kept at reset value.

Bit 20 **GPU2DRSTS**: GPU2D reset
Written at 1 to set GPU2DRST.

Bit 19 **GFXMMURSTS**: GFXMMU reset
Written at 1 to set GFXMMURST.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **XSPI3RSTS**: XSPI3 reset
Written at 1 to set XSPI3RST.

Bits 16:14 Reserved, must be kept at reset value.

Bit 13 **XSPIMRSTS**: XSPIM reset
Written at 1 to set XSPIMRST.

Bit 12 **XSPI2RSTS**: XSPI2 reset
Written at 1 to set XSPI2RST.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1RSTS**: SDMMC1 reset
Written at 1 to set SDMMC1RST.

Bit 7 **SDMMC2RSTS**: SDMMC2 reset
Written at 1 to set SDMMC2RST.

Bit 6 **PSSIRSTS**: PSSI reset
Written at 1 to set PSSIRST.

Bit 5 **XSPI1RSTS**: XSPI1 reset
Written at 1 to set XSPI1RST.

Bit 4 **FMCRSTS**: FMC reset
Written at 1 to set FMCRST.

Bit 3 **JPEGRSTS**: JPEG reset
Written at 1 to set JPEGRST.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DRSTS**: DMA2D reset
Written at 1 to set DMA2DRST.

Bit 0 **HPDMA1RSTS**: HPDMA1 reset
Written at 1 to set HPDMA1RST.

14.10.137 RCC APB1L reset register (RCC_APB1LRSTSR)

Address offset: 0xA24

Reset value: 0x0000 0000

This register is used to reset the RCC APB1L. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 31 **UART8RSTS**: UART8 reset
Written at 1 to set UART8RST.

Bit 30 **UART7RSTS**: UART7 reset
Written at 1 to set UART7RST.

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **I3C2RSTS**: I3C2 reset
Written at 1 to set I3C2RST.

Bit 24 **I3C1RSTS**: I3C1 reset
Written at 1 to set I3C1RST.

Bit 23 **I2C3RSTS**: I2C3 reset
Written at 1 to set I2C3RST.

Bit 22 **I2C2RSTS**: I2C2 reset
Written at 1 to set I2C2RST.

Bit 21 **I2C1RSTS**: I2C1 reset
Written at 1 to set I2C1RST.

Bit 20 **UART5RSTS**: UART5 reset
Written at 1 to set UART5RST.

Bit 19 **UART4RSTS**: UART4 reset
Written at 1 to set UART4RST.

Bit 18 **USART3RSTS**: USART3 reset
Written at 1 to set USART3RST.

Bit 17 **USART2RSTS**: USART2 reset
Written at 1 to set USART2RST.

Bit 16 **SPDIFRX1RSTS**: SPDIFRX1 reset
Written at 1 to set SPDIFRX1RST.

Bit 15 **SPI3RSTS**: SPI3 reset
Written at 1 to set SPI3RST.

Bit 14 **SPI2RSTS**: SPI2 reset
Written at 1 to set SPI2RST.

Bit 13 **TIM11RSTS**: TIM11 reset
Written at 1 to set TIM11RST.

Bit 12 **TIM10RSTS**: TIM10 reset
Written at 1 to set TIM10RST.

Bit 11 **WWDGRSTS**: WWDG reset
Written at 1 to set WWDGRST.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1RSTS**: LPTIM1 reset
Written at 1 to set LPTIM1RST.

Bit 8 **TIM14RSTS**: TIM14 reset
Written at 1 to set TIM14RST.

Bit 7 **TIM13RSTS**: TIM13 reset
Written at 1 to set TIM13RST.

Bit 6 **TIM12RSTS**: TIM12 reset
Written at 1 to set TIM12RST.

Bit 5 **TIM7RSTS**: TIM7 reset
Written at 1 to set TIM7RST.

Bit 4 **TIM6RSTS**: TIM6 reset
Written at 1 to set TIM6RST.

Bit 3 **TIM5RSTS**: TIM5 reset
Written at 1 to set TIM5RST.

Bit 2 **TIM4RSTS**: TIM4 reset
Written at 1 to set TIM4RST.

Bit 1 **TIM3RSTS**: TIM3 reset
Written at 1 to set TIM3RST.

Bit 0 **TIM2RSTS**: TIM2 reset
Written at 1 to set TIM2RST.

14.10.138 RCC APB1H reset register (RCC_APB1HRSTSR)

Address offset: 0xA28

Reset value: 0x0000 0000

This register is used to reset the RCC APB1H. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Written at 1 to set SAI2RST.

Bit 21 **SAI1RSTS**: SAI1 reset
Written at 1 to set SAI1RST.

Bit 20 **SPI5RSTS**: SPI5 reset
Written at 1 to set SPI5RST.

Bit 19 **TIM9RSTS**: TIM9 reset
Written at 1 to set TIM9RST.

Bit 18 **TIM17RSTS**: TIM17 reset
Written at 1 to set TIM17RST.

Bit 17 **TIM16RSTS**: TIM16 reset
Written at 1 to set TIM16RST.

Bit 16 **TIM15RSTS**: TIM15 reset
Written at 1 to set TIM15RST.

Bit 15 **TIM18RSTS**: TIM18 reset
Written at 1 to set TIM18RST.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **SPI4RSTS**: SPI4 reset
Written at 1 to set SPI4RST.

Bit 12 **SPI1RSTS**: SPI1 reset
Written at 1 to set SPI1RST.

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10RSTS**: USART10 reset
Written at 1 to set USART10RST.

Bit 6 **UART9RSTS**: UART9 reset
Written at 1 to set UART9RST.

Bit 5 **USART6RSTS**: USART6 reset
Written at 1 to set USART6RST.

Bit 4 **USART1RSTS**: USART1 reset
Written at 1 to set USART1RST.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8RSTS**: TIM8 reset
Written at 1 to set TIM8RST.

Bit 0 **TIM1RSTS**: TIM1 reset
Written at 1 to set TIM1RST.

14.10.140 RCC APB4L reset register (RCC_APB4LRSTSR)

Address offset: 0xA34

Reset value: 0x0000 0000

This register is used to reset the RCC APB4L. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RTCRSTS**: RTC reset
Written at 1 to set RTCRST.

Bit 15 **VREFBUFRSTS**: VREFBUF reset
Written at 1 to set VREFBUFRST.

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5RSTS**: LPTIM5 reset
Written at 1 to set LPTIM5RST.

Bit 11 **LPTIM4RSTS**: LPTIM4 reset
Written at 1 to set LPTIM4RST.

Bit 10 **LPTIM3RSTS**: LPTIM3 reset
Written at 1 to set LPTIM3RST.

Bit 9 **LPTIM2RSTS**: LPTIM2 reset
Written at 1 to set LPTIM2RST.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4RSTS**: I2C4 reset
Written at 1 to set I2C4RST.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6RSTS**: SPI6 reset
Written at 1 to set SPI6RST.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1RSTS**: LPUART1 reset
Written at 1 to set LPUART1RST.

Bit 2 **HDPRSTS**: HDP reset
Written at 1 to set HDPRST.

Bits 1:0 Reserved, must be kept at reset value.

14.10.141 RCC APB4H reset register (RCC_APB4HRSTSR)

Address offset: 0xA38

Reset value: 0x0000 0000

This register is used to reset the RCC APB4H. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CSIRSTS**: CSI reset
Written at 1 to set CSIRST.

Bit 5 **VENCRSTS**: VENC reset
Written at 1 to set VENCRST.

Bit 4 **GFXTIMRSTS**: GFXTIM reset
Written at 1 to set GFXTIMRST.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPRSTS**: DCMIPP reset
Written at 1 to set DCMIPPRST.

Bit 1 **LTDCRSTS**: LTDC reset
Written at 1 to set LTDCRST.

Bit 0 Reserved, must be kept at reset value.

14.10.143 RCC divider enable register (RCC_DIVENSR)

Address offset: 0xA40

Reset value: 0x0000 0000

This register is used to enable the RCC IC dividers in Run, Sleep, or Stop mode. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 4 **IC5ENS**: IC5 enable
Written at 1 to set IC5EN.

Bit 3 **IC4ENS**: IC4 enable
Written at 1 to set IC4EN.

Bit 2 **IC3ENS**: IC3 enable
Written at 1 to set IC3EN.

Bit 1 **IC2ENS**: IC2 enable
Written at 1 to set IC2EN.

Bit 0 **IC1ENS**: IC1 enable
Written at 1 to set IC1EN.

14.10.144 RCC bus enable register (RCC_BUSENSR)

Address offset: 0xA44

Reset value: 0x0000 0000

This register is used to enable the RCC bus in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **ACLKNCENS**: ACLKNC enable
Written at 1 to set ACLKNCEN.

Bit 0 **ACLKNENS**: ACLKN enable
Written at 1 to set ACLKNEN.

14.10.145 RCC miscellaneous enable register (RCC_MISCENSR)

Address offset: 0xA48

Reset value: 0x0000 0000

This register is used to enable the RCC miscellaneous in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PERENS**: PER enable
Written at 1 to set PEREN.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **XSPIPHYCOMPENS**: XSPIPHYCOMP enable
Written at 1 to set XSPIPHYCOMPEN.

Bit 2 **MCO2ENS**: MCO2 enable
Written at 1 to set MCO2EN.

Bit 1 **MCO1ENS**: MCO1 enable
Written at 1 to set MCO1EN.

Bit 0 **DBGENS**: DBG enable
Written at 1 to set DBGEN.

14.10.146 RCC memory enable register (RCC_MEMENSR)

Address offset: 0xA4C

Reset value: 0x0000 0000

This register is used to enable the RCC memory in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **BOOTROMENS**: BootROM enable
Written at 1 to set BOOTROMEN.

Bit 11 **VENCRAMENS**: VENCRAM enable
Written at 1 to set VENCRAMEN.

Bit 10 **CACHEAXIRAMENS**: CACHEAXIRAM enable
Written at 1 to set CACHEAXIRAMEN.

Bit 9 **FLEXRAMENS**: FLEXRAM enable
Written at 1 to set FLEXRAMEN.

Bit 8 **AXISRAM2ENS**: AXISRAM2 enable
Written at 1 to set AXISRAM2EN.

Bit 7 **AXISRAM1ENS**: AXISRAM1 enable
Written at 1 to set AXISRAM1EN.

Bit 6 **BKPSRAMENS**: BKPSRAM enable
Written at 1 to set BKPSRAMEN.

Bit 5 **AHBSRAM2ENS**: AHBSRAM2 enable
Written at 1 to set AHBSRAM2EN.

Bit 4 **AHBSRAM1ENS**: AHBSRAM1 enable
Written at 1 to set AHBSRAM1EN.

Bit 3 **AXISRAM6ENS**: AXISRAM6 enable
Written at 1 to set AXISRAM6EN.

Bit 2 **AXISRAM5ENS**: AXISRAM5 enable
Written at 1 to set AXISRAM5EN.

Bit 1 **AXISRAM4ENS**: AXISRAM4 enable
Written at 1 to set AXISRAM4EN.

Bit 0 **AXISRAM3ENS**: AXISRAM3 enable
Written at 1 to set AXISRAM3EN.

14.10.147 RCC AHB1 enable register (RCC_AHB1ENSR)

Address offset: 0xA50

Reset value: 0x0000 0000

This register is used to enable the RCC AHB1 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 18 **PWRENS**: PWR enable
Written at 1 to set PWREN.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **GPIOQENS**: GPIO Q enable
Written at 1 to set GPIOQEN.

Bit 15 **GPIOPENS**: GPIO P enable
Written at 1 to set GPIOPEN.

Bit 14 **GPIOOENS**: GPIO O enable
Written at 1 to set GPIOOEN.

Bit 13 **GPIONENS**: GPIO N enable
Written at 1 to set GPIONEN.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHENS**: GPIO H enable
Written at 1 to set GPIOHEN.

Bit 6 **GPIOGENS**: GPIO G enable
Written at 1 to set GPIOGEN.

Bit 5 **GPIOFENS**: GPIO F enable
Written at 1 to set GPIOFEN.

Bit 4 **GPIOEENS**: GPIO E enable
Written at 1 to set GPIOEEN.

Bit 3 **GPIODENS**: GPIO D enable
Written at 1 to set GPIODEN.

Bit 2 **GPIOCENS**: GPIO C enable
Written at 1 to set GPIOCEN.

Bit 1 **GPIOBENS**: GPIO B enable
Written at 1 to set GPIOBEN.

Bit 0 **GPIOAENS**: GPIO A enable
Written at 1 to set GPIOAEN.

14.10.151 RCC AHB5 enable register (RCC_AHB5ENSR)

Address offset: 0xA60

Reset value: 0x0000 0000

This register is used to enable the RCC AHB5 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1ENS**: SDMMC1 enable
Written at 1 to set SDMMC1EN.

Bit 7 **SDMMC2ENS**: SDMMC2 enable
Written at 1 to set SDMMC2EN.

Bit 6 **PSSIENS**: PSSI enable
Written at 1 to set PSSIEN.

Bit 5 **XSPI1ENS**: XSPI1 enable
Written at 1 to set XSPI1EN.

Bit 4 **FMCENS**: FMC enable
Written at 1 to set FMCEN.

Bit 3 **JPEGENS**: JPEG enable
Written at 1 to set JPEGEN.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DENS**: DMA2D enable
Written at 1 to set DMA2DEN.

Bit 0 **HPDMA1ENS**: HPDMA1 enable
Written at 1 to set HPDMA1EN.

14.10.152 RCC APB1L enable register (RCC_APB1LENSR)

Address offset: 0xA64

Reset value: 0x0000 0000

This register is used to enable the RCC APB1L in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 2 **DTSENS**: DTS enable
Written at 1 to set DTSEN.

Bit 1 **BSECENS**: BSEC enable
Written at 1 to set BSECEN.

Bit 0 **SYSCFGENS**: SYSCFG enable
Written at 1 to set SYSCFGEN.

14.10.158 RCC APB5 enable register (RCC_APB5ENSR)

Address offset: 0xA7C

Reset value: 0x0000 0000

This register is used to enable the RCC APB5 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CSIENS**: CSI enable
Written at 1 to set CSIEN.

Bit 5 **VENCENS**: VENC enable
Written at 1 to set VENCEN.

Bit 4 **GFXTIMENS**: GFXTIM enable
Written at 1 to set GFXTIMEN.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPENS**: DCMIPP enable
Written at 1 to set DCMIPPEN.

Bit 1 **LTDCENS**: LTDC enable
Written at 1 to set LTDCEN.

Bit 0 Reserved, must be kept at reset value.

14.10.159 RCC bus sleep enable register (RCC_BUSLPENSR)

Address offset: 0xA84

Reset value: 0x0000 0000

This register is used to enable the RCC bus in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **ACLKNCLPENS**: ACLKNC enable
Written at 1 to set ACLKNCLPEN.

Bit 0 **ACLKNLPENS**: ACLKN enable
Written at 1 to set ACLKNLPEN.

14.10.160 RCC miscellaneous sleep enable register (RCC_MISCLPENSR)

Address offset: 0xA88

Reset value: 0x0000 0000

This register is used to enable the RCC miscellaneous in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PERLPENS**: PER enable
Written at 1 to set PERLPEN.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **XSPIPHYCOMPLPENS**: XSPIPHYCOMP enable
Written at 1 to set XSPIPHYCOMPLPEN.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **DBGLPENS**: DBG enable
Written at 1 to set DBGLPEN.

14.10.161 RCC memory sleep enable register (RCC_MEMLPENSR)

Address offset: 0xA8C

Reset value: 0x0000 0000

This register is used to enable the RCC memory in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **BOOTROMLPENS**: BootROM enable
Written at 1 to set BOOTROMLPEN.

Bit 11 **VENCRAMLPENS**: VENCRAM enable
Written at 1 to set VENCRAMLPEN.

Bit 10 **CACHEAXIRAMLPENS**: CACHEAXIRAM enable
Written at 1 to set CACHEAXIRAMLPEN.

Bit 9 **FLEXRAMLPENS**: FLEXRAM enable
Written at 1 to set FLEXRAMLPEN.

Bit 8 **AXISRAM2LPENS**: AXISRAM2 enable
Written at 1 to set AXISRAM2LPEN.

Bit 7 **AXISRAM1LPENS**: AXISRAM1 enable
Written at 1 to set AXISRAM1LPEN.

Bit 6 **BKPSRAMLPENS**: BKPSRAM enable
Written at 1 to set BKPSRAMLPEN.

Bit 5 **AHBSRAM2LPENS**: AHBSRAM2 enable
Written at 1 to set AHBSRAM2LPEN.

Bit 4 **AHBSRAM1LPENS**: AHBSRAM1 enable
Written at 1 to set AHBSRAM1LPEN.

Bit 3 **AXISRAM6LPENS**: AXISRAM6 enable
Written at 1 to set AXISRAM6LPEN.

Bit 2 **AXISRAM5LPENS**: AXISRAM5 enable
Written at 1 to set AXISRAM5LPEN.

Bit 1 **AXISRAM4LPENS**: AXISRAM4 enable
Written at 1 to set AXISRAM4LPEN.

Bit 0 **AXISRAM3LPENS**: AXISRAM3 enable
Written at 1 to set AXISRAM3LPEN.

14.10.162 RCC AHB1 sleep enable register (RCC_AHB1LPENSR)

Address offset: 0xA90

Reset value: 0x0000 0000

This register is used to enable the RCC AHB1 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **RISAFLPENS**: RISAF enable
Written at 1 to set RISAFLPEN.

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **IACLPENS**: IAC enable in Sleep mode
Written at 1 to set IACLPEN.

Bit 9 **RIFSCLPENS**: RIFSC enable
Written at 1 to set RIFSCLPEN.

Bit 8 **PKALPENS**: PKA enable
Written at 1 to set PKALPEN.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SAESLPENS**: SAES enable
Written at 1 to set SAESLPEN.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPLPENS**: CRYP enable
Written at 1 to set CRYPLPEN.

Bit 1 **HASHLPENS**: HASH enable
Written at 1 to set HASHLPEN.

Bit 0 **RNGLPENS**: RNG enable
Written at 1 to set RNGLPEN.

14.10.165 RCC AHB4 sleep enable register (RCC_AHB4LPENSR)

Address offset: 0xA9C

Reset value: 0x0000 0000

This register is used to enable the RCC AHB4 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CRCLPENS**: CRC enable
Written at 1 to set CRCLPEN.

Bit 18 **PWRLPENS**: PWR enable
Written at 1 to set PWRLPEN.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **GPIOQLPENS**: GPIO Q enable
Written at 1 to set GPIOQLPEN.

Bit 15 **GPIOPLPENS**: GPIO P enable
Written at 1 to set GPIOPLPEN.

Bit 14 **GPIOOLPENS**: GPIO O enable
Written at 1 to set GPIOOLPEN.

Bit 13 **GPIONLPENS**: GPIO N enable
Written at 1 to set GPIONLPEN.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHLPENS**: GPIO H enable
Written at 1 to set GPIOHLPEN.

Bit 6 **GPIOGLPENS**: GPIO G enable
Written at 1 to set GPIOGLPEN.

Bit 5 **GPIOFLPENS**: GPIO F enable
Written at 1 to set GPIOFLPEN.

Bit 4 **GPIOELPENS**: GPIO E enable
Written at 1 to set GPIOELPEN.

Bit 3 **GPIODLPENS**: GPIO D enable
Written at 1 to set GPIODLPEN.

Bit 2 **GPIOCLPENS**: GPIO C enable
Written at 1 to set GPIOCLPEN.

Bit 1 **GPIOBLPENS**: GPIO B enable
Written at 1 to set GPIOBLPEN.

Bit 0 **GPIOALPENS**: GPIO A enable
Written at 1 to set GPIOALPEN.

14.10.166 RCC AHB5 sleep enable register (RCC_AHB5LPENSR)

Address offset: 0xAA0

Reset value: 0x0000 0000

This register is used to enable the RCC AHB5 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 16 **MCE3LPENS**: MCE3 enable
Written at 1 to set MCE3LPEN.

Bit 15 **MCE2LPENS**: MCE2 enable
Written at 1 to set MCE2LPEN.

Bit 14 **MCE1LPENS**: MCE1 enable
Written at 1 to set MCE1LPEN.

Bit 13 **XSPIMLPENS**: XSPIM enable
Written at 1 to set XSPIMLPEN.

Bit 12 **XSPI2LPENS**: XSPI2 enable
Written at 1 to set XSPI2LPEN.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1LPENS**: SDMMC1 enable
Written at 1 to set SDMMC1LPEN.

Bit 7 **SDMMC2LPENS**: SDMMC2 enable
Written at 1 to set SDMMC2LPEN.

Bit 6 **PSSILPENS**: PSSI enable
Written at 1 to set PSSILPEN.

Bit 5 **XSPI1LPENS**: XSPI1 enable
Written at 1 to set XSPI1LPEN.

Bit 4 **FMCLPENS**: FMC enable
Written at 1 to set FMCLPEN.

Bit 3 **JPEGLPENS**: JPEG enable
Written at 1 to set JPEGLPEN.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DLPENS**: DMA2D enable
Written at 1 to set DMA2DLPEN.

Bit 0 **HPDMA1LPENS**: HPDMA1 enable
Written at 1 to set HPDMA1LPEN.

14.10.167 RCC APB1L sleep enable register (RCC_APB1LLPENSR)

Address offset: 0xAA4

Reset value: 0x0000 0000

This register is used to enable the RCC APB1L in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Written at 1 to set USART6LPEN.

Bit 4 **USART1LPENS**: USART1 enable
Written at 1 to set USART1LPEN.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8LPENS**: TIM8 enable
Written at 1 to set TIM8LPEN.

Bit 0 **TIM1LPENS**: TIM1 enable
Written at 1 to set TIM1LPEN.

14.10.170 RCC APB3 sleep enable register (RCC_APB3LPENSR)

Address offset: 0xAB0

Reset value: 0x0000 0000

This register is used to enable the RCC APB3 in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DFTLPENS**: DFT enable
Written at 1 to set DFTLPEN.

Bits 1:0 Reserved, must be kept at reset value.

14.10.171 RCC APB4L sleep enable register (RCC_APB4LLPENSR)

Address offset: 0xAB4

Reset value: 0x0000 0000

This register is used to enable the RCC APB4L in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RTCAPBLPENS**: RTCAPB enable
Written at 1 to set RTCAPBLPEN.

Bit 16 **RTCLPENS**: RTC enable
Written at 1 to set RTCLPEN.

Bit 15 **VREFBUFLPENS**: VREFBUF enable
Written at 1 to set VREFBUFLPEN.

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5LPENS**: LPTIM5 enable
Written at 1 to set LPTIM5LPEN.

Bit 11 **LPTIM4LPENS**: LPTIM4 enable
Written at 1 to set LPTIM4LPEN.

Bit 10 **LPTIM3LPENS**: LPTIM3 enable
Written at 1 to set LPTIM3LPEN.

Bit 9 **LPTIM2LPENS**: LPTIM2 enable
Written at 1 to set LPTIM2LPEN.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4LPENS**: I2C4 enable
Written at 1 to set I2C4LPEN.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6LPENS**: SPI6 enable
Written at 1 to set SPI6LPEN.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1LPENS**: LPUART1 enable
Written at 1 to set LPUART1LPEN.

Bit 2 **HDPLPENS**: HDP enable
Written at 1 to set HDPLPEN.

Bits 1:0 Reserved, must be kept at reset value.

14.10.172 RCC APB4H sleep enable register (RCC_APB4HLPENSR)

Address offset: 0xAB8

Reset value: 0x0000 0000

This register is used to enable the RCC APB4H in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CSILPENS**: CSI enable
Written at 1 to set CSILPEN.

Bit 5 **VENCLPENS**: VENC enable
Written at 1 to set VENCLPEN.

Bit 4 **GFXTIMLPENS**: GFXTIM enable
Written at 1 to set GFXTIMLPEN.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPLPENS**: DCMIPP enable
Written at 1 to set DCMIPPLPEN.

Bit 1 **LTDCLPENS**: LTDC enable
Written at 1 to set LTDCLPEN.

Bit 0 Reserved, must be kept at reset value.

14.10.174 RCC oscillator privilege configuration set register 0 (RCC_PRIVCFGSR0)

Address offset: 0xF84

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the oscillators. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privileged protection for the configuration registers of the oscillator: a write access is denied if the access is unprivileged while the respective bit is set.

											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSEPRIVS**: Privileged protection of HSE configuration bits (enable, ready, divider)
Written at 1 to set HSEPRIV by secure privileged software only. It can be read by any software.

Bit 3 **HSIPRIVS**: Privileged protection of HSI configuration bits (enable, ready, divider)
Written at 1 to set HSIPRIV by secure privileged software only. It can be read by any software.

Bit 2 **MSIPRIVS**: Privileged protection of MSI configuration bits (enable, ready, divider)
Written at 1 to set MSIPRIV by secure privileged software only. It can be read by any software.

Bit 1 **LSEPRIVS**: Privileged protection of LSE configuration bits (enable, ready, divider)
Written at 1 to set LSEPRIV by secure privileged software only. It can be read by any software.

Bit 0 **LSIPRIVS**: Privileged protection of the LSI configuration bits (enable, ready, divider)
Written at 1 to set LSIPRIV by secure privileged software only. It can be read by any software.

14.10.175 RCC oscillator public configuration set register 0 (RCC_PUBCFGSR0)

Address offset: 0xF8C

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the oscillators. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of the oscillator: a write access is denied if the access is non-public while the respective bit is set.

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSEPUBS**: Public protection of he HSE configuration bits (enable, ready, divider)
Written at 1 to set HSEPUB by secure privileged software only. It can be read by any software.

Bit 3 **HSIPUBS**: Public protection of HSI configuration bits (enable, ready, divider)
Written at 1 to set HSIPUB by secure privileged software only. It can be read by any software.

Bit 2 **MSIPUBS**: Public protection of MSI configuration bits (enable, ready, divider)
Written at 1 to set MSIPUB by secure privileged software only. It can be read by any software.

Bit 1 **LSEPUBS**: Public protection of LSE configuration bits (enable, ready, divider)
Written at 1 to set LSEPUB by secure privileged software only. It can be read by any software.

Bit 0 **LSIPUBS**: Public protection of LSI configuration bits (enable, ready, divider)
Written at 1 to set LSIPUB by secure privileged software only. It can be read by any software.

14.10.176 RCC PLL privilege configuration set register 1 (RCC_PRIVCFGSR1)

Address offset: 0xF94

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the PLLs. It is reset by sys_rst, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privileged protection for the configuration registers of the PLL: a write access is denied if the access is unprivilege while the respective bit is set.

Bit 19 **IC20PUBS**: Public protection of IC20 configuration bits (enable, ready, divider)
Written at 1 to set IC20PUB by secure privileged software only. It can be read by any software.

Bit 18 **IC19PUBS**: Public protection of IC19 configuration bits (enable, ready, divider)
Written at 1 to set IC19PUB by secure privileged software only. It can be read by any software.

Bit 17 **IC18PUBS**: Public protection of IC18 configuration bits (enable, ready, divider)
Written at 1 to set IC18PUB by secure privileged software only. It can be read by any software.

Bit 16 **IC17PUBS**: Public protection of IC17 configuration bits (enable, ready, divider)
Written at 1 to set IC17PUB by secure privileged software only. It can be read by any software.

Bit 15 **IC16PUBS**: Public protection of th IC16 configuration bits (enable, ready, divider
Written at 1 to set IC16PUB by secure privileged software only. It can be read by any software.

Bit 14 **IC15PUBS**: Public protection of IC15 configuration bits (enable, ready, divider)
Written at 1 to set IC15PUB by secure privileged software only. It can be read by any software.

Bit 13 **IC14PUBS**: Public protection of IC14 configuration bits (enable, ready, divider)
Written at 1 to set IC14PUB by secure privileged software only. It can be read by any software.

Bit 12 **IC13PUBS**: Public protection of IC13 configuration bits (enable, ready, divider)
Written at 1 to set IC13PUB by secure privileged software only. It can be read by any software.

Bit 11 **IC12PUBS**: Public protection of IC12 configuration bits (enable, ready, divider)
Written at 1 to set IC12PUB by secure privileged software only. It can be read by any software.

Bit 10 **IC11PUBS**: Public protection of IC11 configuration bits (enable, ready, divider)
Written at 1 to set IC11PUB by secure privileged software only. It can be read by any software.

Bit 9 **IC10PUBS**: Public protection of IC10 configuration bits (enable, ready, divider)
Written at 1 to set IC10PUB by secure privileged software only. It can be read by any software.

Bit 8 **IC9PUBS**: Public protection of IC9 configuration bits (enable, ready, divider)
Written at 1 to set IC9PUB by secure privileged software only. It can be read by any software.

Bit 7 **IC8PUBS**: Public protection of IC8 configuration bits (enable, ready, divider)
Written at 1 to set IC8PUB by secure privileged software only. It can be read by any software.

Bit 6 **IC7PUBS**: Public protection of IC7 configuration bits (enable, ready, divider)
Written at 1 to set IC7PUB by secure privileged software only. It can be read by any software.

Bit 5 **IC6PUBS**: Public protection of IC6 configuration bits (enable, ready, divider)
Written at 1 to set IC6PUB by secure privileged software only. It can be read by any software.

Bit 4 **IC5PUBS**: Public protection of IC5 configuration bits (enable, ready, divider)
Written at 1 to set IC5PUB by secure privileged software only. It can be read by any software.

Bit 3 **IC4PUBS**: Public protection of IC4 configuration bits (enable, ready, divider)
Written at 1 to set IC4PUB by secure privileged software only. It can be read by any software.

Bit 2 **IC3PUBS**: Public protection of IC3 configuration bits (enable, ready, divider)
Written at 1 to set IC3PUB by secure privileged software only. It can be read by any software.

Bit 1 **IC2PUBS**: Public protection of IC2 configuration bits (enable, ready, divider)
Written at 1 to set IC2PUB by secure privileged software only. It can be read by any software.

Bit 0 **IC1PUBS**: Public protection of IC1 configuration bits (enable, ready, divider)
Written at 1 to set IC1PUB by secure privileged software only. It can be read by any software.

14.10.180 RCC system privilege configuration set register 3 (RCC_PRIVCFGSR3)

Address offset: 0xFB4

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the system. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privilege protection for the configuration registers of the system: a write access is denied if the access is unprivileged while the respective bit is set.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **DFTPRIVS**: Privileged protection of DFT configuration bits (enable, ready, divider)
Written at 1 to set DFTPRIV by secure privileged software only. It can be read by any software.

Bit 5 **RSTPRIVS**: Privileged protection of RST configuration bits (enable, ready, divider)
Written at 1 to set RSTPRIV by secure privileged software only. It can be read by any software.

Bit 4 **INTPRIVS**: Privileged protection of INT configuration bits (enable, ready, divider)
Written at 1 to set INTPRIV by secure privileged software only. It can be read by any software.

Bit 3 **PERPRIVS**: Privileged protection of PER configuration bits (enable, ready, divider)
Written at 1 to set PERPRIV by secure privileged software only. It can be read by any software.

Bit 2 **BUSPRIVS**: Privileged protection of BUS configuration bits (enable, ready, divider)
Written at 1 to set BUSPRIV by secure privileged software only. It can be read by any software.

Bit 1 **SYSPRIVS**: Privileged protection of SYS configuration bits (enable, ready, divider)
Written at 1 to set SYSPRIV by secure privileged software only. It can be read by any software.

Bit 0 **MODPRIVS**: Privileged protection of MOD configuration bits (enable, ready, divider)
Written at 1 to set MODPRIV by secure privileged software only. It can be read by any software.

14.10.181 RCC system public configuration set register 3 (RCC_PUBCFGSR3)

Address offset: 0xFBC

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the system. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of the system: a write access is denied if the access is non-public while the respective bit is set.

										w	w	w	w	w	w

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RSTPUBS**: Public protection of RST configuration bits (enable, ready, divider)
Written at 1 to set RSTPUB by secure privileged software only. It can be read by any software.

Bit 4 **INTPUBS**: Public protection of INT configuration bits (enable, ready, divider)
Written at 1 to set INTPUB by secure privileged software only. It can be read by any software.

Bit 3 **PERPUBS**: Public protection of PER configuration bits (enable, ready, divider)
Written at 1 to set PERPUB by secure privileged software only. It can be read by any software.

Bit 2 **BUSPUBS**: Public protection of BUS configuration bits (enable, ready, divider)
Written at 1 to set BUSPUB by secure privileged software only. It can be read by any software.

Bit 1 **SYSPUBS**: Public protection of SYS configuration bits (enable, ready, divider)
Written at 1 to set SYSPUB by secure privileged software only. It can be read by any software.

Bit 0 **MODPUBS**: Public protection of MOD configuration bits (enable, ready, divider)
Written at 1 to set MODPUB by secure privileged software only. It can be read by any software.

14.10.182 RCC privilege configuration set register 4 (RCC_PRIVCFGSR4)

Address offset: 0xFC4

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the buses. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privileged protection for the configuration registers of each bus: a write access is denied if the access is unprivileged while the respective bit is set.

		w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NOCPRIVS**: Privileged protection of NOC configuration bits (enable, ready, divider)
Written at 1 to set NOCPRIV by secure privileged software only. It can be read by any software.

Bit 12 **APB5PRIVS**: Privileged protection of APB5 configuration bits (enable, ready, divider)
Written at 1 to set APB5PRIV by secure privileged software only. It can be read by any software.

Bit 11 **APB4PRIVS**: Privileged protection of APB4 configuration bits (enable, ready, divider)
Written at 1 to set APB4PRIV by secure privileged software only. It can be read by any software.

Bit 10 **APB3PRIVS**: Privileged protection of APB3 configuration bits (enable, ready, divider)
Written at 1 to set APB3PRIV by secure privileged software only. It can be read by any software.

Bit 9 **APB2PRIVS**: Privileged protection of APB2 configuration bits (enable, ready, divider)
Written at 1 to set APB2PRIV by secure privileged software only. It can be read by any software.

Bit 8 **APB1PRIVS**: Privileged protection of APB1 configuration bits (enable, ready, divider)
Written at 1 to set APB1PRIV by secure privileged software only. It can be read by any software.

Bit 7 **AHB5PRIVS**: Privileged protection of AHB5 configuration bits (enable, ready, divider)
Written at 1 to set AHB5PRIV by secure privileged software only. It can be read by any software.

Bit 6 **AHB4PRIVS**: Privileged protection of AHB4 configuration bits (enable, ready, divider)
Written at 1 to set AHB4PRIV by secure privileged software only. It can be read by any software.

Bit 5 **AHB3PRIVS**: Privileged protection of AHB3 configuration bits (enable, ready, divider)
Written at 1 to set AHB3PRIV by secure privileged software only. It can be read by any software.

Bit 4 **AHB2PRIVS**: Privileged protection of AHB2 configuration bits (enable, ready, divider)
Written at 1 to set AHB2PRIV by secure privileged software only. It can be read by any software.

Bit 3 **AHB1PRIVS**: Privileged protection of AHB1 configuration bits (enable, ready, divider)
Written at 1 to set AHB1PRIV by secure privileged software only. It can be read by any software.

Bit 2 **AHBMPRIVS**: Privileged protection of AHBM configuration bits (enable, ready, divider)
Written at 1 to set AHBMPRIV by secure privileged software only. It can be read by any software.

Bit 1 **ACLKNCPRIVS**: Privileged protection of th ACLKNC configuration bits (enable, ready, divider)
Written at 1 to set ACLKNCPRIV by secure privileged software only. It can be read by any software.

Bit 0 **ACLKNPRIVS**: Privileged protection of ACLKN configuration bits (enable, ready, divider)
Written at 1 to set ACLKNPRIV by secure privileged software only. It can be read by any software.

14.10.183 RCC public configuration set register 4 (RCC_PUBCFGSR4)

Address offset: 0xFCC

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the buses. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of each bus: a write access is denied if the access is non-public while the respective bit is set.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NOCPUBS**: Public protection of NOC configuration bits (enable, ready, divider)
Written at 1 to set NOCPUB by secure privileged software only. It can be read by any software.

Bit 12 **APB5PUBS**: Public protection of APB5 configuration bits (enable, ready, divider)
Written at 1 to set APB5PUB by secure privileged software only. It can be read by any software.

Bit 11 **APB4PUBS**: Public protection of APB4 configuration bits (enable, ready, divider)
Written at 1 to set APB4PUB by secure privileged software only. It can be read by any software.

Bit 10 **APB3PUBS**: Public protection of APB3 configuration bits (enable, ready, divider)
Written at 1 to set APB3PUB by secure privileged software only. It can be read by any software.

Bit 9 **APB2PUBS**: Public protection of APB2 configuration bits (enable, ready, divider)
Written at 1 to set APB2PUB by secure privileged software only. It can be read by any software.

Bit 8 **APB1PUBS**: Public protection of APB1 configuration bits (enable, ready, divider)
Written at 1 to set APB1PUB by secure privileged software only. It can be read by any software.

Bit 7 **AHB5PUBS**: Public protection of AHB5 configuration bits (enable, ready, divider)
Written at 1 to set AHB5PUB by secure privileged software only. It can be read by any software.

Bit 6 **AHB4PUBS**: Public protection of AHB4 configuration bits (enable, ready, divider)
Written at 1 to set AHB4PUB by secure privileged software only. It can be read by any software.

Bit 5 **AHB3PUBS**: Public protection of AHB3 configuration bits (enable, ready, divider)
Written at 1 to set AHB3PUB by secure privileged software only. It can be read by any software.

Bit 4 **AHB2PUBS**: Public protection of AHB2 configuration bits (enable, ready, divider)
Written at 1 to set AHB2PUB by secure privileged software only. It can be read by any software.

Bit 3 **AHB1PUBS**: Public protection of AHB1 configuration bits (enable, ready, divider)
Written at 1 to set AHB1PUB by secure privileged software only. It can be read by any software.

Bit 2 **AHBMPUBS**: Public protection of AHBM configuration bits (enable, ready, divider)
Written at 1 to set AHBMPUB by secure privileged software only. It can be read by any software.

Bit 1 **ACLKNCPUBS**: Public protection of ACLKNC configuration bits (enable, ready, divider)
Written at 1 to set ACLKNCPUB by secure privileged software only. It can be read by any software.

Bit 0 **ACLKNPUBS**: Public protection of ACLKN configuration bits (enable, ready, divider)
Written at 1 to set ACLKNPUB by secure privileged software only. It can be read by any software.

14.10.184 RCC public configuration set register 5 (RCC_PUBCFGSR5)

Address offset: 0xFD0

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the SRAMs. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of each SRAM: a write access is denied if the access is non-public while the respective bit is set.

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **VENCRAMPUBS**: Public protection of VENCRAM configuration bits (enable, ready, divider)
Written at 1 to set VENCRAMPUB by secure privileged software only. It can be read by any software.

Bit 10 **CACHEAXIRAMPUBS**: Public protection of CACHEAXIRAM configuration bits (enable, ready, divider)
Written at 1 to set CACHEAXIRAMPUB by secure privileged software only. It can be read by any software.

Bit 9 **FLEXRAMPUBS**: Public protection of FLEXRAM configuration bits (enable, ready, divider)
Written at 1 to set FLEXRAMPUB by secure privileged software only. It can be read by any software.

Bit 8 **AXISRAM2PUBS**: Public protection of AXISRAM2 configuration bits (enable, ready, divider)
Written at 1 to set AXISRAM2PUB by secure privileged software only. It can rbe ead by any software.

Bit 7 **AXISRAM1PUBS**: Public protection of AXISRAM1 configuration bits (enable, ready, divider)
Written at 1 to set AXISRAM1PUB by secure privileged software only. It can be read by any software.

Bit 6 **BKPSRAMPUBS**: Public protection of BKPSRAM configuration bits (enable, ready, divider)
Written at 1 to set BKPSRAMPUB by secure privileged software only. It can be read by any software.

Bit 5 **AHBSRAM2PUBS**: Public protection of AHBSRAM2 configuration bits (enable, ready, divider)
Written at 1 to set AHBSRAM2PUB by secure privileged software only. It can be read by any software.

Bit 4 **AHBSRAM1PUBS**: Public protection of AHBSRAM1 configuration bits (enable, ready, divider)
Written at 1 to set AHBSRAM1PUB by secure privileged software only. It can be read by any software.

Bit 3 **AXISRAM6PUBS**: Public protection of AXISRAM6 configuration bits (enable, ready, divider)
Written at 1 to set AXISRAM6PUB by secure privileged software only. It can be read by any software.

Bit 2 **AXISRAM5PUBS**: Public protection of AXISRAM5 configuration bits (enable, ready, divider)
Written at 1 to set AXISRAM5PUB by secure privileged software only. It can be read by any software.

Bit 1 **AXISRAM4PUBS**: Public protection of AXISRAM4 configuration bits (enable, ready, divider)
Written at 1 to set AXISRAM4PUB by secure privileged software only. It can be read by any software.

Bit 0 **AXISRAM3PUBS**: Public protection of AXISRAM3 configuration bits (enable, ready, divider)
Written at 1 to set AXISRAM3PUB by secure privileged software only. It can be read by any software.

14.10.185 RCC control clear register (RCC_CCR)

Address offset: 0x1000

Reset value: 0x0000 0000

This register is used to enable the RCC oscillators and PLLs in Run or Sleep mode. It is reset by nreset_rstn, and is in the V_{CORE} voltage domain.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **PLL4ONC**: PLL4 oscillator enable
Written at 1 to clear PLL4ON.

Bit 10 **PLL3ONC**: PLL3 oscillator enable
Written at 1 to clear PLL3ON.

Bit 9 **PLL2ONC**: PLL2 oscillator enable
Written at 1 to clear PLL2ON.

Bit 8 **PLL1ONC**: PLL1 oscillator enable
Written at 1 to clear PLL1ON.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **HSEONC**: HSE oscillator enable
Written at 1 to clear HSEON.

Bit 3 **HSIONC**: HSI oscillator enable
Written at 1 to clear HSION.

Bit 2 **MSIONC**: MSI oscillator enable
Written at 1 to clear MSION.

Bit 1 **LSEONC**: LSE oscillator enable
Written at 1 to clear LSEON.

Bit 0 **LSIONC**: LSI oscillator enable
Written at 1 to clear LSION.

14.10.186 RCC Stop mode configuration clear register (RCC_STOPCCR)

Address offset: 0x1008

Reset value: 0x0000 0000

This register is used to enable the RCC oscillators and PLLs in Stop mode. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

							w	w		w	w				w

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC2DLLRSTC**: SDMMC2DLL reset
Written at 1 to clear SDMMC2DLLRST.

Bit 7 **SDMMC1DLLRSTC**: SDMMC1DLL reset
Written at 1 to clear SDMMC1DLLRST.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **XSPIPHY2RSTC**: XSPIPHY2 reset
Written at 1 hto clear XSPIPHY2RST.

Bit 4 **XSPIPHY1RSTC**: XSPIPHY1 reset
Written at 1 to clear XSPIPHY1RST.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DBGRSTC**: DBG reset
Written at 1 to clear DBGRST.

14.10.188 RCC memory reset clear register (RCC_MEMRSTCR)

Address offset: 0x120C

Reset value: 0x0000 0000

This register is used to reset the RCC memory. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **BOOTROMRSTC**: BootROM reset
Written at 1 to clear BOOTROMRST.

Bit 11 **VENCRAMRSTC**: VENCRAM reset
Written at 1 to clear VENCRAMRST.

Bit 10 **CACHEAXIRAMRSTC**: CACHEAXIRAM reset
Written at 1 to clear CACHEAXIRAMRST.

Bit 9 **FLEXRAMRSTC**: FLEXRAM reset
Written at 1 to clear FLEXRAMRST.

Bit 8 **AXISRAM2RSTC**: AXISRAM2 reset
Written at 1 to clear AXISRAM2RST.

Bit 7 **AXISRAM1RSTC**: AXISRAM1 reset
Written at 1 to clear AXISRAM1RST.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **AHBSRAM2RSTC**: AHBSRAM2 reset
Written at 1 to clear AHBSRAM2RST.

Bit 4 **AHBSRAM1RSTC**: AHBSRAM1 reset
Written at 1 to clear AHBSRAM1RST.

Bit 3 **AXISRAM6RSTC**: AXISRAM6 reset
Written at 1 to clear AXISRAM6RST.

Bit 2 **AXISRAM5RSTC**: AXISRAM5 reset
Written at 1 to clear AXISRAM5RST.

Bit 1 **AXISRAM4RSTC**: AXISRAM4 reset
Written at 1 to clear AXISRAM4RST.

Bit 0 **AXISRAM3RSTC**: AXISRAM3 reset
Written at 1 to clear AXISRAM3RST.

14.10.189 RCC AHB1 reset clear register (RCC_AHB1RSTCR)

Address offset: 0x1210

Reset value: 0x0000 0000

This register is used to reset the RCC AHB1. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CRCRSTC**: CRC reset
Written at 1 to clear CRCRST.

Bit 18 **PWRRSTC**: PWR reset
Written at 1 to clear PWRRST.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **GPIOQRSTC**: GPIO Q reset
Written at 1 to clear GPIOQRST.

Bit 15 **GPIOPRSTC**: GPIO P reset
Written at 1 to clear GPIOPRST.

Bit 14 **GPIOORSTC**: GPIO O reset
Written at 1 to clear GPIOORST.

Bit 13 **GPIONRSTC**: GPIO N reset
Written at 1 to clear GPIONRST.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHRSTC**: GPIO H reset
Written at 1 to clear GPIOHRST.

Bit 6 **GPIOGRSTC**: GPIO G reset
Written at 1 to clear GPIOGRST.

Bit 5 **GPIOFRSTC**: GPIO F reset
Written at 1 to clear GPIOFRST.

Bit 4 **GPIOERSTC**: GPIO E reset
Written at 1 to clear GPIOERST.

Bit 3 **GPIODRSTC**: GPIO D reset
Written at 1 to clear GPIODRST.

Bit 2 **GPIOCRSTC**: GPIO C reset
Written at 1 to clear GPIOCRST.

Bit 1 **GPIOBRSTC**: GPIO B reset
Written at 1 to clear GPIOBRST.

Bit 0 **GPIOARSTC**: GPIO A reset
Written at 1 to clear GPIOARST.

14.10.193 RCC AHB5 reset clear register (RCC_AHB5RSTCR)

Address offset: 0x1220

Reset value: 0x0000 0000

This register is used to reset the RCC AHB5. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 4 **GPDMA1ENC**: GPDMA1 enable
Written at 1 to clear GPDMA1EN.

Bits 3:0 Reserved, must be kept at reset value.

14.10.205 RCC AHB2 enable clear register (RCC_AHB2ENCR)

Address offset: 0x1254

Reset value: 0x0000 0000

This register is used to enable the RCC AHB2 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **RISAFENC**: RISAF enable
Written at 1 to clear RISAFEN.

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **IACENC**: IAC enable
Written at 1 to clear IACEN.

Bit 9 **RIFSCENC**: RIFSC enable
Written at 1 to clear RIFSCEN.

Bit 8 **PKAENC**: PKA enable
Written at 1 to clear PKAEN.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SAESENC**: SAES enable
Written at 1 to clear SAESEN.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPENC**: CRYP enable
Written at 1 to clear CRYPEN.

Bit 1 **HASHENC**: HASH enable
Written at 1 to clear HASHEN.

Bit 0 **RNGENC**: RNG enable
Written at 1 to clear RNGEN.

14.10.207 RCC AHB4 enable clear register (RCC_AHB4ENCR)

Address offset: 0x125C

Reset value: 0x0000 0000

This register is used to enable the RCC AHB4 in Run and Sleep modes (in Sleep mode, each bit of this register is AND-ed with the LPEN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PERLPENC**: PER enable in Sleep mode
Written at 1 to clear PERLPEN.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **XSPIPHYCOMPLPENC**: XSPIPHYCOMP enable in Sleep mode
Written at 1 to clear XSPIPHYCOMPLPEN.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **DBGLPENC**: DBG enable in Sleep mode
Written at 1 to clear DBGLPEN.

14.10.218 RCC memory sleep enable clear register (RCC_MEMLPENCR)

Address offset: 0x128C

Reset value: 0x0000 0000

This register is used to enable the RCC AXISRAM3 memory in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **BOOTROMLPENC**: BootROM enable in Sleep mode
Written at 1 to clear BOOTROMLPEN.

Bit 11 **VENCRAMLPENC**: VENCRAM enable in Sleep mode
Written at 1 to clear VENCRAMLPEN.

Bit 10 **CACHEAXIRAMLPENC**: CACHEAXIRAM enable in Sleep mode
Written at 1 to clear CACHEAXIRAMLPEN.

Bit 9 **FLEXRAMLPENC**: FLEXRAM enable in Sleep mode
Written at 1 to clear FLEXRAMLPEN.

Bit 8 **AXISRAM2LPENC**: AXISRAM2 enable in Sleep mode
Written at 1 to clear AXISRAM2LPEN.

Bit 7 **AXISRAM1LPENC**: AXISRAM1 enable in Sleep mode
Written at 1 to clear AXISRAM1LPEN.

Bit 6 **BKPSRAMLPENC**: BKPSRAM enable in Sleep mode
Written at 1 to clear BKPSRAMLPEN.

Bit 5 **AHBSRAM2LPENC**: AHBSRAM2 enable in Sleep mode
Written at 1 to clear AHBSRAM2LPEN.

Bit 4 **AHBSRAM1LPENC**: AHBSRAM1 enable in Sleep mode
Written at 1 to clear AHBSRAM1LPEN.

Bit 3 **AXISRAM6LPENC**: AXISRAM6 enable in Sleep mode
Written at 1 to clear AXISRAM6LPEN.

Bit 2 **AXISRAM5LPENC**: AXISRAM5 enable in Sleep mode
Written at 1 to clear AXISRAM5LPEN.

Bit 1 **AXISRAM4LPENC**: AXISRAM4 enable in Sleep mode
Written at 1 to clear AXISRAM4LPEN.

Bit 0 **AXISRAM3LPENC**: AXISRAM3 enable in Sleep mode
Written at 1 to clear AXISRAM3LPEN.

14.10.219 RCC AHB1 sleep enable clear register (RCC_AHB1LPENCR)

Address offset: 0x1290

Reset value: 0x0000 0000

This register is used to enable the RCC AHB1 in Sleep mode (each bit of this register is AND-ed with the EN bit).It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bit 17 **RTCAPBLPENC**: RTCAPB enable
Written at 1 to clear RTCAPBLPEN.

Bit 16 **RTCLPENC**: RTC enable
Written at 1 to clear RTCLPEN.

Bit 15 **VREFBUFLPENC**: VREFBUF enable
Written at 1 to clear VREFBUFLPEN.

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5LPENC**: LPTIM5 enable
Written at 1 to clear LPTIM5LPEN.

Bit 11 **LPTIM4LPENC**: LPTIM4 enable
Written at 1 to clear LPTIM4LPEN.

Bit 10 **LPTIM3LPENC**: LPTIM3 enable
Written at 1 to clear LPTIM3LPEN.

Bit 9 **LPTIM2LPENC**: LPTIM2 enable
Written at 1 to clear LPTIM2LPEN.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4LPENC**: I2C4 enable
Written at 1 to clear I2C4LPEN.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6LPENC**: SPI6 enable
Written at 1 to clear SPI6LPEN.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1LPENC**: LPUART1 enable
Written at 1 to clear LPUART1LPEN.

Bit 2 **HDPLPENC**: HDP enable
Written at 1 to clear HDPLPEN.

Bits 1:0 Reserved, must be kept at reset value.

14.10.229 RCC APB4H sleep enable clear register (RCC_APB4HLPENCR)

Address offset: 0x12B8

Reset value: 0x0000 0000

This register is used to enable the RCC APB4H in Sleep mode (each bit of this register is AND-ed with the EN bit). It is reset by sys_rstn, and is in the V_{CORE} voltage domain.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CSILPENC**: CSI sleep enable
Written at 1 to clear CSILPEN.

Bit 5 **VENCLPENC**: VENC sleep enable
Written at 1 to clear VENCLPEN.

Bit 4 **GFXTIMLPENC**: GFXTIM sleep enable
Written at 1 to clear GFXTIMLPEN.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPLPENC**: DCMIPP sleep enable
Written at 1 to clear DCMIPPLPEN.

Bit 1 **LTDCLPENC**: LTDC sleep enable
Written at 1 to clear LTDCLPEN.

Bit 0 Reserved, must be kept at reset value.

14.10.231 RCC oscillator privilege configuration clear register 0 (RCC_PRIVCFGCR0)

Address offset: 0x1784

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the oscillators. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privileged protection for the configuration registers of the oscillator: a write access is denied if the access is unprivileged while the respective bit is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSEPRIVC**: Privileged protection of HSE configuration bits (enable, ready, divider)
Written at 1 to clear HSEPRIV by secure privileged software only. It can be read by any software.

Bit 3 **HSIPRIVC**: Privileged protection of HSI configuration bits (enable, ready, divider)
Written at 1 to clear HSIPRIV by secure privileged software only. It can be read by any software.

Bit 2 **MSIPRIVC**: Privileged protection of MSI configuration bits (enable, ready, divider)
Written at 1 to clear MSIPRIV by secure privileged software only. It can be read by any software.

Bit 1 **LSEPRIVC**: Privileged protection of LSE configuration bits (enable, ready, divider)
Written at 1 to clear LSEPRIV by secure privileged software only. It can be read by any software.

Bit 0 **LSIPRIVC**: Privileged protection of LSI configuration bits (enable, ready, divider)
Written at 1 to clear LSIPRIV by secure privileged software only. It can be read by any software.

14.10.232 RCC oscillator public configuration clear register 0 (RCC_PUBCFGCR0)

Address offset: 0x178C

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the oscillators. It is reset by sys_rstn and is in VCORE voltage domain. Each xxPUB bit defines the public protection for the configuration registers of the oscillator: a write access is denied if the access is non-public while the respective bit is set.

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSEPUBC**: Public protection of HSE configuration bits (enable, ready, divider)
Written at 1 to clear HSEPUB by secure privileged software only. It can be read by any software.

Bit 3 **HSIPUBC**: Public protection of HSI configuration bits (enable, ready, divider)
Written at 1 to clear HSIPUB by secure privileged software only. It can be read by any software.

Bit 2 **MSIPUBC**: Public protection of MSI configuration bits (enable, ready, divider)
Written at 1 to clear MSIPUB by secure privileged software only. It can be read by any software.

Bit 1 **LSEPUBC**: Public protection of LSE configuration bits (enable, ready, divider)
Written at 1 to clear LSEPUB by secure privileged software only. It can be read by any software.

Bit 0 **LSIPUBC**: Public protection of LSI configuration bits (enable, ready, divider)
Written at 1 to clear LSIPUB by secure privileged software only. It can be read by any software.

14.10.233 RCC PLL privilege configuration clear register 1 (RCC_PRIVCFGCR1)

Address offset: 0x1794

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the PLLs. It is reset by sys_rstn and is in VCORE voltage domain. Each xxPRIV bit defines the privileged protection for the configuration registers of the PLL: a write access is denied if the access is unprivileged while the respective bit is set.

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **IC20PRIVC**: Privileged protection of IC20 configuration bits (enable, ready, divider)
Written at 1 to clear IC20PRIV by secure privileged software only. It can be read by any software.

Bit 18 **IC19PRIVC**: Privileged protection of IC19 configuration bits (enable, ready, divider)
Written at 1 to clear IC19PRIV by secure privileged software only. It can be read by any software.

Bit 17 **IC18PRIVC**: Privileged protection of IC18 configuration bits (enable, ready, divider)
Written at 1 to clear IC18PRIV by secure privileged software only. It can be read by any software.

Bit 16 **IC17PRIVC**: Privileged protection of IC17 configuration bits (enable, ready, divider)
Written at 1 to clear IC17PRIV by secure privileged software only. It can be read by any software.

Bit 15 **IC16PRIVC**: Privileged protection of IC16 configuration bits (enable, ready, divider)
Written at 1 to clear IC16PRIV by secure privileged software only. It can be read by any software.

Bit 14 **IC15PRIVC**: Privileged protection of IC15 configuration bits (enable, ready, divider)
Written at 1 to clear IC15PRIV by secure privileged software only. It can be read by any software.

Bit 13 **IC14PRIVC**: Privileged protection of IC14 configuration bits (enable, ready, divider)
Written at 1 to clear IC14PRIV by secure privileged software only. It can be read by any software.

Bit 12 **IC13PRIVC**: Privileged protection of IC13 configuration bits (enable, ready, divider)
Written at 1 to clear IC13PRIV by secure privileged software only. It can be read by any software.

Bit 11 **IC12PRIVC**: Privileged protection of IC12 configuration bits (enable, ready, divider)
Written at 1 to clear IC12PRIV by secure privileged software only. It can be read by any software.

Bit 10 **IC11PRIVC**: Privileged protection of IC11 configuration bits (enable, ready, divider)
Written at 1 to clear IC11PRIV by secure privileged software only. It can be read by any software.

Bit 9 **IC10PRIVC**: Privileged protection of IC10 configuration bits (enable, ready, divider)
Written at 1 to clear IC10PRIV by secure privileged software only. It can be read by any software.

Bit 8 **IC9PRIVC**: Privileged protection of IC9 configuration bits (enable, ready, divider)
Written at 1 to clear IC9PRIV by secure privileged software only. It can be read by any software.

Bit 7 **IC8PRIVC**: Privileged protection of IC8 configuration bits (enable, ready, divider)
Written at 1 to clear IC8PRIV by secure privileged software only. It can be read by any software.

Bit 6 **IC7PRIVC**: Privileged protection of IC7 configuration bits (enable, ready, divider)
Written at 1 to clear IC7PRIV by secure privileged software only. It can be read by any software.

Bit 5 **IC6PRIVC**: Privileged protection of IC6 configuration bits (enable, ready, divider)
Written at 1 to clear IC6PRIV by secure privileged software only. It can be read by any software.

Bit 4 **IC5PRIVC**: Privileged protection of the IC5 configuration bits (enable, ready, divider).
Written at 1 to clear IC5PRIV by secure privileged software only. It can read by any software.

Bit 3 **IC4PRIVC**: Privileged protection of the IC4 configuration bits (enable, ready, divider).
Written at 1 to clear IC4PRIV by secure privileged software only. It can read by any software.

Bit 2 **IC3PRIVC**: Privileged protection of the IC3 configuration bits (enable, ready, divider).
Written at 1 to clear IC3PRIV by secure privileged software only. It can read by any software.

Bit 1 **IC2PRIVC**: Privileged protection of the IC2 configuration bits (enable, ready, divider).
Written at 1 to clear IC2PRIV by secure privileged software only. It can read by any software.

Bit 0 **IC1PRIVC**: Privileged protection of the IC1 configuration bits (enable, ready, divider).
Written at 1 to clear IC1PRIV by secure privileged software only. It can read by any software.

14.10.236 RCC divider public configuration clear register 2 (RCC_PUBCFGCR2)

Address offset: 0x17AC

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the dividers. It is reset by sys_rstn, and is in the V_{CORE} voltage domain.Each xxPUB bit defines the public protection for the configuration registers of the divider: a write access is denied if the access is non-public while the respective bit here is set.

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RSTPUBC**: Public protection of RST configuration bits (enable, ready, divider)
Written at 1 to clear RSTPUB by secure privileged software only. It can be read by any software.

Bit 4 **INTPUBC**: Public protection of INT configuration bits (enable, ready, divider)
Written at 1 to clear INTPUB by secure privileged software only. It can be read by any software.

Bit 3 **PERPUBC**: Public protection of PER configuration bits (enable, ready, divider)
Written at 1 to clear PERPUB by secure privileged software only. It can be read by any software.

Bit 2 **BUSPUBC**: Public protection of BUS configuration bits (enable, ready, divider)
Written at 1 to clear BUSPUB by secure privileged software only. It can be read by any software.

Bit 1 **SYSPUBC**: Public protection of SYS configuration bits (enable, ready, divider)
Written at 1 to clear SYSPUB by secure privileged software only. It can be read by any software.

Bit 0 **MODPUBC**: Public protection of MOD configuration bits (enable, ready, divider)
Written at 1 to clear MODPUB by secure privileged software only. It can be read by any software.

14.10.239 RCC privilege configuration clear register 4 (RCC_PRIVCFGCR4)

Address offset: 0x17C4

Reset value: 0x0000 0000

This register is used to control the privileged access rights to the configuration register of the buses. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPRIV bit defines the privileged protection for the configuration registers of each bus: a write access is denied if the access is unprivileged while the respective bit here is set.

		w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NOCPRIVC**: Privileged protection of NOC configuration bits (enable, ready, divider)
Written at 1 to clear NOCPRIV by secure privileged software only. It can be read by any software.

Bit 12 **APB5PRIVC**: Privileged protection of APB5 configuration bits (enable, ready, divider)
Written at 1 to clear APB5PRIV by secure privileged software only. It can be read by any software.

Bit 11 **APB4PRIVC**: Privileged protection of APB4 configuration bits (enable, ready, divider)
Written at 1 to clear APB4PRIV by secure privileged software only. It can be read by any software.

Bit 10 **APB3PRIVC**: Privileged protection of APB3 configuration bits (enable, ready, divider)
Written at 1 to clear APB3PRIV by secure privileged software only. It can be read by any software.

Bit 9 **APB2PRIVC**: Privileged protection of APB2 configuration bits (enable, ready, divider)
Written at 1 to clear APB2PRIV by secure privileged software only. It can be read by any software.

Bit 8 **APB1PRIVC**: Privileged protection of APB1 configuration bits (enable, ready, divider)
Written at 1 to clear APB1PRIV by secure privileged software only. It can be read by any software.

Bit 7 **AHB5PRIVC**: Privileged protection of AHB5 configuration bits (enable, ready, divider)
Written at 1 to clear AHB5PRIV by secure privileged software only. It can be read by any software.

Bit 6 **AHB4PRIVC**: Privileged protection of AHB4 configuration bits (enable, ready, divider)
Written at 1 to clear AHB4PRIV by secure privileged software only. It can be read by any software.

Bit 5 **AHB3PRIVC**: Privileged protection of AHB3 configuration bits (enable, ready, divider)
Written at 1 to clear AHB3PRIV by secure privileged software only. It can be read by any software.

Bit 4 **AHB2PRIVC**: Privileged protection of AHB2 configuration bits (enable, ready, divider)
Written at 1 to clear AHB2PRIV by secure privileged software only. It can be read by any software.

Bit 3 **AHB1PRIVC**: Privileged protection of AHB1 configuration bits (enable, ready, divider)
Written at 1 to clear AHB1PRIV by secure privileged software only. It can be read by any software.

Bit 2 **AHBMPRIVC**: Privileged protection of AHBM configuration bits (enable, ready, divider)
Written at 1 to clear AHBMPRIV by secure privileged software only. It can be read by any software.

Bit 1 **ACLKNCPRIVC**: Privileged protection of ACLKNC configuration bits (enable, ready, divider)
Written at 1 to clear ACLKNCPRIV by secure privileged software only. It can read by any software.

Bit 0 **ACLKNPRIVC**: Privileged protection of ACLKN configuration bits (enable, ready, divider)
Written at 1 to clear ACLKNPRIV by secure privileged software only. It can read by any software.

14.10.240 RCC public configuration clear register 4 (RCC_PUBCFGCR4)

Address offset: 0x17CC

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the buses. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of each bus: a write access is denied if the access is non-public while the respective bit is set.

		w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NOCPUBC**: Public protection of NOC configuration bits (enable, ready, divider)
Written at 1 to clear NOCPUB by secure privileged software only. It can be read by any software.

Bit 12 **APB5PUBC**: Public protection of APB5 configuration bits (enable, ready, divider)
Written at 1 to clear APB5PUB by secure privileged software only. It can be read by any software.

Bit 11 **APB4PUBC**: Public protection of APB4 configuration bits (enable, ready, divider)
Written at 1 to clear APB4PUB by secure privileged software only. It can be read by any software.

Bit 10 **APB3PUBC**: Public protection of APB3 configuration bits (enable, ready, divider)
Written at 1 to clear APB3PUB by secure privileged software only. It can be read by any software.

Bit 9 **APB2PUBC**: Public protection of APB2 configuration bits (enable, ready, divider)
Written at 1 to clear APB2PUB by secure privileged software only. It can be read by any software.

Bit 8 **APB1PUBC**: Public protection of APB1 configuration bits (enable, ready, divider)
Written at 1 to clear APB1PUB by secure privileged software only. It can be read by any software.

Bit 7 **AHB5PUBC**: Public protection of AHB5 configuration bits (enable, ready, divider)
Written at 1 to clear AHB5PUB by secure privileged software only. It can be read by any software.

Bit 6 **AHB4PUBC**: Public protection of AHB4 configuration bits (enable, ready, divider)
Written at 1 to clear AHB4PUB by secure privileged software only. It can be read by any software.

Bit 5 **AHB3PUBC**: Public protection of AHB3 configuration bits (enable, ready, divider)
Written at 1 to clear AHB3PUB by secure privileged software only. It can be read by any software.

Bit 4 **AHB2PUBC**: Public protection of AHB2 configuration bits (enable, ready, divider)
Written at 1 to clear AHB2PUB by secure privileged software only. It can be read by any software.

Bit 3 **AHB1PUBC**: Public protection of AHB1 configuration bits (enable, ready, divider)
Written at 1 to clear AHB1PUB by secure privileged software only. It can be read by any software.

Bit 2 **AHBMPUBC**: Public protection of AHBM configuration bits (enable, ready, divider)
Written at 1 to clear AHBMPUB by secure privileged software only. It can be read by any software.

Bit 1 **ACLKNCPUBC**: Public protection of ACLKNC configuration bits (enable, ready, divider)
Written at 1 to clear ACLKNCPUB by secure privileged software only. It can be read by any software.

Bit 0 **ACLKNPUBC**: Public protection of ACLKN configuration bits (enable, ready, divider)
Written at 1 to clear ACLKNPUB by secure privileged software only. It can be read by any software.

14.10.241 RCC public configuration clear register 4 (RCC_PUBCFGCR5)

Address offset: 0x17D0

Reset value: 0x0000 0000

This register is used to control the public access rights to the configuration register of the SRAMs. It is reset by sys_rstn, and is in the V_{CORE} voltage domain. Each xxPUB bit defines the public protection for the configuration registers of each SRAM: a write access is denied if the access is non-public while the respective bit is set.

				w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **VENCRAMPUBC**: Public protection of VENCRAM configuration bits (enable, ready, divider)
This bit is written to 1 to clear VENCRAMPUB by secure privileged software only. It can be read by any software.

Bit 10 **CACHEAXIRAMPUBC**: Public protection of CACHEAXIRAM configuration bits (enable, ready, divider)
This bit is written to 1 to clear CACHEEXIRAMPUB by secure privileged software only. It can be read by any software.

Bit 9 **FLEXRAMPUBC**: Public protection of FLEXRAM configuration bits (enable, ready, divider)
This bit is written to 1 to clear FLEXRAMPUB by secure privileged software only. It can be read by any software.

Bit 8 **AXISRAM2PUBC**: Public protection of AXISRAM2 configuration bits (enable, ready, divider)
This bit is written to 1 to clear AXISRAM2PUB by secure privileged software only. It can be read by any software.

Bit 7 **AXISRAM1PUBC**: Public protection of AXISRAM1 configuration bits (enable, ready, divider)
This bit is written to 1 to clear AXISRAM1PUB by secure privileged software only. It can be read by any software.

Bit 6 **BKPSRAMPUBC**: Public protection of BKPSRAM configuration bits (enable, ready, divider)
This bit is written to 1 to clear BKPSRAMPUB by secure privileged software only. It can be read by any software.

Bit 5 **AHBSRAM2PUBC**: Public protection of AHBSRAM2 configuration bits (enable, ready, divider)
This bit is written to 1 to clear AHBSRAM2PUB by secure privileged software only. It can be read by any software.

Bit 4 **AHBSRAM1PUBC**: Public protection of AHBSRAM1 configuration bits (enable, ready, divider)
This bit is written to 1 to clear AHBSRAM1PUB by secure privileged software only. It can be read by any software.

Bit 3 **AXISRAM6PUBC**: Public protection of AXISRAM6 configuration bits (enable, ready, divider)
This bit is written to 1 to clear AXISRAM6PUB by secure privileged software only. It can be read by any software.

Bit 2 **AXISRAM5PUBC**: Public protection of AXISRAM5 configuration bits (enable, ready, divider)
Written at 1 to clear AXISRAM5PUB by secure privileged software only. It can be read by any software.

Bit 1 **AXISRAM4PUBC**: Public protection of AXISRAM4 configuration bits (enable, ready, divider)
Written at 1 to clear AXISRAM4PUB by secure privileged software only. It can be read by any software.

Bit 0 **AXISRAM3PUBC**: Public protection of AXISRAM3 configuration bits (enable, ready, divider)
Written at 1 to clear AXISRAM3PUB by secure privileged software only. It can be read by any software.

15 General-purpose I/Os (GPIO)

15.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16-bit reset register (GPIOx_BRR), and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two couples of 32-bit advanced configuration registers (GPIOx_DELAYRL/H, GPIOx_ADVCFGRL/H), and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

Access to each general-purpose I/O configuration bit can be restricted to secure-only and/or privileged-only.

15.2 GPIO main features

- Multiple choice of configurations per I/O port:
  - Input configuration in floating, pull-up/down, or analog state
  - Analog configuration (output buffer and Schmitt trigger input disabled)
  - Output configuration, or alternate function configuration, in push-pull or open drain state, with pull-up or pull-down activated
- Data present on the I/O pin sampled to the input data register GPIOx_IDR (input configuration) or to the peripheral (alternate function configuration)
- Output buffer on the I/O pin driven by the output data register GPIOx_ODR (output configuration) or by the peripheral (alternate function configuration)
- I/O data output atomic read/modify through GPIOx_ BSRR and GPIOx_BRR
- Speed selection for each I/O (GPIOx_OSPEEDR)
- Lock mechanism (GPIOx_LCKR) to selectively freeze the I/O port configurations
- Highly-flexible pin multiplexing, enabling the use of I/O pins as GPIOs, or as one of several possible peripheral functions
- Programmable delay to the input or the output path (GPIOx_DELAYR)
- Double edge selection, clock inversion, and optional retime (GPIOx_ADVCFGR)
- Possibility to restrict each I/O control to secure-only and/or privileged-only

15.3 GPIO functional description

The specific hardware characteristics of each I/O port are detailed in the datasheet.

Each port bit of the GPIO ports can be individually configured by software in several modes:

- input floating
- input pull-up
- input-pull-down
- analog
- output open-drain with pull-up or pull-down capability

- output push-pull with pull-up or pull-down capability
- alternate function push-pull with pull-up or pull-down capability
- alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words, or bytes. GPIOx_BSRR and GPIOx_BRR allow atomic read/modify accesses to any of GPIOx_ODR. In this way, there is no risk of IRQ occurring between the read and the modify access.

Figure 65 shows the basic structure of a standard I/O port bit.

Figure 65. Basic structure of an I/O port bit

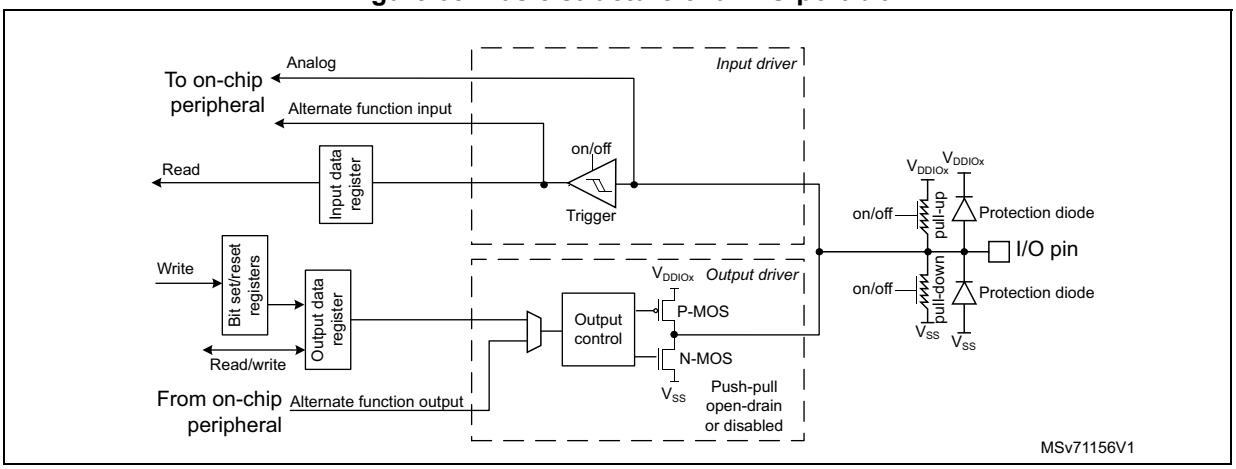

Table 79 gives the possible port bit configurations.

Table 79. Port x bit configurations

Port x bit configurations					I/O configuration(1)	
MODEx[1:0]	OTx	OSPEEDx[1:0]	PUPDx[1:0]			
01	0	SPEED[1:0]	0	0	GP output	PP
			0	1		PP + PU
			1	0		PP + PD
			1	1	Reserved (GP output PP)	
	1		0	0	GP output (open drain)	OD
			0	1		OD + PU
			1	0		OD + PD
			1	1	Reserved (GP output OD)	

Table 79. Port x bit configurations (continued)

Port x bit configurations						I/O configuration(1)	
MODEx[1:0]	OTx	OSPEEDx[1:0]		PUPDx[1:0]			
10	0	SPEED[1:0]		0	0	AF	PP
				0	1		PP + PU
				1	0		PP + PD
				1	1	Reserved (AF PP)	
	1			0	0	AF (open drain)	OD
				0	1		OD + PU
				1	0		OD + PD
				1	1	Reserved (AF OD)	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1		PU
	x	x	x	1	0		PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1		Analog
	x	x	x	1	0		Analog + PD
	x	x	x	1	1		Analog

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

15.3.1 General-purpose I/O (GPIO)

During and just after reset, AFs (alternate functions) are not active, and most of the I/O ports are configured in analog mode, as defined through GPIOx_MODER register.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB5: JTDO/TRACESWO in floating state no pull-up/pull-down

When the pin is configured as output, the value written to GPIOx_ODR is output on the I/O pin. The output driver can be used in push-pull mode or open-drain mode (only the low level is driven, high level is Hi-Z).

GPIOx_IDR captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, that can be activated or not, depending on the value in GPIOx_PUPDR.

15.3.2 I/O pin AF multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer used to connect only one peripheral AF to an I/O pin at a time. There is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 AF inputs (AF0 to AF15), which can be configured through GPIOx_AFRL (for pins 0 to 7) and GPIOx_AFRH (for pins 8 to 15):

- During and just after reset, AFs are not active and most of the I/O ports are configured in analog mode, as defined through GPIOx_MODER. When one AF is active, AF0 is selected by default.
- Specific AF assignments for each I/O pin are detailed in the device datasheet.

This flexible I/O multiplexing architecture is used to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user must proceed as follows:

- Debug function: after each device reset, these pins are assigned as AF pins immediately usable by the debugger host.
- GPIO modes: the desired I/O is configured as output, input, or analog in GPIOx_MODER.
- Peripheral AF:
  - For a given peripheral function, the ‘Alternate functions’ table in the datasheet helps to identify the AF to use with a given I/O. One of GPIOx_AFRL or GPIOx_AFRH must be used.
  - Configure the desired I/O as an AF in GPIOx_MODER. Select the type, pull-up/pull-down, and output speed via GPIOx_OTYPER, GPIOx_PUPDR, and GPIOx_OSPEEDR respectively.
- Cortex®-M55 alternate function (EVENTOUT)
  - The output EVENTOUT signal can be used by configuring the I/O pin to output at AF15. An event can be signaled through the configured pin after executing SEV instruction.
  - EVENTOUT signal can be used internally as a trigger for some peripherals (see *Section 17: Peripherals interconnect matrix*)
- Additional functions:
  - The additional functions listed in the datasheet give the peripheral functions that directly select/enable its allocated I/O port(s). Typical peripherals are RTC/TAMP, PWR (WKUPx pins), or RCC (oscillator pins). These functions have priority over the configuration in standard GPIO registers.
  - For ADCs, configure the desired I/O in analog mode in GPIOx_MODER, and configure the required function in ADC registers.

15.3.3 I/O port control registers

Each GPIO port has four 32-bit memory-mapped control registers to configure up to 16 I/Os:

- GPIOx_MODER is used to select the I/O mode (input, output, AF, analog).
- GPIOx_OTYPER and GPIOx_OSPEEDR are respectively used to select the output type (push-pull or open-drain) and the speed.
- GPIOx_PUPDR is used to select the pull-up/pull-down whatever the I/O direction.

15.3.4 I/O port data registers

Each GPIO port has two 16-bit memory-mapped data registers: GPIOx_ODR. These read/writable register store the data to be output per I/O. Data input through each I/O are stored into read-only GPIOx_IDR.

15.3.5 I/O data bitwise handling

GPIOx_BSRR is a 32-bit register that allows the application to set/reset each individual bit in GPIOx_ODR). GPIOx_BSRR has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i). When written to 1, BR(i) resets the corresponding ODR(i).

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using GPIOx_BSRR to change the values of individual bits in GPIOx_ODR is a one-shot effect that does not lock GPIOx_ODR bits: these bits can always be accessed directly. GPIOx_BSRR provides a way of performing atomic bitwise handling.

The software does not need to disable interrupts when programming GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

15.3.6 GPIO locking mechanism

GPIO control registers can be frozen by applying a specific write sequence to GPIOx_LCKR. Indeed, each GPIOx_LCKR bit freezes the corresponding bit in the IO ports control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_DELAYRL/H, GPIOx_ADVCFGR, and GPIOx_AFRL/H).

To write GPIOx_LCKR, a specific write/read sequence must be applied. When the right lock sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same, during the write sequence, only the IOs for which LCKR[15:0] stays to 1 for all the specific write sequence are locked; other IOs configuration are not (lock sequence aborted). When the lock sequence is applied to a port bit, the value of the port bit can no longer be modified until a next device or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_DELAYRL/H, GPIOx_ADVCFGR, and GPIOx_AFRL/H).

The LOCK sequence can be performed only using a word (32-bit long) access to GPIOx_LCKR, because GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

Note: A lock sequence aborts in the event of an AHB bus error (see Section 15.1), or insufficient access rights (see Section 15.3.16).

A lock sequence automatically suspends when accessing a different register from GPIOx_LCKR. It resumes with the next access to GPIOx_LCKR.

15.3.7 I/O AF input/output

Two registers are provided to select one of the AF inputs/outputs available for each I/O: GPIOx_AFRL and GPIOx_AFRH. With these registers, the user can connect an AF to some other pin, as required by the application.

A number of possible peripheral functions are multiplexed on each GPIO using these registers. The application can select any one of the possible functions for each I/O. As the AF selection signal is common to the AF input and output, a single channel is selected for the AF input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the datasheet.

15.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the ports can be configured in input, output, or AF mode (the ports must not be configured in analog mode). Refer to *Section 25: Extended interrupts and event controller (EXTI)* for more details.

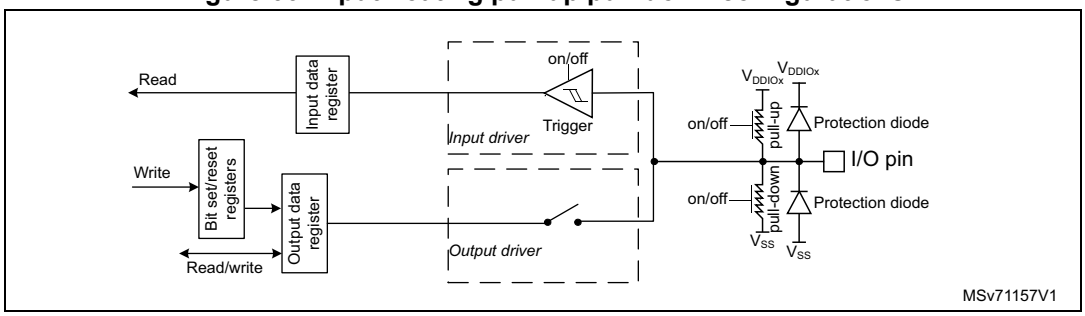
15.3.9 Input configuration

When the I/O port is programmed as input:

- the output buffer is disabled
- the Schmitt trigger input is activated
- the pull-up and pull-down resistors are activated, depending on the value in GPIOx_PUPDR.
- data present on the I/O pin are sampled into the input data register every AHB clock cycle
- a read access to the input data register provides the I/O state

Figure 66 shows the input configuration of the I/O port bit.

Figure 66. Input floating/pull-up/pull-down configurations



15.3.10 Output configuration

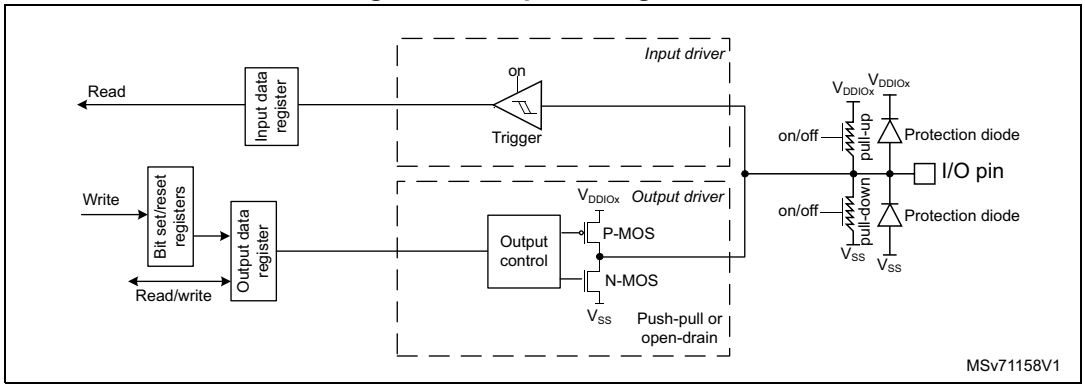
When the I/O port is programmed as output:

- The output buffer is enabled:
  - open-drain mode: a 0 in the output register activates the N-MOS, whereas a 1 in the output register leaves the port in Hi-Z (P-MOS never activated).
  - push-pull mode: a 0 in the output register activates the N-MOS, whereas a 1 in the output register activates the P-MOS.

- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in GPIOx_PUPDR.
- Data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

Figure 67 shows the output configuration of the I/O port bit.

Figure 67. Output configuration



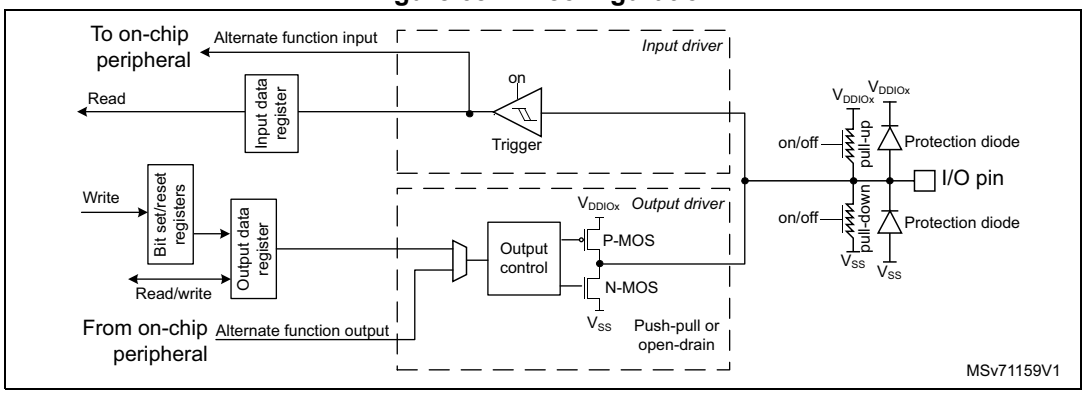
15.3.11 AF configuration

When the I/O port is programmed as AF:

- the output buffer can be configured in open-drain or push-pull mode
- the output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- the Schmitt trigger input is activated
- the weak pull-up and pull-down resistors are activated or not, depending on the value in GPIOx_PUPDR
- data present on the I/O pin are sampled into the input data register every AHB clock cycle
- aread access to the input data register gets the I/O state.

Figure 68 shows the AF configuration of the I/O port bit.

Figure 68. AF configuration



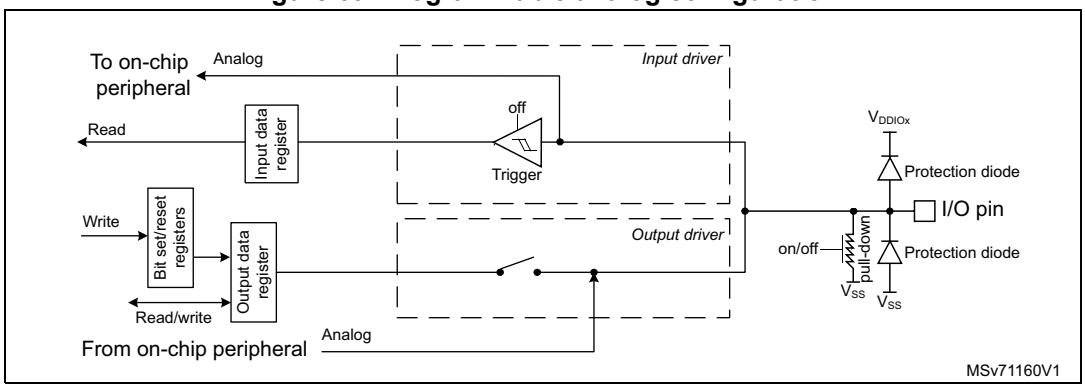
15.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up resistor is disabled by hardware. The weak pull-down resistor is activated or not, depending on the value in GPIOx_PUPDR.
- Read access to the input data register gets the value 0.

Figure 69 shows the programmable, analog-input configuration of the I/O port bits.

Figure 69. Programmable analog configuration



ADC analog configuration

The ADC voltage is 1.8 V. Refer to the product datasheet for more details on the allowed voltage on ADC input pins.

Warning: Permanent damage to the ADC can occur if the voltage on input pins exceeds 1.8 V.

15.3.13 Using HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs, but only in input mode (output mode is not supported).

When the HSE or LSE oscillator is switched on (HSEON or LSEON set in RCC_CSR), the oscillator takes control of its associated pins, and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input (OSC_OUT or OSC32_OUT pins can still be used, in input mode only).

15.3.14 Using GPIO pins in V_{SW} supply domain

The functionality of PC13, PC14, PC15, and PQ7 GPIOs is lost when the core supply domain is powered off (the device enters Standby mode). If their GPIO configuration is not bypassed by the RTC/TAMP configuration or by the RCC (LSE), these pins are set in analog input mode.

For details about I/O control by the RTC, refer to *Section 61.3: RTC functional description*.

15.3.15 Advanced I/O configurations

I/O compensation cell

The I/O commutation slew rate (t_{fall}/t_{rise}) can be adapted by software depending on process, voltage, and temperature conditions, to reduce the I/O noise on the power supply. Refer to *Section 16: System configuration controller (SYSCFG)* for more details.

Input/output path configurable delay

A delay programmed in GPIOx_DELAYRL/H can be applied to either input or output path, based on DLYPATH in GPIOx_ADVCFGRL/R.

Input/output data double edge selection

Input and output data can be managed as single- or double-edge, according to DE in GPIOx_ADVCFGRL/R.

Input/output data retiming

When RET is set in GPIOx_ADVCFGRL/R, input and output data are retimed to either rising or falling clock edge, depending upon INVCLK value.

15.3.16 I/O pin isolation using TrustZone

As TrustZone-aware peripheral, each I/O pin of GPIO port x can be individually configured as secure through GPIOx_SECCFGR. After reset, all GPIO ports are secure.

The I/Os connected to peripheral functions can be conditioned by the peripheral security configuration:

- Peripherals for which the I/O pin selection is done through GPIOx_AFRL/H

  If the peripheral is configured as secure, it cannot be connected to a nonsecure I/O pin. If this is not respected, input data to the secure peripheral are forced to 0 (I/O input pin value ignored), and the output pin value is forced to 0, thus avoiding any secure

information leak through nonsecure I/Os. TrustZone-aware logic around GPIO ports is summarized in *Table 80*.

- Peripherals (like ADC) with embedded analog functions that directly select/enable its allocated I/O ports using analog switches

  If the I/O is secure, this analog switch cannot be controlled by a nonsecure peripheral. If the peripheral is configured as nonsecure and the I/O is secure, the switch remains open. This prevents the redirection of secure data to a nonsecure peripheral or I/O through analog path. Refer to *Section 3: System security* for the list of peripherals using this security.
- The list of I/Os without a hardware protection linked to TrustZone is given in *Section 3: System security*. More specifically, the listed signals (input and/or outputs) are not blocked when the I/O is set as secure, and the associated peripheral is non secure. For each of these listed I/Os, a secure application must decide if a potential effect on data integrity or confidentiality is critical or not.

Refer to the pins definitions table in the datasheet for more information about AFs and additional functions mapping.

Table 80. Secure AF between peripherals and allocated I/Os

Security configuration		AF logic		Comment
Peripheral	**Allocated I/O pin**	**Input**	**Output**	
Secure	Secure	I/O data	Peripheral data	-
Nonsecure				Out of reset configuration
Secure	Nonsecure	Zero	Zero	-
Nonsecure		I/O data	Peripheral data	

Table 81 gives a summary of the I/O port y secured bits, following the setting of SECy in GPIOx_SECCFGR. The following is valid for each register in the table:

- When a bit is secured, read/write operations are only allowed by a secure access. Non-secure read or write accesses on secured bits are RAZ/WI, with no illegal access event generated.
- When a bit is nonsecure, there is no TrustZone restriction. Read/write operations are allowed by both secure and nonsecure accesses.

Table 81. GPIO secured bits

Secured bitfield(s)	Register name	Nonsecure access on secure bits
MODEy[1:0]	GPIOx_MODER	RAZ/WI
OTy	GPIOx_OTYPER	
OSPEEDy[1:0]	GPIOx_OSPEEDR	
PUPDy[1:0]	GPIOx_PUPDR	
IDy	GPIOx_IDR	
ODy	GPIOx_ODR	
BSy and BRy	GPIOx_BSRR	

Table 81. GPIO secured bits (continued)

Secured bitfield(s)	Register name	Nonsecure access on secure bits
BRy	GPIOx_BRR	RAZ/WI
LCKy	GPIOx_LCKR	
AFSELy[3:0]	GPIOx_AFRH	
	GPIOx_AFRL	
DELAYy[3:0]	GPIOx_DELAYRL	
	GPIOx_DELAYRH	
RETy, INVCLKy, DEy, and DLYPATHy	GPIOx_ADVCFGRL	
	GPIOx_ADVCFGRH	

Note: GPIOx_SECCFGR is readable by any application. Each bit in this register is write-locked until the next device reset, when setting the corresponding bit in GPIOx_RCFGLOCKR.

15.3.17 I/O pin isolation using privilege

As RIF-aware peripheral, each I/O pin of GPIO port x can be individually configured as privileged through GPIOx_PRIVCFGR. After reset, all GPIO registers can be read and written by privileged and unprivileged accesses, if security is enough and the CPU is allowed.

Table 81 gives a summary of the I/O port y protected bits, following the setting of PRIVy in GPIOx_PRIVCFGR. The following is valid for each register in the table:

- When a bit is privileged, read/write operations are only allowed by a privileged access. Unprivileged read or write accesses on privileged bits are RAZ/WI, with no illegal access event generated.
- When a bit is unprivileged, there is no privilege restriction. Read and write operations are allowed by both privileged and unprivileged accesses.

Note: GPIOx_PRIVCFGR is readable by any application, writable by only privileged applications. Each bit in GPIOx_PRIVCFGR is write locked until next device reset, when setting the corresponding bit in GPIOx_RCFGLOCKR.

15.4 GPIO registers

GPIO registers are accessible through 32-bit word, half-word, or byte single access. Double-word and instruction fetch accesses trigger an AHB bus error. Byte or half-word writes to GPIOx_LCKR are silently ignored (no bus error).

15.4.1 GPIO port x mode register (GPIOx_MODER) (x = A to H, N to Q)

Address offset:0x00

Reset value: Port A: 0xABFF EFFF

Reset value: Port B: 0xFFFF FAFF

Reset value: 0xFFFF FFFF (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODE15[1:0]		MODE14[1:0]		MODE13[1:0]		MODE12[1:0]		MODE11[1:0]		MODE10[1:0]		MODE9[1:0]		MODE8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODE7[1:0]		MODE6[1:0]		MODE5[1:0]		MODE4[1:0]		MODE3[1:0]		MODE2[1:0]		MODE1[1:0]		MODE0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MODEy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O mode.

00: General-purpose input mode

01: General-purpose output mode

10: Alternate function mode (refer to device datasheet for available options)

11: Analog mode (reset state)

Note: Each bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to MODEy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.2 GPIO port x output type register (GPIOx_OTYPER) (x =A to H, N to Q)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OT15	OT14	OT13	OT12	OT11	OT10	OT9	OT8	OT7	OT6	OT5	OT4	OT3	OT2	OT1	OT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output type.

0: Output push-pull (reset state)

1: Output open-drain

Note: Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to OTy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.3 GPIO port x output speed register (GPIOx_OSPEEDR) (x =A to H, N to Q)

Address offset: 0x08

Reset value: Port A: 0x0C00 0000

Reset value: Port B: 0x0000 0C00

Reset value: 0x0000 0000 (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEED15[1:0]		OSPEED14[1:0]		OSPEED13[1:0]		OSPEED12[1:0]		OSPEED11[1:0]		OSPEED10[1:0]		OSPEED9[1:0]		OSPEED8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDy[1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very high speed

Note: Refer to the device datasheet for frequency specifications, power supply, and load conditions for each speed. Each bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to OSPEEDy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.4 GPIO port x pull-up/pull-down register (GPIOx_PUPDR) (x= A to H, N to Q)

Address offset: 0x0C

Reset value: Port A: 0x6400 0000

Reset value: Port B: 0x0000 0100

Reset value: 0x0000 0000 (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PUPD15[1:0]		PUPD14[1:0]		PUPD13[1:0]		PUPD12[1:0]		PUPD11[1:0]		PUPD10[1:0]		PUPD9[1:0]		PUPD8[1:0]

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

Note: Each bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to PUPDy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.5 GPIO port x input data register (GPIOx_IDR) (x = A to H, N to Q)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Port x input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

Note: Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read to IDy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.6 GPIO port x output data register (GPIOx_ODR) (x = A to H, N to Q)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Port x output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, OD bits can be individually set and/or reset by writing to GPIOx_BSRR or GPIOx_BRR. Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to ODy must be secure if SECy= 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.7 GPIO port x bit set/reset register (GPIOx_BSRR) (x = A to H, N to Q)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns 0x0000.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful write to BRy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

Bits 15:0 **BSy:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns 0x0000.

0: No action on the corresponding ODx bit

1: Sets the corresponding ODx bit

Note: Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful write to BSy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.8 GPIO port x configuration lock register (GPIOx_LCKR) (x = A to H, N to Q)

Address offset: 0x1C

Reset value: 0x0000 0000

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the GPIO configuration. During the lock sequence, only bit port unlock can be changed.

Note: Only word access (32-bit long) is allowed during this locking sequence.

Byte or half-word writes are silently ignored (no bus error, no abort to lock sequence).

When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset. Each lock bit freezes a specific configuration register (control and AF registers). See *Section 15.3.6* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

Lock key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]

WR LCKR[16] = 0 + LCKR[15:0]

WR LCKR[16] = 1 + LCKR[15:0]

RD LCKR

RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: Any error in the sequence aborts the lock. After the first lock sequence on any bit of the port, any read access on LCKK bit returns 1 until the next device or peripheral reset.

Bits 15:0 **LCKy:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when LCKK = 0.

0: Port configuration not locked

1: Port configuration locked

Note: Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to LCKy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.9 GPIO port x AF low register (GPIOx_AFRL) (x = A to H, N to Q)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:0 **AFSELy[3:0]:** AF selection for port x I/O pin y (y = 15 to 8)

These bits are written by software to configure AF I/Os (see GPIOx_AFRL for details).

Note: Each bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to the bitfield AFRHy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.11 GPIO port x bit reset register (GPIOx_BRR) (x = A to H, N to Q)

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BRy:** Port x reset IO pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns 0x0000.

0: No action on the corresponding ODx bit

1: Reset the corresponding ODx bit

Note: Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful write to BRy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.12 GPIO port x secure configuration register (GPIOx_SECCFGR) (x = A to H, N to Q)

Address offset: 0x30

Reset value: Port A: 0x0000 FFFF

Reset value: Port B: 0x0000 FFFF

Reset value: Port C: 0x0000 FFFF

Reset value: Port D: 0x0000 FFFF

Reset value: Port E: 0x0000 FFFF

Reset value: Port F: 0x0000 FFFF

Reset value: Port G: 0x0000 FFFF

Reset value: Port H: 0x0000 03FF

Reset value: Port N: 0x0000 1FFF

Reset value: Port O: 0x0000 003F

Reset value: Port P: 0x0000 FFFF

Reset value: Port Q: 0x0000 00FF

This register is used to configure a selected I/O as secure. Nonsecure or unprivileged writes to this register are ignored, while any read is allowed.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SECy**: I/O pin y of Port x security configuration (y = 15 to 0)

0: The I/O pin y is nonsecure. Secure access is also possible.

1: The I/O pin y is secure (see *Table 81* for all corresponding secure bits).

Note: Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

15.4.13 GPIO port x privileged configuration register (GPIOx_PRIVCFGR) (x = A to H, N to Q)

Address offset: 0x34

Reset value: Port A: 0x0000 FFFF

Reset value: Port B: 0x0000 FFFF

Reset value: Port C: 0x0000 FFFF

Reset value: Port D: 0x0000 FFFF

Reset value: Port E: 0x0000 FFFF

Reset value: Port F: 0x0000 FFFF

Reset value: Port G: 0x0000 FFFF

Reset value: Port H: 0x0000 03FF

Reset value: Port N: 0x0000 1FFF

Reset value: Port O: 0x0000 003F

Reset value: Port P: 0x0000 FFFF

Reset value: Port Q: 0x0000 00FF

Unprivileged writes to this register are ignored, while any read is allowed.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PRIVy**: I/O pin y of Port x privilege configuration (y = 15 to 0)

0: The I/O pin y is unprivileged. Privileged access is also possible.

1: The I/O pin y is privileged only (see *Table 81* for all corresponding protected bits).

If the corresponding SECy = 1 in GPIOx_SECCFGR, PRIVy can only be written by a secure privileged application.

Note: Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

15.4.14 GPIO port x resource configuration lock register (GPIOx_RCFGLOCKR) (x = A to H, N to Q)

Address offset: 0x38

Reset value: 0x0000 0000

Secure privileged write access only. Write only by trusted domain CID. Any read access is allowed on this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RLOCKy**: I/O pin y of port x resource lock (y = 15 to 0)

This bit is set to lock this I/O resource. It is cleared by default, and once set, it cannot be cleared until the GPIOx is reset.

0: SECy in GPIOx_SECCFGR and PRIVy in GPIOx_PRIVCFGR are writable.

1: Writes to SECy in GPIOx_SECCFGR and PRIVy in GPIOx_PRIVCFGR are ignored.

Note: Each bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

15.4.15 GPIO port x delay low register (GPIOx_DELAYRL) (x = A to H, N to Q)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DLY7[3:0]				DLY6[3:0]				DLY5[3:0]				DLY4[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DLY3[3:0]				DLY2[3:0]				DLY1[3:0]				DLY0[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DLYy[3:0]:** Port x IO pin y delay setup (y = 7 to 0)

Configure delay applied to the input (data IN from the pin) or the output path (data OUT to the pin), depending on the value of the corresponding DLYPATHy in GPIOx_ADVCFGRL.

0000: No delay
0001: Delay 0.3 ns
0010: Delay 0.5 ns
0011: Delay 0.75 ns
0100: Delay 1.0 ns
0101: Delay 1.25 ns
0110: Delay 1.5 ns
0111: Delay 1.75 ns
1000: Delay 2.0 ns
1001: Delay 2.25 ns
1010: Delay 2.5 ns
1011: Delay 2.75 ns
1100: Delay 3.0 ns
1101: Delay 3.25 ns
1110 to 1111: Delay 3.25 ns (maximum)

Note: Each bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to DELAYy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.16 GPIO port x delay high register (GPIOx_DELAYRH) (x = A to H, N to Q)

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DLY11[3:0]				DLY10[3:0]				DLY9[3:0]				DLY8[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DLYy[3:0]:** Port x I/O pin y delay setup (y = 15 to 8)

Configure delay on input or output data prior to retiming (see GPIOx_DELAYRL for details).

Note: Each bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Successful read or write to DELAYy must be secure if SECy = 1 in GPIOx_SECCFGR, and must be privileged if PRIVy = 1 in GPIOx_PRIVCFGR.

15.4.17 GPIO port x advanced configuration low register (GPIOx_ADVCFGRL) (x = A to H, N to Q)

Address offset: 0x48

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31, 27, 23, 19, 15, 11, 7, 3 **RETy:** Data retime selection (y = 7 to 0)
0: Input and output data are not synchronized or retimed on clock edges.
1: Input and output data are retimed to rising or falling clock edge, depending upon value of INVCLKy.

Bits 30, 26, 22, 18, 14, 10, 6, 2 **INVCLKy:** Clock inversion selection (y = 7 to 0)
0: I/O clocks are not inverted. Input and output data are retimed to rising clock edge.
1: I/O clocks are inverted. Input and output data are retimed to falling clock edge

Bits 29, 25, 21, 17, 13, 9, 5, 1 **DEy:** Input/Output data double edge selection (cfg_double_edge) (y = 7 to 0)
0: Input and output data is single-edge (changing on rising or falling clock edge, but not both)
1: Input and output data is double-edge (changing on both rising and falling clock edges)

Bits 28, 24, 20, 16, 12, 8, 4, 0 **DLYPATHy:** Clock inversion selection (y = 7 to 0)
Controls which path contains the configurable delay, input or output
0: Delay is switched into the output path, while the input path is set as pass through.
1: Delay is switched into the input path, while the output path is set as pass through.

15.4.18 GPIO port x advanced configuration high register (GPIOx_ADVCFGRH) (x =A to H, N to Q)

Address offset: 0x4C

Reset value: 0x0000 0000

Refer to *Section 2.3* for the register boundary addresses.

16 System configuration controller (SYSCFG)

STM32N6x7xx devices feature a set of configuration registers. The SYSCFG manages:

- Cortex-M55 internal settings (such as TCM, CACHE, or vectors)
- interconnect, security, and memory settings
- compensation cells

16.0.1 I/O compensation cell

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), that depends on PVT operating conditions (process, voltage, temperature).

These bits are used to control the current slew-rate and output impedance in the I/O buffer. Five compensation cells are embedded: one for I/Os supplied by V_{DD}, and four for I/Os supplied by V_{DDIO2},V_{DDIO3},V_{DDIO4}, and V_{DDIO5}.

By default, the compensation cells are disabled, and a fixed code is applied to all I/Os.

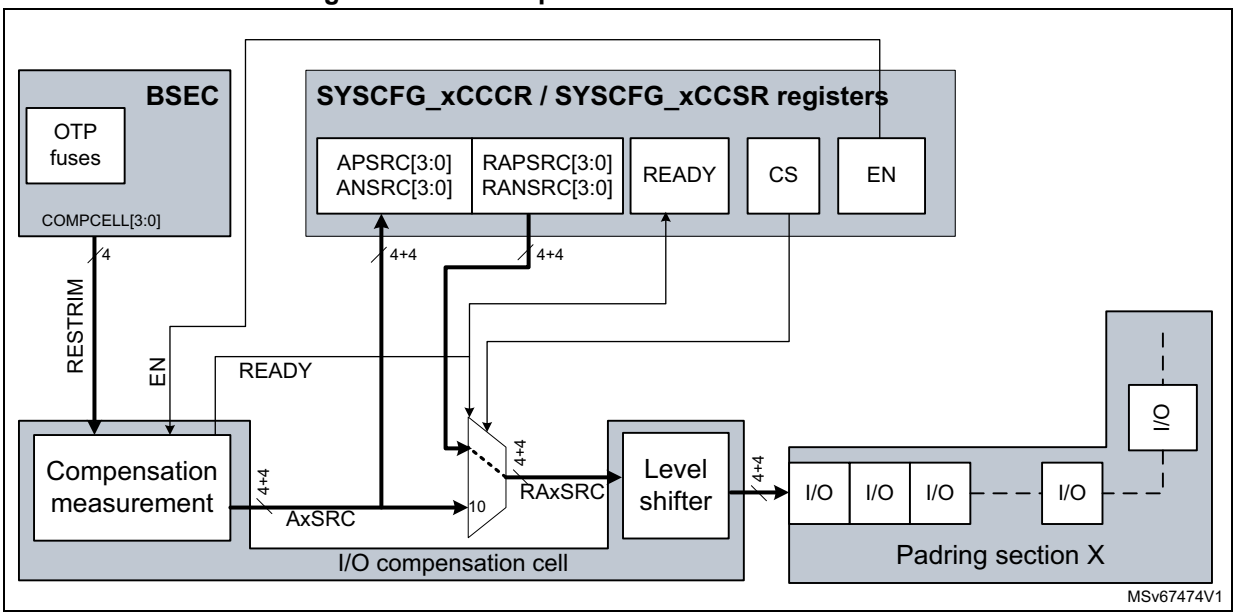
When enabled, the compensation cell tracks the PVT, and the 4-bit APSRC and ANSRC values are available in SYSCFG_xCCSR (with x = V_{DD}, V_{DDIO2}, V_{DDIO3}, V_{DDIO4}, or V_{DDIO5}) once the corresponding READY is set in SYSCFG_xCCSR.

If CS is cleared in SYSCFG_xCCCR, and READY is set, I/Os receive the APSRC and ANSRC values that result from the compensation cell.

To optimize the trimming, these values can be adjusted using RAPSRC and RANSRC in SYSCFG_xCCCR (see *Figure 70*).

To reduce the power consumption, it is recommended to copy the values from SYSCFG_xCCSR to SYSCFG_xCCCR. When the result is ready, set CS and disable the compensation cell.

Figure 70. I/O compensation cell control overview



16.1 SYSCFG registers

16.1.1 SYSCFG boot pin control register (SYSCFG_BOOTCR)

Address offset: 0x000

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOT1_PD	BOOT0_PD
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **BOOT1_PD**: BOOT1 pin pull-down disable
This is used to save power when BOOT1 pin is connected to VDD.
0:Pull-down enabled. The BOOT1 pin can be left open and takes a value of 0 if open.
1: Pull-down disabled. The BOOT1 pin must not be left open.

Bit 0 **BOOT0_PD**: BOOT0 pin pull-down disable
This is used to save power when BOOT0 pin is connected to VDD.
0: Pull-down enabled. The BOOT0 pin can be left open and takes a value of 0 if open.
1: Pull-down disabled. The BOOT0 pin must not be left open.

16.1.2 SYSCFG Cortex-M55 control register (SYSCFG_CM55CR)

Address offset: 0x004

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKDCAIC	LOCKSAU	LOCKNSMPU	LOCKSMPU	LOCKNSVTOR	LOCKSVTAIRCR
										rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPU_IT_EN[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **LOCKDCAIC**: Disable access to the instruction cache direct cache access registers DCAICLR and DCAICRR.

Bit 20 **LOCKSAU**: Prevent changes to secure SAU memory regions already programmed.

Bit 19 **LOCKNSMPU**: Prevent changes to nonsecure MPU memory regions already programmed.

Bit 18 **LOCKSMPU**: Prevent changes to programmed secure MPU memory regions.

Bit 17 **LOCKNSVTOR**: Prevent changes to the nonsecure vector table base address.

Bit 16 **LOCKSVTAIRCR**: Prevent changes to:
- the secure vector table base address
- handling of secure interrupt priority
- BusFault, HardFault, and NMI security target settings in the processor

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **FPU_IT_EN[5:0]**: Enable FPU exception
bit 5: Input abnormal interrupt enable
bit 4: Inexact interrupt enable
bit 3: Underflow operation interrupt enable
bit 2: Overflow interrupt enable
bit 1: Divide-by-zero interrupt enable
bit 0: Invalid operation interrupt enable

16.1.3 SYSCFG Cortex-M55 TCM control register (SYSCFG_CM55TCMCR)

Address offset: 0x008

Reset value: 0x0000 0087

Reset on pwr_vsw_rstn.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTCMWSDISABLE	ITCMWSDISABLE	Res.	Res.	Res.	Res.	LOCKDTGU	LOCKITGU	LOCKTCM
							rw	rw					rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CFGDTCMSZ[3:0]				CFGITCMSZ[3:0]			
								rwo	rwo	rwo	rwo	rwo	rwo	rwo	rwo

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DTCMWSDISABLE**: Disable wait-state applied by default on extended DTCM memory.

Bit 23 **ITCMWSDISABLE**: Disable wait-state applied by default on extended ITCM memory.

Bits 22:19 Reserved, must be kept at reset value.

Bit 18 **LOCKDTGU**: Disable writes to registers associated with the DTCM interface security gating.

Bit 17 **LOCKITGU**: Disable writes to registers associated with the ITCM interface security gating.

Bit 16 **LOCKTCM**: Disable writes to registers associated with the TCM region

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:4 **CFGDTCMSZ[3:0]**: Select DTCM memory size
0x8: 128 Kbytes (default value)
0x9: 256 Kbytes
Others: Reserved

Bits 3:0 **CFGITCMSZ[3:0]**: Select ITCM memory size
0x7: 64 Kbytes (default value)
0x8: 128 Kbytes
0x9: 256 Kbytes
Others: Reserved

Note: CFGDTCMSZ and CFGITCMSZ must be written in the same data access, because they are write-once bitfields locked together. Writing only one of them blocks write-access to the other up to the next power-on reset.

16.1.4 SYSCFG Cortex-CM55 memory RW margin register (SYSCFG_CM55RWMCR)

Address offset: 0x00C

Reset value: 0x0000 1020

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	BC2_CACHE	BC1_CACHE	RM_CACHE[3:0]				RME_CACHE	BC2_TCM	BC1_TCM	RM_TCM[3:0]				RME_TCM
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **BC2_CACHE**: Biasing level adjust input recommended for Vnom + 10%
Its setting gives a higher value of rise on V_{SS}-core voltage to give enough head room for retention.

Bit 12 **BC1_CACHE**: Biasing level adjust input recommended for Vnom.
Its setting gives a smaller value of rise on V_{SS}-core voltage to give enough head room for retention.

Bits 11:8 **RM_CACHE[3:0]**: External read/write (RW) margin inputs for caches memories

Bit 7 **RME_CACHE**: RW margin enable input for caches memories
0: Default RW margin settings
1: Use external pin RW margin setting

Bit 6 **BC2_TCM**: Biasing level adjust input recommended for Vnom + 10%
Its setting gives a higher value of rise on V_{SS}-core voltage to give enough head room for retention.

Bit 5 **BC1_TCM**: Biasing level adjust input recommended for Vnom
Its setting gives a smaller value of rise on V_{SS}-core voltage to give enough head room for retention.

Bits 4:1 **RM_TCM[3:0]**: External RW margin inputs for TCM memories

Bit 0 **RME_TCM**: RW margin enable input for TCM memories
0: Default RW margin settings
1: Use external pin RW margin setting

16.1.5 SYSCFG Cortex-M55 SVTOR control register (SYSCFG_INITSVTORCR)

Address offset: 0x010

Reset value: 0x1800 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw							

Bits 31:7 **SVTOR_ADDR[24:0]**: Secure vector table base address

Bits 6:0 Reserved, must be kept at reset value.

16.1.6 SYSCFG Cortex-M55 NSVTOR control register (SYSCFG_INITNSVTORCR)

Address offset: 0x014

Reset value: 0x0800 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NSVTOR_ADDR[24:9]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NSVTOR_ADDR[8:0]									Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw							

Bits 31:7 **NSVTOR_ADDR[24:0]**: Nonsecure vector table base address

Bits 6:0 Reserved, must be kept at reset value.

16.1.7 SYSCFG Cortex-M55 reset type control register (SYSCFG_CM55RSTCR)

Address offset: 0x018

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKUP_NMI_EN	LOCKUP_RST_EN	CORE_RESET_TYPE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKUP_NMI_EN**: Select action to perform on a lockup state on the core
- 0: Lockup state must be recovered from NVIC interrupt (default value)
- 1: Lockup generates a NMI on the core.

Bit 1 **LOCKUP_RST_EN**: Select action to perform on a lockup state on the core
- 0: Lockup state must be recovered from interrupt (default value)
- 1: Lockup requests a warm reset to the RCC.

Bit 0 **CORE_RESET_TYPE**: Select reset to apply on core upon SYSRESETREQ
- 0: Warm reset (default value)
- 1: Power-on reset

16.1.8 SYSCFG Cortex-M55 P-AHB write posting control register (SYSCFG_CM55PAHBWPR)

Address offset: 0x01C

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PAHB_ERROR_ACK
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **PAHB_ERROR_ACK**: Error capture in write posting buffer
0: Error capture
1: Clean error

16.1.9 SYSCFG VENCRAM control register (SYSCFG_VENCRAMCR)

Address offset: 0x020

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VENCRAM_EN
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **VENCRAM_EN**: VENCRAM allocation VENC if active, or to system (if VENC inactive)
0: VENCRAM reserved for the VENC
1: VENCRAM available for the system (VENC inactive)

16.1.10 SYSCFG potential tamper reset register (SYSCFG_POTTAMPRSTCR)

Address offset: 0x024

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	POTTAMPERSETMASK
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **POTTAMPERSETMASK**:

This bit can be set by software to mask PKA, SAES, CRYP, and HASH reset, in case of potential tamper.

0: PKA, SAES, CRYP, and HASH reset in case of potential tamper

1: PKA, SAES, CRYP, and HASH not reset in case of potential tamper

16.1.11 SYSCFG NPUNIC QoS control register (SYSCFG_NPUNICQOSCR)

Address offset: 0x028

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPUSS_AWQOS[3:0]				CPUSS_ARQOS[3:0]			
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NPU2_AWQOS[3:0]				NPU2_ARQOS[3:0]				NPU1_AWQOS[3:0]				NPU1_ARQOS[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **CPUSS_AWQOS[3:0]**: NPUNIC write QoS information for master port from CPUSS

Bits 19:16 **CPUSS_ARQOS[3:0]**: NPUNIC read QoS information for master port from CPUSS

Bits 15:12 **NPU2_AWQOS[3:0]**: NPUNIC write QoS information for NPU2 master port

Bits 11:8 **NPU2_ARQOS[3:0]**: NPUNIC read QoS information for NPU2 master port

Bits 7:4 **NPU1_AWQOS[3:0]**: NPUNIC write QoS information for NPU1 master port

Bits 3:0 **NPU1_ARQOS[3:0]**: NPUNIC read QoS information for NPU1 master port

16.1.12 SYSCFG AHB-AXI bridge early write response control register (SYSCFG_ICNEWRCR)

Address offset: 0x034

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	USB2_EARLY_WR_RSP_ENABLE	USB1_EARLY_WR_RSP_ENABLE	SDMMC2_EARLY_WR_RSP_ENABLE	SDMMC1_EARLY_WR_RSP_ENABLE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **USB2_EARLY_WR_RSP_ENABLE**:

0: Early-write response disabled. The last AHB write data beat receives the AXI buffered response for the complete AHB transaction.

1: Early-write response enabled. AHB-Lite write data beats receive an automatic OK response from the AHB-to-AXI bridge, whatever the B-channel AXI response.

Bit 2 **USB1_EARLY_WR_RSP_ENABLE**:

0: Early-write response disabled. The last AHB write data beat receives the AXI buffered response for the complete AHB transaction.

1: Early-write response enabled. AHB-Lite write data beats receive an automatic OK response from the AHB-to-AXI bridge, whatever the B-channel AXI response.

Bit 1 **SDMMC2_EARLY_WR_RSP_ENABLE**:

0: Early-write response disabled. The last AHB write data beat receives the AXI buffered response for the complete AHB transaction.

1: Early-write response enabled. AHB-Lite write data beats receive an automatic OK response from the AHB-to-AXI bridge, whatever the B-channel AXI response.

Bit 0 **SDMMC1_EARLY_WR_RSP_ENABLE**:

0: Early-write response disabled. The last AHB write data beat receives the AXI buffered response for the complete AHB transaction.

1: Early-write response enabled. AHB-Lite write data beats receive an automatic OK response from the AHB-to-AXI bridge, whatever the B-channel AXI response.

16.1.13 SYSCFG ICN clock gating control register (SYSCFG_ICNCGCR)

Address offset: 0x038

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CPU_NOC_CG_DISABLE**: CPU_NOC clock gating disable

0: CPU_NOC clock gating enabled (default value)

1: CPU_NOC clock gating disabled

Bit 1 **CPU_NIC_CG_DISABLE**: CPU_NIC clock gating disable

0: CPU_NIC clock gating enabled (default value)

1: CPU_NIC clock gating disabled

Bit 0 **NPU_NOC_CG_DISABLE**: NPU_NOC clock gating disable

0: NPU_NOC clock gating enabled (default value)

1: NPU_NOC clock gating disabled

16.1.14 SYSCFG VDDIOx compensation cell control register (SYSCFG_VDDIOxCCCR)

Address offset: 0x044 + 0x8 * (x - 2), (x = 2 to 5)

Reset value: 0x0000 0078

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	CS	EN	RAPSRC[3:0]				RANSRC[3:0]			
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **CS**: Selects the code to be applied for the compensation cell of I/Os supplied by VDDIOx.
0: VDDIOx I/O code from the cell (available in the SYSCFG_VDDIOxCCSR)
1: VDDIOx I/O code from RANSRC[3:0] and RAPSRC[3:0] in this register

Note: CS = 0 is not taken into account until READY = 1. Whenever CS, RANSRC[3:0], and RAPSRC[3:0] are used for I/O compensation when the compensation cell is not enabled (EN = 0, which is the case after a reset).

Bit 8 **EN**: Enables the compensation cell of I/Os supplied by VDDIOx.
0: VDDIOx I/O compensation cell disabled
1: VDDIOx I/O compensation cell enabled

Note: The HSI oscillator must be enabled and ready (controlled in RCC) before EN can be set to 1. The HSI oscillator can be disabled only if EN is set to 0.

Bits 7:4 **RAPSRC[3:0]**: These bits are written by software to define an I/O compensation code for PMOS transistors. This code is applied to the I/O compensation cell when CS = 1.

Bits 3:0 **RANSRC[3:0]**: These bits are written by software to define an I/O compensation code for NMOS transistors. This code is applied to the I/O compensation cell when the CS = 1.

16.1.15 SYSCFG VDDIOx compensation cell status register (SYSCFG_VDDIOxCCSR)

Address offset: 0x048 + 0x8 * (x - 2), (x = 2 to 5)

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	READY	APSRC[3:0]				ANSRC[3:0]			
							r	r	r	r	r	r	r	r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **READY**: Provides the compensation cell status of I/Os supplied by VDDIOx
0: VDDIOx I/O compensation cell not ready
1: VDDIOx I/O compensation cell ready

Bits 7:4 **APSRC[3:0]**: This value is provided by the cell, and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors.
This code is applied to the I/O compensation cell when the CS = 0 in SYSCFG_VDDIOxCCCR, and READY = 1 in this register.

Bits 3:0 **ANSRC[3:0]**: This value is provided by the cell, and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors.
This code is applied to the I/O compensation cell when the CS = 0 in SYSCFG_VDDIOxCCCR, and READY = 1 in this register.

16.1.16 SYSCFG VDD compensation cell control register (SYSCFG_VDDCCCR)

Address offset: 0x064

Reset value: 0x0000 0078

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	CS	EN	RAPSRC[3:0]				RANSRC[3:0]			
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **CS**: Selects the code to be applied for the compensation cell of I/Os supplied by VDD.
0: VDD I/O code from the cell (available in the SYSCFG_VDDCCSR)
1: VDD I/O code from RANSRC[3:0] and RAPSRC[3:0]

Note: CS = 0 is not taken into account until READY = 1. Whenever CS, RANSRC[3:0] and RAPSRC[3:0] are used for I/O compensation when the compensation cell is not enabled (EN = 0, which is the case after a reset).

Bit 8 **EN**: Enables the compensation cell of I/Os supplied by VDD.
0: VDD I/O compensation cell disabled
1: VDD I/O compensation cell enabled

Note: The HSI oscillator must be enabled and ready (controlled in RCC) before EN can be set to 1. The HSI oscillator can be disabled only if EN is set to 0.

Bits 7:4 **RAPSRC[3:0]**: These bits are written by software to define an I/O compensation code for PMOS transistors. This code is applied to the I/O compensation cell when CS = 1.

Bits 3:0 **RANSRC[3:0]**: These bits are written by software to define an I/O compensation code for NMOS transistors. This code is applied to the I/O compensation cell when CS = 1.

16.1.17 SYSCFG VDD compensation cell status register (SYSCFG_VDDCCSR)

Address offset: 0x068

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	READY	APSRC[3:0]				ANSRC[3:0]			
							r	r	r	r	r	r	r	r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **READY**: Provides the compensation cell status of I/Os supplied by VDD
0: VDD I/O compensation cell not ready
1: VDD I/O compensation cell ready

Bits 7:4 **APSRC[3:0]**: This value is provided by the cell, and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors.
This code is applied to the I/O compensation cell when CS = 0 in SYSCFG_VDDCCCR, and READY = 1.

Bits 3:0 **ANSRC[3:0]**: This value is provided by the cell, and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors.
This code is applied to the I/O compensation cell when CS = 0 in SYSCFG_VDDCCCR, and READY = 1.

16.1.18 SYSCFG control timer break register (SYSCFG_CBR)

Address offset: 0x06C

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CM55TCML	CM55CACHEL	BKPRAML	Res.	Res.	Res.	Res.	Res.	PVDEN	Res.	CM55L
					rw	rw	rw						rw		rw

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **CM55TCML**: Cortex-M55 TCM double ECC error lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Cortex-M55 TCM double ECC error signal connection to TIM1/8/15/16/17 break inputs.

0: Cortex-M55 TCM double ECC error signal disconnected from TIM1/8/15/16/17 break inputs

1: Cortex-M55 TCM double ECC error signal connected to TIM1/8/15/16/17 break inputs

Bit 9 **CM55CACHEL**: Cortex-M55 cache double ECC error lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Cortex-M55 cache double ECC error signal connection to TIM1/8/15/16/1break inputs.

0: Cortex-M55 cache double ECC error signal disconnected from TIM1/8/15/16/17 break inputs

1: Cortex-M55 cache double ECC error signal connected to TIM1/8/15/16/17 break inputs

Bit 8 **BKPRAML**: Backup SRAM double ECC error lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the backup SRAM double ECC error signal connection to TIM1/8/15/16/17 break inputs.

0: Backup SRAM double ECC error signal disconnected from TIM1/8/15/16/17 break inputs

1: Backup SRAM double ECC error signal connected to TIM1/8/15/16/17 break inputs

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **PVDEN**: PVD lock enable

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection to TIM1/8/15/16/17 break input, as well as the PVDE in PWR_CR2.

0: PVD interrupt disconnected from TIM1/8/15/16/17 break input. PVDE bits can be programmed by the application.

1: PVD interrupt connected to TIM1/8/15/16/17 break input. PVDE and bits are read only.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CM55L**: CM55 lockup lock enable

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Cortex-M55 lockup (HardFault) output connection to TIM1/8/15/16/17 break input.

0: Cortex-M55 lockup output disconnected from TIM1/8/15/16/17 break inputs

1: Cortex-M55 lockup output disconnected from TIM1/8/15/16/17 break inputs

16.1.19 SYSCFG DMA CID secure control register (SYSCFG_SEC_AIDCR)

Address offset: 0x070

Reset value: 0x0000 0001

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **SDFBCLK_180**: Delay on feedback clock
- 0: No delay on the feedback clock
- 1: Half a cycle delay on the feedback clock

Bit 1 **CFG_RETIME_TX**: Retiming on Tx path
- 0: No retiming on Tx path
- 1: Retiming on Tx path

Bit 0 **CFG_RETIME_RX**: Retiming on Rx path
- 0: No retiming on Rx path
- 1: Retiming on Rx path

16.1.21 SYSCFG NPU RAM interleaving control register (SYSCFG_NPU_ICNCR)

Address offset: 0x078

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	INTERLEAVING_ACTIVE
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **INTERLEAVING_ACTIVE**: Control interleaving on NPU RAMs
0: Interleaving disabled
1: Interleaving enabled

16.1.22 SYSCFG boot pin status register (SYSCFG_BOOTSR)

Address offset: 0x100

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOT1	BOOT0
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **BOOT1**: BOOT1 pin value
0: BOOT1 pin connected to VSS (or left open if BOOT1_PD = 0 in SYSCFG_BOOTCR)
1: BOOT1 pin connected to VDD

Bit 0 **BOOT0**: BOOT0 pin value
0: BOOT0 pin connected to VSS (or left open if BOOT0_PD = 0)
1: BOOT0 pin connected to VDD

16.1.23 SYSCFG AHB write posting address error register (SYSCFG_AHBWP_ERROR_SR)

Address offset: 0x104

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PAHB_ERROR_ADDR[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PAHB_ERROR_ADDR[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **PAHB_ERROR_ADDR[31:0]**: Reports address of the first error in P-AHB write-posting buffer

16.1.24 SYSCFG SMPS observable signals through HDP selection configuration register (SYSCFG_SMPSHDPCR)

Address offset: 0x400

Reset value: 0x0000 0000

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SMPSHDPSEL[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **SMPSHDPSEL[3:0]**:
0000: Standard run mode (no HDP)
1100: Analyze fsm mode analysis
1101: Analyze fsm mos analysis
1110: Analyze fsm rampe analysis
1111: Analyze fsm mode analysis
Others: Reserved

16.1.25 SYSCFG DMA CID nonsecure control register (SYSCFG_SECPRIV_AIDCR)

Address offset: 0x800

Reset value: 0x0000 0001

Reset by system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Refer to *Section 2.3* for the register boundary addresses.

17 Peripherals interconnect matrix

17.1 Introduction

Several peripherals have direct connections between them. This allows autonomous communication and or synchronization between peripherals, saving CPU resources, thus power supply consumption. In addition, these hardware connections remove software latency, and improve the predictability of the system design.

Depending on peripherals, these interconnections can operate in various power modes: Run, Standby, Sleep, and Stop modes.

17.2 Connection summary

The table below summarizes which master can access which memory-mapped resource.

Table 84. Connectivity matrix

1. The CPU accesses internally to its DTCM and ITCM. The DAP uses the CPU internal to reach TCMs.
2. By default, the CPU uses P-AHB master port to reach the AHBx/APBx target.

18 High-performance direct memory access controller (HPDMA)

18.1 HPDMA introduction

The high-performance direct memory access (HPDMA) controller is a bus master and system peripheral.

The HPDMA is used to perform programmable data transfers between memory-mapped peripherals, and/or memories via linked-lists, upon the control of an off-loaded CPU.

18.2 HPDMA main features

- Single bidirectional AXI master and single bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent HPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 18.3.1*)
  - Intra-channel HPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel HPDMA transfers chaining via programmable HPDMA input triggers connection to HPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at block level, between successive burst transfers

  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 18.3.1*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Selection of programmable HPDMA request and trigger
  - Generation of programmable HPDMA half-transfer and transfer-complete event
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the HPDMA linked-list control registers
  - Channel abort and restart
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- TrustZone support:
  - Support for secure and nonsecure HPDMA transfers, independently at a first channel level, and independently at a source/destination and link sublevels
  - Secure and nonsecure interrupts reporting, resulting from any of the respectively secure and nonsecure channels
  - TrustZone-aware AHB slave port, protecting any HPDMA secure resource (register, bitfield) from a nonsecure access
- Privileged/unprivileged support:
  - Support for privileged and unprivileged HPDMA transfers, independently at channel level
  - Privileged-aware AHB slave port
- Channel isolation support:
  - Support for compartmented DMA transfers, independently at channel level, via compartment IDs (named CIDs)
  - CID-aware interrupts reporting
  - CID-aware AHB slave port, with integrated semaphores for a concurrent control, from any of the CPUs

18.3 HPDMA implementation

18.3.1 HPDMA channels

A given HPDMA channel x is implemented with the following features and intended use.

To make the best use of the HPDMA performance, the following table lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested HPDMA transfer.

Table 85. Implementation of HPDMA1 channels

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 11	3	0	Channel x (x = 0 to 11) is implemented with: – a FIFO of 16 bytes, 4 words, 2 double-words – fixed/contiguously incremented addressing These channels can be used for HPDMA transfers between an APB or AHB peripheral, an AHB/AXI SRAM, or CPU TCM.
x = 12 to 15	5	1	Channel x (x = 12 to 15) is implemented with: – a FIFO of 64 bytes, 8 double-words – 2D addressing These channels can be also used for HPDMA transfers, including AXI external memories.

18.3.2 HPDMA allowed AXI maximum burst length

For a data transfer, the user has to program:

– the source (and destination) burst length that a given channel x ideally performs, via SBL_1[5:0] (and respectively DBL_1[5:0]) field in HPDMA_CxTR1.

– the allocated master port, AXI or AHB, on which this source (or destination) data transfer must be performed, via SAP (or respectively DAP) field in HPDMA_CxTR1.

Caution: The maximum allowed AXI burst length is restricted to 16:

1. if SAP = 0 (AXI allocated port): the maximum allowed value of SBL_1[5:0] is 15.
2. if DAP = 0 (AXI allocated port): the maximum allowed value of DBL_1[5:0] is 15.

18.3.3 HPDMA in low-power modes

The HPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 86. HPDMA1 in low-power modes

Feature	Low-power modes
Wake-up	HPDMA1 in Sleep mode

18.3.4 HPDMA requests

An HPDMA request from a peripheral can be assigned to a HPDMA channel x, via REQSEL[7:0] in HPDMA_CxTR2, provided that SWREQ = 0.

The HPDMA requests mapping is specified in the table below.

Table 87. Programmed HPDMA1 request

143	i3c2_tc_dma
144	i3c2_rs_dma

18.3.5 HPDMA block requests

Some HPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in HPDMA_CxTR2 must be set for a correct HPDMA execution of the requested peripheral transfer at the hardware level.

Table 88. Programmed HPDMA1 request as a block request

HPDMA block requests
lptim1/2/3_ue

18.3.6 HPDMA channels with peripheral early termination

An HPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 89. HPDMA1 channel with peripheral early termination

HPDMA channel x with peripheral early termination
x = 0, x = 1, and x = 15

This HPDMA support is activated when the channel x is programmed with HPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before that the HPDMA has transferred the whole block (see *Section 18.4.14* for more details).

Table 90. Programmed HPDMA1 request with peripheral early termination

Programmed HPDMA channel x request with peripheral early termination
i3c1_rx_dma
i3c2_rx_dma
jpeg_tx_dma

18.3.7 HPDMA triggers

An HPDMA trigger can be assigned to an HPDMA channel x, via TRIGSEL[6:0] in HPDMA_CXTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

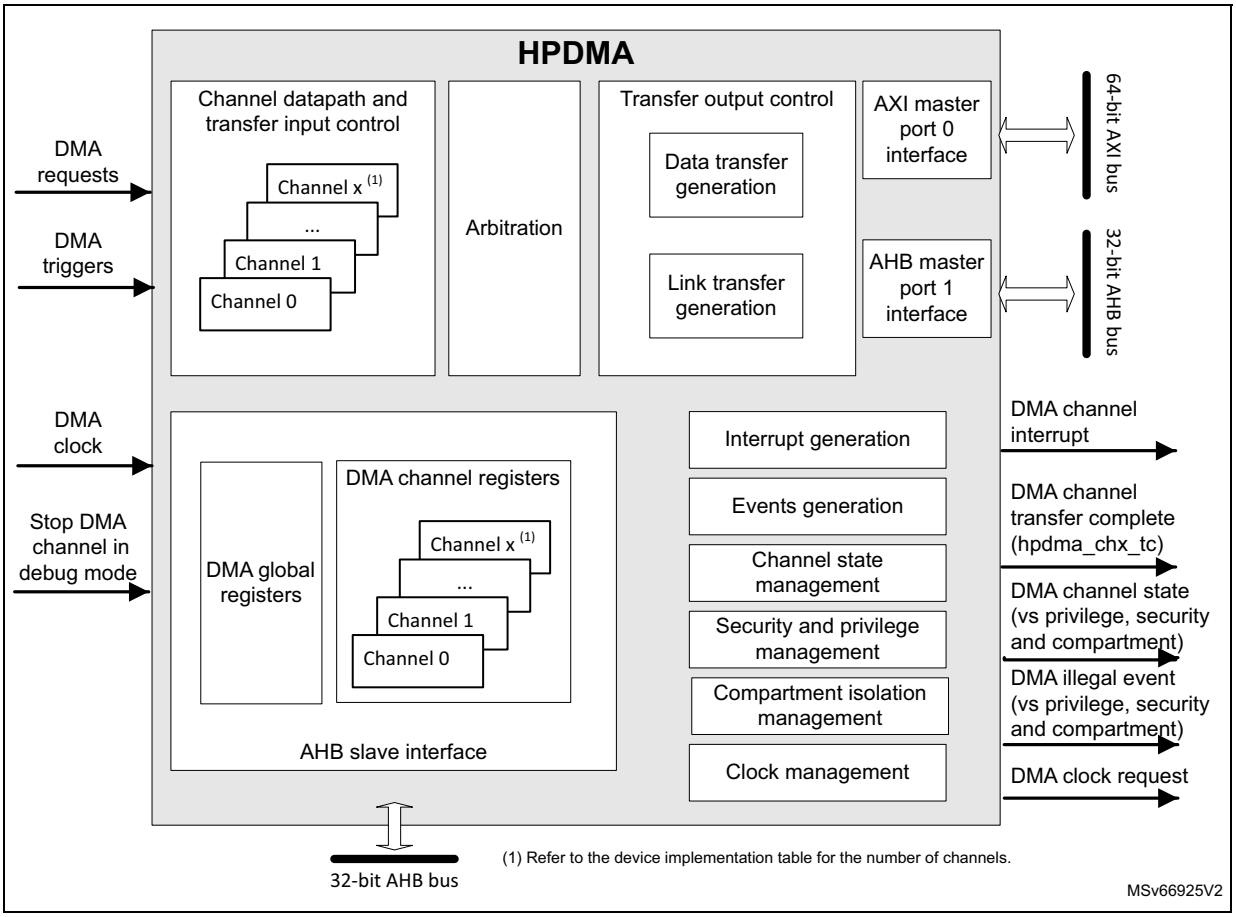
18.4 HPDMA functional description

18.4.1 HPDMA block diagram

Figure 71. HPDMA block diagram



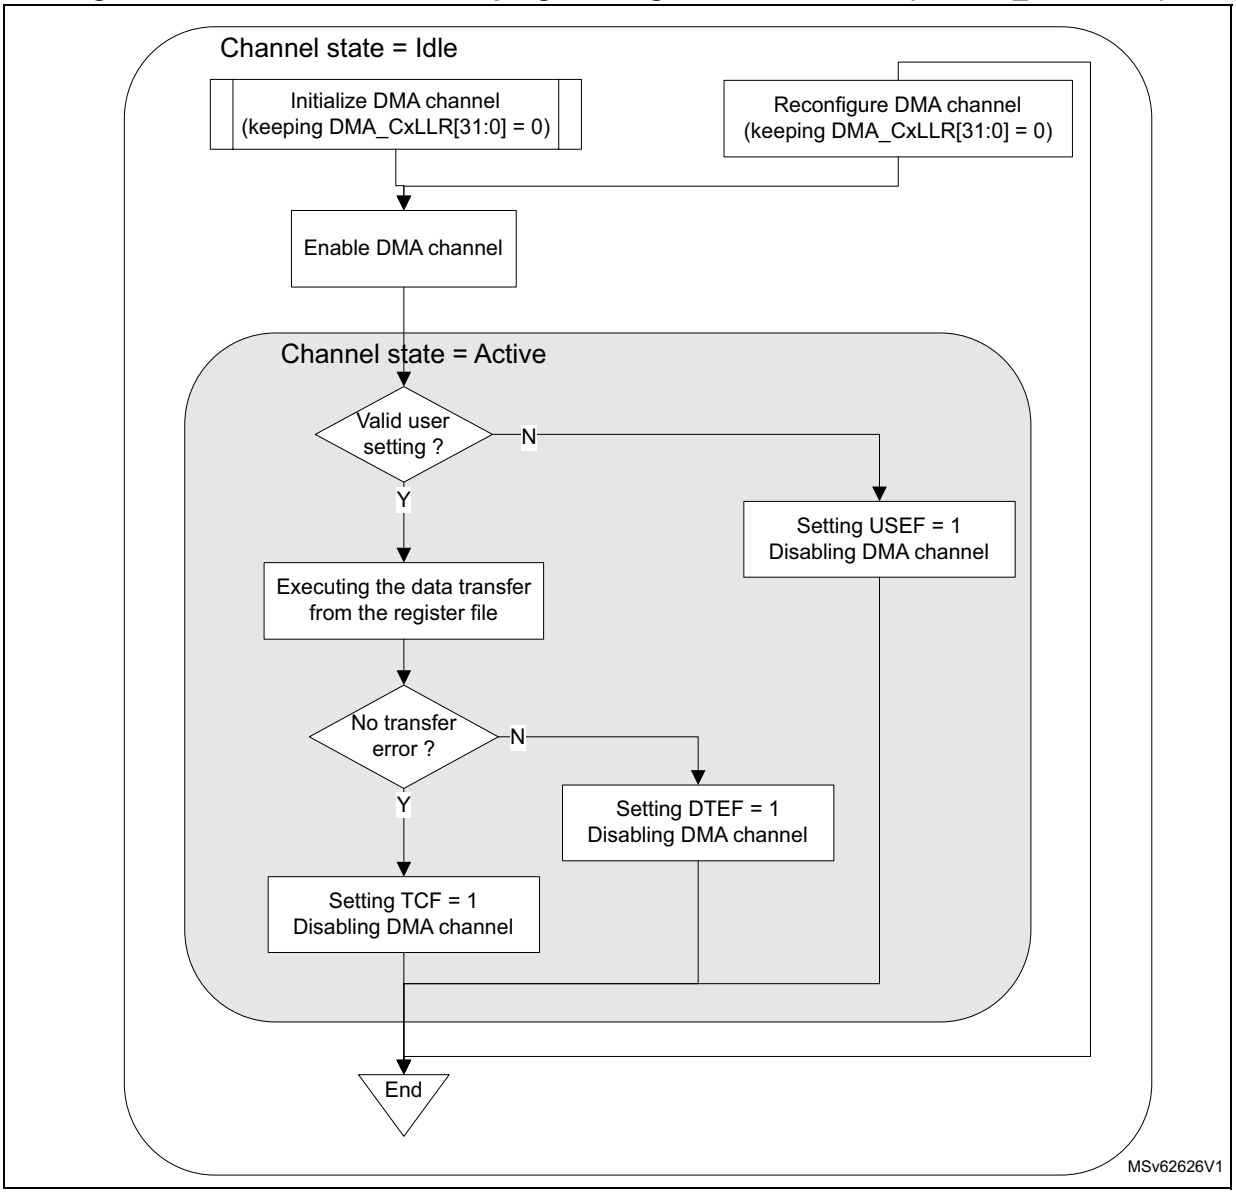
18.4.2 HPDMA channel state and direct programming without any linked-list

After an HPDMA reset, an HPDMA channel x is in idle state. When the software writes 1 into the HPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (HPDMA_CxXXX), switches to the active/non-idle state, and starts to execute the corresponding requested data transfers.

After enabling/starting an HPDMA channel transfer by writing 1 into HPDMA_CxCR.EN, an HPDMA channel interrupt on a complete transfer notifies the software that the HPDMA channel is back in idle state (EN is then deasserted by hardware), and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this HPDMA direct programming without any linked-list (HPDMA_CxLLR = 0).

Figure 72. HPDMA channel direct programming without linked-list (HPDMA_CxLLR = 0)



18.4.3 HPDMA channel suspend and resume

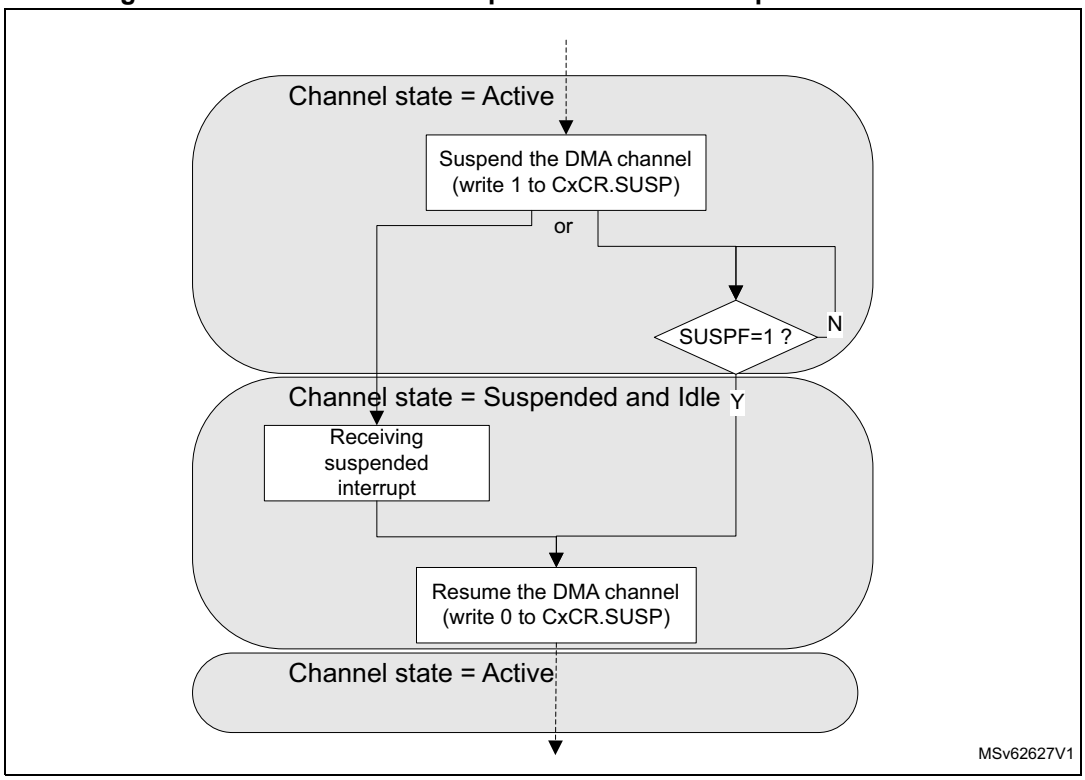
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or bitfield that is hardware modifiable.

Note: An ongoing HPDMA transfer can be a data transfer (a source/destination burst transfer,) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to HPDMACxCR.SUSP.

Figure 73. HPDMA channel suspend and resume sequence



Note: A suspend and resume sequence does not impact the HPDMA_*CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.*

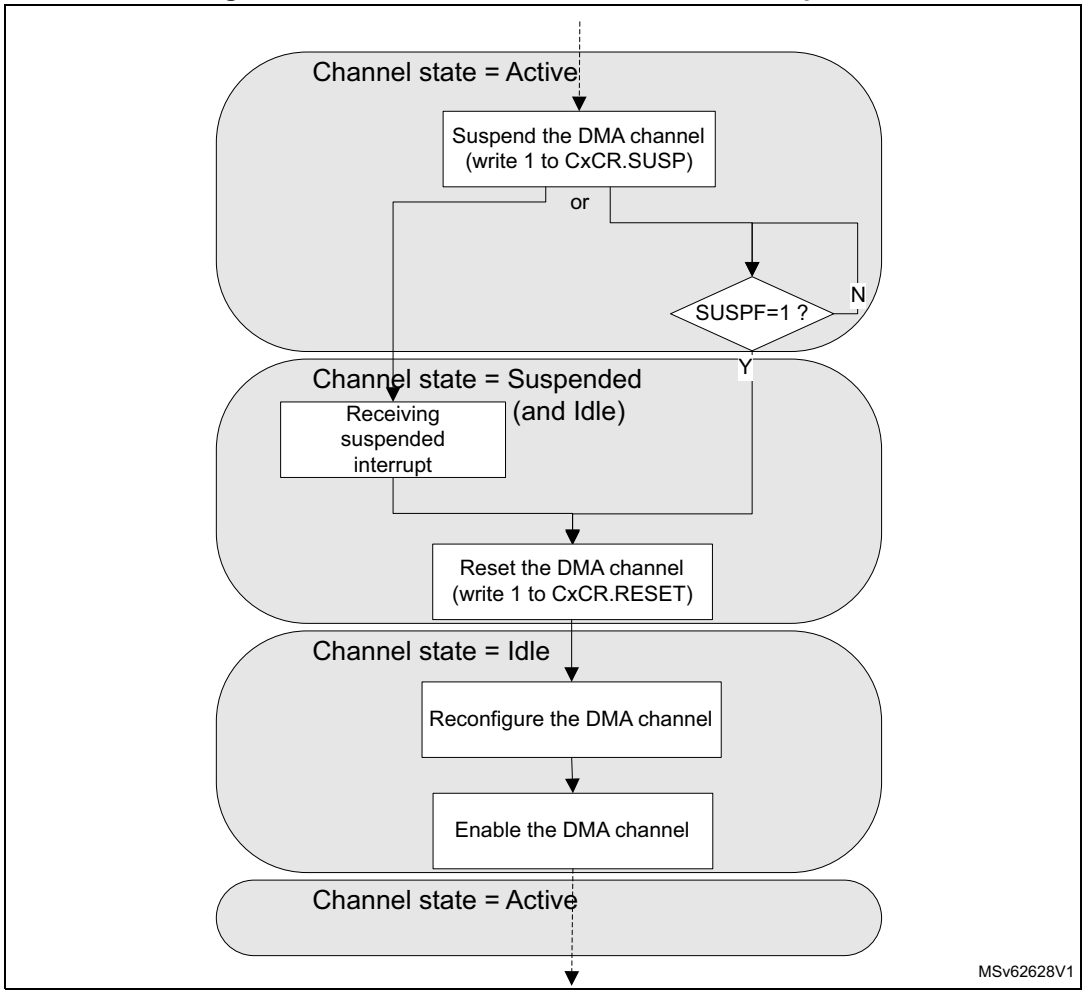
18.4.4 HPDMA channel abort and restart

Alternatively, like for aborting a continuous HPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master port.
3. The software resets the channel by writing 1 to HPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the HPDMA_CxCR.EN bit, and the reset of the HPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram hardware-modified HPDMA_CxBR1, HPDMA_CxSAR, and HPDMA_CxDAR.

5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the HPDMA_CxCR.EN bit.

Figure 74. HPDMA channel abort and restart sequence



18.4.5 HPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

For a channel x, the base address in memory of the data structure of a next LLI_{n+1} is the sum of the following:

- the link base address of the channel x (in HPDMA_CxLBAR)
- the link address offset LA[15:2] bitfield in HPDMA_CxLLR, that is the updated result from the data structure of the previous LLIn of the channel x

The data structure for each LLI can be specific.

A linked-list data structure is addressed following the value of UT1, UT2, UB1, USA, UDA, and ULL bits, plus UB2 and UT3 when present, in HPDMA_CxLLR.

In linked-list mode, each HPDMA linked-list register (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR or HPDMA_CxLLR,

plus HPDMA_CxTR3 or HPDMA_CxBR2 when present) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of HPDMA_CxLLR that was conditionally updated from the linked-list data structure of the previous LLI.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA, and ULL, plus UB2 and UT3 when present) in HPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x, x = 0 to 11, six contiguous 32-bit locations, including HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR (see *Figure 75*) and including the first linked-list register file (LLI_0), and the next LLIs (LLI_1, LLI_2,...) in the memory
- channel x, x = 12 to 15, eight contiguous 32-bit locations, including HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 (see *Figure 76*), including the first linked-list register file (LLI_0), and the next LLIs (LLI_1, LLI_2,...) in the memory

Figure 75. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x

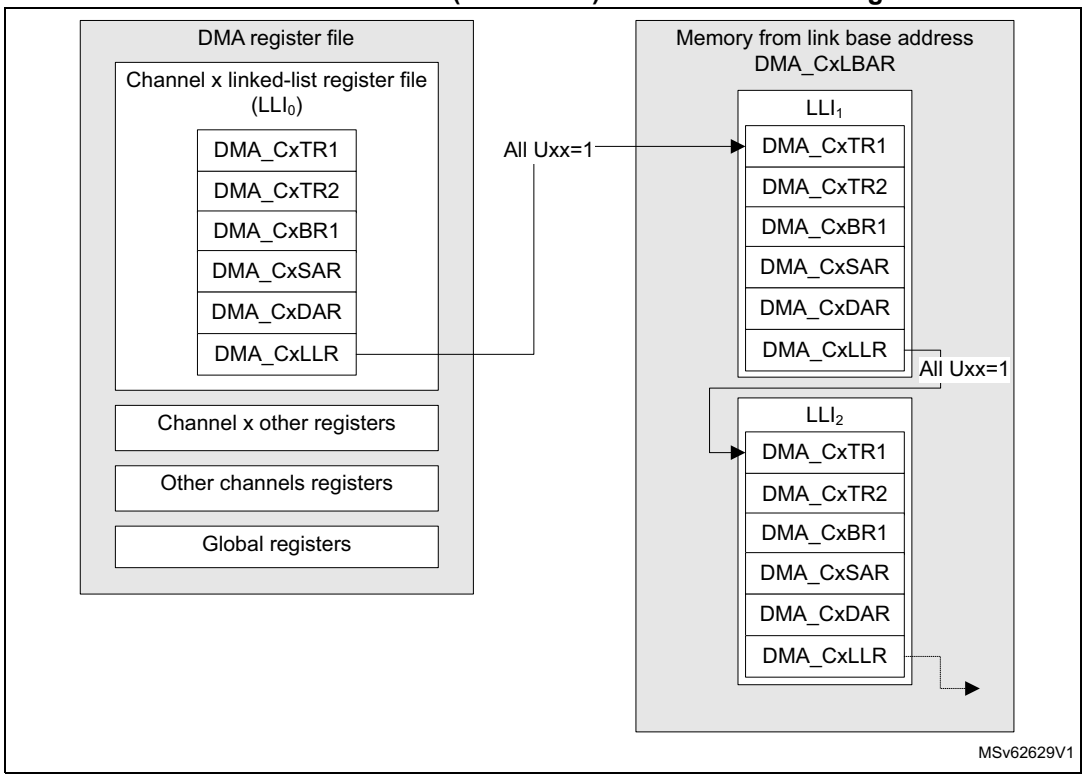


Figure 76. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

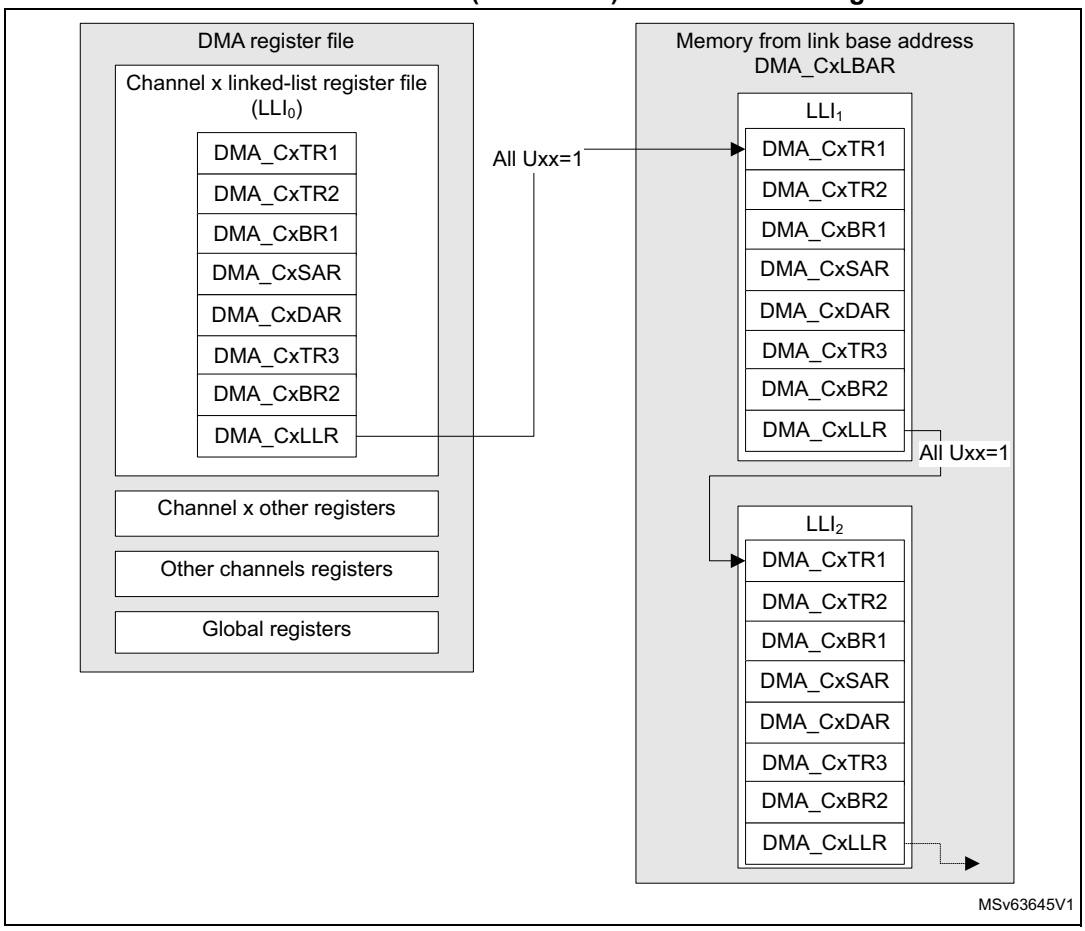

Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of HPDMA_CxLLR points to the updated value of HPDMA_CxTR2, instead of HPDMA_CxTR1 which is not to be modified (see *Figure 77*).

Example: if UT1 = UB1 = USA = 0, and if UT3 = UB2 = 0 when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for HPDMA_CxTR1, nor HPDMA_CxBR1, nor HPDMA_CxSAR, nor HPDMA_CxTR3, nor HPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for HPDMA_CxTR2, HPDMA_CxDAR, and HPDMA_CxLLR, as shown in *Figure 78*.

Figure 77. HPDMA dynamic linked-list data structure of linear addressing channel x

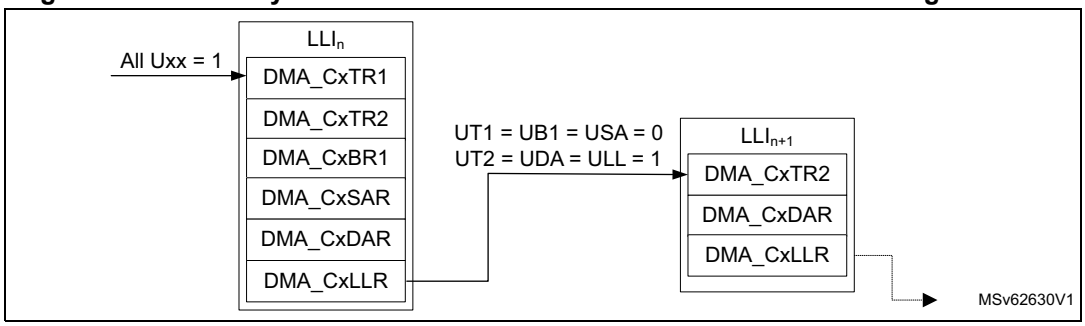

Figure 78. HPDMA dynamic linked-list data structure of a 2D addressing channel x

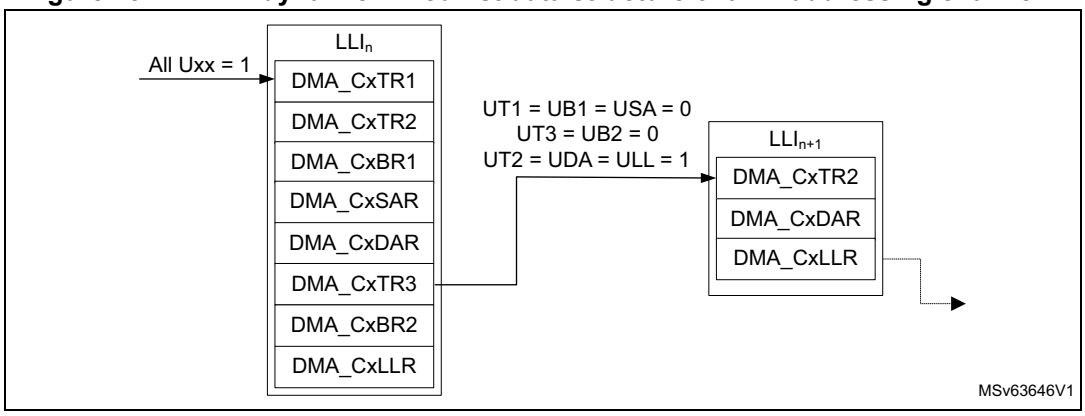


The user must program HPDMA_CxLLR for each LLI$_n$ to be 32-bit aligned, and not to exceed the 64-Kbyte addressable space pointed by HPDMA_CxLBAR.

18.4.6 Linked-list item transfer execution

An LLI$_n$ transfer is the sequence of:

1. a data transfer: the HPDMA executes the data transfer as described by the HPDMA internal register file (this data transfer can be void/null for LLI$_0$).
2. a conditional link transfer: the HPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI$_{n+1}$, as defined by the HPDMA_CxLLR value of the LLI$_n$.

Note: The initial data transfer, as defined by the internal register file (LLI$_0$), can be null (HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxTR2.PFREQ = 0), provided that UB1 is set in HPDMA_CxLLR (meaning there is a non-null data transfer described by the next LLI$_1$ in the memory to be executed).

Depending on the intended HPDMA use, an HPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, HPDMA_CxCR.LSM = 0), or can be programmed for a single execution of a LLI (link step mode, HPDMA_CxCR.LSM = 1), as described in the next sections.

18.4.7 HPDMA channel state and linked-list programming in run-to-completion mode

When HPDMA_CxCR.LSM = 0 (in full-list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), an HPDMA channel x is initially programmed, started by writing 1 to HPDMA_CxCR.EN, and after completed at channel level.
The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 when present
  - the last LLI_N described by the linked-list data structure in memory, as defined by HPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when HPDMA_CxLLR[31:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0, if BRC[10:0] is present and HPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

HPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion, and means the following:

- The 16 low significant bits HPDMA_CxLLR.LA[15:0] of the next link address are null.
- All bits HPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA, and ULL, plus UB2 and UT3 when present).

The channel may never be completed when HPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI, in one of the following:
  - HPDMA_CxLLR.ULL = 1 and HPDMA_CxLLR.LA[15:2] is updated by the same value.
  - HPDMA_CxLLR.ULL = 0
- If LLI_N points to a previous LLI

In the regular data transfer completion at a block level, HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 18.4.14* for more details).

In the typical run-to-completion mode, the allocation of an HPDMA channel, including its fine programming, is done once during the HPDMA initialization. In order to have a reserved data communication link and HPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

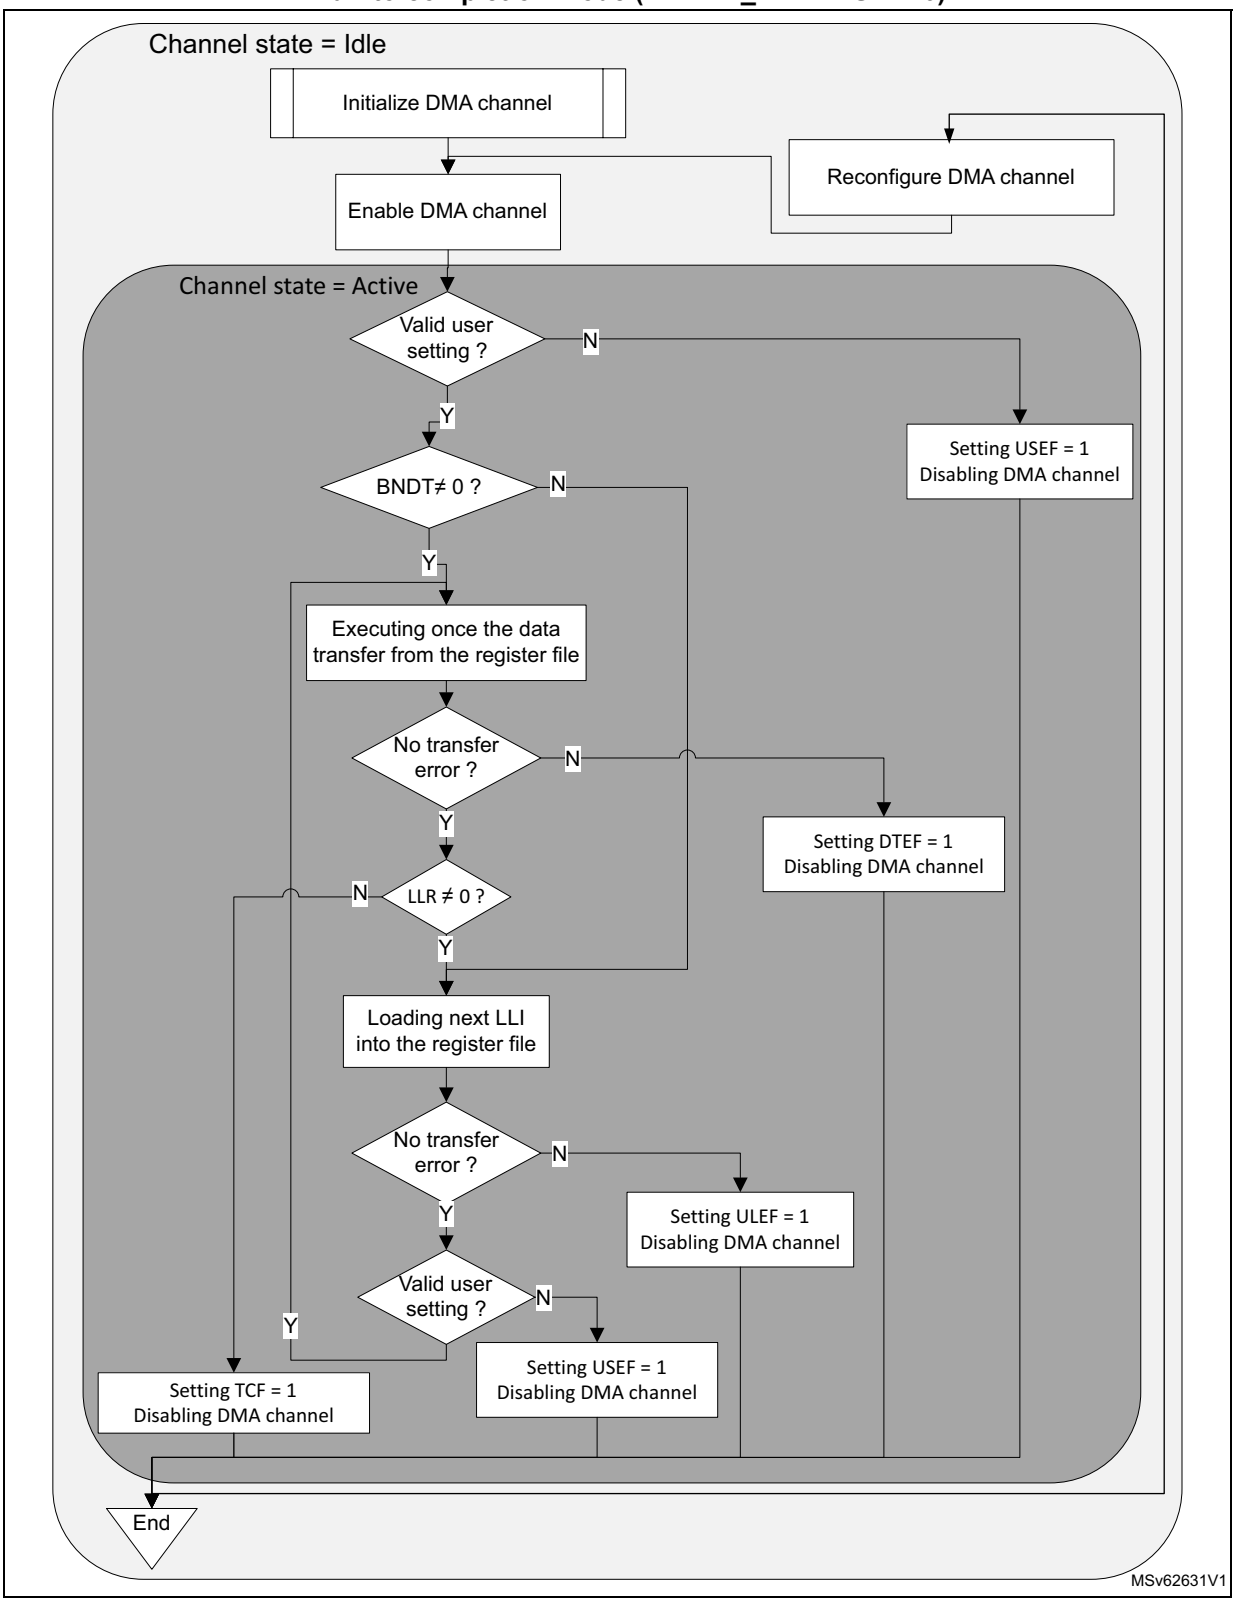
Figure 79 depicts the HPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 79 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel

completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 79, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 18.3.6).

Figure 79. HPDMA channel execution and linked-list programming in run-to-completion mode (HPDMA_CxCR.LSM = 0)



Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following bitfields of HPDMA_CxTR2 in the data structure of the LLI_{n-1}:

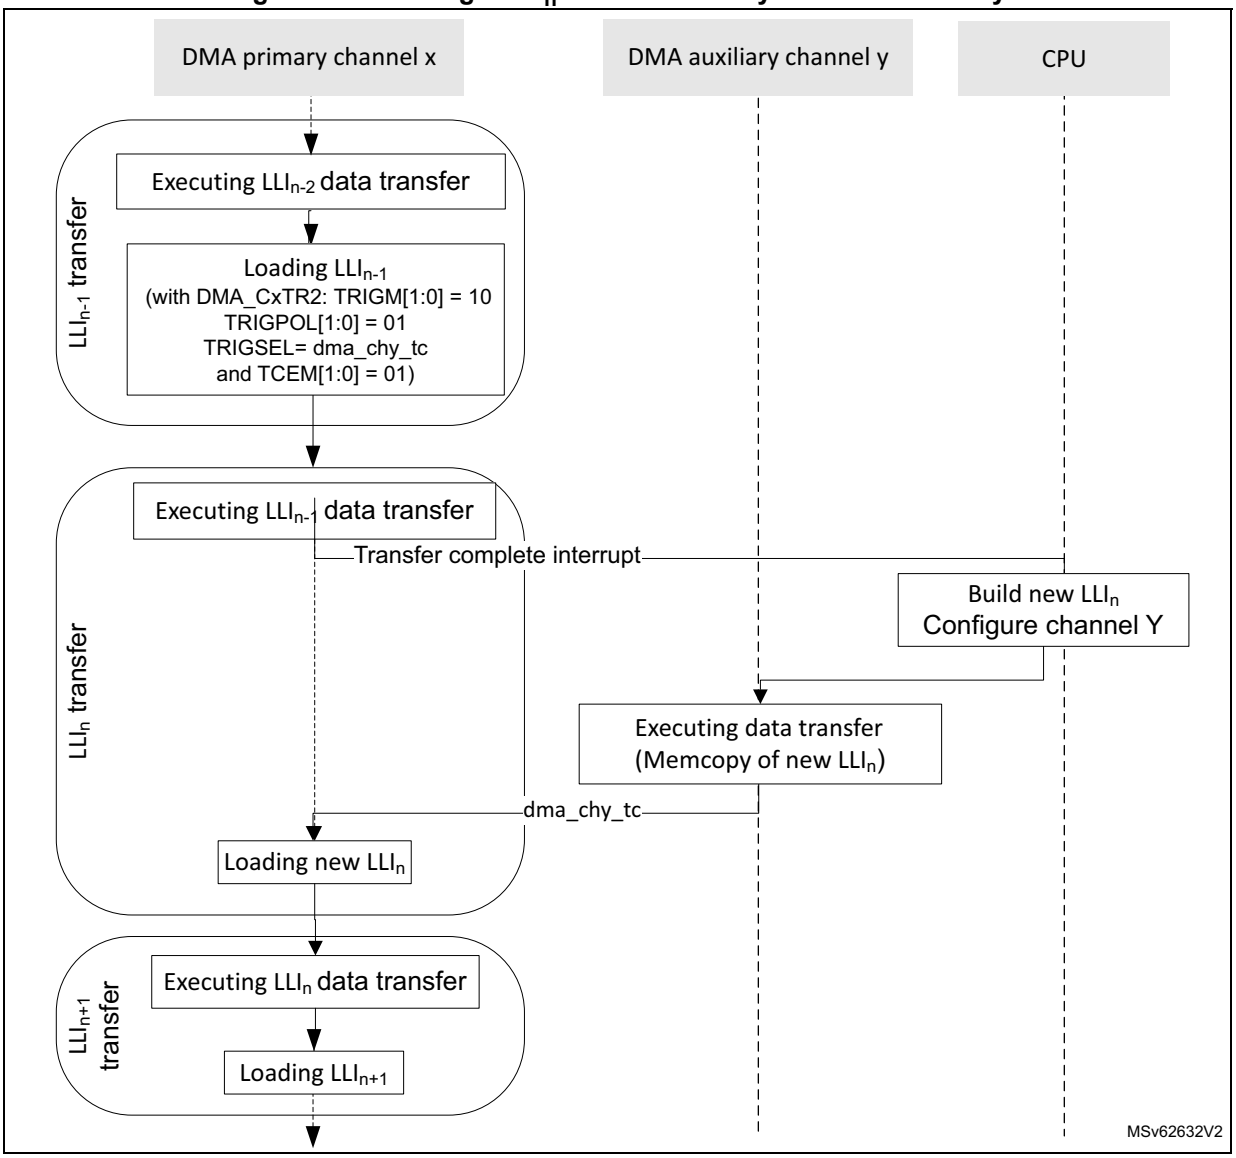
- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[6:0] (see *Section 18.3.7* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory, and to generate a transfer complete event hpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 80 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with an LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 80. Inserting a LLI_n with an auxiliary HPDMA channel y



18.4.8 HPDMA channel state and linked-list programming in link step mode

When HPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

An HPDMA channel transfer can be programmed at an LLI level, started by writing 1 into HPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with the following:
  - HPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - HPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]), for channel x = 12 to 15, the number of blocks at a 2D/repeated block level (BRC[10:0]+1), and the incrementing/decrementing mode for address offsets.

  - HPDMA_CxTR2 defines the input control (request, trigger), and the output control (transfer-complete event) of the transfer.
  - HPDMA_CxSAR and HPDMA_CxDAR define the source/destination transfer start address.
  - HPDMA_CxTR3 (for channel x = 12 to 15) defines the source/destination additional address offset between burst transfers.
  - HPDMA_CxBR2 (for channel x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - HPDMA_CxLLR defines the data structure, and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when HPDMA_CxBR1.BRC[10:0] = 0 if BRC[10:0] is present, and HPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the HPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If an LLI is recursive (pointing to itself as a next LLI, either HPDMA_CxLLR.ULL = 1 and HPDMA_CxLLR.LA[15:2] is updated by the same value, or HPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer can be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 18.4.14* for more details).

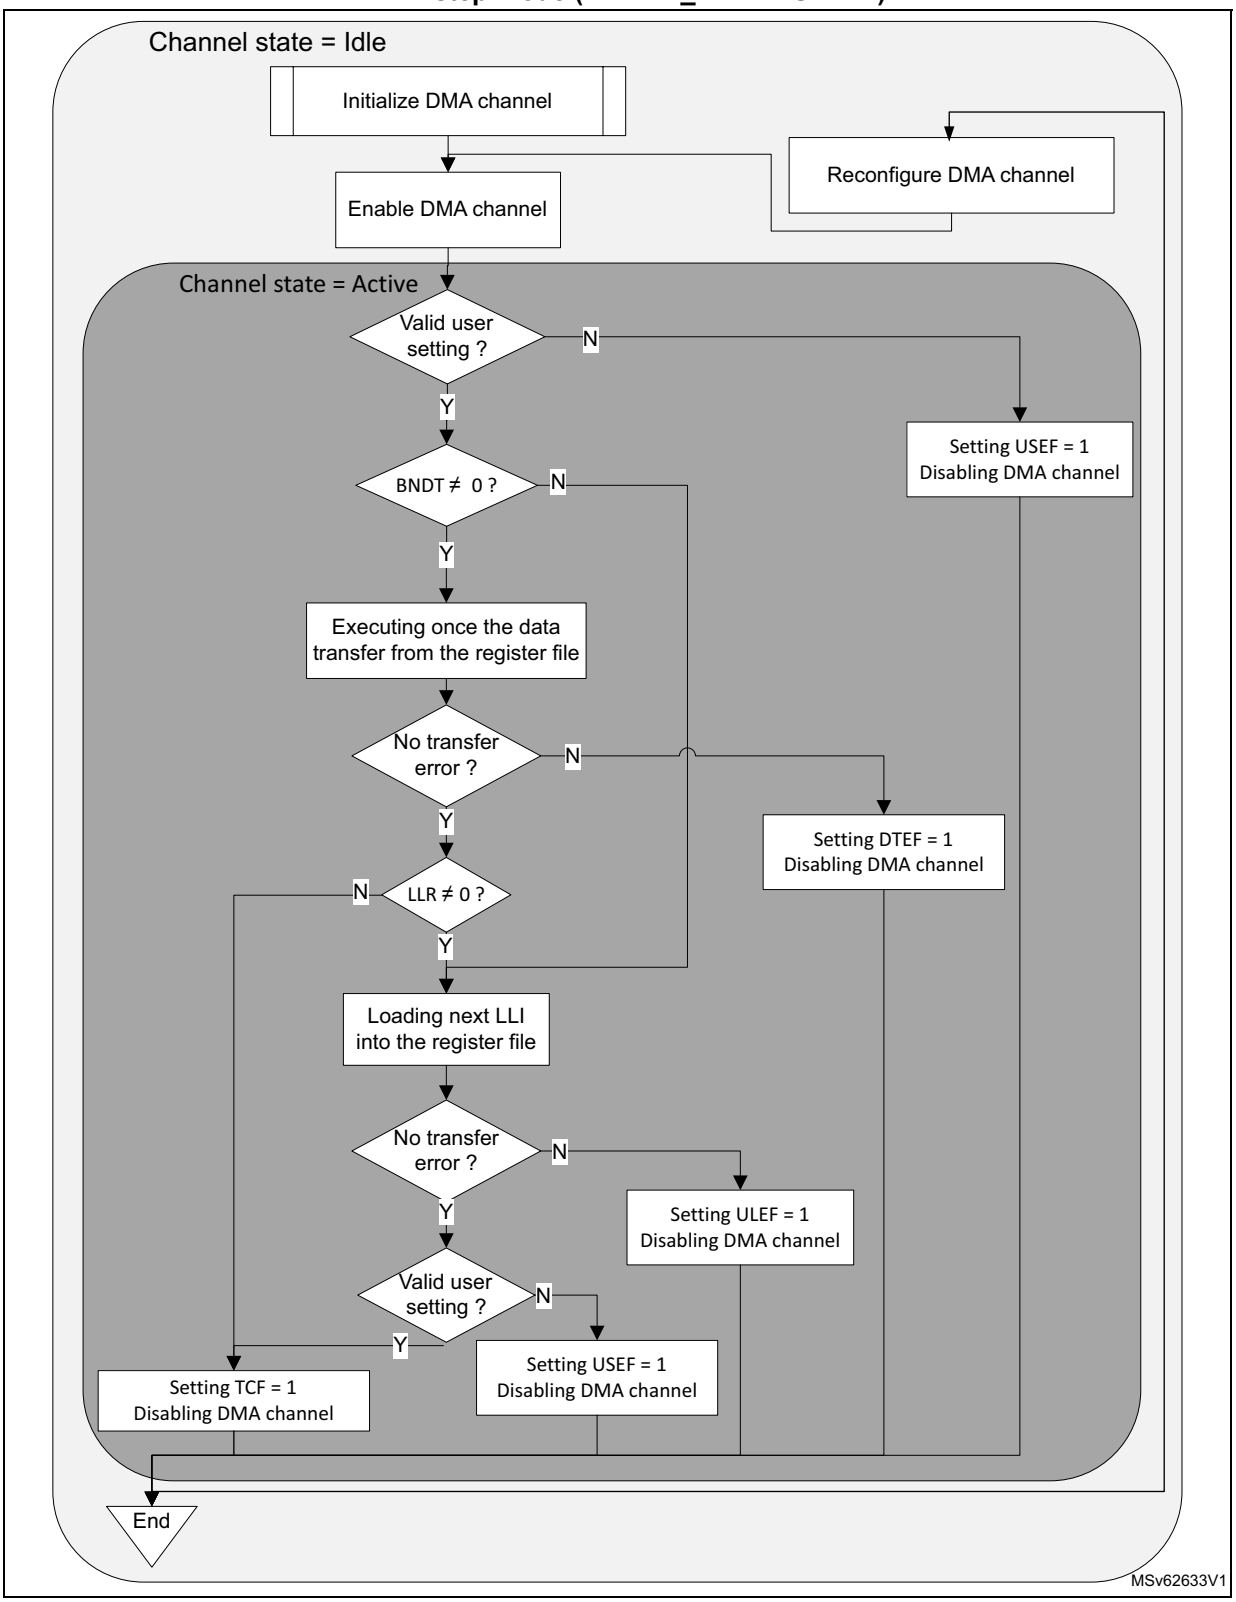
The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of HPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 81 depicts the HPDMA channel execution mode, and its programming in link step mode.

Note: Figure 81 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 81, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes BNDT ≠ 0 and PFREQ = 1 if the peripheral requests a data transfer with early termination (see Section 18.3.6).

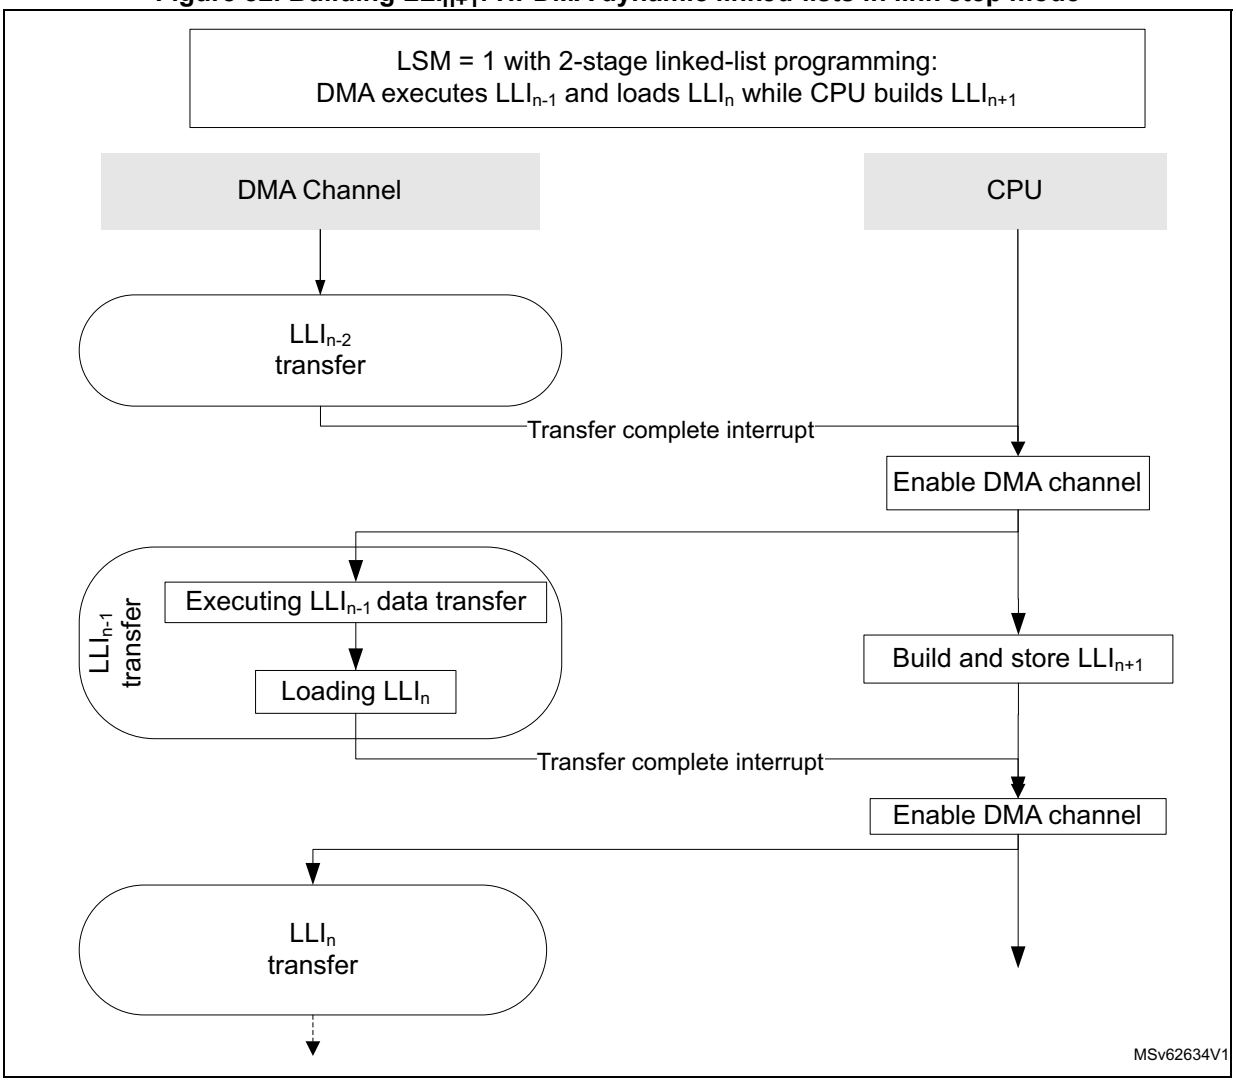
Figure 81. HPDMA channel execution and linked-list programming in link step mode (HPDMA_CxCR.LSM = 1)



Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after the HPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

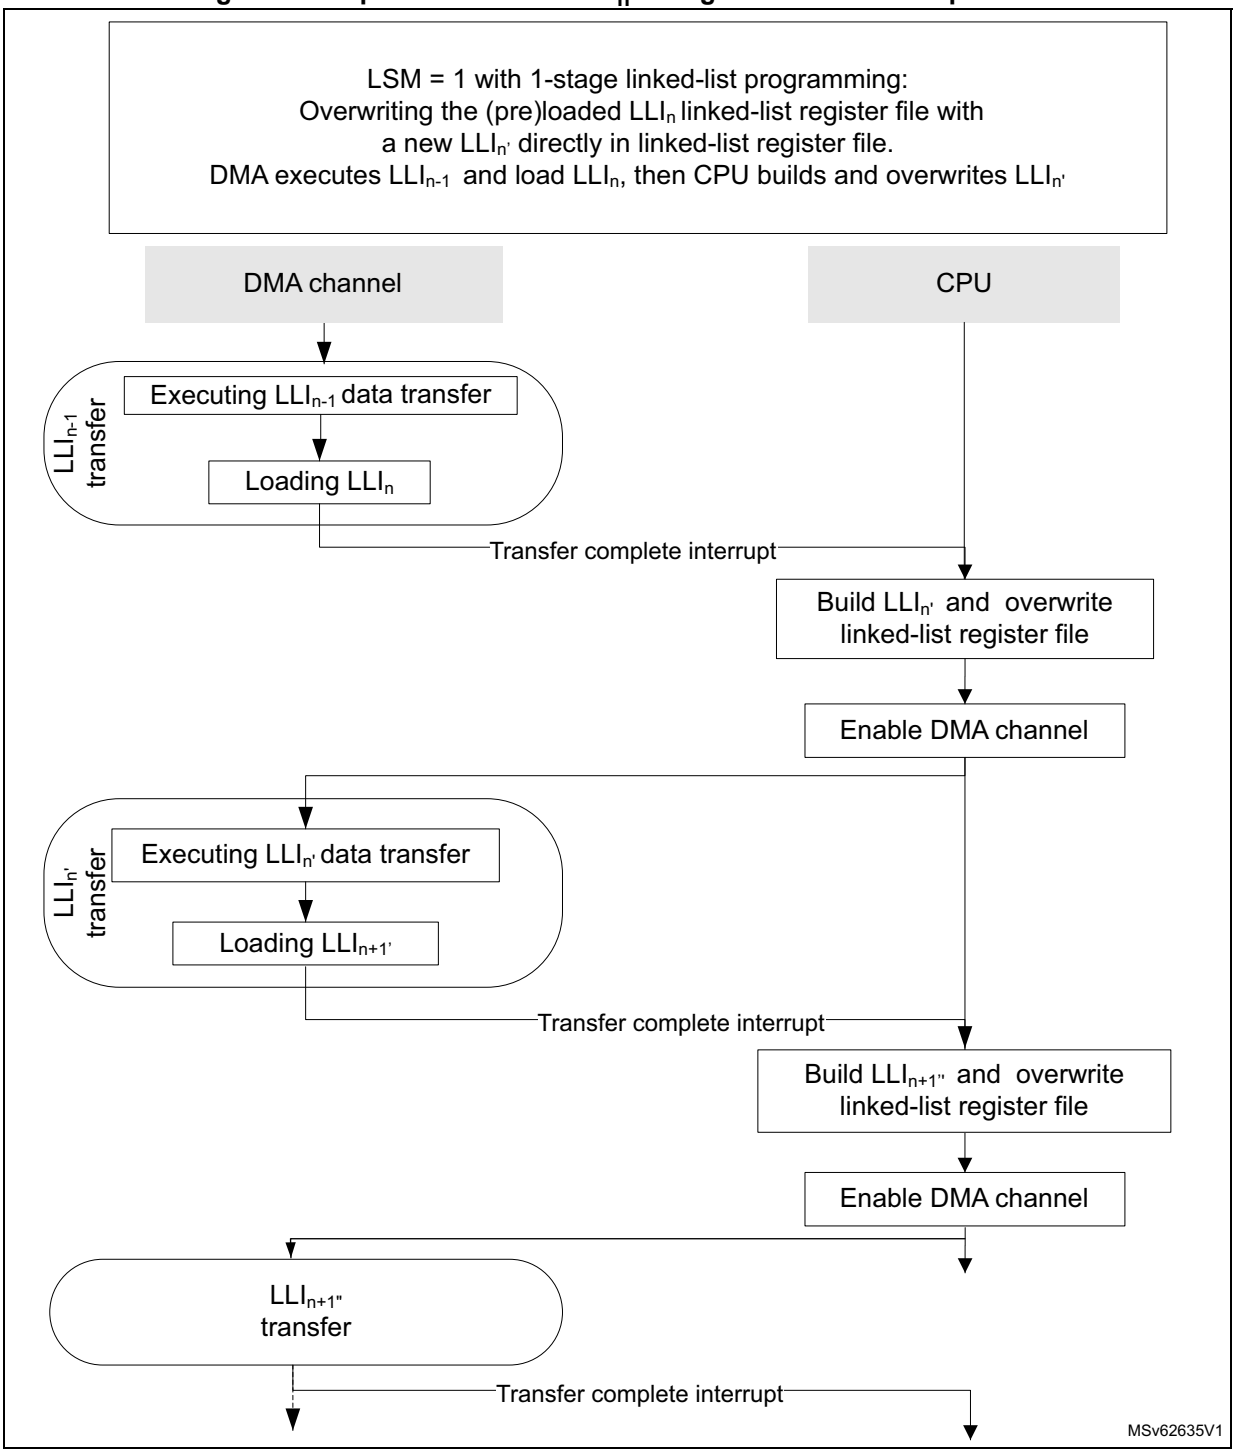
Figure 82. Building LLI_{n+1}: HPDMA dynamic linked-lists in link step mode



Run-time replacing an LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after the HPDMA executed the transfer from the LLI_{n-1}, and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in *Figure 83*.

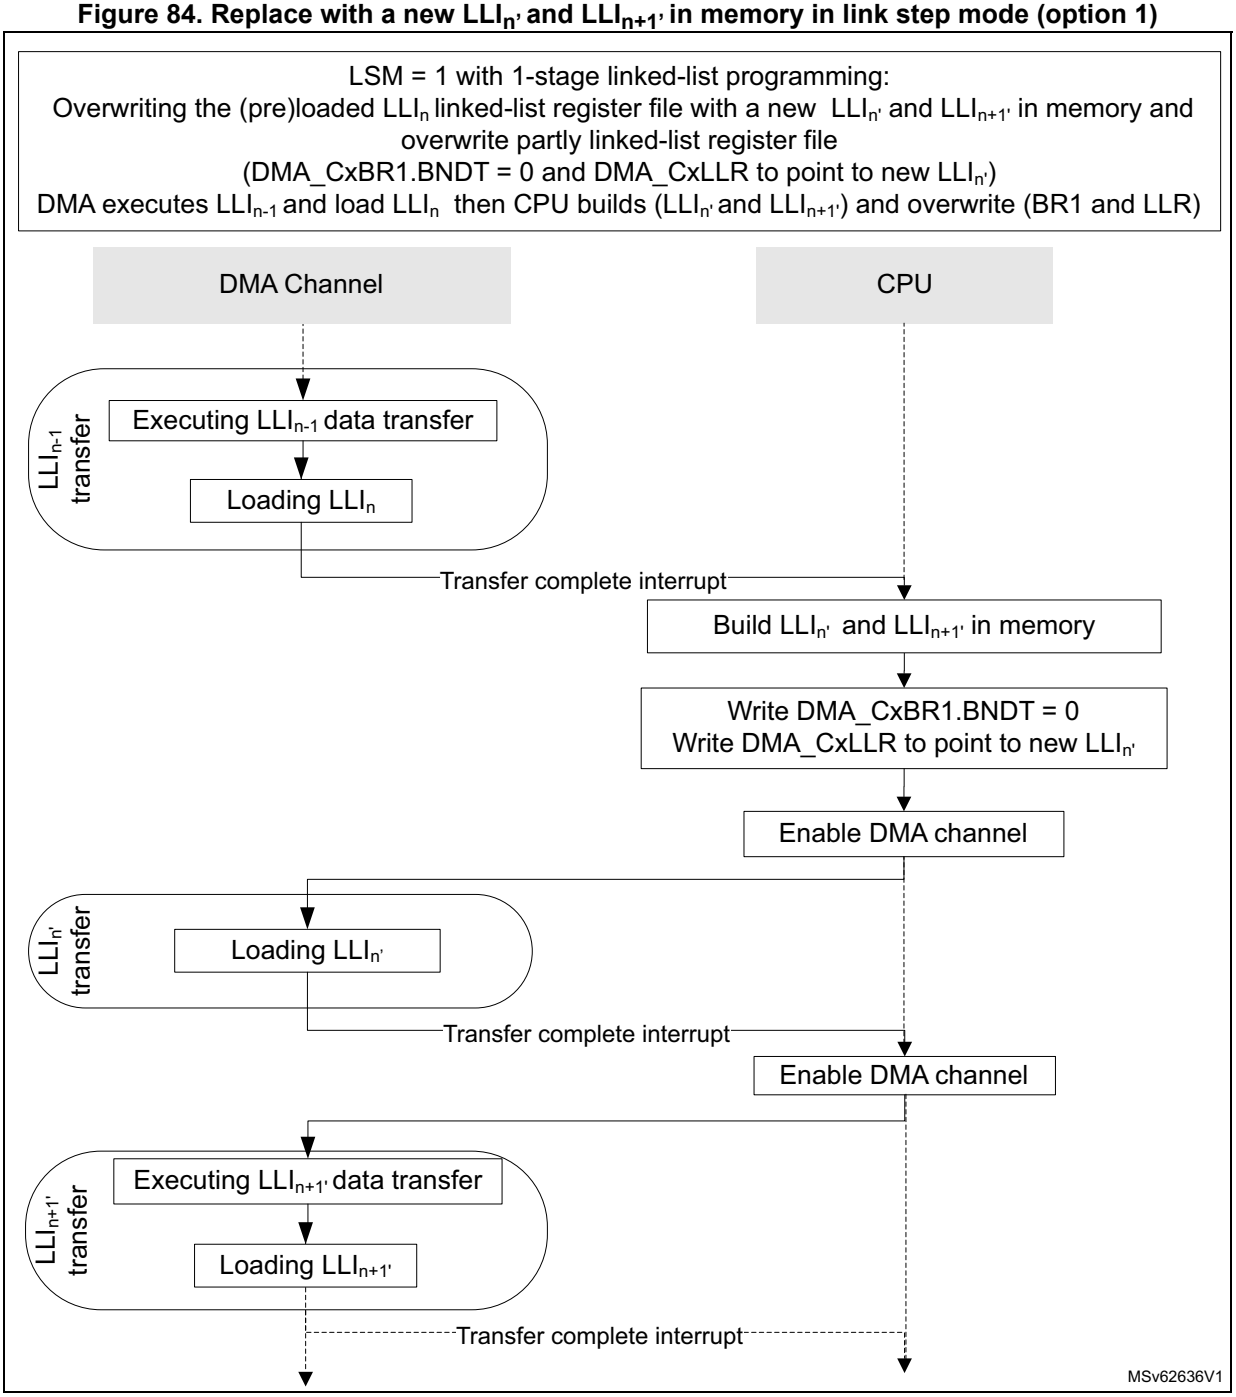
Figure 83. Replace with a new $LLI_{n'}$ in register file in link step mode



Run-time replacing an LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after HPDMA executed the transfer from the LLI_{n-1}, and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (HPDMA_CxBR1.BNDT[15:0] to be null, and HPDMA_CxLLR to point to new LLI_n) as shown in *Figure 84*.

Figure 84. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



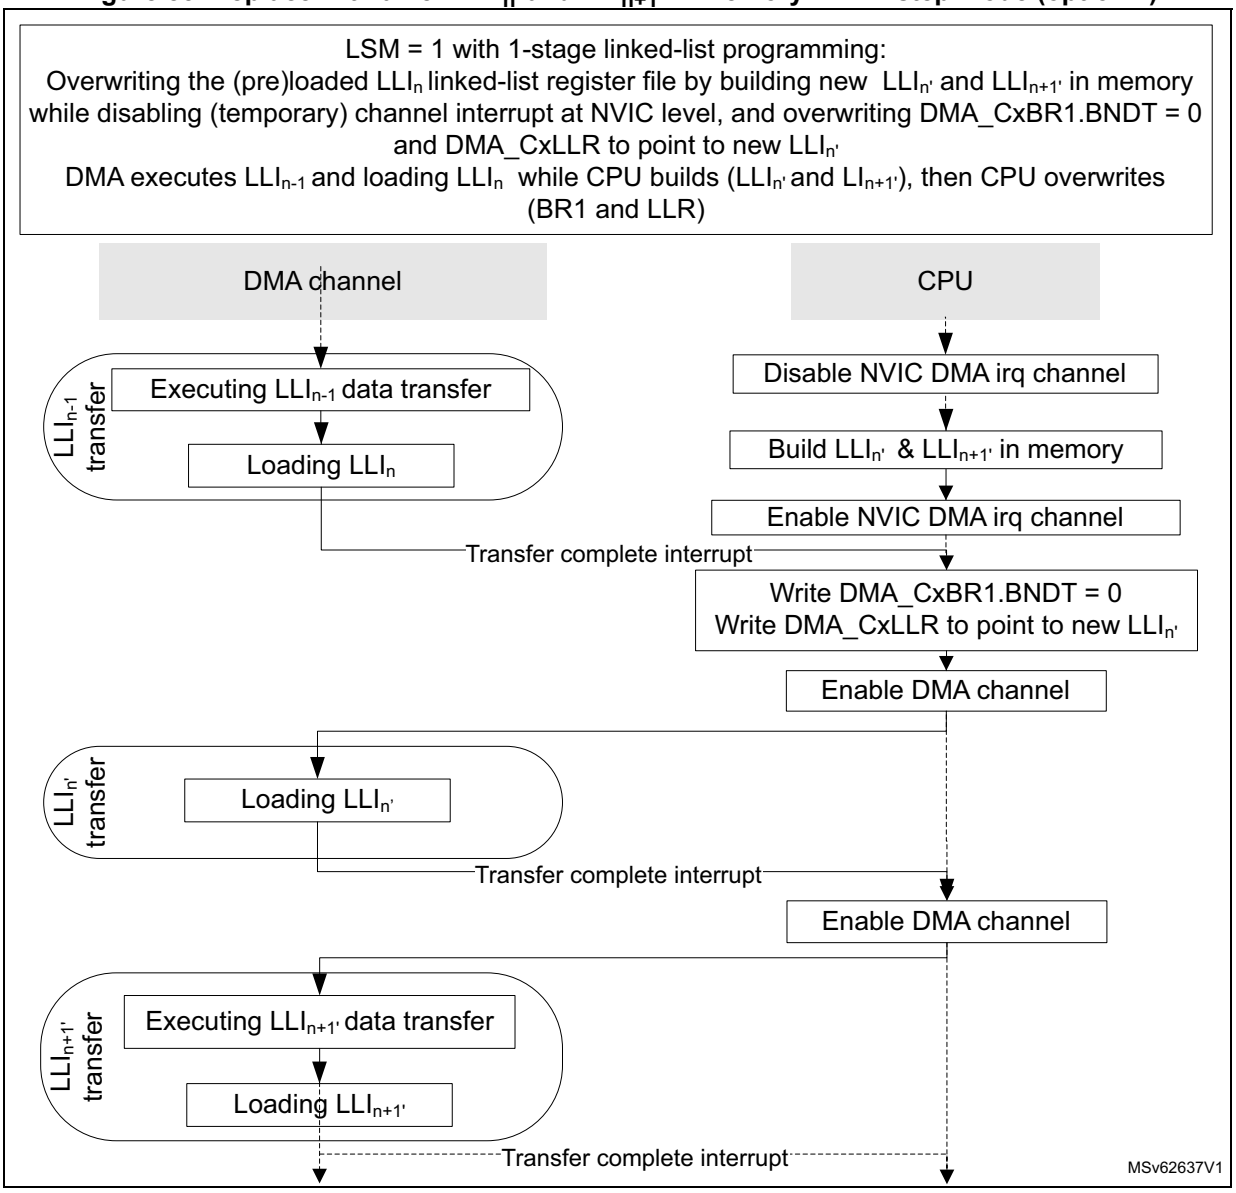
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile the HPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite HPDMA_CxBR1.BNDT[15:0] to be null and HPDMA_CxLLR to point to new $LLI_{n'}$, as shown in the figure below.

Figure 85. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)



18.4.9 HPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (HPDMA_CxCR.EN = 0), and update the execution mode (HPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the HPDMA_CxLLR of this LLI_{n+1}), before this LLI_{n+1} is loaded/used by the HPDMA channel
- abort and reconfigure the channel with an LSM update (see *Section 18.4.4*.)

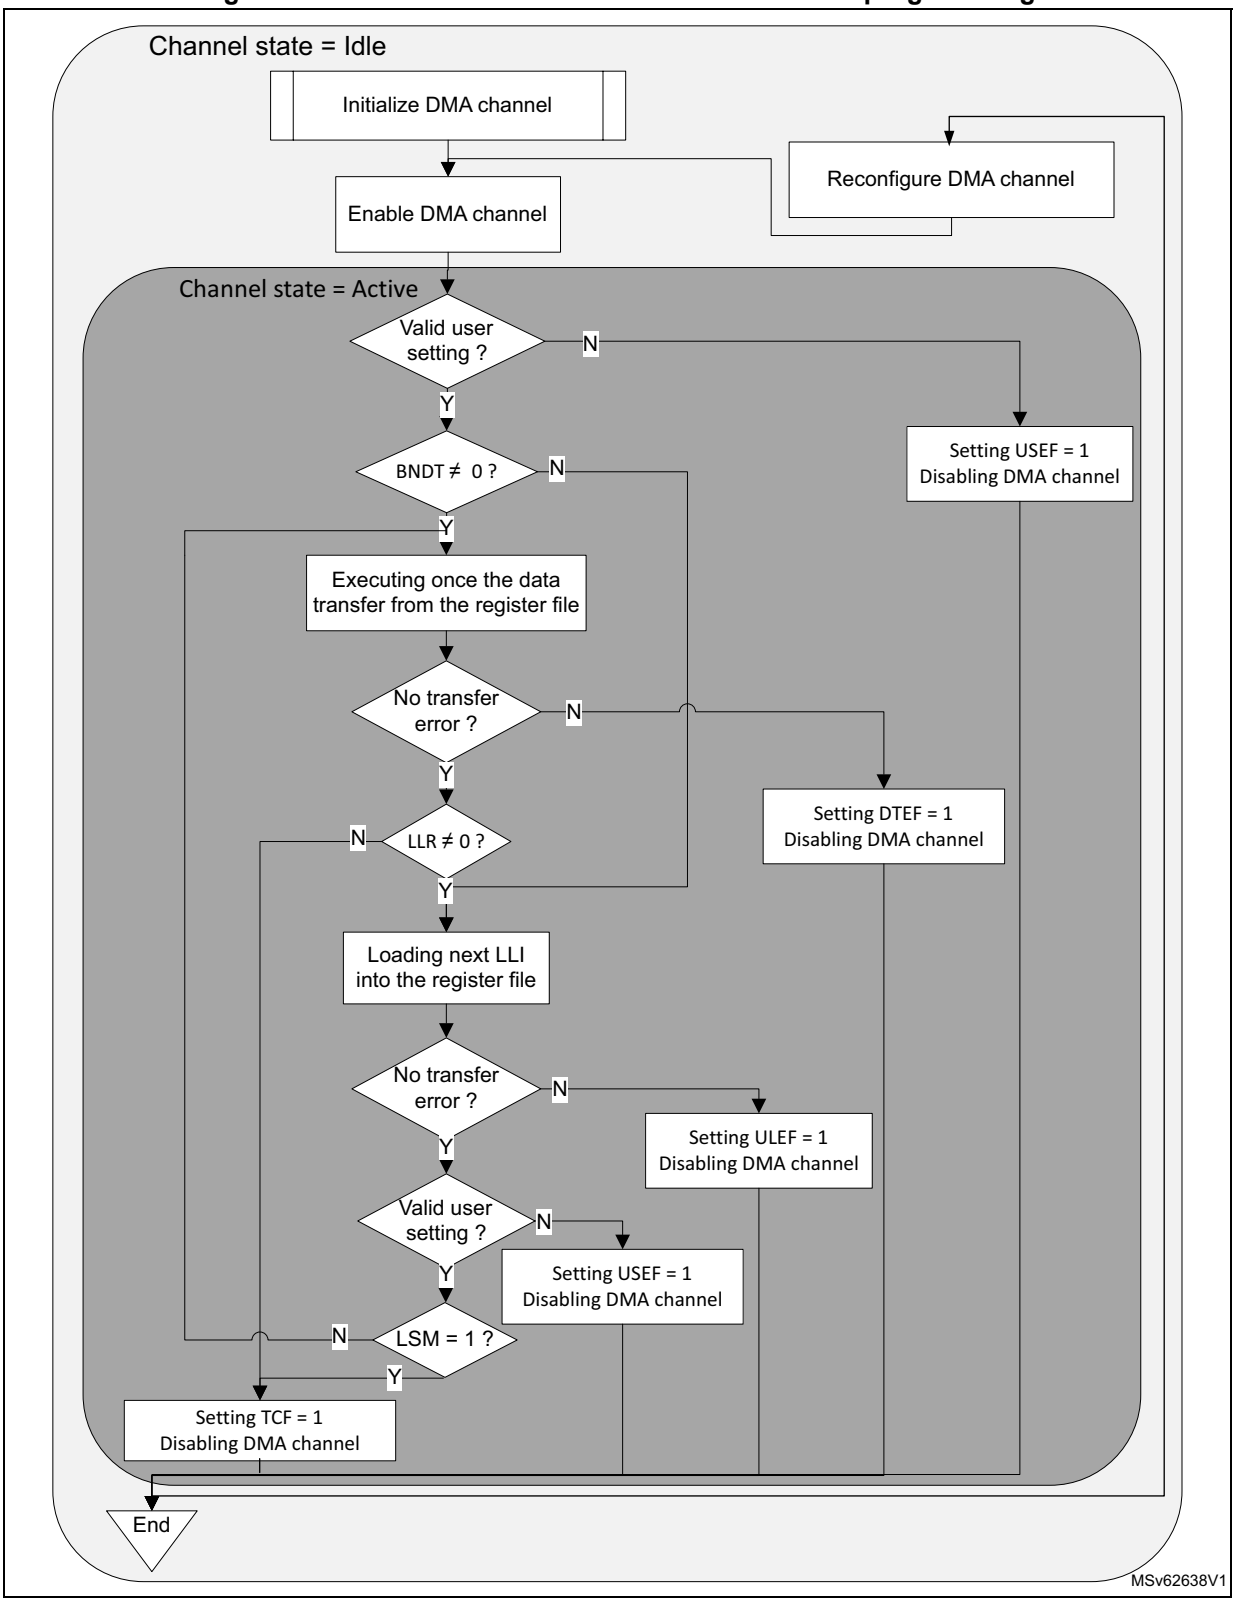
In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 86 shows the overall and unified HPDMA linked-list programming, whatever is the execution mode.

Note: Figure 86 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 86, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes BNDT ≠ 0 and PFREQ = 1 if the peripheral requests a data transfer with early termination (see Section 18.3.6).

Figure 86. HPDMA channel execution and linked-list programming



18.4.10 HPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 18.3.1* for more details).

HPDMA burst

A programmed transfer at the lowest level is an HPDMA burst.

An HPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in HPDMA_CxTR1.

The addressing mode after each data (named beat) of an HPDMA burst is defined by SINC and DINC in HPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of an HPDMA source/destination burst (defined by HPDMA_CxSAR and HPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of an HPDMA burst.

Table 92. Programmed HPDMA source/destination burst

<table>
<tr><th>SAP/DAP (allocated port)</th><th>SDW_LOG2[1:0] DDW_LOG2[1:0]</th><th>Data width (bytes)</th><th>SINC/DINC</th><th>SBL_1[5:0] DBL_1[5:0]</th><th>Burst length (data/ beats)</th><th>Next data/ beat address</th><th>Next burst address</th><th>Burst address alignment</th></tr>
<tr><td rowspan="3">0: AXI
1: AHB</td><td>00</td><td>1</td><td rowspan="4">0 (fixed)</td><td rowspan="6">n = 0 to 63(1)(2)</td><td rowspan="6">n+1</td><td rowspan="4">+ 0</td><td rowspan="4">+ 0</td><td>1</td></tr>
<tr><td>01</td><td>2</td><td>2</td></tr>
<tr><td>10</td><td>4</td><td>4</td></tr>
<tr><td>0: AXI</td><td>11</td><td>8</td><td>8</td></tr>
<tr><td rowspan="3">0: AXI
1: AHB</td><td>00</td><td>1</td><td rowspan="3">1
(contiguously incremented)</td><td>+ 1</td><td>+ (n + 1)</td><td>1</td></tr>
<tr><td>01</td><td>2</td><td>+ 2</td><td>+ 2 * (n + 1)</td><td>2</td></tr>
<tr><td>10</td><td>4</td><td>+ 4</td><td>+ 4 * (n + 1)</td><td>4</td></tr>
<tr><td>0: AXI</td><td>11</td><td>8</td><td>+ 8</td><td>+ 8 * (n + 1)</td><td>8</td></tr>
<tr><td>0: AHB</td><td>11</td><td colspan="7">forbidden user setting, causing USEF generation and none burst to be issued.</td></tr>
</table>

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.
2. As highlighted in *Section 18.3.2*, the maximum allowed AXI burst length is 16. The user must set SBL_1[5:0] lower or equal to 15 if the source allocated port is AXI (if SAP = 0). The user must set DBL_1[5:0] lower or equal to 15 if the destination allocated port is AXI (if DAP = 0).

The next burst address in the above table is the next source/destination default address pointed by HPDMA_CxSAR or HPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.

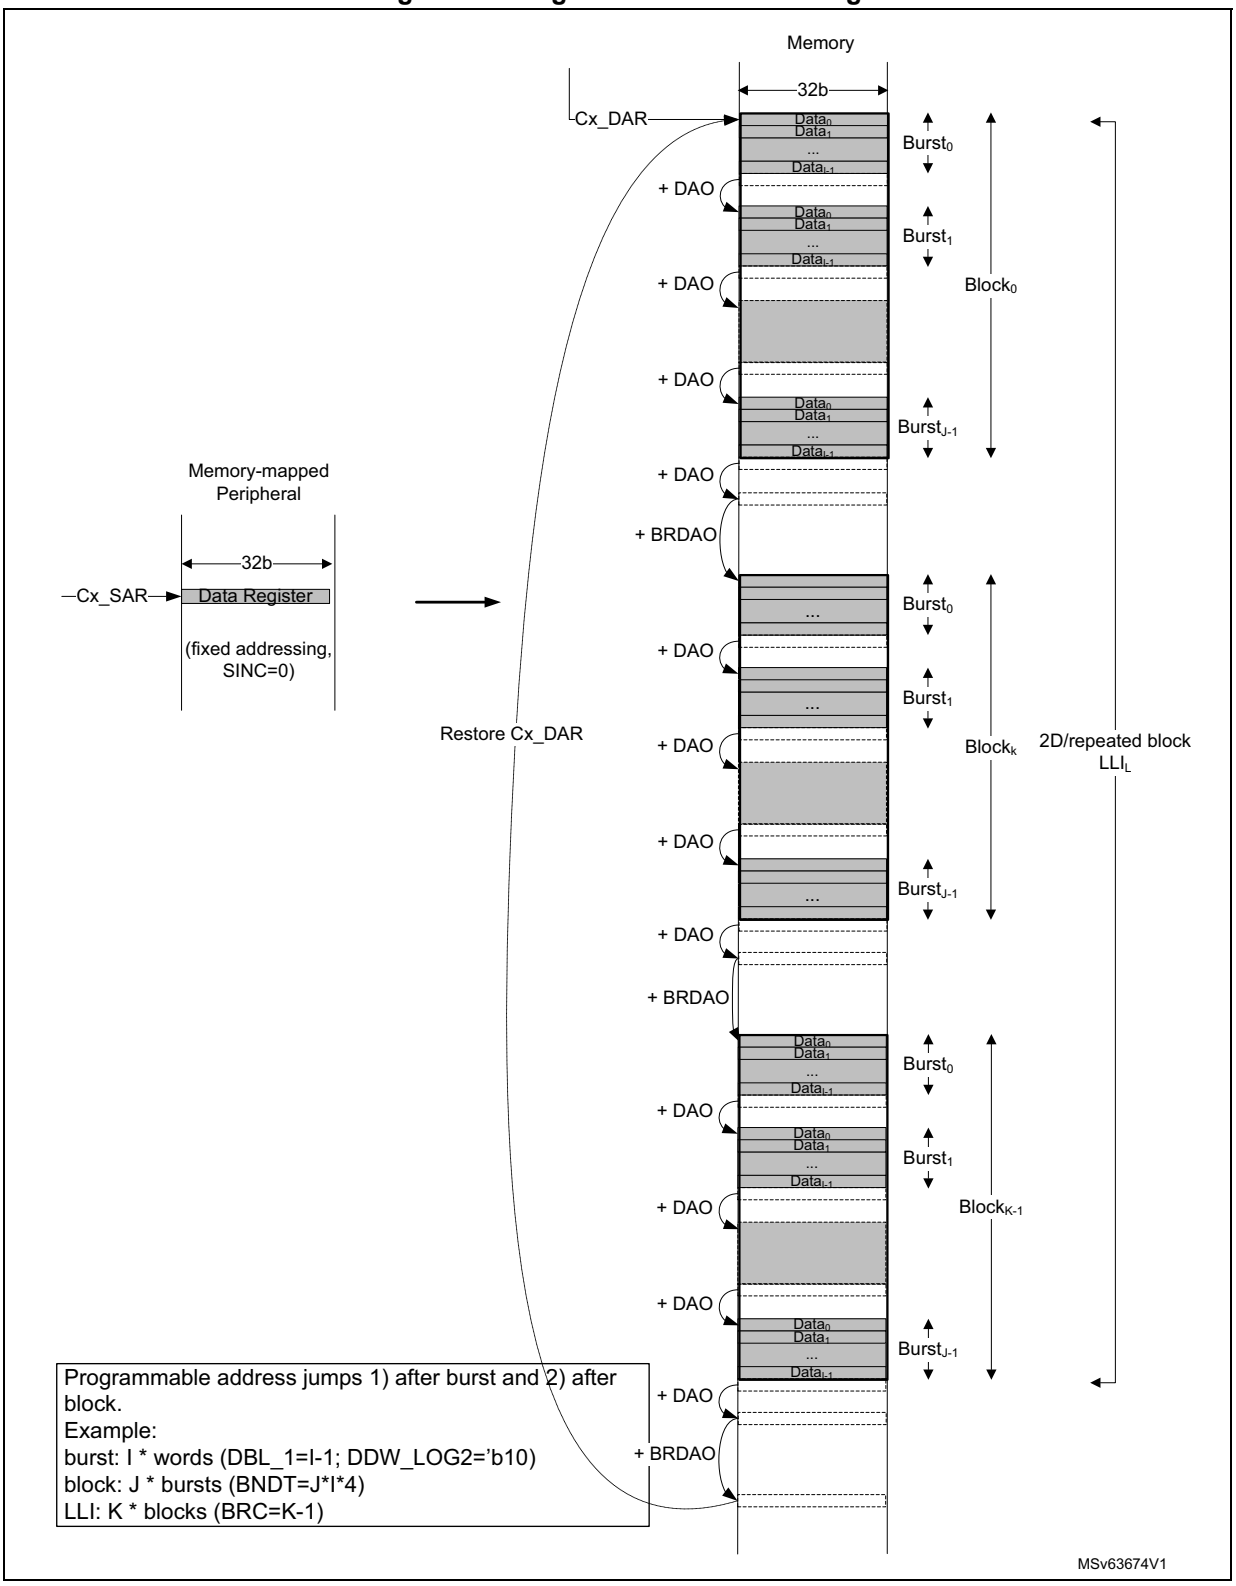
HPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by HPDMA_CxTR2.SAO[12:0]/DAO[12:0] and HPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by HPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and HPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 87* with a 2D destination buffer.

Figure 87. Programmed 2D addressing



HPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by HPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by HPDMA_CxTR1.DAP

HPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is the channel x FIFO size, in bytes (see *Section 18.3.1* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (HPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

HPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

HPDMA burst versus source block size, 1- or 4-Kbyte address boundary and FIFO size

The programmed source/destination HPDMA burst is implemented with an AHB/AXI burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination HPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (HPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (HPDMA_CxTR1.SDW_LOG2[1:0]), the HPDMA modifies and shortens bursts into

singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1- or 4-Kbyte address boundary on, respectively, an AHB or AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, or if the source/destination burst on an AXI transfer is both with fixed addressing and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol, without any user constraint.

In any case, the HPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in HPDMA_CxSR) is compared to and updated with the effective transfer size, and the HPDMA re-arbitrates between each AHB/AXI single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the HPDMA read transfers related to the update of the linked-list parameters from the memory to the internal HPDMA registers, are scheduled over the link allocated port, as programmed by HPDMA_CxCR.LAP.

HPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension, and left/right alignment

The data handling is controlled by HPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word, word, or double-word, as per SDW_LOG2[1:0] and DDW_LOG2[1:0] (see *Table 93*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if the source data width is a word or a double-word (for AXI source bus, SAP = 0), the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data-width conversion by packing, unpacking, padding, or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.

3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.
   - If DWX = 1and if the destination data width is a double-word and the destination bus is AXI (DAP = 0), the two aligned words are exchanged within aligned (post PAM[1:0]) double-words).

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding, and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 93. Programmed data handling

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.
3. RA= right aligned. LA = left aligned. RT = right truncated. LT = left truncated.
4. 0P= zero-bit padding up to the destination data width. SE = sign bit extended up to the destination data width.
5. if DDW_LOG2[1:0] = 11 and if DAP = 0 (destination allocated port is AXI). Else if DDW_LOG2[1:0] = 11 and DAP = $\overline{1}$ (AHB), a user setting error (USEF) is reported.
6. if SDW_LOG2[1:0] = 11 and if SAP = 0 (source allocated source port is AXI). Else if SDW_LOG2[1:0] = 11 and SAP = $\overline{1}$ (AHB), a user setting error (USEF) is reported.

18.4.11 HPDMA transfer request and arbitration

HPDMA transfer request

As defined by HPDMA_CxTR2, a programmed HPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the HPDMA hardware peripheral request is driven by REQSEL[7:0] (see *Section 18.3.5*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in HPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control register update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign the same input hardware peripheral HPDMA request via HPDMA_CxTR.REQSEL[7:0] to two different channels, if at a given time this request is asserted by the peripheral, and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

HPDMA transfer request for arbitration

A ready FIFO-based HPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (HPDMA_CxTR1.SAP) is arbitrated based on the channel priority (HPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested HPDMA transfers to the same master port.

A ready FIFO-based HPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (HPDMA_CxTR1.DAP) is arbitrated based on the channel priority (HPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested HPDMA transfers to the same master port.

An arbitrated HPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in the memory to one of the linked-list registers (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, HPDMA_CxTR3, HPDMA_CxBR2 or HPDMA_CxLLR). Each 32-bit read from the memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (HPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (HPDMA_CxTR2.SWREQ = 1), or with a hardware request (HPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (HPDMA_CxTR2.SWREQ = 0 and HPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request

to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

HPDMA arbitration

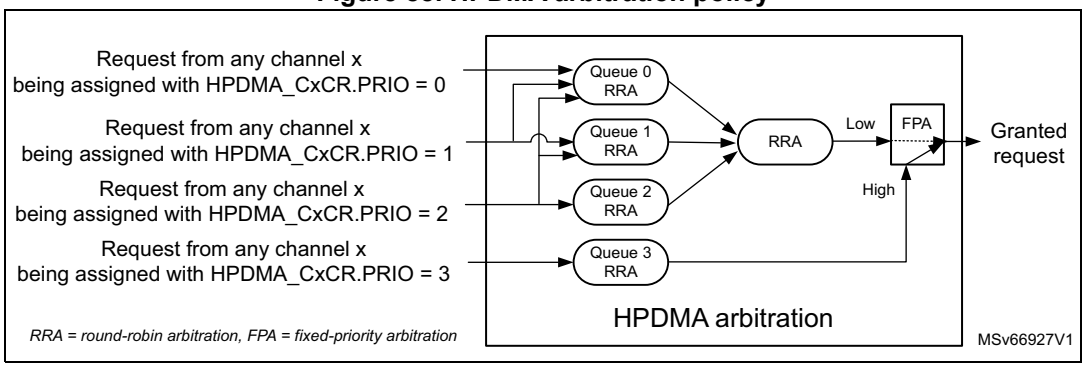
The HPDMA arbitration is directed from the 4-grade assigned channel priority (HPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 88*, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
  - Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
  - Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
  - Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

Figure 88. HPDMA arbitration policy



HPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- equal maximum bandwidth between requests with same priority
- reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive HPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).

    $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).

    $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$

    $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).

    $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$

    $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$

  The above computed bandwidth calculation is based on a theoretical input request, always active for any HPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one HPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.
- **Example 2**: application where the user distributes a same non-null N number of HPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is

    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is

    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is

    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is

    $B_{n, P0} = 1/N * 1/9 * (1 - B_{Q3})$

    $B_{n, P1} = 1/N * 5/18 * (1 - B_{Q3})$

    $B_{n, P2} = 1/N * 11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for J > 0 (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ (K>0 in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 (K > 0)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 (K = 0)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the HPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

18.4.12 HPDMA triggered transfer

A programmed HPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by HPDMA_CxTR2.TRIGPOL[1:0] and HPDMA_CxTR2.TRIGSEL[6:0] (see *Section 18.3.7* for the trigger selection).

The triggered transfer, as defined by the trigger mode in HPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block (for channel x = 12 to 15), or each programmed burst read/write. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in *HPDMA channel x transfer register 2 (HPDMA_CxTR2)* for more details).

Trigger hit memorization and trigger overrun flag generation

The HPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

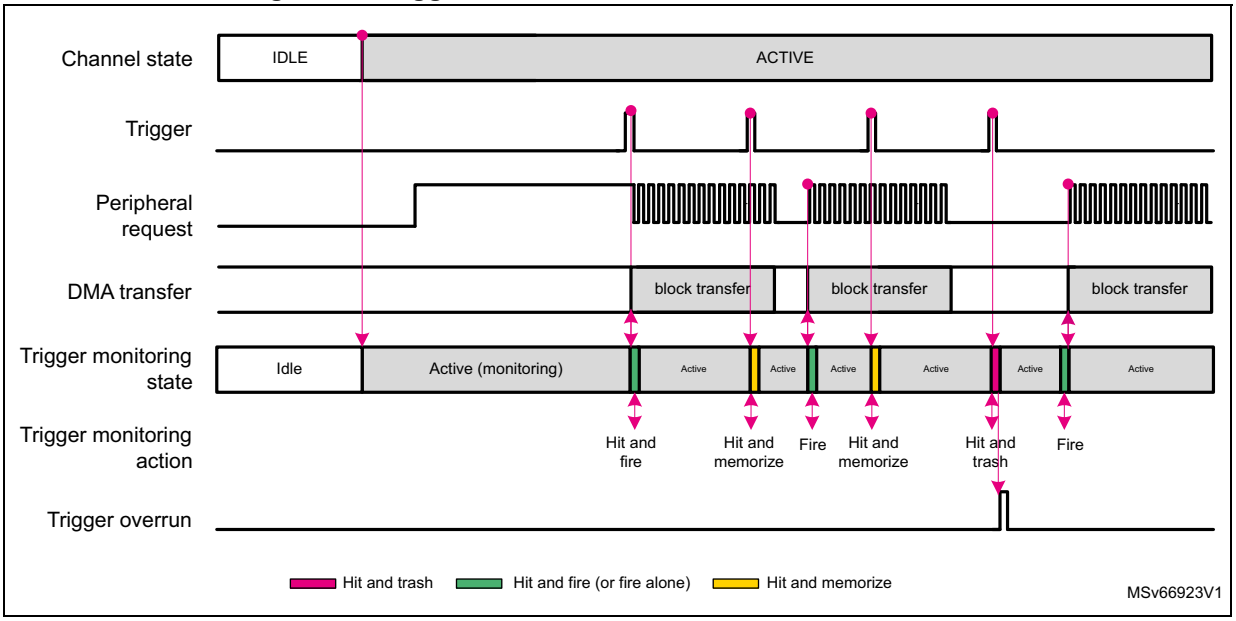
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[6:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates HPDMA_CxTR2 with a new value for any of TRIGSEL[6:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger, hit_{n+1} is memorized. If another trigger hit_{n+2} is detected, and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (HPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if HPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization, and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 89. Trigger hit, memorization and overrun waveform



Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

18.4.13 HPDMA circular buffering with linked-list programming

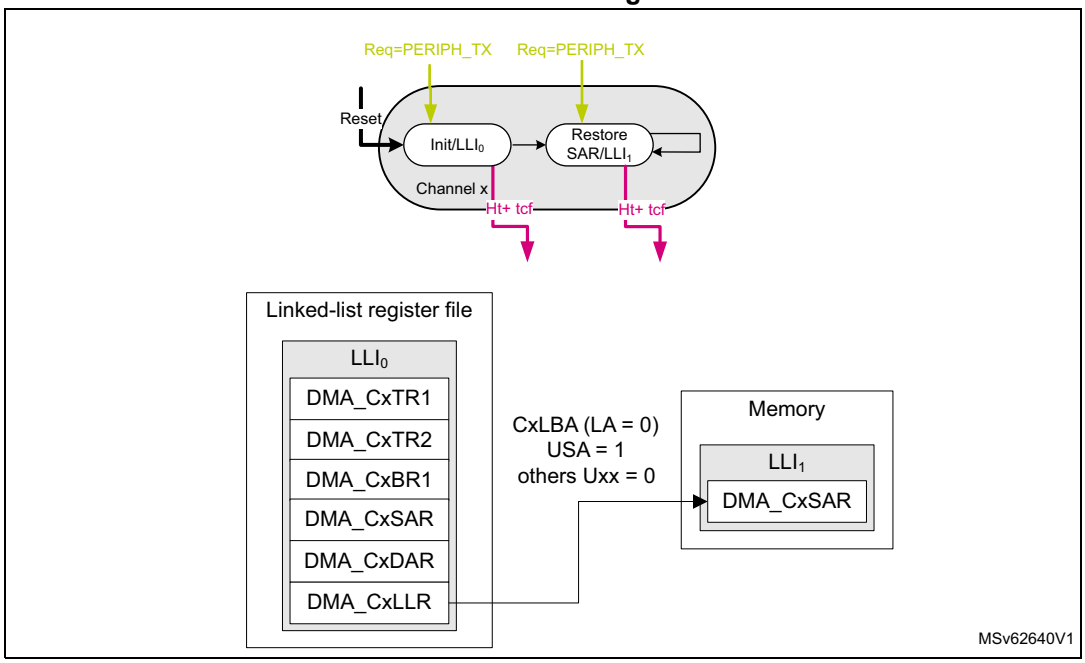
HPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half-transfer and complete-transfer event/interrupt generation (HPDMA_CxCR.HTIE = 1 and HPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel.
A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address for the memory-to-peripheral transfer (respectively the peripheral-to-memory).
The HPDMA automatically reloads the initially programmed HPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore HPDMA_CxBR1.

The figure below illustrates this programming with a linear addressing HPDMA channel and a source circular buffer.

Figure 90. HPDMA circular buffer programming: update of the memory start address with a linear addressing channel

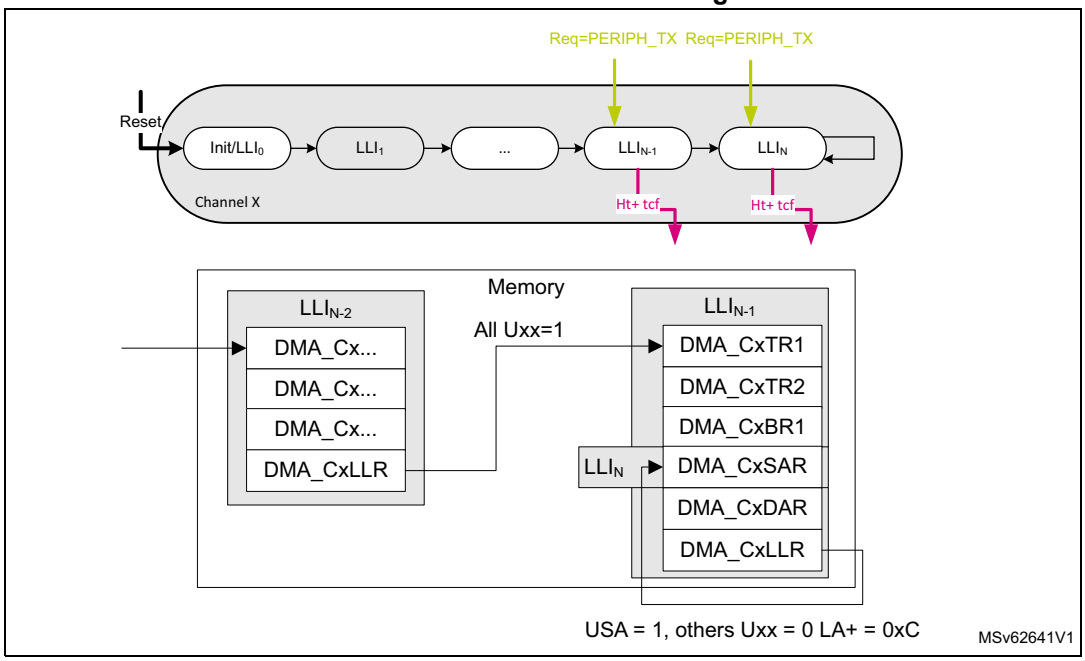


Note: With a 2D addressing channel, a single LLI can be used with HPDMA_CxBR1.BRC[10:0] = 1. The user can program a negative memory block address offset with HDMA_CxBR2 and HDMA_CxBR1, in order to jump back to the memory source or destination start address.

If the circular buffering must be executed after some other transfers over the shared HPDMA channel x, the before-last LLI_{N-1} in the memory is needed to configure the first block transfer. The last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory).

The figure below illustrates this programming with a linear addressing shared HPDMA channel, and a source circular buffer.

Figure 91. Shared HPDMA channel with circular buffering: update of the memory start address with a linear addressing channel



18.4.14 HPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate an HPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 18.3.6*).

If the related HPDMA channel x is also programmed in peripheral flow-control mode (HPDMA_CxTR2.PFREQ = 1):

- The HPDMA block transfer starts as follows:
  - If HPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the HPDMA hardware.
  - If HPDMA_CxBR1.BNDT[15:0] = 0, the HPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The HPDMA block transfer is completed as soon as the first occurrence of any of the following condition occurs:
  - when HPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on HPDMA_CxTR2. Then the software can read the current number of transferred bytes from the source (HPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (HPDMA_CxSAR[31:0] or HPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with an hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- HPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

18.4.15 HPDMA secure/nonsecure channel

The HPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and nonsecure worlds at any given time.

Any channel x is a secure or nonsecure hardware resource, as configured by HPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A nonsecure read access to a bitfield of this channel is forced to return 0, except for HPDMA_SECCFGR, HPDMA_PRIVCFGR, HPDMA_RCFGLOCKR, and HPDMA_CxSEMCR that are readable by a nonsecure agent.
- A nonsecure write access to a bitfield of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or nonsecure the HPDMA data transfer from the source (HPDMA_CxTR1.SSEC), and to the destination (HPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the HPDMA memory into its register file, is automatically performed with secure transfers via the HPDMA_CxCR.LAP allocated master port.

The HPDMA generates a secure bus that reflects HPDMA_SECCFGR, to keep the other peripherals informed of the secure/nonsecure state of each HPDMA channel x.

The HPDMA also generates a security illegal access pulse signal on an illegal nonsecure access to a secure HPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a nonsecure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next nonsecure transfer as a nonsecure software is not allowed to do so, and must have HPDMA_CxCR.EN = 0 before the nonsecure software can reprogram HPDMA_CxCR for a next transfer. The secure software can reset not only the channel x (HPDMA_CxCR.RESET = 1), but also the full channel x register file to its reset value.

18.4.16 HPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via HPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a bitfield of this channel is forced to return 0, except for HPDMA_PRIVCFGR, HPDMA_SECCFGR, HPDMA_CxCIDCFGR and HPDMA_CxSEMCR that are readable by an unprivileged agent.
- An unprivileged write access to a bitfield of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB/AXI master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the HPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the HPDMA_CxCR.LAP allocated master port.

The HPDMA generates a privileged bus that reflects HPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each HPDMA channel x.

Additionally, the HPDMA generates a privileged illegal access pulse signal on an illegal unprivileged access to a privileged HPDMA register. This signal can be used or not, depending on the product (see the system security section for more details).

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel, or wait until the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer, as an unprivileged software is not allowed to do so, and must have HPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the HPDMA_CxCR for a next transfer. The privileged software can reset not only the channel x (HPDMA_CxCR.RESET = 1), but also the full channel x register file to its reset value.

HPDMA compartmented channel

The HPDMA controller performs bus transfers over its master port, under the control of a resource isolation domain identification named compartment identification (CID), at a channel level. For more details about resource isolation and CID, refer to the RIF section in the product reference manual.

18.4.17 HPDMA error management

The HPDMA can manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as an AHB/AXI single or a burst) to the source or the destination

- The source or destination target reports an AHB/AXI error.
- The programmed channel transfer is stopped (HPDMA_CxCR.EN cleared by the HPDMA hardware). The channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1) and the data error (HPDMA_CxSR.DTEF = 1).

- After an HPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After an HPDMA data transfer error, the user must issue a channel reset (set HPDMA_CxCR.RESET) to reset the hardware HPDMA channel data path and the FIFO content, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a HPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB/AXI error.
- The programmed channel transfer is stopped (HPDMA_CxCR.EN cleared by the HPDMA hardware), the channel status register reports an idle state HPDMA_CxSR.IDLEF = 1), and the link error (HPDMA_CxSR.ULEF = 1).
- After an HPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (HPDMA_CxLBAR and HPDMA_CxLLR), including the protection attributes.
- After an HPDMA link error, the user must explicitly write the linked-list register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 when present), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of an HPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (HPDMA_CxCR.EN forced and cleared by the HPDMA hardware), preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1), and a user setting error (HPDMA_CxSR.USEF = 1).
- After an HPDMA user setting error, the user must perform a debug session, taking care of the HPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxSAR[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])

- for channel x =12 to 15, a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxTR3.SAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
- for channel x =12 to 15, a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxBR2.BRSAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
- a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxDAR[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
- for channel x =12 to 15, a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxTR3.DAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
- for channel x =12 to 15, a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR2.BRDAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width and a programmed AHB source allocated port (HPDMA_CxTR1.SDW_LOG2[1:0] = 11 and HPDMA_CxTR1.SAP = 1)
- a programmed double-word destination data width and a programmed AHB destination allocated port (HPDMA_CxTR1.DDW_LOG2[1:0] = 11 and HPDMA_CxTR1.DAP = 1)
- a programmed linked-list item LLI_{n+1} with a null data transfer (HPDMA_CxLLR.UB1 = 1 and HPDMA_CxBR1. BNDT = 0)

18.5 HPDMA in debug mode

When the device enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, HPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, HPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

18.6 HPDMA in low-power modes

Table 94. Effect of low-power modes on HPDMA

Mode	Description
Sleep	No effect. HPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of HPDMA registers is kept when entering Stop mode.
Standby	The HPDMA is powered down, and must be reinitialized after exiting Standby mode.

1. Refer to *Section 18.3.3* to know which Stop mode is supported.

18.7 HPDMA interrupts

There is one HPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 95. HPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
HPDMA_CHx	Transfer complete	HPDMA_CxCR.TCIE	HPDMA_CxSR.TCF	Writes 1 to HPDMA_CxFCR.TCF
	Half transfer	HPDMA_CxCR.HTIE	HPDMA_CxSR.HTF	Writes 1 to HPDMA_CxFCR.HTF
	Data transfer error	HPDMA_CxCR.DTEIE	HPDMA_CxSR.DTEF	Writes 1 to HPDMA_CxFCR.DTEF
	Update link error	HPDMA_CxCR.ULEIE	HPDMA_CxSR.ULEF	Writes 1 to HPDMA_CxFCR.ULEF
	User setting error	HPDMA_CxCR.USEIE	HPDMA_CxSR.USEF	Writes 1 to HPDMA_CxFCR.USEF
	Suspended	HPDMA_CxCR.SUSPIE	HPDMA_CxSR.SUSPF	Writes 1 to HPDMA_CxFCR.SUSPF
	Trigger overrun	HPDMA_CxCR.TOFIE	HPDMA_CxSR.TOF	Writes 1 to HPDMA_CxFCR.TOF

An HPDMA channel x event can be:

- a transfer complete
- an half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal hpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (HPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (HPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into HPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by HPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer-complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode HPDMA_CxTR2.TCEM[1:0].
- A half-transfer event is an half-block transfer, or a half 2D/repeated block transfer, depending on the transfer complete event mode HPDMA_CxTR2.TCEM[1:0].

An half-block transfer occurs when half of the source block size bytes (rounded-up integer of HPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

An half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (HPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *HPDMA channel x transfer register 2 (HPDMA_CxTR2)* for more details.

Note: The interrupt mode must be used (not the polling mode) to be notified on an half transfer when the write data transaction has been completed over the AXI destination allocated port (written at the destination memory-mapped address), and not just before when has been issued, at HPDMA level, this AXI burst transaction.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of an HPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of an HPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the HPDMA channel programming versus the USEF root causes list (see *Section 18.4.17*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

18.8 HPDMA registers

The HPDMA registers must be accessed with an aligned 32-bit word data access.

18.8.1 HPDMA secure configuration register (HPDMA_SECCFGR)

Address offset: 0x000

Reset value: 0x0000 0000

A write access to this register must be secure and privileged. A read access is secure or nonsecure, privileged, or unprivileged, and with any CID.

A write access is ignored at bit level if the corresponding channel x is locked (HPDMA_RCFGLOCKR.LOCKx = 1).

This register can mix information from different CIDs. If a channel x is configured as CID filtered (HPDMA_CxCIDCFGR.CFEN = 1), the SECx bit can be written only by an authorized CID (and secure and privileged) agent. If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of an HPDMA channel (when HPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or nonsecure world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEC15	SEC14	SEC13	SEC12	SEC11	SEC10	SEC9	SEC8	SEC7	SEC6	SEC5	SEC4	SEC3	SEC2	SEC1	SEC0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SECx**: Secure state of channel x (x = 15 to 0)
0: Nonsecure
1: Secure

18.8.2 HPDMA privileged configuration register (HPDMA_PRIVCFGR)

Address offset: 0x004

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or nonsecure, and with any CID.

This register can mix secure and nonsecure information. If a channel x is configured as secure (HPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

This register can mix information from different CIDs. If a channel x is configured as CID filtered (HPDMA_CxCIDCFGR.CFEN = 1), the PRIVx bit can be written only by an authorized CID (and privileged) agent. If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

A write access is ignored at bit level if the corresponding channel x is locked (HPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a HPDMA channel (HPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PRIVx**: Privileged state of channel x (x = 15 to 0)
0: Unprivileged
1: Privileged

18.8.3 HPDMA configuration lock register (HPDMA_RCFGLOCKR)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged and trusted domain CID attributes in order to individually lock, for example at boot time, the secure privileged and CID attributes of any HPDMA channel/resource (to lock the setting of HPDMA_SECCFGR, HPDMA_PRIVCFGR, and HPDMA_CxCIDCFGR for any channel x at, for example at boot time).

A read access may be privileged or unprivileged, secure or nonsecure, and with any CID.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKx**: Lock of the configuration of HPDMA_SECCFGR.SECx, HPDMA_PRIVCFGR.PRIVx, and HPDMA_CxCIDCFGR until a global HPDMA reset (x = 15 to 0)
This bit is cleared after reset and, once set, it cannot be reset until a global HPDMA reset.
0: Secure privilege and CID configuration of the channel x is writable.
1: Secure privilege and CID configuration of the channel x is not writable.

18.8.4 HPDMA nonsecure masked interrupt status register (HPDMA_MISR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register is a read register.

This is a nonsecure register, containing the masked interrupt status bit MISx for each non-secure channel x (channel x configured with HPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of HPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of HPDMA_CxCR.

Every bit is deasserted by hardware when writing 1 to the corresponding flag clear bit in HPDMA_CxFCR.

If a channel x is in secure state (HPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel HPDMA_PRIVCFGR.PRIVx. A privileged software can read the full nonsecure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and nonsecure) channels, other privileged bitfields returning zero.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: Masked interrupt status of channel x (x = 15 to 0)
0: No interrupt occurred on channel x.
1: An interrupt occurred on channel x.

18.8.5 HPDMA secure masked interrupt status register (HPDMA_SMISR)

Address offset: 0x010

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (HPDMA_SECCFGR.SECx = 1). It is a logical OR of all the HPDMA_CxSR flags, each source flag being enabled by the corresponding HPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when securely writing 1 to the corresponding HPDMA_CxFCR flag clear bit.

This register does not contain any information about a nonsecure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel HPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bitfields returning zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: Masked interrupt status of the secure channel x (x = 15 to 0)
0: No interrupt occurred on the secure channel x.
1: An interrupt occurred on the secure channel x.

18.8.6 HPDMA channel x linked-list base address register (HPDMA_CxLBAR)

Address offset: 0x050 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x HPDMA_PRIVCFGR.PRIVx.

This register is either secure or nonsecure depending on the secure state of the channel x (HPDMA_SECCFGR.SECx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the HPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit HPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LBA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:16 **LBA[31:16]**: Linked-list base address of HPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

18.8.7 HPDMA channel x CID register (HPDMA_CxCIDCFGR)

Address offset: 0x054+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This channel-based register can be written by the secure, privileged, and trusted domain CID, in order to individually configure the CID allocation of any HPDMA channel x. If the debug domain feature is activated, a read/write access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register must be written when the resource configuration of the channel x is unlocked (HPDMA_RCFGLOCKR.LOCKx = 0) and when the channel is disabled (HPDMA_CxCR.EN = 0).

A read access may be privileged or unprivileged, secure or nonsecure, and with any CID.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SCID[2:0]			Res.	Res.	SEM_EN	CFEN
									rw	rw	rw			rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SEM_WLIST_CID6**: White-listed CID6 in the CID allocation pool (for when the channel x in semaphore mode)
0: CID6 black-listed in the semaphore-based CID allocation pool
1: CID6 white-listed in the semaphore-based CID allocation pool

Bit 21 **SEM_WLIST_CID5**: White-listed CID5 in the CID allocation pool (for when the channel x in semaphore mode)
0: CID5 black-listed in the semaphore-based CID allocation pool
1: CID5 white-listed in the semaphore-based CID allocation pool

Bit 20 **SEM_WLIST_CID4**: White-listed CID4 in the CID allocation pool (for when the channel x in semaphore mode)
0: CID4 black-listed in the semaphore-based CID allocation pool
1: CID4 white-listed in the semaphore-based CID allocation pool

Bit 19 **SEM_WLIST_CID3**: White-listed CID3 in the CID allocation pool (for when the channel x in semaphore mode)
0: CID3 black-listed in the semaphore-based CID allocation pool
1: CID3 white-listed in the semaphore-based CID allocation pool

Bit 18 **SEM_WLIST_CID2**: White-listed CID2 in the CID allocation pool (for when the channel x in semaphore mode)
0: CID2 black-listed in the semaphore-based CID allocation pool
1: CID2 white-listed in the semaphore-based CID allocation pool

Bit 17 **SEM_WLIST_CID1**: White-listed CID1 in the CID allocation pool (for when the channel x in semaphore mode)
0: CID1 black-listed in the semaphore-based CID allocation pool
1: CID1 white-listed in the semaphore-based CID allocation pool

Bit 16 **SEM_WLIST_CID0**: White-listed CID0 in the CID allocation pool (for when the channel x in semaphore mode)
0: CID0 black-listed in the semaphore-based CID allocation pool
1: CID0 white-listed in the semaphore-based CID allocation pool

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **SCID[2:0]**: Allocation of a static/single CID to the channel x (for when the channel x CID configuration is not in semaphore mode)
000: CID0 allocated to the channel x
001: CID1 allocated to the channel x
010: CID2 allocated to the channel x
011: CID3 allocated to the channel x
100: CID4 allocated to the channel x
101: CID5 allocated to the channel x
110: CID6 allocated to the channel x
111: Reserved (write ignored)

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **SEM_EN**: Semaphore mode enable (for the CID allocation policy to the channel x)
0: Semaphore mode disabled. CID allocation policy to the channel x is defined by SCID[1:0].
1: Semaphore mode enabled. CID allocation policy to the channel x is defined by the white-listed allocation pool SEM_WLIST_CIDx and HPDMA_CxSEMCR.SEM_MUTEX.
Note: If SEM_EN = 1 and if a trusted domain or debug domain CID agent clears this bit, then the HPDMA hardware automatically clears the HPDMA_CxSEMCR.SEM_MUTEX.

Bit 0 **CFEN**: CID filtering enable of the channel x
0: CID filtering disabled for when accessing a channel x register/bitfield
1: CID filtering enabled for when accessing a channel x register/bitfield
Note: If CFEN = 1 and if a trusted domain or debug domain CID agent clears this bit, then the HPDMA hardware automatically clears the HPDMA_CxSEMCR.SEM_MUTEX.

18.8.8 HPDMA channel x semaphore control register (HPDMA_CxSEMCR)

Address offset: 0x058+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

When the secure, privileged and trusted domain has set up the channel x in semaphore mode (HPDMA_CxCIDCFGR.SEM_EN = 1), this register is used during run-time by an authorized white-listed CID agent, in order to take and after possibly release the control of the channel x.

A read access may be privileged or unprivileged, secure or nonsecure, and with any CID.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEM_CCID[2:0]			Res.	Res.	Res.	SEM_MUTEX
									r	r	r				rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **SEM_CCID[2:0]**: Current CID allocated to the channel x (in semaphore mode)
This read-only bitfield is internally updated when a white-listed CID took the control of the channel x, in semaphore mode. If SEM_MUTEX = 0, this same CID also released it.
000: CID0 is the last white-listed CID that took the control of the channel x.
001: CID1 is the last white-listed CID that took the control of the channel x.
010: CID2 is the last white-listed CID that took the control of the channel x.
011: CID3 is the last white-listed CID that took the control of the channel x.
100: CID4 is the last white-listed CID that took the control of the channel x.
101: CID5 is the last white-listed CID that took the control of the channel x.
110: CID6 is the last white-listed CID that took the control of the channel x.
111: Reserved

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **SEM_MUTEX**: Mutual exclusion semaphore for the CID allocation of the channel x (in semaphore mode)
If the channel x is in secure state (HPDMA_SECCFGR.SECx = 1), this bit can only be written by a secure agent. If the channel x is in privileged state (HPDMA_PRIVCFGR.PRIVx = 1), this bit can only be written by a privileged agent.
If the channel x is CID-filtered (HPDMA_CxCIDCFGR.CFEN = 1) and in semaphore mode (HPDMA_CIDCFGR.SEM_EN = 1), this bit can only be written either by an authorized (white-listed) CID agent to take the control, or by the same (white-listed) CID agent to release the control.

Condition: write
0: Release the control of the channel x (in semaphore mode) to any white-listed CID.
1: Take the control of the channel x (in semaphore mode), from one of the white-listed CID pool.
Condition: read
0: Channel x CID-free (not currently under the control of any white-listed CID)
1: Channel x CID-allocated (currently taken and under the control of one white-listed CID)

Note: This bit must be written when HPDMA_CxCR.EN = 0. This bit is read-only when HPDMA_CxCR.EN = 1.
When SEM_EN or CFEN bit is cleared in HPDMA_CxSEMCR, the HPDMA hardware automatically clears this SEM_MUTEX bit.

18.8.9 HPDMA channel x flag clear register (HPDMA_CxFCR)

Address offset: 0x05C+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This is a write register, secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

1: Corresponding TOF flag cleared

Bit 13 **SUSPF**: Completed suspension flag clear
0: No effect
1: Corresponding SUSPF flag cleared

Bit 12 **USEF**: User setting error flag clear
0: No effect
1: Corresponding USEF flag cleared

Bit 11 **ULEF**: Update link transfer error flag clear
0: No effect
1: Corresponding ULEF flag cleared

Bit 10 **DTEF**: Data transfer error flag clear
0: No effect
1: Corresponding DTEF flag cleared

Bit 9 **HTF**: Half transfer flag clear
0: No effect
1: Corresponding HTF flag cleared

Bit 8 **TCF**: Transfer complete flag clear
0: No effect
1: Corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

18.8.10 HPDMA channel x status register (HPDMA_CxSR)

Address offset: 0x060 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or nonsecure, depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[8:0]								
							r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOF	SUSPF	USEF	ULEF	DTEF	HTF	TCF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDLEF
	r	r	r	r	r	r	r								r

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **FIFOL[8:0]**: Monitored FIFO level

Number of available write beats in the FIFO, in units of the programmed destination data width (see *Section 18.8.12: HPDMA channel x transfer register 1 (HPDMA_CxTR1)* DDW_LOG2[1:0], in units of bytes, half-words, words or double-words).

Note: After having suspended an active transfer, the user may need to read FIFOL[8:0], additionally to HPDMA_CxBR1.BDNT[15:0] and HPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (HPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: Trigger overrun flag

0: No trigger overrun event

1: A trigger overrun event occurred.

Bit 13 **SUSPF**: Completed suspension flag

0: No completed suspension event

1: A completed suspension event occurred.

Bit 12 **USEF**: User setting error flag

0: No user setting error event

1: A user setting error event occurred.

Bit 11 **ULEF**: Update link transfer error flag

0: No update link transfer error event

1: A master bus error event occurred while updating a linked-list register from memory.

Bit 10 **DTEF**: Data transfer error flag

0: No data transfer error event

1: A master bus error event occurred on a data transfer.

Bit 9 **HTF**: Half transfer flag

0: No half transfer event

1: An half transfer event occurred.

An half transfer event is either an half block transfer or an half 2D/repeated block transfer, depending on the transfer complete event mode (HPDMA_CxTR2.TCEM[1:0]).

An half block transfer occurs when half of the bytes of the source block size (rounded up integer of HPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.

An half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (HPDMA_CxBR1.BRC[10:0]+1)/2)) has been transferred to the destination.

Bit 8 **TCF**: Transfer complete flag

0: No transfer complete event

1: A transfer complete event occurred.

A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (HPDMA_CxTR2.TCEM[1:0]).

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: Idle flag

0: Channel not in idle state

1: Channel in idle state

This idle flag is deasserted by hardware when the channel is enabled (HPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).

This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

18.8.11 HPDMA channel x control register (HPDMA_CxCR)

Address offset: 0x064 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM

	rw	rw	rw	rw	rw	rw	rw						rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** Priority level of the channel x HPDMA transfer versus others
00: Low priority, low weight
01: Low priority, mid weight
10: Low priority, high weight
11: High priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: lLnked-list allocated port
This bit is used to allocate the master port for the update of the HPDMA linked-list registers from the memory.
0: Port 0 (AXI) allocated
1: Port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: Channel executed for the full linked-list and completed at the end of the last LLI (HPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0 if present). Then HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 if present.
1: Channel executed once for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0, if present. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by HPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: Trigger overrun interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 13 **SUSPIE**: cCmpleted suspension interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 12 **USEIE**: User setting error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 11 **ULEIE**: Update link transfer error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 10 **DTEIE**: Data transfer error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 9 **HTIE**: Half transfer complete interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 8 **TCIE**: Transfer complete interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** Suspend

Writing 1 to RESET in this register causes the hardware to deassert this SUSP bit, whatever is written into this SUSP. Else:

Software must write 1 in order to suspend an active channel (a channel with an ongoing HPDMA transfer over its master ports).

The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 73*.

0: Write: resume channel, read: channel not suspended

1: Write: suspend channel, read: channel suspended

Bit 1 **RESET:** Reset

This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).

The reset is effective when the channel is in steady state, meaning one of the following:

- active channel in suspended state (HPDMA_CxSR.SUSPF = 1 and HPDMA_CxSR.IDLEF = HPDMA_CxCR.EN = 1)
- channel in disabled state (HPDMA_CxSR.IDLEF = 1 and HPDMA_CxCR.EN = 0).

After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (HPDMA_CxBR1, HPDMA_CxSAR and HPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 74*).

0: No channel reset

1: Channel reset

Bit 0 **EN:** Enable

Writing 1 to RESET in this register causes the hardware to deassert this EN bit, whatever is written into this bit 0. Else:

This bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: Write: ignored, read: channel disabled

1: Write: enable channel, read: channel enabled

18.8.12 HPDMA channel x transfer register 1 (HPDMA_CxTR1)

Address offset: 0x090 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or unprivileged, depending on the privileged state of the channel x in HPDMA_PRIVCFGR.PRIVx.

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory if HPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DSEC	DAP	Res.	DWX	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSEC	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 **DSEC**: Security attribute of the HPDMA transfer to the destination

If HPDMA_SECCFGR.SECx = 1 and the access is secure:

0: HPDMA transfer nonsecure

1: HPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when HPDMA_SECCFGR.SECx = 1. A secure write is ignored when HPDMA_SECCFGR.SECx = 0.

When HPDMA_SECCFGR.SECx is deasserted, this DSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the HPDMA transfer to the destination is nonsecure.

Bit 30 **DAP**: Destination allocated port

This bit is used to allocate the master port for the destination transfer

0: Port 0 (AXI) allocated

1: Port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DWX**: Destination word exchange

If the destination data size is not a double-word, this bit is ignored.

If the destination data size is a double-word and if destination bus is AXI (DAP = 0):

0: No word-based exchanged within double-word

1: The two consecutive (post PAM) words are exchanged in each destination double-word.

Bit 27 **DHX**: Destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word or double-word and if destination bus is AXI (DAP = 0):

0: No half-word-based exchanged within word

1: The two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: Destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0: No byte-based exchange within half-word

1: The two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: Destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Caution: As highlighted in *Section 18.3.2*, the maximum allowed AXI burst length is 16. The user must set DBL_1[5:0] lower or equal to 15 if the destination allocated port is AXI (if DAP = 0).

Note: If a burst transfer crossed a 1- or 4-Kbyte address boundary on respectively an AHB or AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol.

If the burst length exceeds 16 on an AHB transfer, or if the burst on an AXI transfer is both with fixed addressing (DINC = 0) and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into bursts of lower length, to be compliant with the AHB or AXI protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with HPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: Destination incrementing burst

0: Fixed burst

1: Contiguously incremented burst

The destination address, pointed by HPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: Binary logarithm of the destination data width of a burst, in bytes
00: Byte
01: Half-word (2 bytes)
10: Word (4 bytes)
11: If DAP = 0 (AXI), double-word (8 bytes)
if DAP = 1, user setting error reported and no transfer issued

Note: A destination burst transfer must have an aligned address with its data width (start address HPDMA_CxDAR[2:0] and if present address offset HPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

When configured in packing mode (PAM[1] = 1 and destination data width different from source data width), a source block size must be a multiple of the destination data width (see HPDMA_CxBR1.BNDT[2:0] versus DDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

A burst with a double-word data width must be allocated to the AXI master port, else a user setting error is reported and none transfer is issued.

Bit 15 **SSEC**: Security attribute of the HPDMA transfer from the source
If HPDMA_SECCFGR.SECx = 1 and the access is secure:
0: HPDMA transfer nonsecure
1: HPDMA transfer secure
This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when HPDMA_SECCFGR.SECx = 1. A secure write is ignored when HPDMA_SECCFGR.SECx = 0.
When HPDMA_SECCFGR.SECx is deasserted, this SSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the HPDMA transfer from the source is nonsecure.

Bit 14 **SAP**: Source allocated port
This bit is used to allocate the master port for the source transfer
0: Port 0 (AXI) allocated
1: Port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: Source byte exchange within the unaligned half-word of each source word
If the source data width is shorter than a word, this bit is ignored.
If the source data width is a word or a double-word, and if source bus is AXI (SAP = 0):
0: No byte-based exchange within the unaligned half-word of each source word
1: The two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: Padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

Condition: PAM_1

00: Source data is transferred as right aligned, padded with 0s up to the destination data width

01: Source data is transferred as right aligned, sign extended up to the destination data width

10-11: Successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

Condition: PAM_2

00: Source data is transferred as right aligned, left-truncated down to the destination data width

01: Source data is transferred as left-aligned, right-truncated down to the destination data width

10-11: Source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: Source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Caution: As highlighted in *Section 18.3.2*, the maximum allowed AXI burst length is 16. The user must set SBL_1[5:0] lower or equal to 15 if the source allocated port is AXI (if SAP = 0).

Note: If a burst transfer crossed a 1- or 4-Kbyte address boundary on respectively an AHB or an AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If the burst length exceeds 16 on a AHB transfer, or if the burst on a AXI transfer is both with fixed addressing (SINC = 0) and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with HPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: Source incrementing burst

0: Fixed burst

1: Contiguously incremented burst

The source address, pointed by HPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: Binary logarithm of the source data width of a burst in bytes
00: Byte
01: Half-word (2 bytes)
10: Word (4 bytes)
11: If SAP = 0 (AXI), double-word (8 bytes)
if SAP = 1, user setting error reported and no transfer issued

Note: A source block size must be a multiple of the source data width (HPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address HPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

A burst with a double-word data width must be allocated to the AXI master port, else a user setting error is reported and none transfer is issued.

18.8.13 HPDMA channel x transfer register 2 (HPDMA_CxTR2)

Address offset: 0x094 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, a write access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory, if HPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	TRIGSEL[6:0]						
rw	rw					rw	rw		rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	REQSEL[7:0]							
rw	rw		rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: Transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: At block level (when HPDMA_CxBR1.BNDT[15:0] = 0): The complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: Channel x = 0 to 11, same as 00; channel x = 12 to 15, at 2D/repeated block level (when HPDMA_CxBR1.BRC[10:0] = 0 and HPDMA_CxBR1.BNDT[15:0] = 0), the complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: At LLI level: The complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer or a 2D/repeated block transfer for channel x = 12 to 15), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: At channel level: The complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address HPDMA_CxLLR.LA[15:2] to zero and clears all the HPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2 if present). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: Trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[6:0].

00: No trigger (masked trigger event)

01: Trigger on the rising edge

10: Trigger on the falling edge

11: Same as 00

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **TRIGSEL[6:0]**: Trigger event input selection

These bits select the trigger event input of the HPDMA transfer (as per *Section 18.3.7*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: Trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (HPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, an HPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x = 12 to 15, for each block if a 2D/repeated block is configured with HPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x = 0 to 11, same as 00; channel x = 12 to 15, at 2D/repeated block level, the first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The HPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the HPDMA_CxTR2 with a new value for any of TRIGSEL[6:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (HPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (HPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1/4-Kbyte boundary address crossing maximum burst length versus AHB/AXI protocol): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 18.3.6 for the list of the implemented channels with this feature.

If the channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in HPDMA control mode. The HPDMA is programmed with HPDMA_CxCBR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The HPDMA block transfer can be early completed by the peripheral itself (see *Section 18.3.6* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (HPDMA_CxBR1.BRC[10:0] must be set to 0 if present)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, HPDMA_CxTR1.PAM[1] must be set to 0).

- HPDMA_CxBR1.BNDT[15:0] must be set as a multiple of the source (peripheral) burst size.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 18.3.5*).

Bit 10 **DREQ**: Destination hardware request

This bit is ignored if channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: Selected hardware request driven by a source peripheral (request signal taken into account by the HPDMA transfer scheduler over the source/read port)

1: Selected hardware request driven by a destination peripheral (request signal taken into account by the HPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (HPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: Software request

This bit is internally taken into account when HPDMA_CxCR.EN is asserted.

0: No software request. The selected hardware request REQSEL[7:0] is taken into account.

1: Software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[7:0] is ignored.

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **REQSEL[7:0]**: Hardware request selection

These bits are ignored if channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 18.3.4*.

Caution: The user must not assign a same input hardware request (same REQSEL[7:0] value) to different active HPDMA channels (HPDMA_CxCR.EN = 1 and HPDMA_CxTR2.SWREQ = 0 for these channels). The HPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

18.8.14 HPDMA channel x block register 1 (HPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, a write access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register controls the transfer of a channel x at a block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer:

- if HPDMA_CxLLR.UB1 = 1, this register is automatically updated by the HPDMA from the next LLI in memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the bitfield BNDT[15:0].
- If all the update bits HPDMA_CxLLR.Uxx are null and if HPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If HPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: Block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this bitfield becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if HPDMA_CxLLR.UB1 = 1, this bitfield is updated by the LLI in the memory.
- if HPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this bitfield is internally restored to the programmed value.
- if all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] = 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).
- if HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (HPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

18.8.15 HPDMA channel x alternate block register 1 (HPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, a write access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register controls the transfer of a channel x at a block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer:

- if HPDMA_CxLLR.UB1 = 1, this register is automatically updated by the HPDMA from the next LLI in memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the bitfields BNDT[15:0] and BRC[10:0].
- If all the update bits HPDMA_CxLLR.Uxx are null and if HPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for the bitfields BNDT[15:0] and BRC[10:0] after each execution of this final LLI

- If HPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: At the end of a block transfer, the HPDMA_CxDAR register is updated by adding the programmed offset HPDMA_CxBR2.BRDAO to the current HPDMA_CxDAR value (current destination address)

1: At the end of a block transfer, the HPDMA_CxDAR register is updated by subtracting the programmed offset HPDMA_CxBR2.BRDAO from the current HPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), HPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the HPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: At the end of a block transfer, the HPDMA_CxSAR register is updated by adding the programmed offset HPDMA_CxBR2.BRSAO to the current HPDMA_CxSAR value (current source address)

1: At the end of a block transfer, the HPDMA_CxSAR register is updated by subtracting the programmed offset HPDMA_CxBR2.BRSAO from the current HPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), HPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the HPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the HPDMA_CxDAR register is updated by adding the programmed offset HPDMA_CxTR3.DAO to the current HPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the HPDMA_CxDAR register is updated by subtracting the programmed offset HPDMA_CxTR3.DAO to the current HPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the HPDMA_CxSAR register is updated by adding the programmed offset HPDMA_CxTR3.SAO to the current HPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the HPDMA_CxSAR register is updated by subtracting the programmed offset HPDMA_CxTR3.SAO to the current HPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This bitfield contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this bitfield becomes read-only. After decrements, this bitfield indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If HPDMA_CxLLR.UB1 = 1, all HPDMA_CxBR1 bitfields are updated by the next LLI in the memory.

– If HPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this bitfield is internally restored to the programmed value.

– if all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] ≠ 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).

– if HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: Block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this bitfield becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred.

BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if HPDMA_CxLLR.UB1 = 1, this bitfield is updated by the LLI in the memory.

- if HPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this bitfield is internally restored to the programmed value.

- if all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] ≠ 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).

- if HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (HPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

18.8.16 HPDMA channel x source address register (HPDMA_CxSAR)

Address offset: 0x09C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register configures the source start address of a transfer.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: Source address

This bitfield is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (HPDMA_CxTR1.SINC), this bitfield is kept fixed or incremented by the data width (HPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (HPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by HPDMA_CxTR1.SBL_1[5:0] and HPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by HPDMA_CxBR1.SDEC and HPDMA_CxTR3.SAO[12:0]

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by HPDMA_CxBR1.BRSDEC and HPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by HPDMA from the memory, provided the LLI is set with HPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional HPDMA_CxTR3.SAO[12:0] is not applied.

18.8.17 HPDMA channel x destination address register (HPDMA_CxDAR)

Address offset: 0x0A0 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, an access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register configures the destination start address of a transfer.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory if HPDMA_CxLLR.UDA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This bitfield is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (HPDMA_CxTR1.DINC), this bitfield is kept fixed or incremented by the data width (HPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (HPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by HPDMA_CxTR1.DBL_1[5:0] and HPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by HPDMA_CxBR1.DDEC and HPDMA_CxTR3.DAO[12:0]

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by HPDMA_CxBR1.BRDDEC and HPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the HPDMA from the memory, provided the LLI is set with HPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

18.8.18 HPDMA channel x transfer register 3 (HPDMA_CxTR3)

Address offset: 0x0A4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, a write access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: Destination address offset increment

The destination address, pointed by HPDMA_CxDAR, is incremented or decremented (depending on HPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (HPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: Source address offset increment

The source address, pointed by HPDMA_CxSAR, is incremented or decremented (depending on HPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (HPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional HPDMA_CxTR3.SAO[12:0] is not applied.

18.8.19 HPDMA channel x block register 2 (HPDMA_CxBR2)

Address offset: 0x0A8 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, a write access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDAO[15:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this bitfield is used to update (by addition or subtraction depending on HPDMA_CxBR1.BRDDEC) the current destination address (HPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if HPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this bitfield is used to update (by addition or subtraction depending on HPDMA_CxBR1.BRSDEC) the current source address (HPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if HPDMA_CxTR2.PFREQ = 1).

18.8.20 HPDMA channel x linked-list address register (HPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register is CID-filtered depending on the CID configuration of the channel x (HPDMA_CxCIDCFGR.CFEN = 1). If the debug domain feature is activated, a write access to this register is granted to the debug domain CID, regardless of any CID filtering.

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.ULL = 1.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update HPDMA_CxTR1 from memory
This bit controls the update of HPDMA_CxTR1 from the memory during the link transfer.
0: No HPDMA_CxTR1 update
1: HPDMA_CxTR1 update

Bit 30 **UT2**: Update HPDMA_CxTR2 from memory
This bit controls the update of HPDMA_CxTR2 from the memory during the link transfer.
0: No HPDMA_CxTR2 update
1: HPDMA_CxTR2 update

Bit 29 **UB1**: Update HPDMA_CxBR1 from memory
This bit controls the update of HPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if HPDMA_CxLLR ≠ 0, the linked-list is not completed.
HPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: No HPDMA_CxBR1 update from memory (HPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: HPDMA_CxBR1 update

Bit 28 **USA**: Update HPDMA_CxSAR from memory
This bit controls the update of HPDMA_CxSAR from the memory during the link transfer.
0: No HPDMA_CxSAR update
1: HPDMA_CxSAR update

Bit 27 **UDA**: Update HPDMA_CxDAR register from memory
This bit is used to control the update of HPDMA_CxDAR from the memory during the link transfer.
0: No HPDMA_CxDAR update
1: HPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update HPDMA_CxLLR register from memory
This bit is used to control the update of HPDMA_CxLLR from the memory during the link transfer.
0: No HPDMA_CxLLR update
1: HPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: Pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list HPDMA register file.
Else, this bitfield is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list HPDMA internal register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR).

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

18.8.21 HPDMA channel x alternate linked-list address register (HPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (HPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update HPDMA_CxTR1 from memory
This bit controls the update of HPDMA_CxTR1 from the memory during the link transfer.
0: No HPDMA_CxTR1 update
1: HPDMA_CxTR1 update

Bit 30 **UT2**: Update HPDMA_CxTR2 from memory
This bit controls the update of HPDMA_CxTR2 from the memory during the link transfer.
0: No HPDMA_CxTR2 update
1: HPDMA_CxTR2 update

Bit 29 **UB1**: Update HPDMA_CxBR1 from memory
This bit controls the update of HPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if HPDMA_CxLLR ≠ 0, the linked-list is not completed.
HPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: No HPDMA_CxBR1 update from memory (HPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: HPDMA_CxBR1 update

Bit 28 **USA**: Update HPDMA_CxSAR from memory
This bit controls the update of HPDMA_CxSAR from the memory during the link transfer.
0: No HPDMA_CxSAR update
1: HPDMA_CxSAR update

Bit 27 **UDA**: Update HPDMA_CxDAR register from memory
This bit is used to control the update of HPDMA_CxDAR from the memory during the link transfer.
0:No HPDMA_CxDAR update
1: HPDMA_CxDAR update

Bit 26 **UT3**: Update HPDMA_CxTR3 from memory
This bit controls the update of HPDMA_CxTR3 from the memory during the link transfer.
0: No HPDMA_CxTR3 update
1: HPDMA_CxTR3 update

Bit 25 **UB2**: Update HPDMA_CxBR2 from memory
This bit controls the update of HPDMA_CxBR2 from the memory during the link transfer.
0: No HPDMA_CxBR2 update
1: HPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update HPDMA_CxLLR register from memory
This bit is used to control the update of HPDMA_CxLLR from the memory during the link transfer.
0: No HPDMA_CxLLR update
1: HPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: Pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL= 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list HPDMA register file.
Else, this bitfield is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list HPDMA internal register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR and HPDMA_CxLLR).
Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.3* for the register boundary addresses.

19 General purpose direct memory access controller (GPDMA)

19.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

19.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 19.3.1*)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers

  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 19.3.1*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Programmable GPDMA request and trigger selection
  - Programmable GPDMA half transfer and transfer complete events generation
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers
  - Channel abort and restart
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- TrustZone support:
  - Support for secure and nonsecure GPDMA transfers, independently at a first channel level, and independently at a source/destination and link sublevels
  - Secure and nonsecure interrupts reporting, resulting from any of the respectively secure and nonsecure channels
  - TrustZone-aware AHB slave port, protecting any GPDMA secure resource (register, register field) from a nonsecure access
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

19.3 GPDMA implementation

19.3.1 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

Table 97. GPDMA1 channel implementation

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 11	2	0	Channel x (x = 0 to 11) is implemented with: – a FIFO of 8 bytes, 2 words – fixed/contiguously incremented addressing These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and SRAM.
x = 12 to 15	4	1	Channel x (x = 12 to 15) is implemented with: – a FIFO of 32 bytes, 8 words – 2D addressing These channels may be also used for GPDMA transfers, between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.

19.3.2 GPDMA in low-power modes

The GPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 98. GPDMA1 wake-up in low-power modes

Feature	Low-power modes
Wake-up	GPDMA1 in Sleep mode

19.3.3 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[7:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

19.3.4 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

Table 100. Programmed GPDMA1 request as a block request

19.3.5 GPDMA channels with peripheral early termination

A GPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 101. GPDMA1 channel with peripheral early termination

GPDMA channel x with peripheral early termination
x = 0, x = 1, and x = 15

This GPDMA support is activated when the channel x is programmed with GPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before that the GPDMA has transferred the whole block (see *Section 19.4.14* for more details).

19.3.6 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[6:0] in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

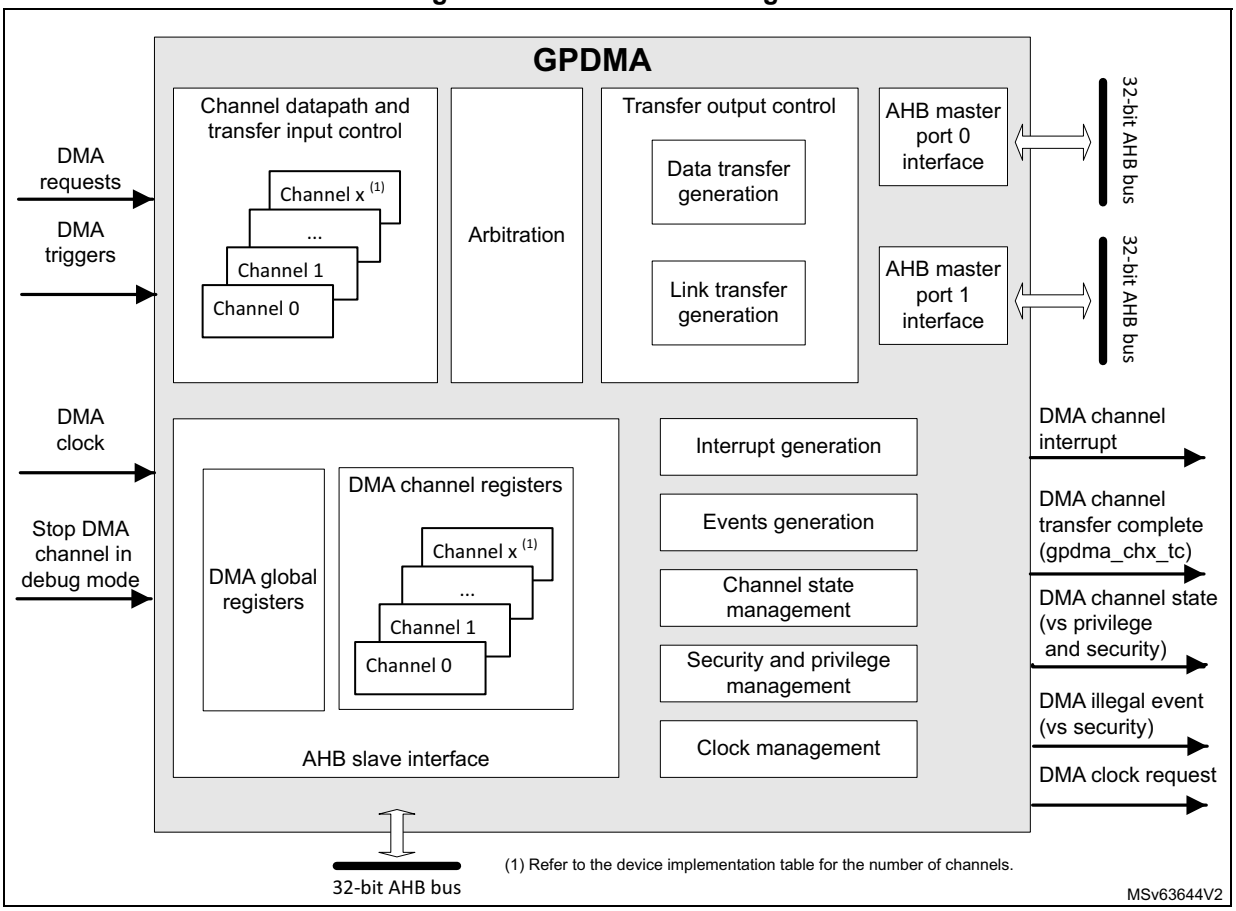
19.4 GPDMA functional description

19.4.1 GPDMA block diagram

Figure 92. GPDMA block diagram



19.4.2 GPDMA channel state and direct programming without any linked-list

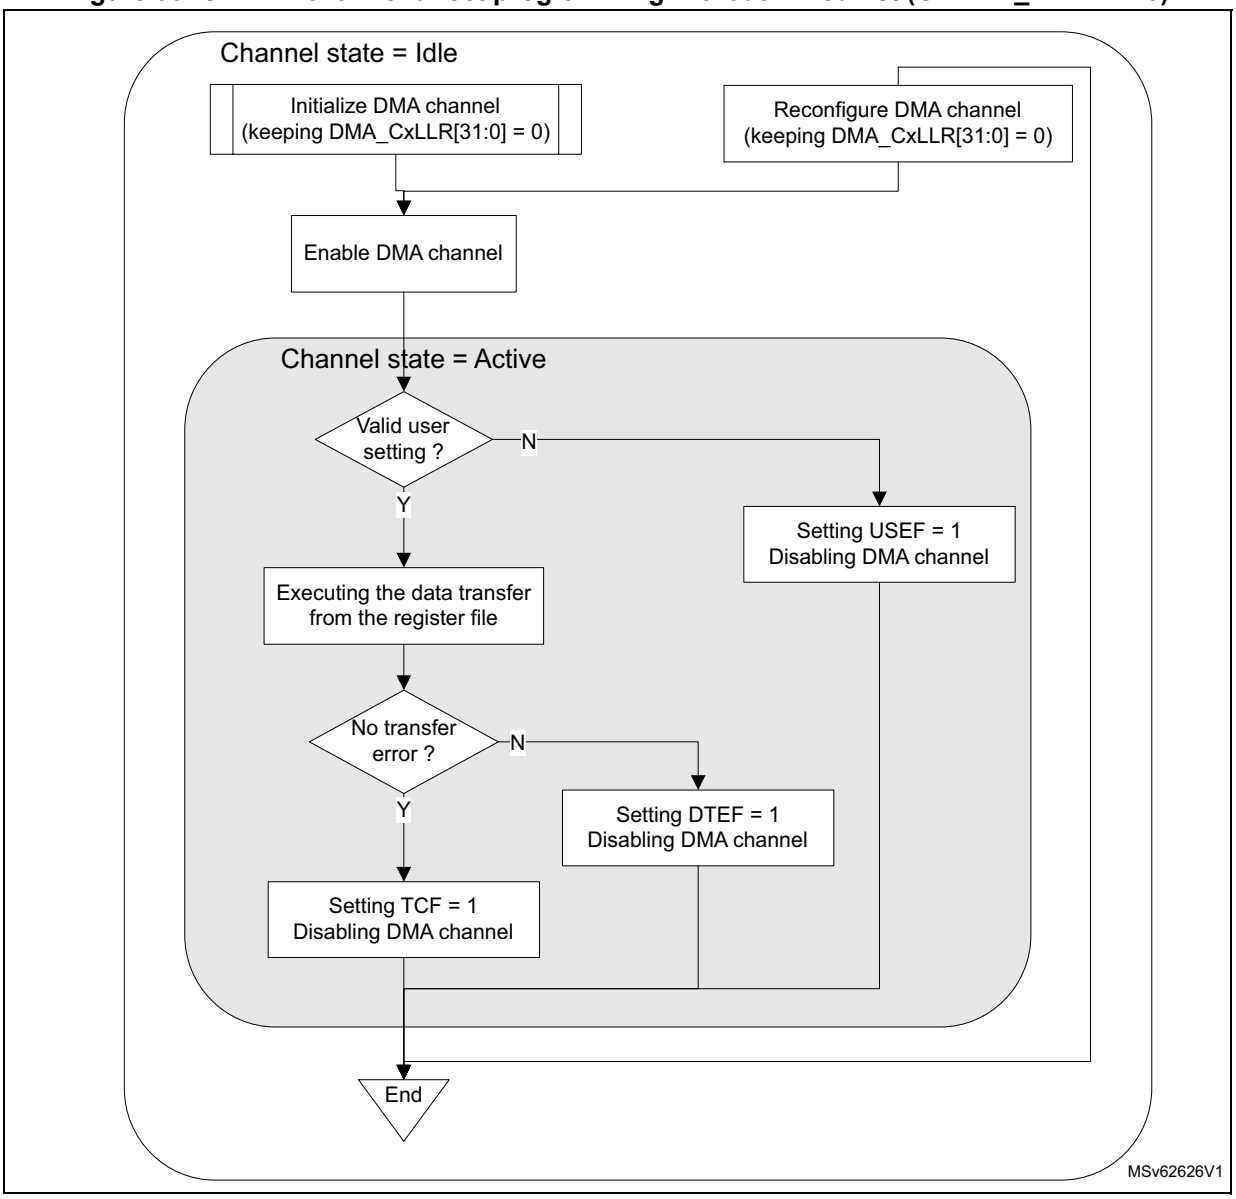
After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA

channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

Figure 93 illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 93. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)



19.4.3 GPDMA channel suspend and resume

The software can suspend on its own a channel still active, with the following sequence:

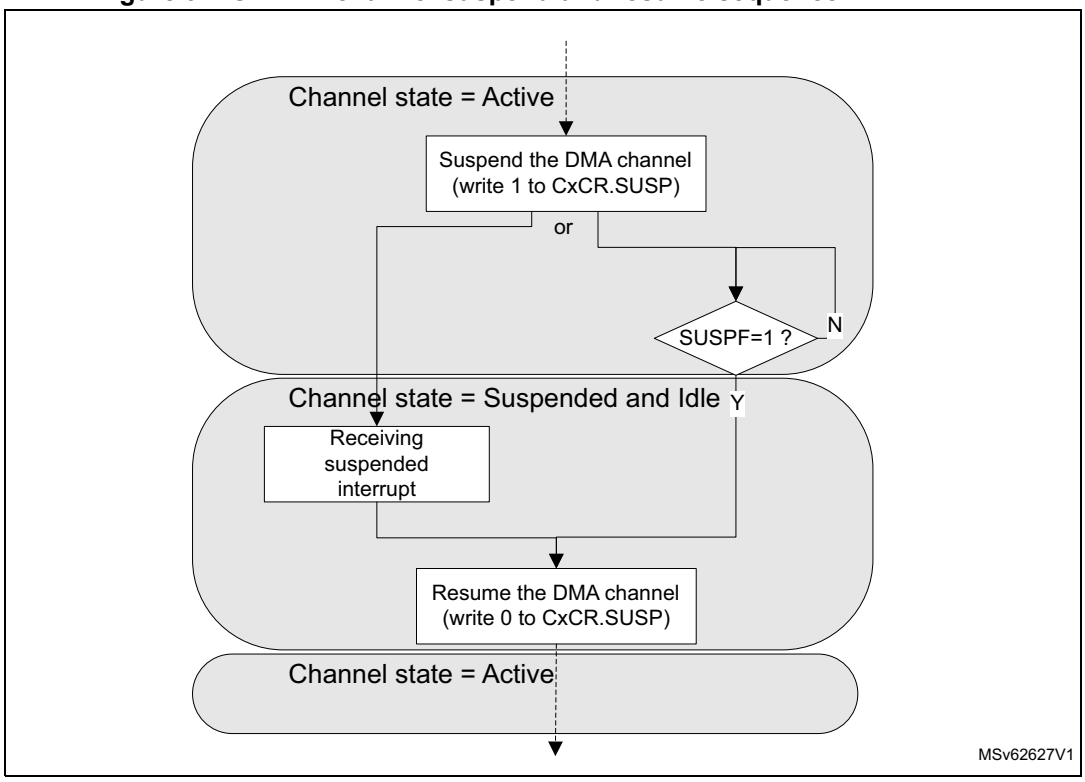
1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of

any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note: An ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 94. GPDMA channel suspend and resume sequence



Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

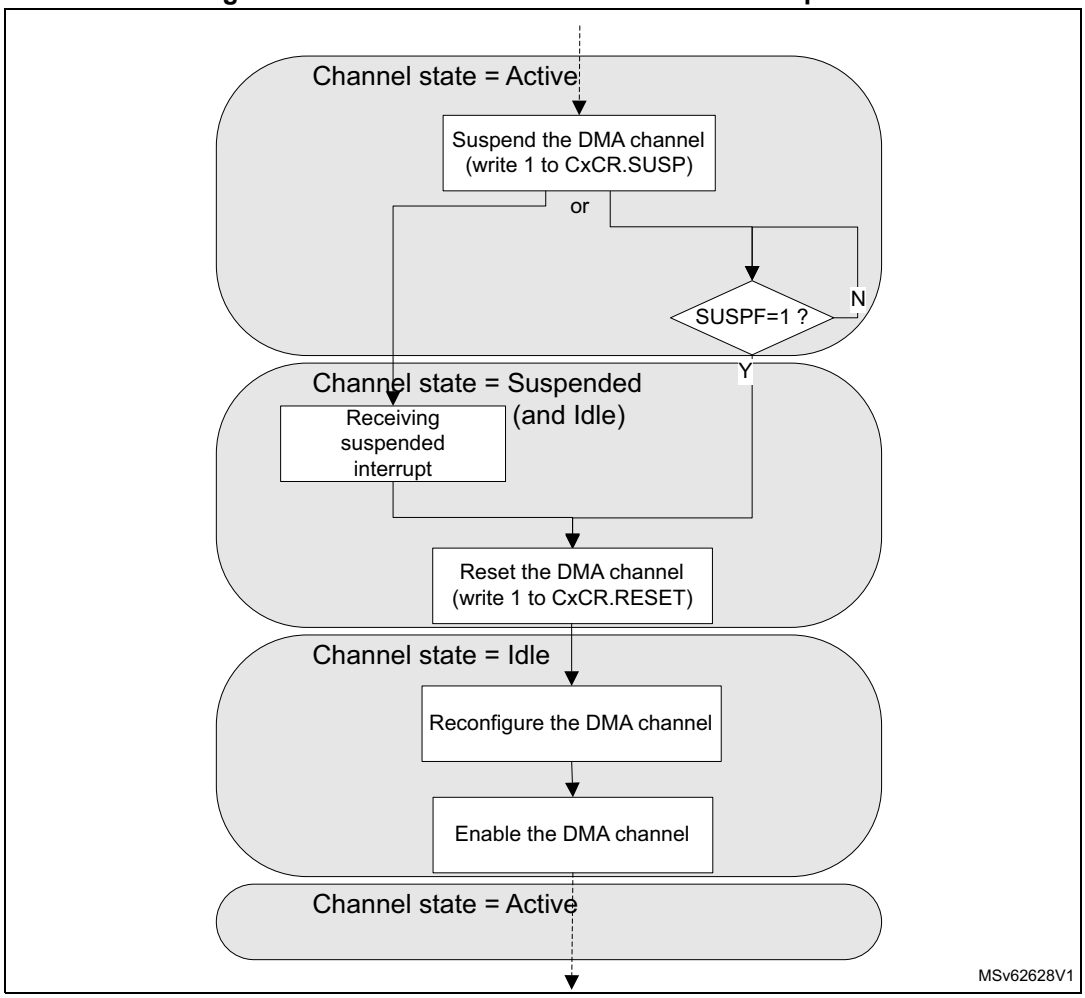
19.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.

4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 95. GPDMA channel abort and restart sequence



19.4.5 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLIn of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits, plus UB2 and UT3, in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3 or GPDMA_CxBR2) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 11) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see *Figure 96*) and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory
- channel x (x = 12 to 15), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 (see *Figure 97*), and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory

Figure 96. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x

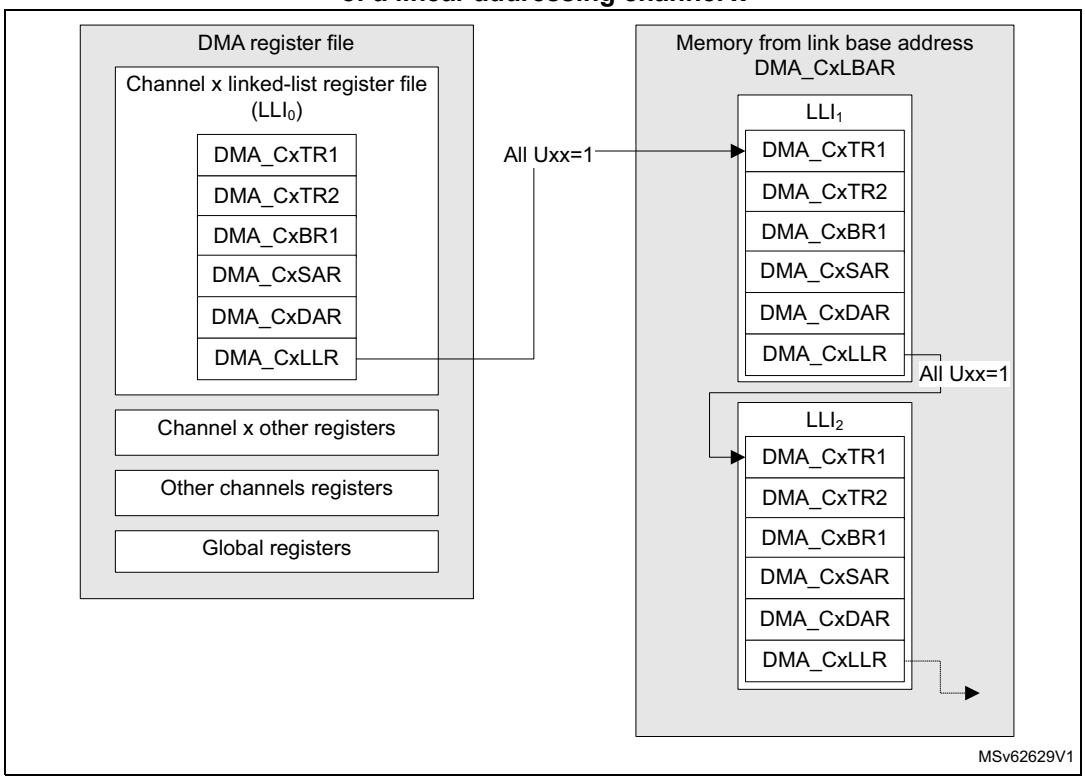


Figure 97. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

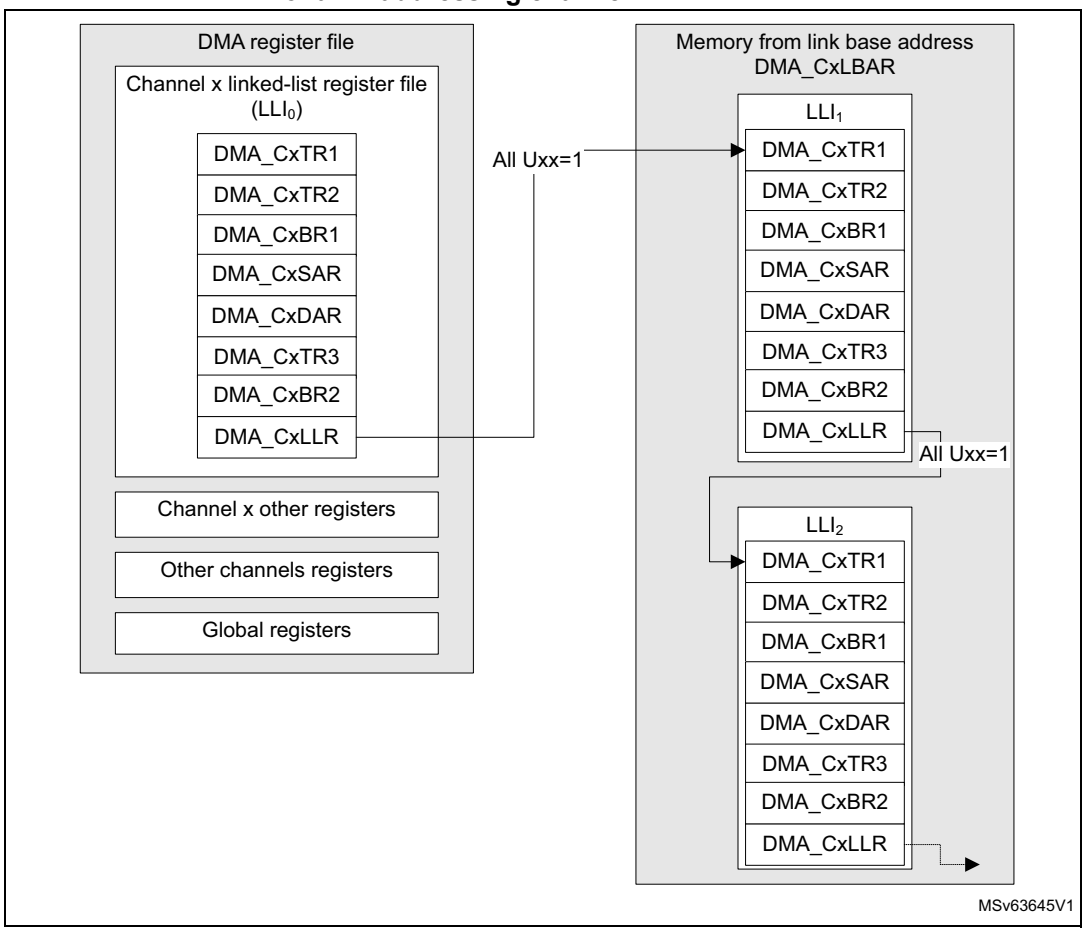

Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see *Figure 98*).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in *Figure 99*.

Figure 98. GPDMA dynamic linked-list data structure of a linear addressing channel x

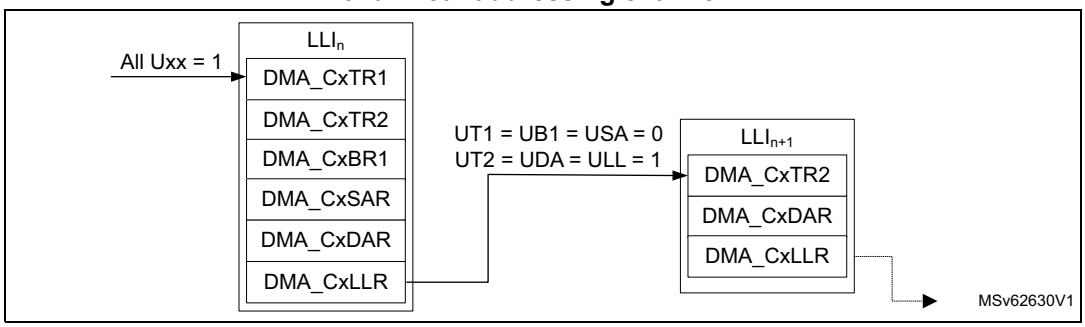

Figure 99. GPDMA dynamic linked-list data structure of a 2D addressing channel x

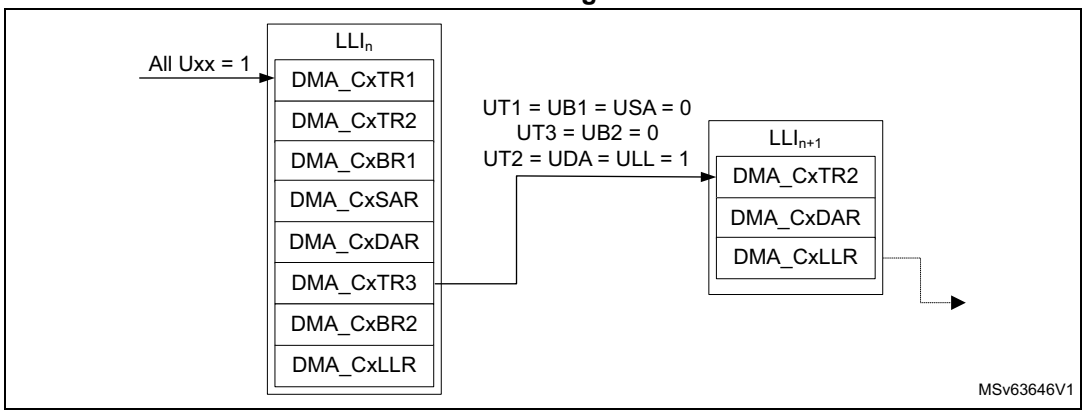


The user must program GPDMA_CxLLR for each LLI_n to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by GPDMA_CxLBAR.

19.4.6 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the GPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxTR2.PFREQ = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.

19.4.7 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLI_N is pointing to a previous LLI

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 19.4.14* for more details).

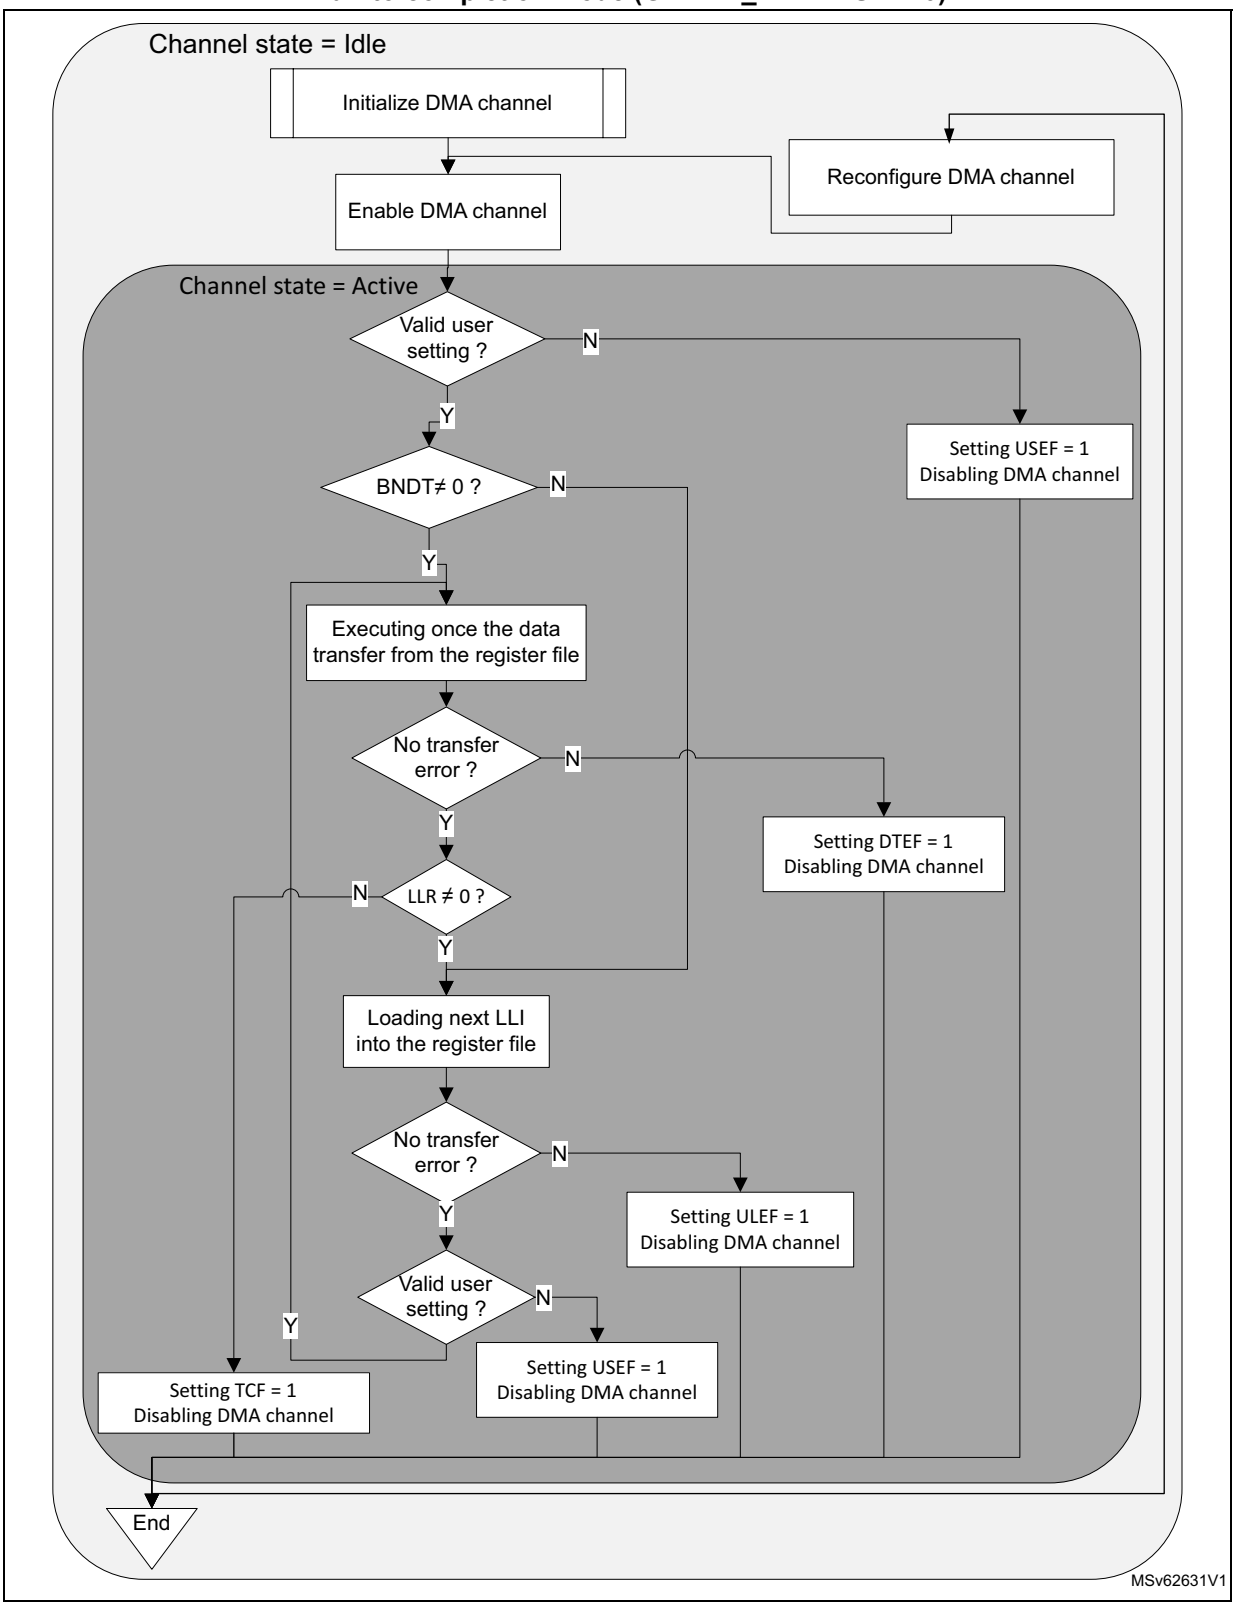
In the typical run-to-completion mode, the allocation of a GPDMA channel, including its fine programming, is done once during the GPDMA initialization. In order to have a reserved data communication link and GPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 100 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 100 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 100, BNDT ≠ 0 is the typical condition for starting the first data transfer in this figure. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 19.3.5).

Figure 100. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)



Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:

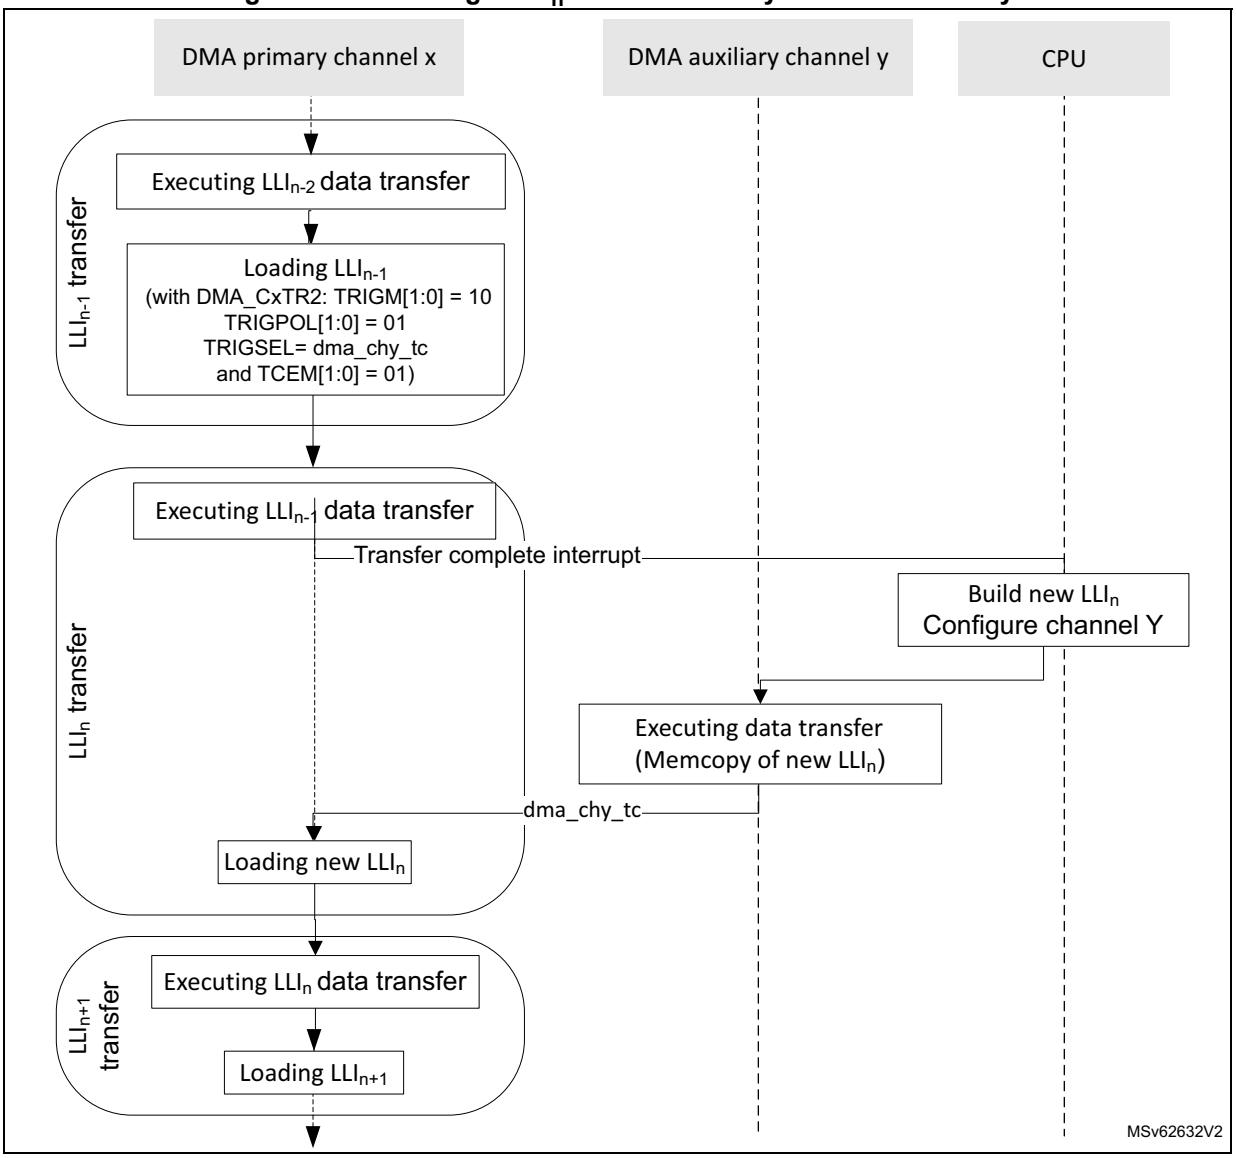
- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[6:0] (see *Section 19.3.6* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 101 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 101. Inserting a LLI_n with an auxiliary GPDMA channel y



19.4.8 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 12 to 15), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.

  - GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
  - GPDMA_CxTR3 for channel x (x = 12 to 15) defines the source/destination additional address offset between burst transfers.
  - GPDMA_CxBR2 for channel x (x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 19.4.14* for more details).

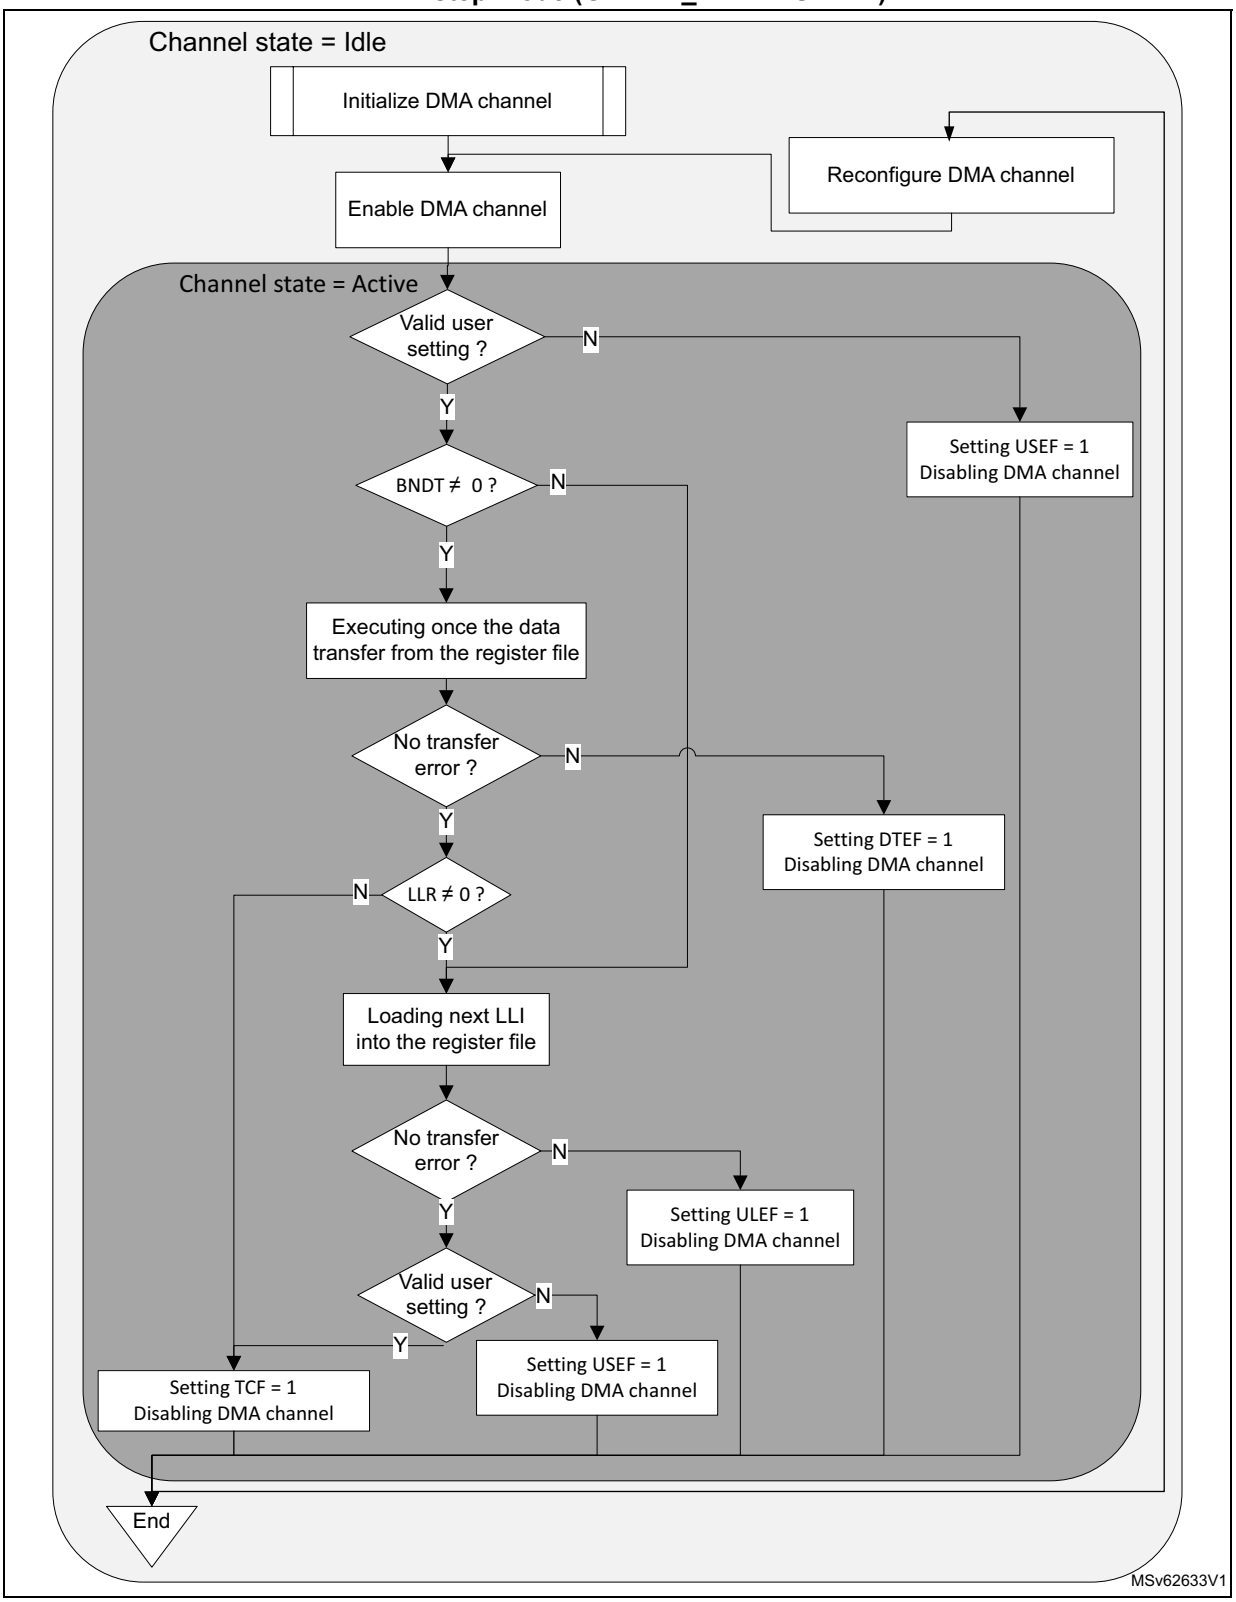
The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 102 depicts the GPDMA channel execution mode, and its programming in link step mode.

Note: Figure 102 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 102, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 19.3.5).

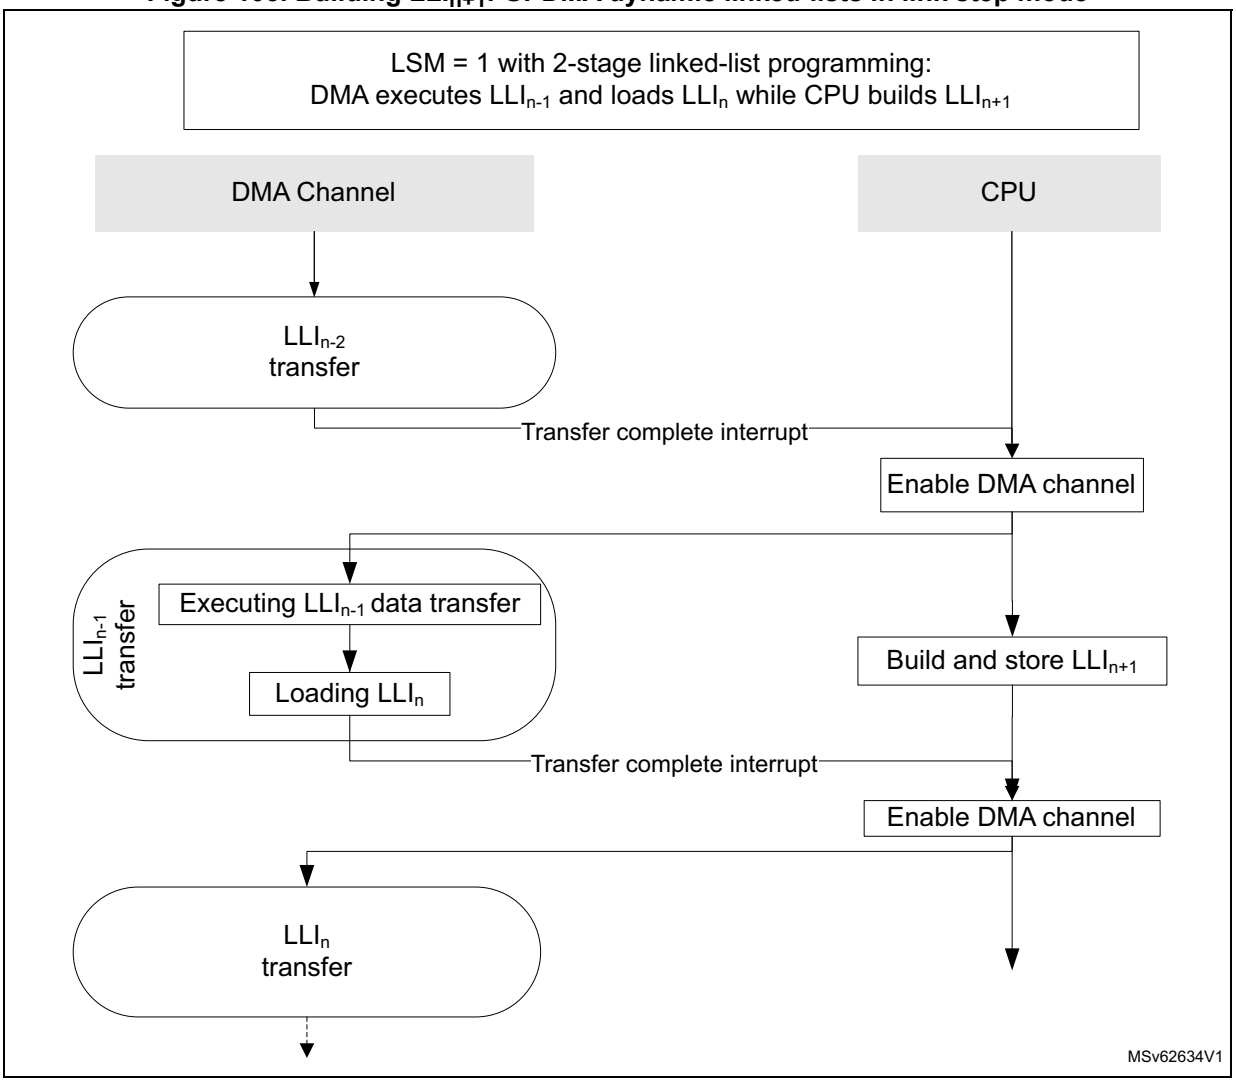
Figure 102. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)



Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in *Figure 103*.

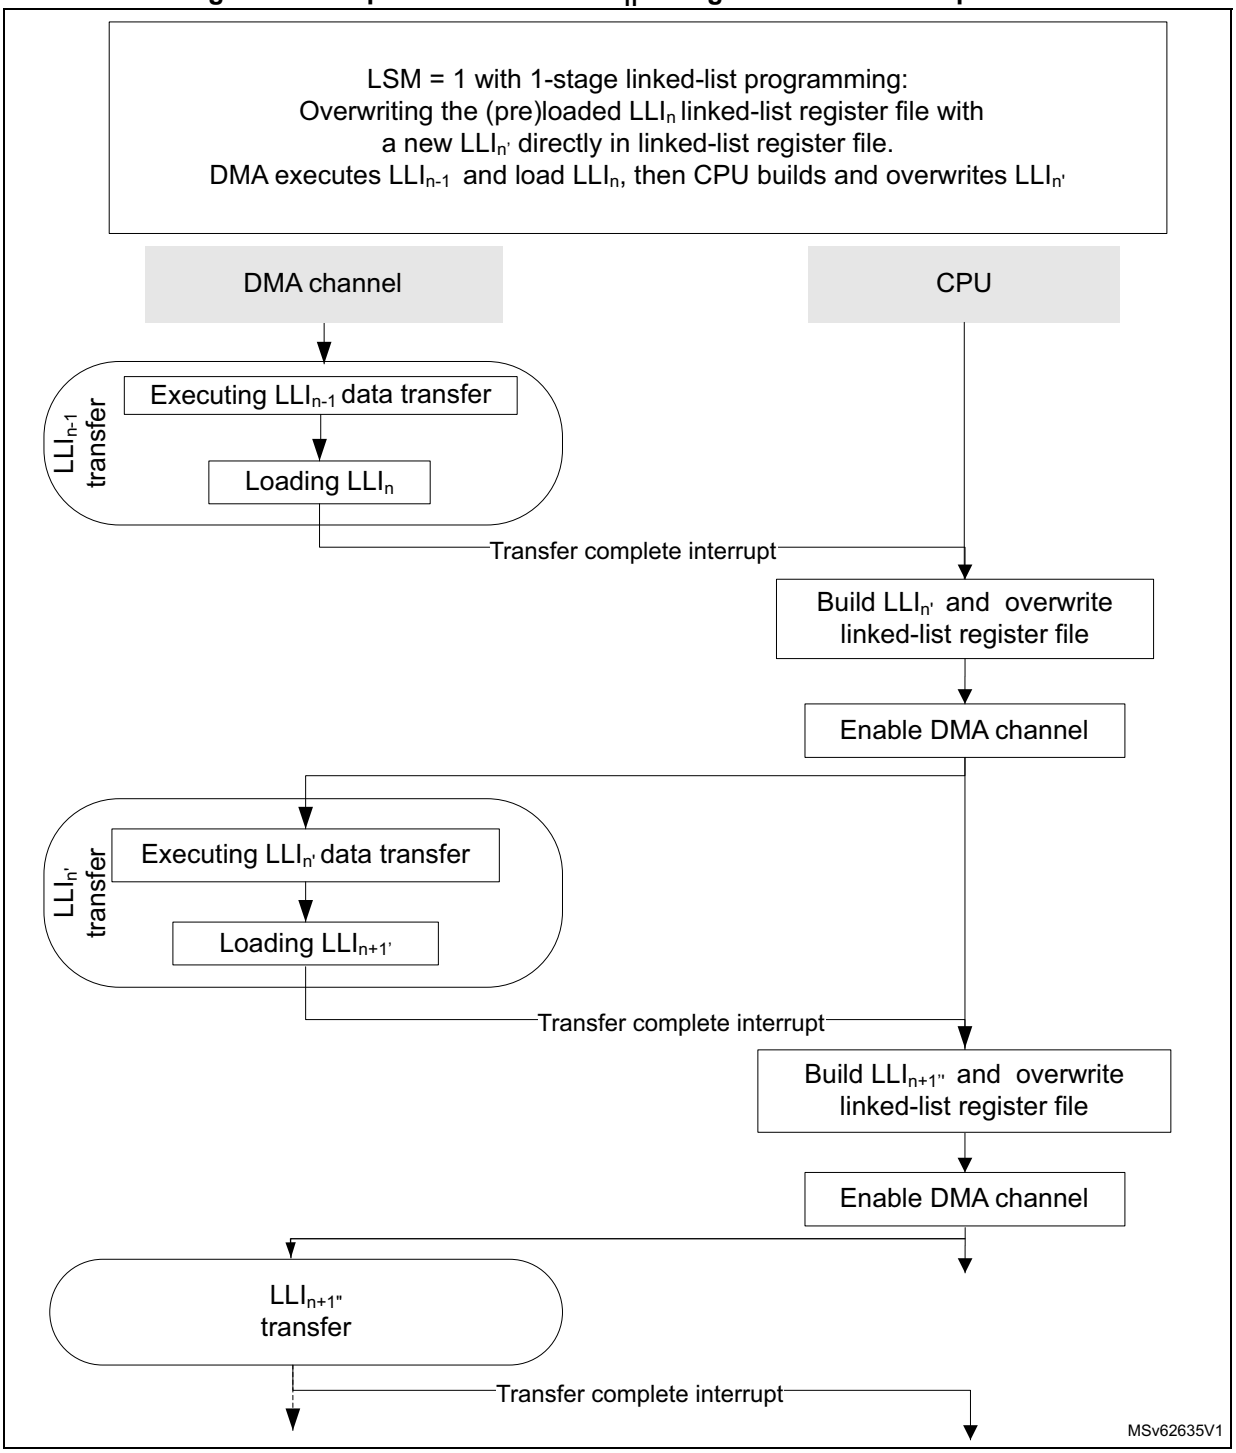
Figure 103. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode



Run-time replacing a LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in *Figure 104*.

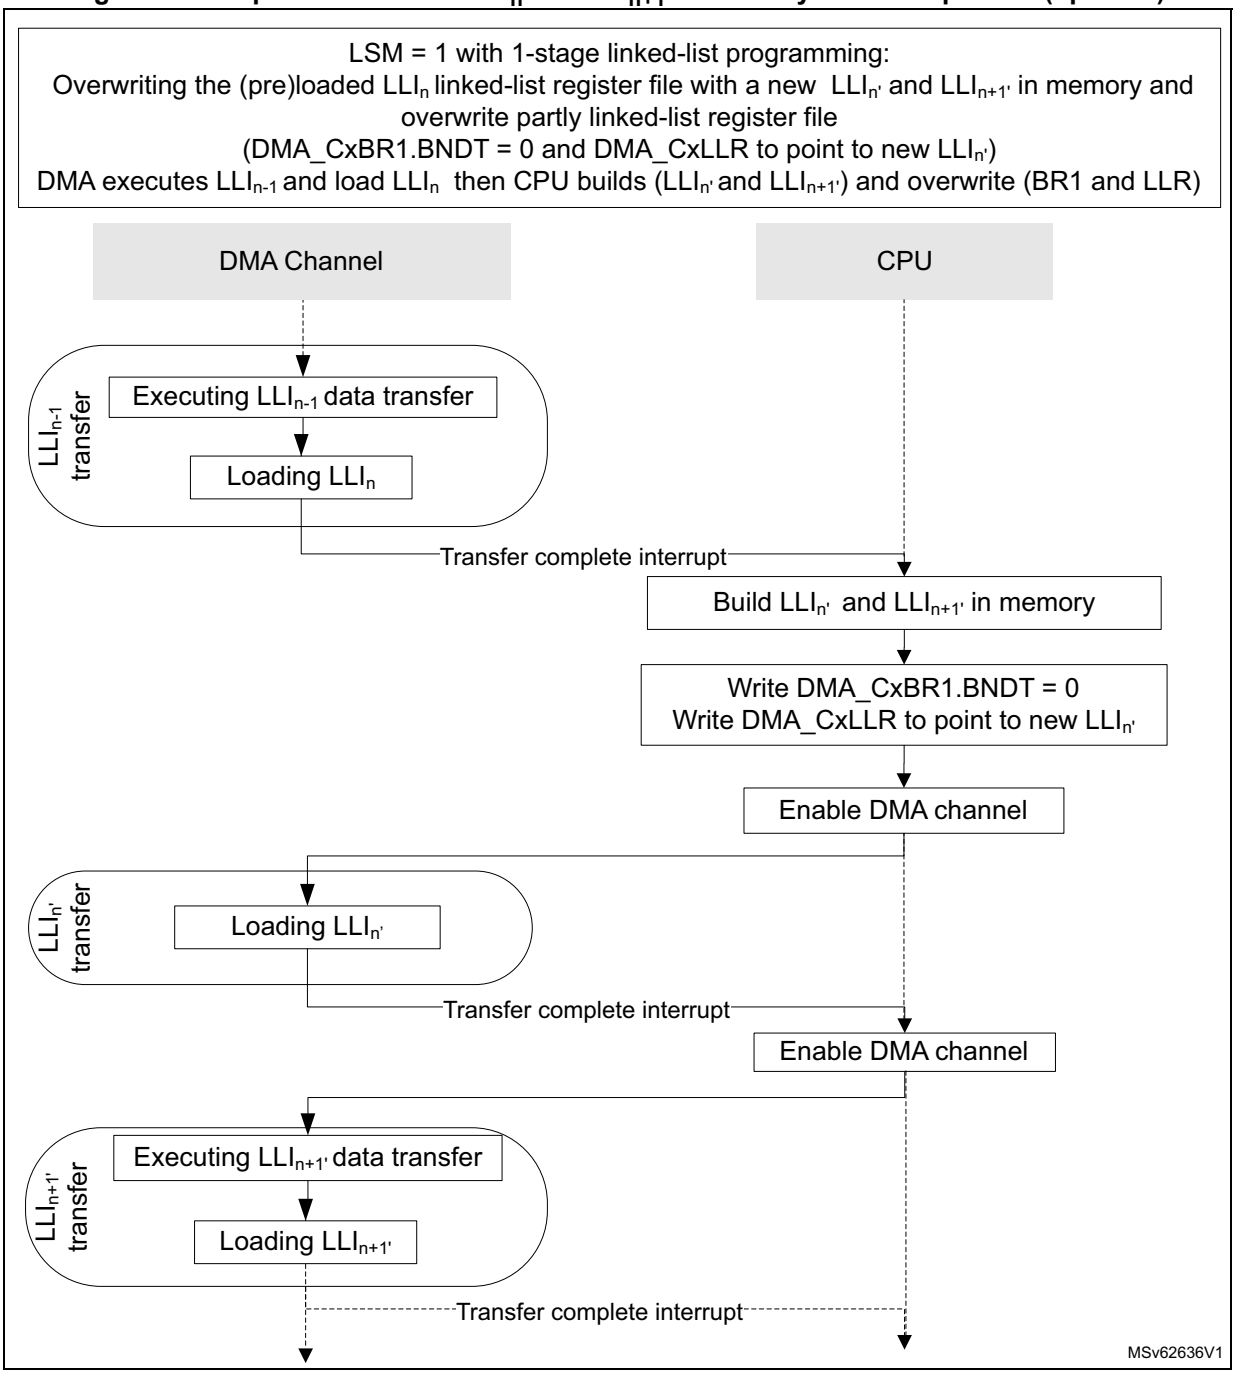
Figure 104. Replace with a new $LLI_{n'}$ in register file in link step mode



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n')}$ as shown in *Figure 105*.

Figure 105. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



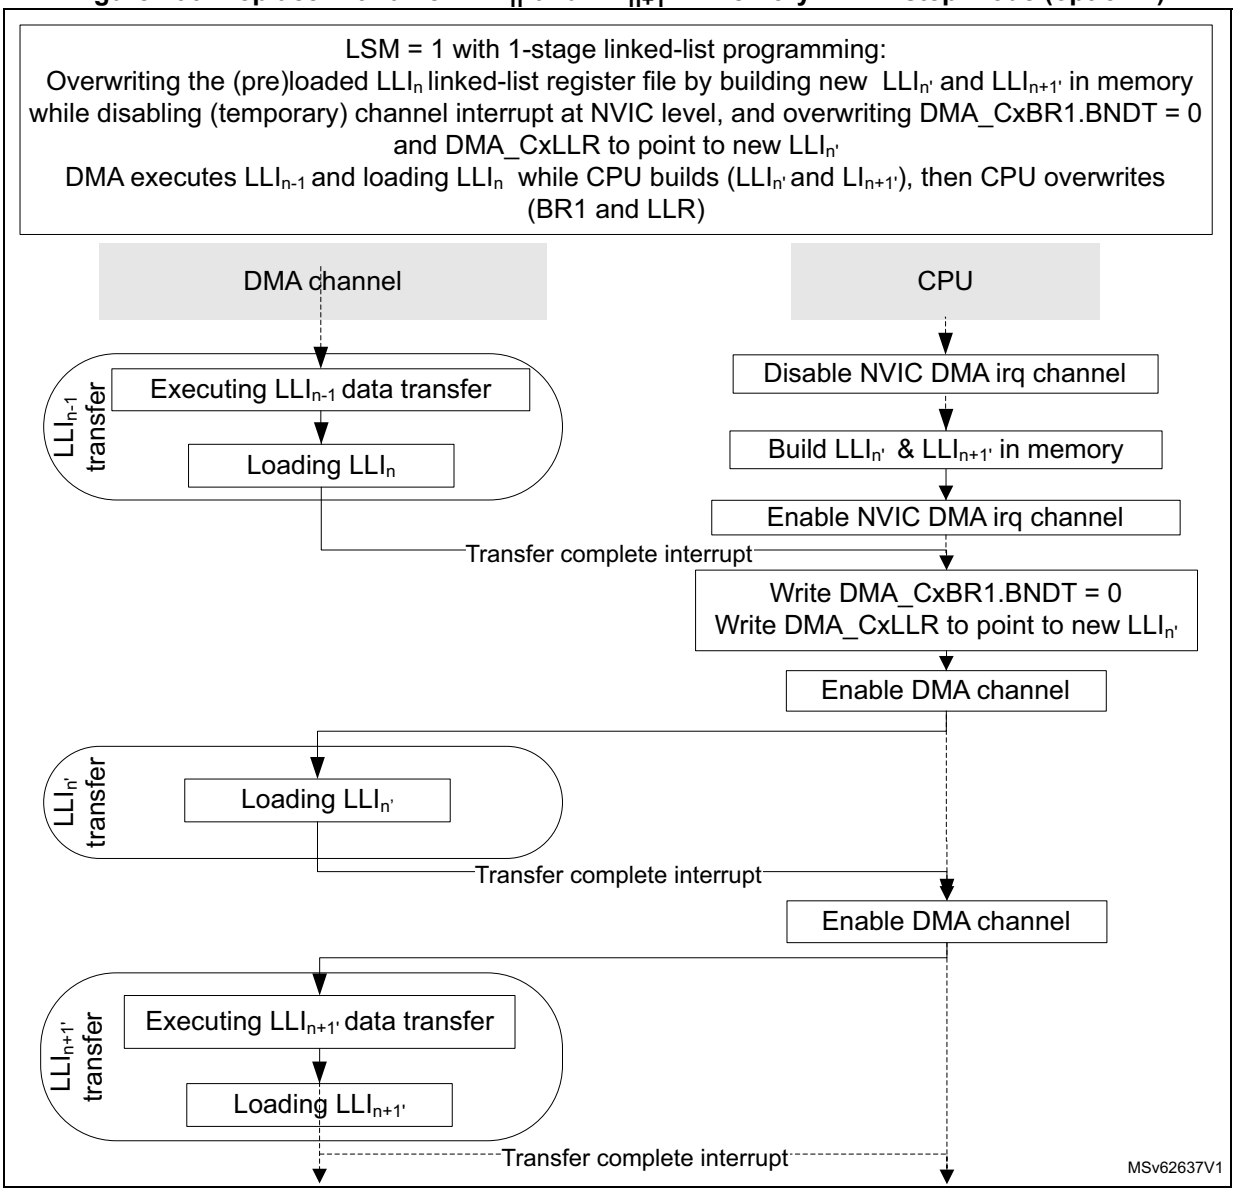
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n'}$, as shown in *Figure 106*.

Figure 106. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)



19.4.9 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 19.4.4*.)

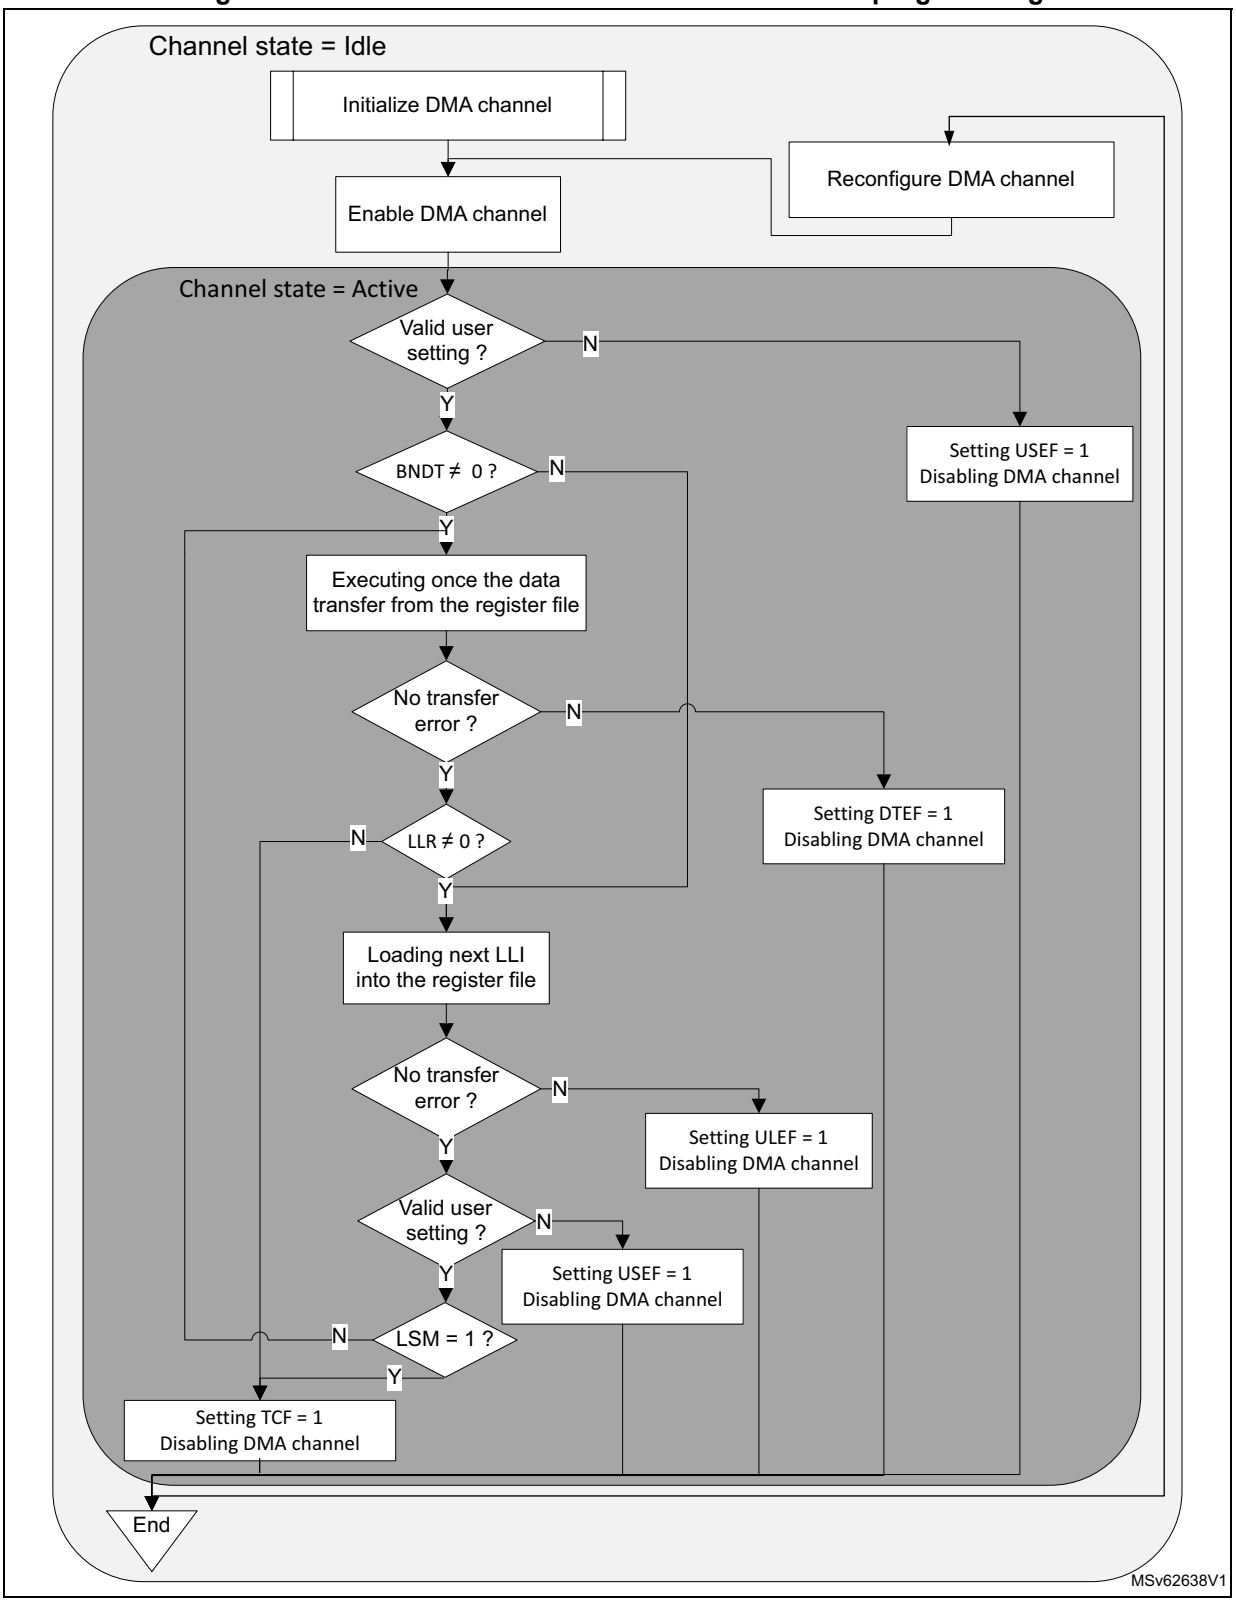
In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 107 shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

Note: Figure 107 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 107, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 19.3.5).

Figure 107. GPDMA channel execution and linked-list programming



19.4.10 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 19.3.1* for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a GPDMA burst.

Table 104. Programmed GPDMA source/destination burst

SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/beats)	Next data/ beat address	Next burst address	Burst address alignment
00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
01	2						2
10	4						4
00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
01	2				+ 2	+ 2 * (n + 1)	2
10	4				+ 4	+ 4 * (n + 1)	4
11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.

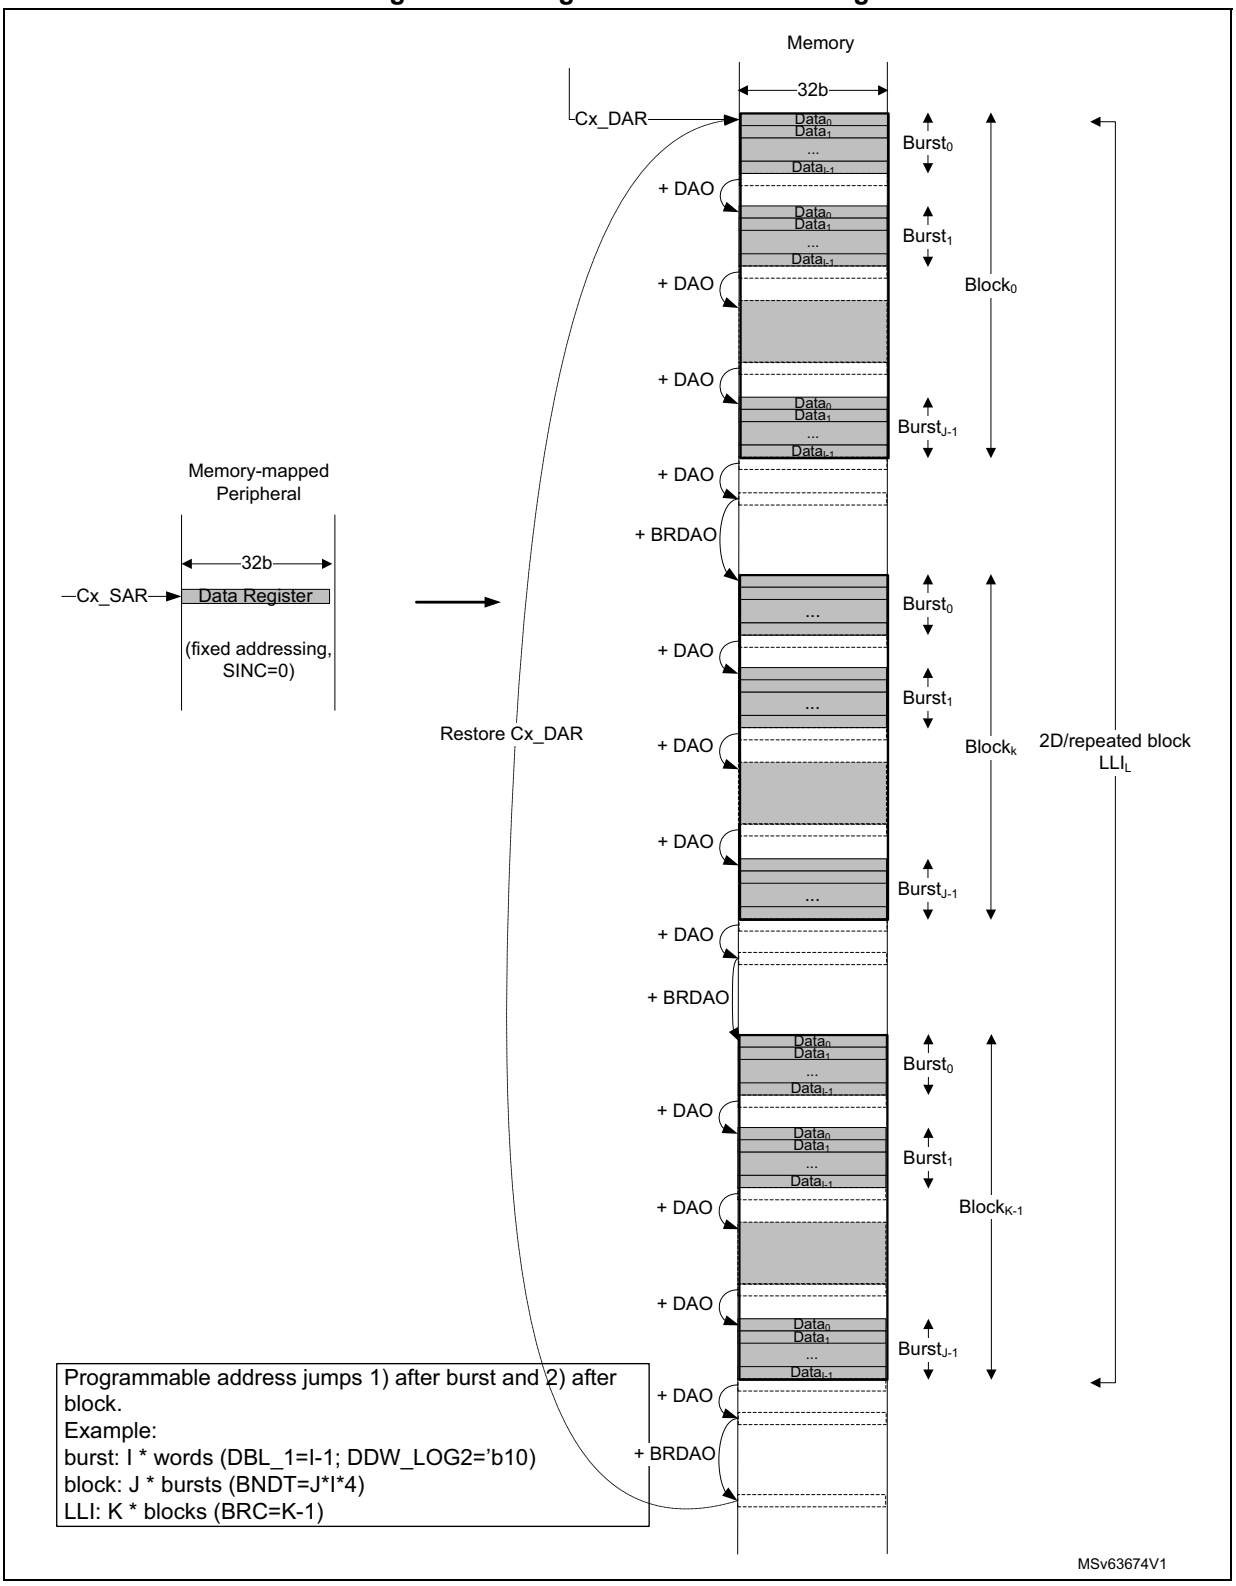
GPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 108* with a 2D destination buffer.

Figure 108. Programmed 2D addressing



GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is the half of the FIFO size of the channel x, in bytes (see *Section 19.3.1* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields (see *Table 105*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 105. Programmed data handling

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.

19.4.11 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[7:0] field (see *Section 19.3.3*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[7:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 109*, is defined by:

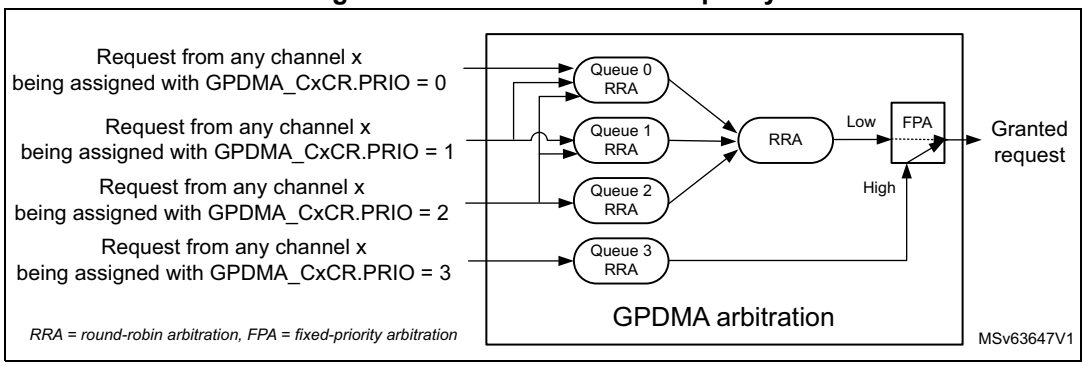
- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1, or 2) for non time-sensitive channels with priority 0, 1, or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.

– Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
– Any queue 0, 1, or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
– Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1, and queue 2.

Figure 109. GPDMA arbitration policy



GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  – If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).
  $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).
  $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$
  $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).
  $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$
  $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$
  The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is
    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is
    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is
    $B_{n, P0} = 1/N *1/9 * (1 - B_{Q3})$
    $B_{n, P1} = 1/N *5/18 * (1 - B_{Q3})$
    $B_{n, P2} = 1/N *11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ ($K>0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 ($K > 0$)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 ($K = 0$)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

19.4.12 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[6:0] (see *Section 19.3.6* for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel x (x = 12 to 15), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).

Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

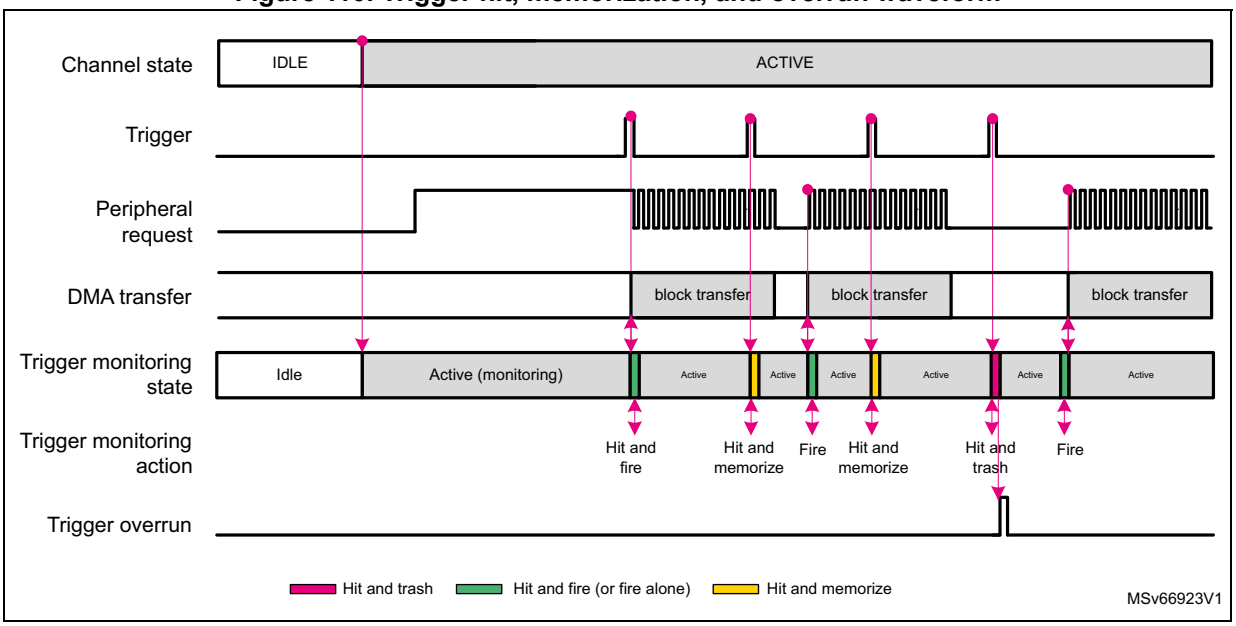
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[6:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[6:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Figure 110 illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 110. Trigger hit, memorization, and overrun waveform



Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

19.4.13 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel

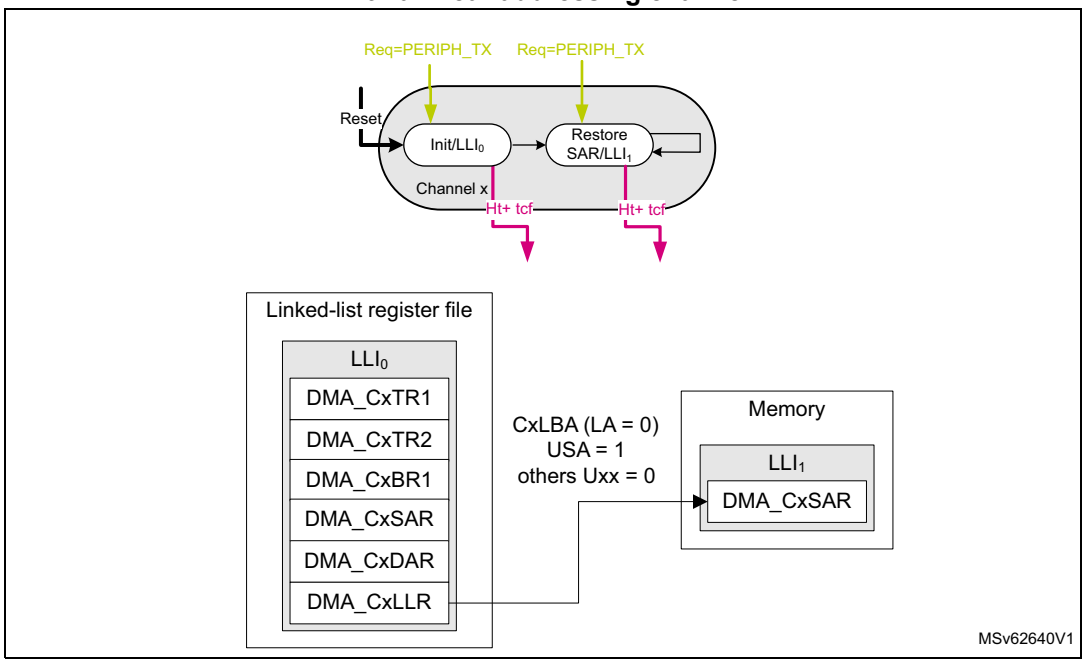
For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer

events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

Figure 111 illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

Figure 111. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel

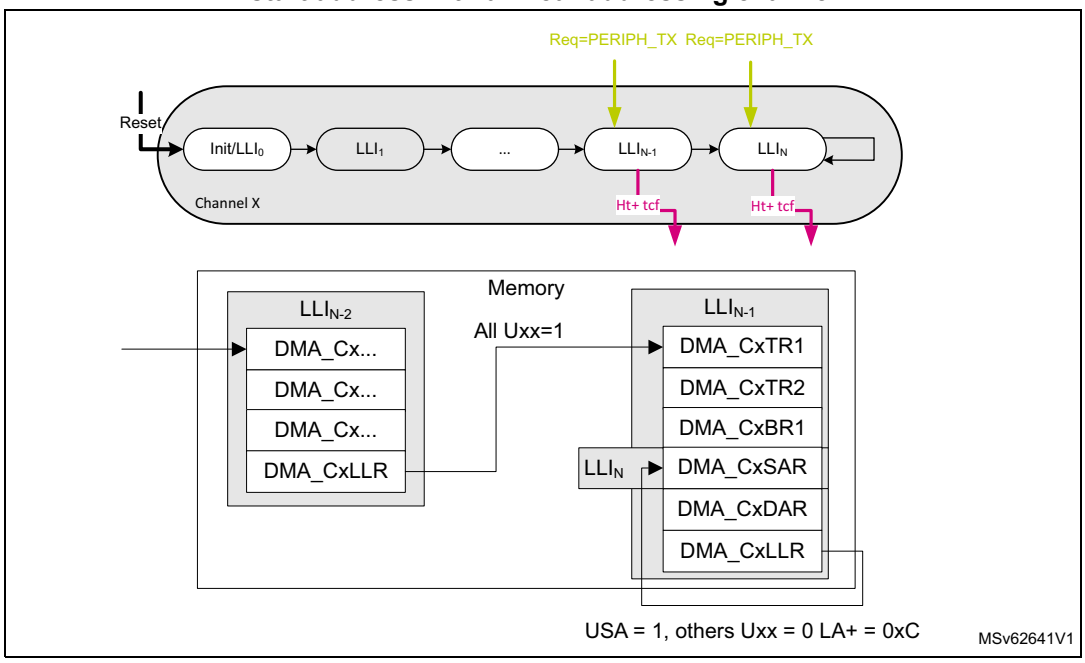


Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

Figure 112 illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

Figure 112. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel



19.4.14 GPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate a GPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 19.3.5*).

If the related GPDMA channel x is also programmed in peripheral flow-control mode (GPDMA_CxTR2.PFREQ = 1):

- The GPDMA block transfer starts as follows:
  - If GPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the GPDMA hardware.
  - If GPDMA_CxBR1.BNDT[15:0] = 0, the GPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The GPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when GPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on GPDMA_CxTR2 (see *GPDMA channel x transfer register 2 (GPDMA_CxTR2)*). Then the software can read the current number of transferred bytes from the source (GPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (GPDMA_CxSAR[31:0] or GPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with a hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

19.4.15 GPDMA secure/nonsecure channel

The GPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and nonsecure worlds at any given time.

Any channel x is a secure or a nonsecure hardware resource, as configured by GPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A nonsecure read access to a register field of this channel is forced to return 0, except for GPDMA_SECCFGR, GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR that are readable by a nonsecure agent.
- A nonsecure write access to a register field of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or nonsecure the GPDMA data transfer from the source (GPDMA_CxTR1.SSEC) and the GPDMA data transfer to the destination (GPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with secure transfers via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a secure bus that reflects GPDMA_SECCFGR, to keep the other peripherals informed of the secure/nonsecure state of each GPDMA channel x.

The GPDMA also generates a security illegal access pulse signal on an illegal nonsecure access to a secure GPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a nonsecure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next nonsecure transfer as a nonsecure software is not allowed to do so and must have GPDMA_CxCR.EN = 0 before the nonsecure software can reprogram the GPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

19.4.16 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR, GPDMA_SECCFGR, and GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

19.4.17 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single or a burst) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).
- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a GPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).
- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])

- for channel x (x = 12 to 15): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width (GPDMA_CxTR1.SDW_LOG2[1:0] = 11)
- a programmed double-word destination data width (GPDMA_CxTR1.DDW_LOG2[1:0] = 11)
- a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1. BNDT = 0)

19.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

19.6 GPDMA in low-power modes

Table 106. Effect of low-power modes on GPDMA

Mode	Description
Sleep	No effect. GPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the GPDMA registers is kept when entering Stop mode.
Standby	The GPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 19.3.2* to know if any Stop mode is supported.

19.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 107. GPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
GPDMA_CHx	Transfer complete	GPDMA_CxCR.TCIE	GPDMA_CxSR.TCF	Write 1 to GPDMA_CxFCR.TCF
	Half transfer	GPDMA_CxCR.HTIE	GPDMA_CxSR.HTF	Write 1 to GPDMA_CxFCR.HTF
	Data transfer error	GPDMA_CxCR.DTEIE	GPDMA_CxSR.DTEF	Write 1 to GPDMA_CxFCR.DTEF
	Update link error	GPDMA_CxCR.ULEIE	GPDMA_CxSR.ULEF	Write 1 to GPDMA_CxFCR.ULEF
	User setting error	GPDMA_CxCR.USEIE	GPDMA_CxSR.USEF	Write 1 to GPDMA_CxFCR.USEF
	Suspended	GPDMA_CxCR.SUSPIE	GPDMA_CxSR.SUSPF	Write 1 to GPDMA_CxFCR.SUSPF
	Trigger overrun	GPDMA_CxCR.TOFIE	GPDMA_CxSR.TOF	Write 1 to GPDMA_CxFCR.TOF

A GPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

- A half transfer event is an half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see *Section 19.4.17*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

19.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

19.8.1 GPDMA secure configuration register (GPDMA_SECCFGR)

Address offset: 0x00

Reset value: 0x0000 0000

A write access to this register must be secure and privileged. A read access is secure or nonsecure, privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (when GPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or nonsecure world.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SECx**: secure state of channel x (x = 15 to 0)
0: Nonsecure
1: Secure

19.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or nonsecure.

This register can mix secure and nonsecure information. If a channel x is configured as secure (GPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN =1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PRIVx**: privileged state of channel x (x = 15 to 0)
0: unprivileged
1: privileged

19.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attributes in order to individually lock, for example at boot time, the secure privileged attributes of any GPDMA

channel/resource (to lock the setting of GPDMA_CxSECCFGR and GPDMA_CxPRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged, secure or nonsecure.

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKx**: lock the configuration of GPDMA_SECCFGR.SECx and GPDMA_PRIVCFGR.PRIVx, until a global GPDMA reset (x = 15 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.

0: secure privilege configuration of the channel x is writable.

1: secure privilege configuration of the channel x is not writable.

19.8.4 GPDMA nonsecure masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This register is a read register.

This is a nonsecure register, containing the masked interrupt status bit MISx for each nonsecure channel x (channel x configured with GPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of GPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of GPDMA_CxCR.

Every bit is deasserted by hardware when writing 1 to the corresponding flag clear bit in GPDMA_CxFCR.

If a channel x is in secure state (GPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full nonsecure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and nonsecure) channels, other privileged bit fields returning zero.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: masked interrupt status of channel x (x = 15 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

19.8.5 GPDMA secure masked interrupt status register (GPDMA_SMISR)

Address offset: 0x10

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (GPDMA_SECCFGR.SECx = 1). It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when securely writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register does not contain any information about a nonsecure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: masked interrupt status of the secure channel x (x = 15 to 0)
0: no interrupt occurred on the secure channel x
1: an interrupt occurred on the secure channel x

19.8.6 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register is either secure or nonsecure depending on the secure state of the channel x (GPDMA_SECCFGR.SECx).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

19.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This is a write register, secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	w	w	w	w	w	w	w								

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: corresponding TOF flag cleared

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

19.8.8 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or nonsecure, depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[7:0]

	r	r	r	r	r	r	r								r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level
Number of available write beats in the FIFO, in units of the programmed destination data width (see GPDMA_CxTR1.DDW_LOG2[1:0], in units of bytes, half-words, or words).

Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag
0: no trigger overrun event
1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag
0: no completed suspension event
1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
0: no user setting error event
1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half transfer flag
0: no half transfer event
1: a half transfer event occurred
A half transfer event is either a half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
A half block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
0: no transfer complete event
1: a transfer complete event occurred
A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag
0: channel not in idle state
1: channel in idle state
This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

19.8.9 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM
								rw	rw					rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	Res.	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw						rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x GPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port
This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed **once** for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 94*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset
This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).
The reset is effective when the channel is in steady state, meaning one of the following:
- active channel in suspended state (GPDMA_CxSR.SUSPF = 1 and GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1)
- channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).
After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 95*).
0: no channel reset
1: channel reset

Bit 0 **EN:** enable
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:
this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).
Else, this bit can be asserted by software.
Writing 0 into this EN bit is ignored.
0: write: ignored, read: channel disabled
1: write: enable channel, read: channel enabled

19.8.10 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in GPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DSEC	DAP	Res.	Res.	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSEC	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 **DSEC**: security attribute of the GPDMA transfer to the destination

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this DSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer to the destination is nonsecure.

Bit 30 **DAP**: destination allocated port

This bit is used to allocate the master port for the destination transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word:

0: no halfword-based exchanged within word

1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0:no byte-based exchange within half-word

1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst

0: fixed burst

1: contiguously incremented burst

The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and if present address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

When configured in packing mode (PAM[1] = 1 and destination data width different from source data width), a source block size must be a multiple of the destination data width (see GPDMA_CxBR1.BNDT[2:0] versus DDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

Bit 15 **SSEC**: security attribute of the GPDMA transfer from the source

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this SSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer from the source is nonsecure.

Bit 14 **SAP**: source allocated port

This bit is used to allocate the master port for the source transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word

If the source data width is shorter than a word, this bit is ignored.

If the source data width is a word:

0:no byte-based exchange within the unaligned half-word of each source word

1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

Condition: PAM_1

00: source data is transferred as right aligned, padded with 0s up to the destination data width

01: source data is transferred as right aligned, sign extended up to the destination data width

10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

Condition: PAM_2

00: source data is transferred as right aligned, left-truncated down to the destination data width

01: source data is transferred as left-aligned, right-truncated down to the destination data width

10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: source incrementing burst

0: fixed burst

1: contiguously incremented burst

The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

Note: A source block size must be a multiple of the source data width (GPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

19.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	TRIGSEL[6:0]						
rw	rw					rw	rw		rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	REQSEL[7:0]							
rw	rw		rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: channel x (x = 0 to 11), same as 00, channel x (x =12 to 15), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x =12 to 15), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[6:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **TRIGSEL[6:0]**: trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per *Section 19.3.6*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x (x = 12 to 15), for each block if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 11), same as 00; channel x (x = 12 to 15), at 2D/repeated block level. The first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[6:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[6:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 19.3.1 for the list of the implemented channels with this feature).

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in GPDMA control mode. The GPDMA is programmed with GPDMA_CxTR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The GPDMA block transfer can be early completed by the peripheral itself (see *Section 19.3.5* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (GPDMA_CxBR1.BRC[10:0] must be set to 0)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, GPDMA_CxTR1.PAM[1] must be set to 0).

- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 19.3.3*).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (GPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[7:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[7:0] is ignored.

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **REQSEL[7:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1(software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 19.3.3*.

Caution: The user must not assign a same input hardware request (same REQSEL[7:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

19.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

19.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is

automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI

- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)

1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)

1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.

– If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

– if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

– if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.

- if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

19.8.14 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

19.8.15 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

19.8.16 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

19.8.17 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

19.8.18 GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0: no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).
Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

19.8.19 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.

0: no GPDMA_CxTR1 update

1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.

0: no GPDMA_CxTR2 update

1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.

0: no GPDMA_CxSAR update

1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0:no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bit 26 **UT3**: Update GPDMA_CxTR3 from memory
This bit controls the update of GPDMA_CxTR3 from the memory during the link transfer.
0: no GPDMA_CxTR3 update
1: GPDMA_CxTR3 update

Bit 25 **UB2**: Update GPDMA_CxBR2 from memory
This bit controls the update of GPDMA_CxBR2 from the memory during the link transfer.
0: no GPDMA_CxBR2 update
1: GPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).
Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

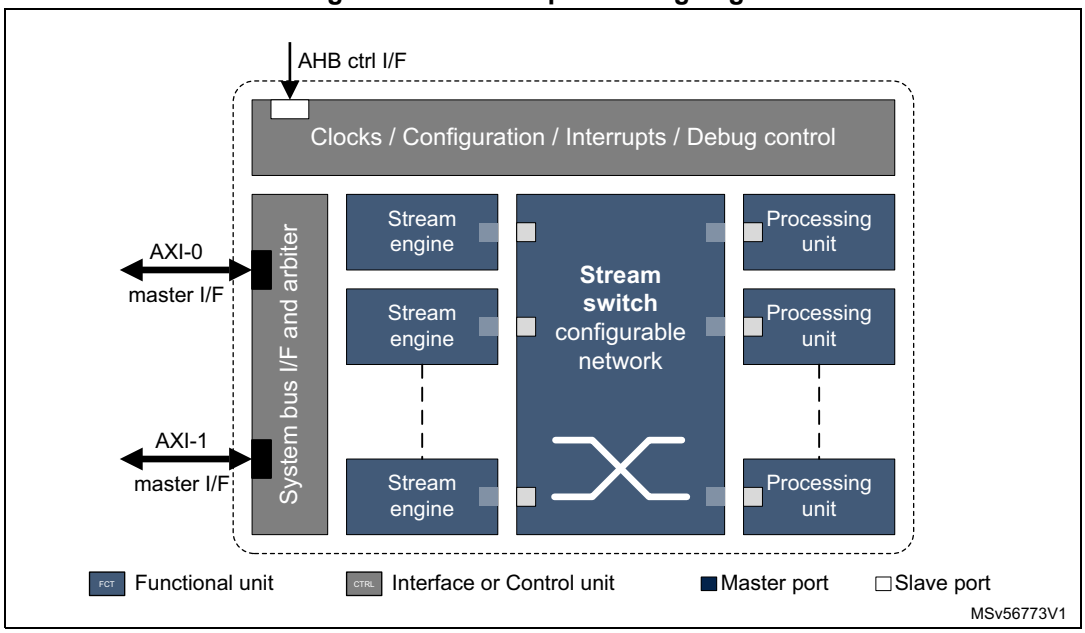
Refer to *Section 2.3: Memory organization* for the register boundary addresses.

20 Neural-ART accelerator™ (NPU)

20.1 NPU introduction

Neural-ART accelerator is a branded family of design-time parametric and runtime reconfigurable neural processing unit (NPU) cores. These cores are specifically designed to accelerate (in area-constrained embedded and IoT devices) the inference execution of a wide range of quantized convolutional neural network (CNN) models.

Figure 113. Stream processing engine



Stream processing

The ST stream processing technology allows the creation of on-demand performance- and area-tailored instances to address artificial intelligence (AI) applications, from the lowest to the highest end class.

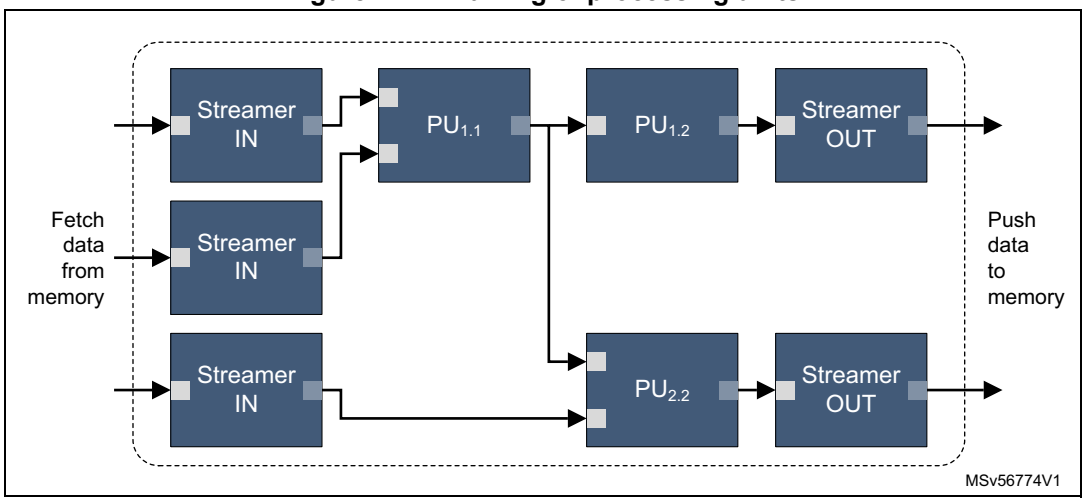
The ST stream processing technology is deemed far more flexible than a hardware data path, and more power-efficient than an on-chip memory bus. The core is a configurable data flow fabric, also known as stream switch, which can be programmed at runtime to create arbitrary virtual chains of processing units (PUs), implementing the sequence of operations to execute. Multiple chains can be active at the same time, provided there are enough available hardware resources.

In the virtual chains, data flow unidirectionally from one PU to the other, hence a processing chain cannot be faster than the slowest element in the chain. A back pressure mechanism controls the data flow in a virtual chain, and data streams can be easily forked or joined to feed multiple destinations, enabling multicasting, context switching, and filtering.

Chaining as many accelerators as possible in a single virtual chain reduces the number of useless and power consuming transfers from/to memory, thus reducing the overall memory traffic and the power consumption.

The resulting IP communicates with the rest of the system through stream engine units. These are smart half-DMAs that can read, and write the data to/from external memory to transfer from/to the IP internal buffers. Although not primarily intended for that, memory-to-memory transfers are possible, connecting two stream engines back to back.

Figure 114. Chaining of processing units



Epoch definition

The execution of CNN models is organized into indivisible processing sequences called epochs. A hardware epoch is defined by the sequence that starts with the configuration of the NPU by the host CPU, and ends with an interrupt sent back to the CPU. The host CPU can then trigger another hardware epoch or execute some software computing for the layers not accelerated by the hardware.

20.2 NPU implementation

The Neural-ART 14 NPU uses a 4CA configuration with the functional units listed in *Table 109*.

Table 109. Neural-ART 14 NPU configuration

Count	Unit	Description
1	STRSWITCH	Central data stream switch
2	DECUN	*Decompression unit*
4	CONVACC	*Convolutional accelerator*
2	POOL	*Pooling unit*
2	ACTIV	*Activation unit*
4	ARITH	*Arithmetic unit* for scalar arithmetic operators
1	RECBUF	*Reconfigurable buffer* (FIFO smart buffer)
10	STRENG	*Stream engines*, with embedded cipher
2	BUSIF	64-bit AXI interface
1	EPOCH	*Epoch controller*

Table 109. Neural-ART 14 NPU configuration (continued)

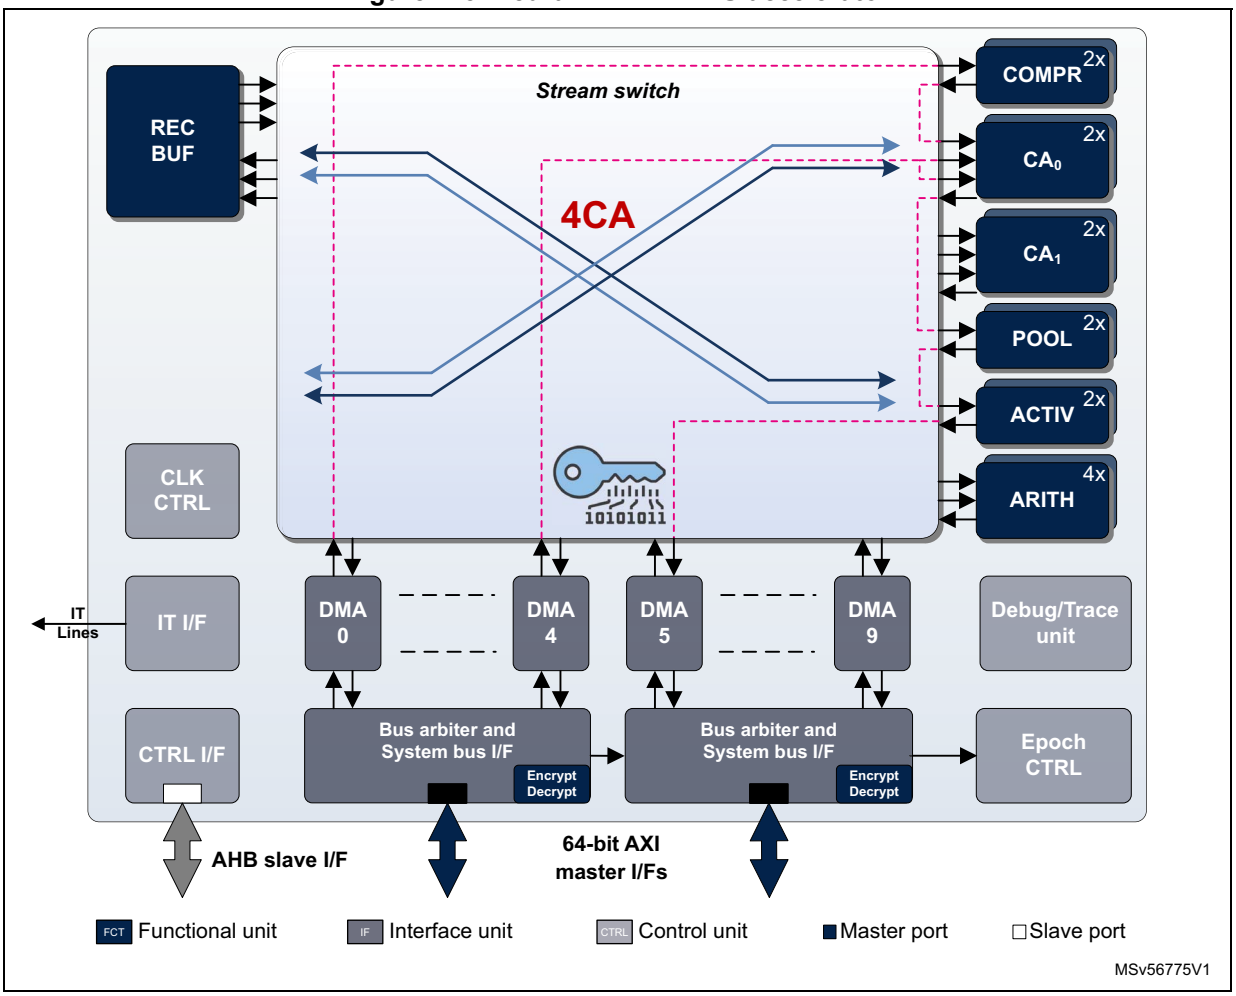
Count	Unit	Description
1	DEBUG	Debug controller
-	SERVICES	Configuration network, Clock and reset manager, Interrupt controller

20.3 NPU functional description

20.3.1 NPU block diagram

The internal organization of the NPU is shown in *Figure 115*.

Figure 115. Neural-ART 14 NPU accelerator



When the NPU is configured and started, it autonomously fetches data from the external memory to feed its internal dynamically interconnected processing units. Similarly, the result of the operation sequence is flushed to the external memory.

Inputs/sources can be the activations/features, but also parameters, such as weights and

biases constant data hosted in a memory-mapped nonvolatile memory. When the data-stream processing pipes are configured and started, the settings cannot be modified until the end-of-transfer event notifications of all DMA-outs and sinks.

20.3.2 NPU pins and internal signals

The NPU connects to the system through:

- One AHB port, used for configuring and controlling the execution of the AI model
- Two fully symmetrical AXI ports, used for fetching data and weights, and flushing outputs.

One interrupt signal fires when the processing for the current epoch is complete. Some additional signals are used for clock, reset, test, and debug. The complete list is given in *Table 110*.

Table 110. Neural-ART 14 NPU signals

Signal	Direction	Width	Description
ipu _clk	In	1	Main clock
ipu_rst_n	In	1	Reset
host_int	Out	4	Host interrupts
dbg_freeze_async	In	1	Debug freeze input signal (active high)
ext_triggers_async	In	4	External synchronization triggers (line based)
trig_sig	Out	8	Trigger signals to an external trace unit (available only in configurations including debug and trace unit)
AXI 0	AXI master port 0		See Arm specification
AXI 1	AXI master port 1		
AHB	AHB slave port		
ATP	In	26	Memory test port
TBYPASS	In	26	
TBISTx	In	26	Memory BIST
HS	In	26	Memory speed select
STDBY	In	26	Memory standby
PSWLARGEMA	In	26	Memory power enable
PSWLARGEMP	In	26	
PSWSMALLMA	In	26	
PSWSMALLMP	In	26	
SLEEP	In	26	Memory sleep

20.3.3 Configuration network

Each of the functional units, whether accelerator or interface, has a configuration space made of a collection of configuration registers. These registers are accessible through the AHB interface. Their detailed description is out of the scope of the present document.

The NPU embeds a configuration network that provides host processor access to the configuration space of the different units in the Neural-ART core. This configuration network connects to the system backbone through a 32-bit AHB5-lite port. It supports a single 32-bit wide read and write transaction, with no pipelining nor outstanding transactions.

20.3.4 Clock/reset manager

The purpose of this unit is twofold:

1. Clock control

   The NPU uses a single functional clock provided by the RCC. This input clock is fed to the clock control unit from where it is gated and fed to the different units of the IP.

   The clock unit generates clocks not gated, and clocks gated by default that need to be enabled after reset.

   Clock gating is controlled by a configuration register bank, accessible via the configuration network, and programmed by the control code generated by the NPU compiler tool chain.

2. Reset control

   The NPU uses a single functional reset provided by the RCC. This reset signal is synchronized inside the IP and fed to the different functional units.

   Setting the clear bit in the control configuration register triggers a global NPU reset.

20.3.5 Stream link

A stream link is a unidirectional interconnection to transport data streams from accelerator units, stream engines, and interfaces to the stream switch and vice versa.

The stream consists of data, messages, or commands, and additional signaling information.

- Data are transported over three 8-bit wide data channels that are either handled individually or can be interpreted as a single 24-bit data value.
- Transported data can use different formats. A raster scan data stream allows the automatic detection of the geometrical dimensions of the received feature data tensor (width and height). A raw data format requires to program additional parameters to handle correctly the received data stream.
- Signaling information is used to identify valid information on the stream link. It indicates the type and format of information transported, and whether this is the first or the last data transmitted.

20.3.6 Stream switch

This switch dynamically connects output stream link ports to input stream link ports, depending on the configuration data written to the configuration registers.

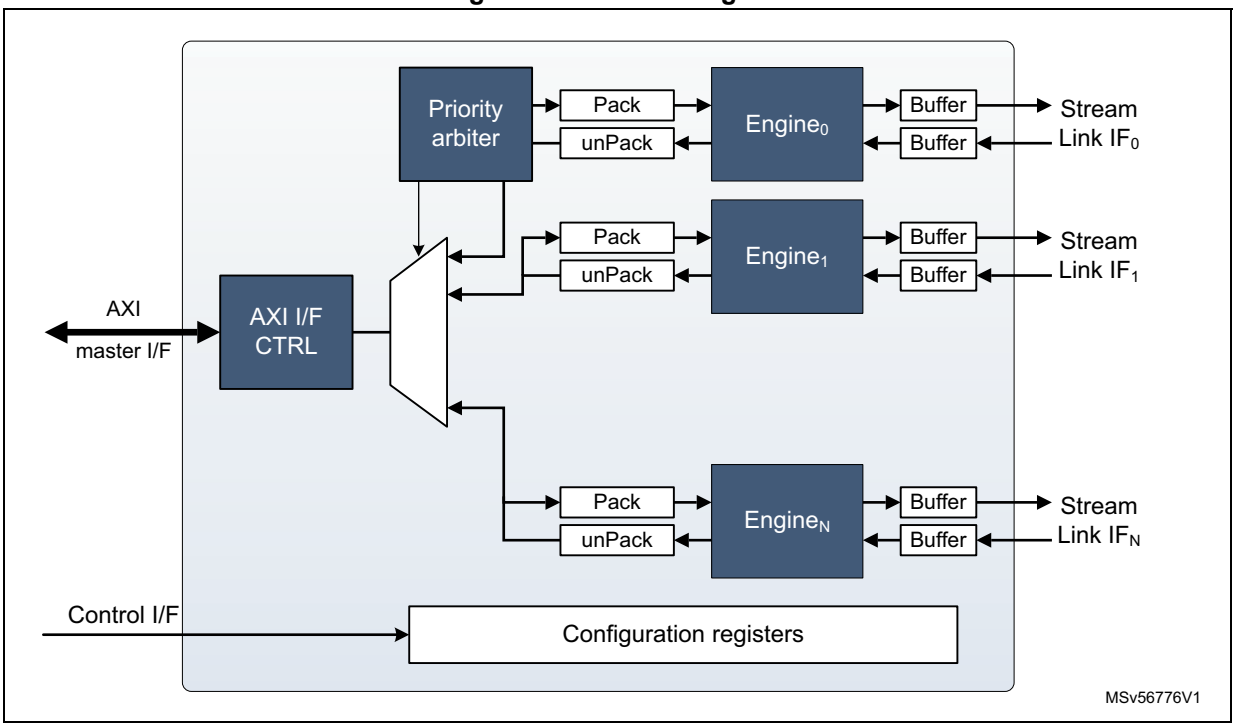
All input stream link ports can forward their data streams to one or multiple (multicast) output ports at the same time, allowing replication of the data stream.

Two stream links can be connected to a single output port of the switch. In this case, the output data are managed using a time-division context switch approach.

20.3.7 Stream engines

These engines manage the transfer from the system to the processing units and vice versa.

Figure 116. Stream engines



A stream engine connects to the stream switch by one input and one output stream link.

The stream engine offers a high configurability on read/write memory patterns:

- 2D and 3D data representations
- Gap management (interleaving)
- High flexibility of data format (size, rounding, subsampling or resampling, MSB or LSB alignment with sign extension).

Linked lists are supported.

20.3.8 Encryption/Decryption unit

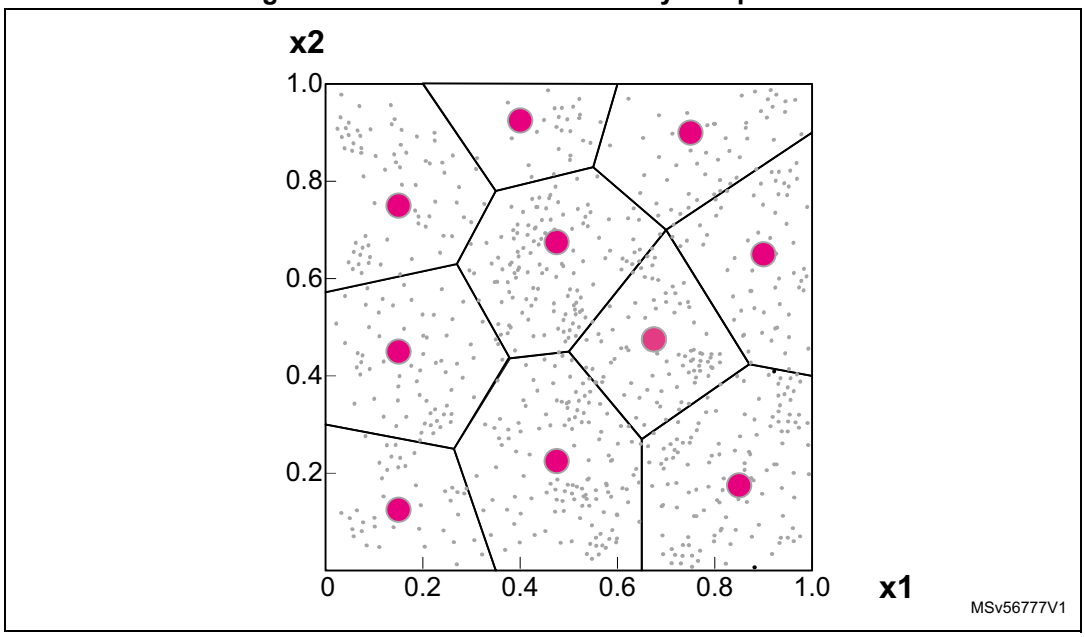
A low overhead/latency encryption/decryption unit based on Keccak-p[200] SHA-3 algorithm cipher, with a programmable number of rounds, is integrated in the bus interface, and can be shared between the different stream engines. It supports both weights and activation decryption and encryption.

20.3.9 Decompression unit

This unit supports on-the-fly decoding for scalar quantized data associated with kernels weights (with arbitrary quantization function), and decoding of vector quantized groups of weights.

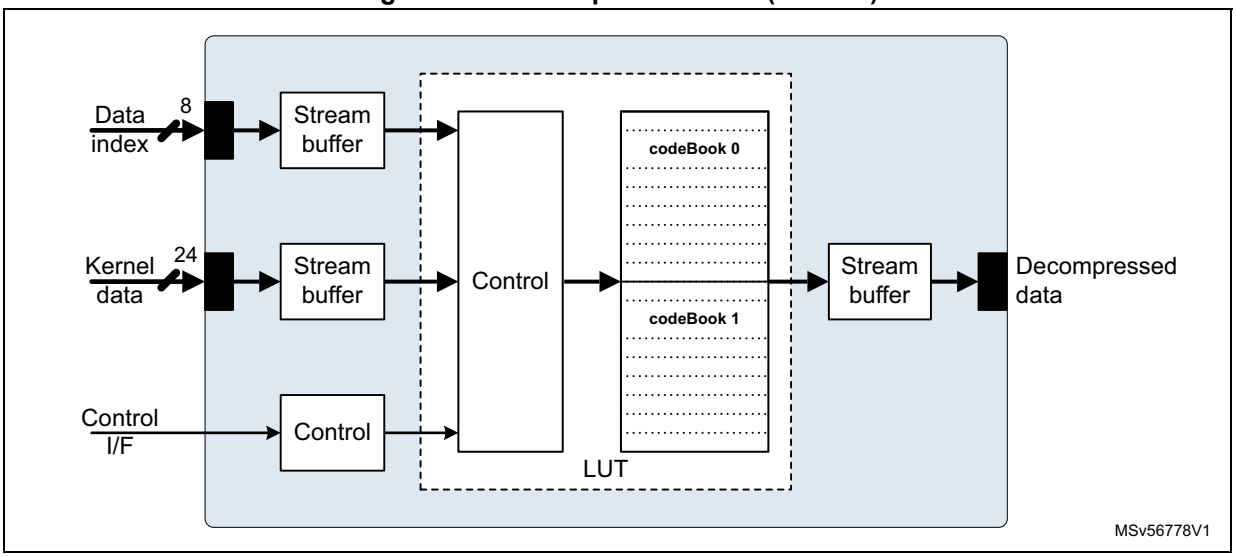
An n-dimensional space can be described in a lossy way, by subdividing it into subvolumes, each described by its centroid. The subvolumes are obtained to minimize a predefined distortion function. The whole signal space can be represented with huge savings in terms of storage, as it is possible to represent the space of interest using only centroid values.

Figure 117. Two dimensional lossy compression



Quantization functions and/or vector quantizer code books (CB) are defined with an offline tool part of the NPU compiler toolchain. The encoder maps the input range into a finite range of rational values, called the code book. Any value stored by the CB is called a code vector. A code vector is made by up to eight code words. Each code book can store up to 256 code vectors (CV).

Figure 118. Decompression unit (DECUN)



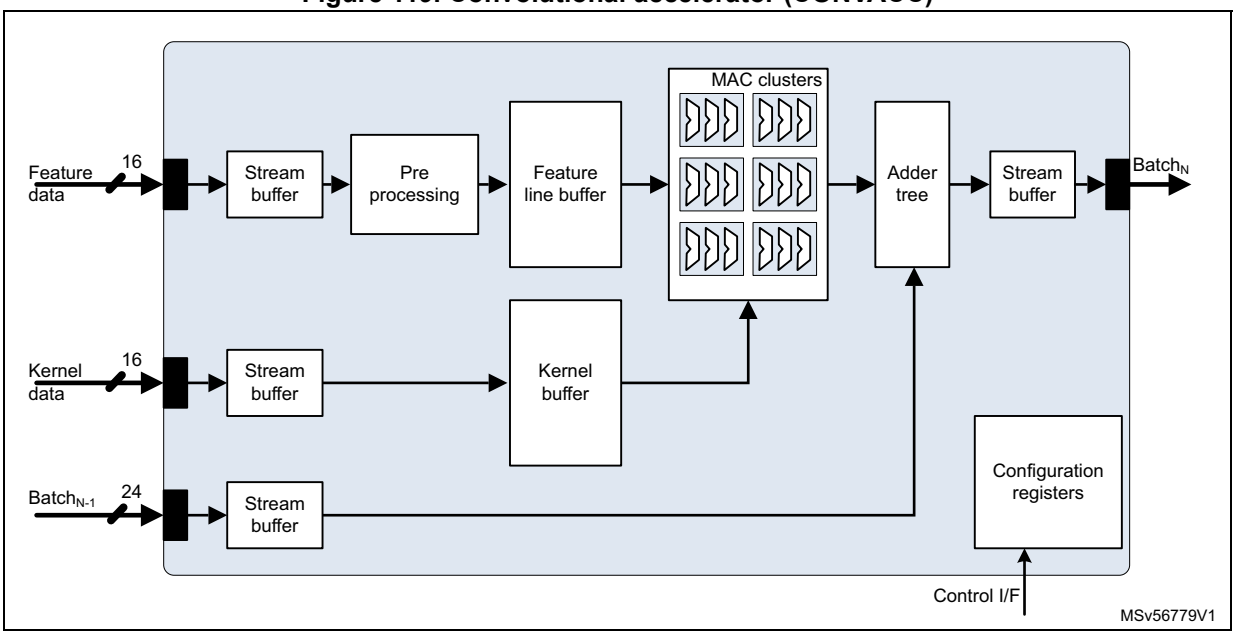
The decompression unit connects to the stream switch by two input stream links and one output stream link.

- iSL_0: receives the 8-bit indexes to decompress the data.
- iSL_1: receives the data to write in the code book, sent as raw data.

20.3.10 Convolutional accelerator

This is the core of the NPU. It implements clusters of multiply-accumulate (MAC) engines supporting fixed-point acceleration of the 3x3 convolutions used by many of the neural network models. It can be configured as 16- or 8-bit MACs, depending on which fixed-point precision for kernels and feature data is considered sufficient.

Figure 119. Convolutional accelerator (CONVACC)



The convolution accelerator connects to the stream switch by three input stream links and one output stream link.

- iSL_0: receives the feature data as 8- or 16-bit raster scan or raw data. Data go through a bit rate adaptation stream buffer and is then transmitted to the feature data preprocessing unit before it is stored in the feature line buffer.
- iSL_1: receives the kernel data as 8- or 16-bit raster scan or raw data.
- oSL: provides convolution results as 8- or 16-bit raster scan or raw data stream, with up to 24-bit wide signed data values.
- iSL_2: can receive intermediate 24-bit signed accumulator values to be accumulated with the convolution results.

Each convolution accelerator supports signed or unsigned arithmetic. It includes eighteen 16-bit MAC units grouped as six clusters of three MAC units. Each MAC performs a single 16x16-, two 16x8-, or four 8x8-bit multiply accumulate operation, which sums up to a maximum of 18 16x16-, 36 16x8-, or 72 8x8-bit multiply accumulate operations per clock cycle and per convolution accelerator unit.

The preprocessing unit implements the following sequence:

1. Format detection: determines if the data is raster scan or raw
2. Shift/round/saturation
3. HOR/VER cropping
4. Zero frame generation: on-the-fly extend the feature tensor structure.
5. Iteration control: simplifies the iterative processing of kernels larger than the 3x3 natively supported by the convolutional accelerator.

20.3.11 Pooling unit

This unit supports pooling operations like local 2D windowed (MxN) min, max, average pooling, as well as global max, min, or average pooling.

Supported features include:

- Native pooling windows of dimensions up to 3x3
- Horizontal and vertical strides ranging from 1 to 15
- Batch size ranging from 1 to 8
- Left, right, and top padding ranging from 0 to 7
- Bottom padding, depending on the window height

Figure 120. Example of pooling operations

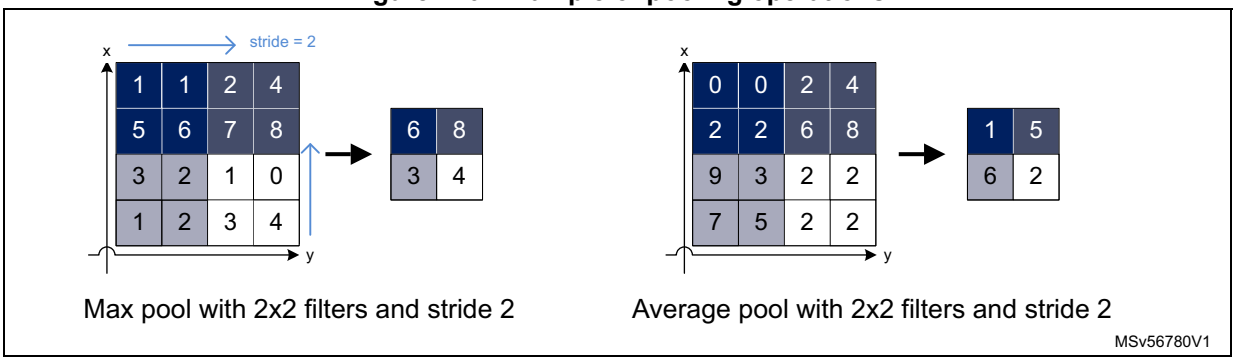


Figure 121. Pooling unit (POOL)

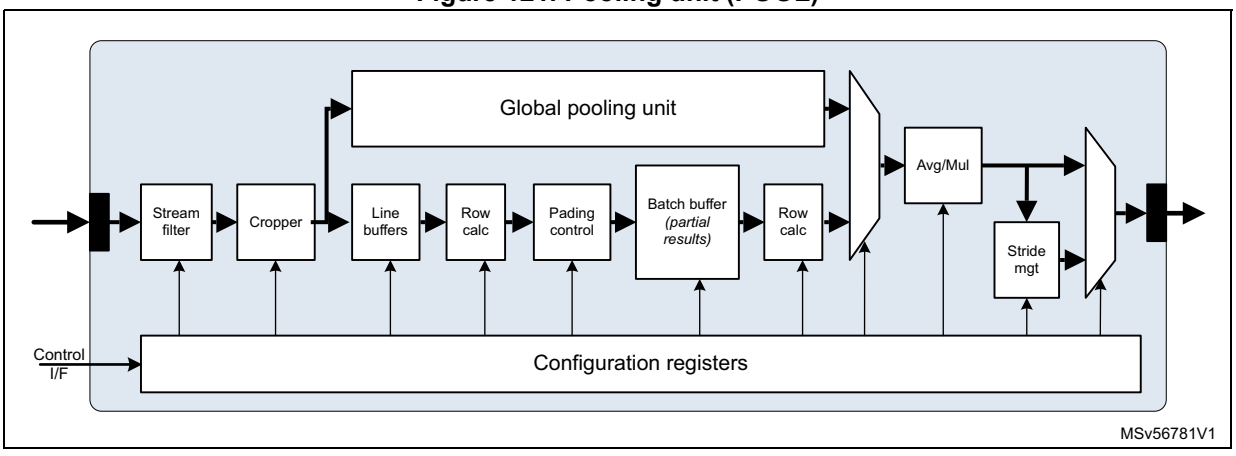


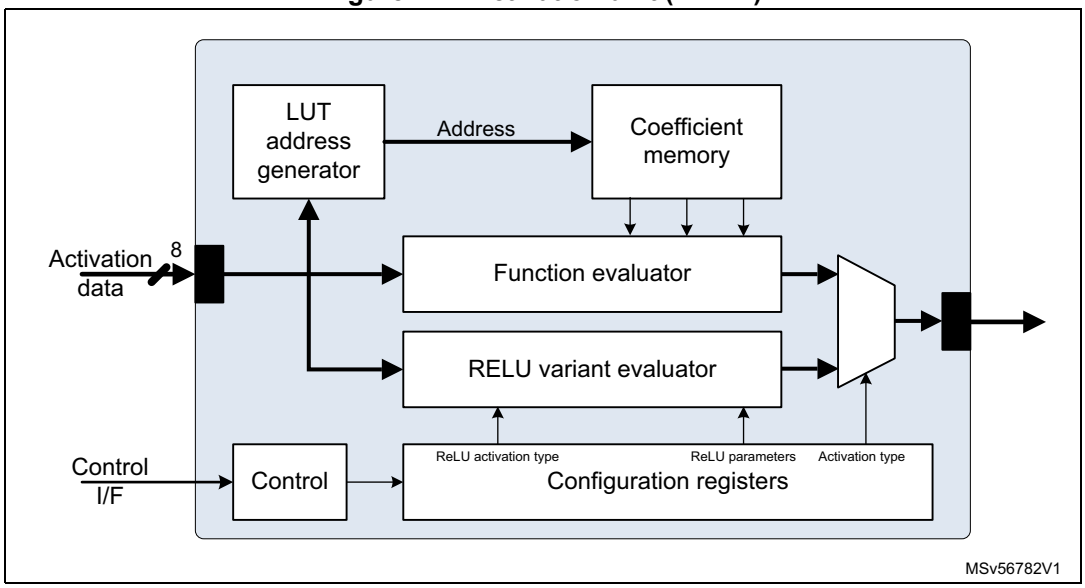
The pooling unit connects to the stream switch by one input and one output stream link:

- iSL_0: receives the activation input values as raster scan or raw data. Input is saturated to 16-bit.
- oSL: produces the pooled output as raw data.

20.3.12 Activation unit

This unit implements the activation functions associated with convolutional neural networks. It provides a dedicated path to compute ReLU-like activations such as plain, parametric, and thresholded ReLUs. There is also a generic function evaluator using a second-degree piece-wise polynomial approximation ($y = ax^2 + bx + c$ or $y = (ax + b) * x + c$). It uses a hierarchical uniform segmentation scheme to implement the evaluator.

Figure 122. Activation unit (ACTIV)



The unit connects to the stream switch by one input stream link and one output stream link.

- iSL_0: receives the activation input values as raster scan or raw data. Input is saturated to 16-bit.
- oSL: produces the result output as raw data.

Table 111 provides examples of usual activation functions.

Table 111. Activation functions example

Function	Plot	Equation	Derivative
Identity		$f(x) = x$	$f(x) = 1$

Table 111. Activation functions example (continued)

Function	Plot	Equation	Derivative
Binary step		$f(x) = \begin{cases} 0 & \text{for } x < 0 \\ 1 & \text{for } x \geq 0 \end{cases}$	$f'(x) = \begin{cases} 0 & \text{for } x \neq 0 \\ \infty & \text{for } x = 0 \end{cases}$
Logistic		$f(x) = \frac{1}{1+e^{-x}}$	$f'(x) = f(x)(1-f(x))$
Hyperbolic tangent		$f(x) = \tanh(x) = \left(\frac{2}{1+e^{-2x}} - 1\right)$	$f'(x) = 1 - f(x)^2$
Arctan		$f(x) = \operatorname{atan}(x)$	$f'(x) = \frac{1}{x^2+1}$
Rectified linear unit (ReLU)		$f(x) = \begin{cases} 0 & \text{for } x < 0 \\ x & \text{for } x \geq 0 \end{cases}$	$f'(x) = \begin{cases} 0 & \text{for } x < 0 \\ 1 & \text{for } x \geq 0 \end{cases}$
Parametric rectified linear unit (PReLU)		$f(x) = \begin{cases} ax & \text{for } x < 0 \\ x & \text{for } x \geq 0 \end{cases}$	$f'(x) = \begin{cases} a & \text{for } x < 0 \\ 1 & \text{for } x \geq 0 \end{cases}$

Table 111. Activation functions example (continued)

Function	Plot	Equation	Derivative
Exponential linear unit (ELU)		$f(x) = \begin{cases} a(e^x - 1) \text{ for } x < 0 \\ x \text{ for } x \geq 0 \end{cases}$	$f'(x) = \begin{cases} f(x) + a \text{ for } x < 0 \\ 1 \text{ for } x \geq 0 \end{cases}$
SoftPlus		$f(x) = \ln(1 + e^x)$	$f'(x) = \frac{1}{1 + e^{-x}}$

20.3.13 Arithmetic unit

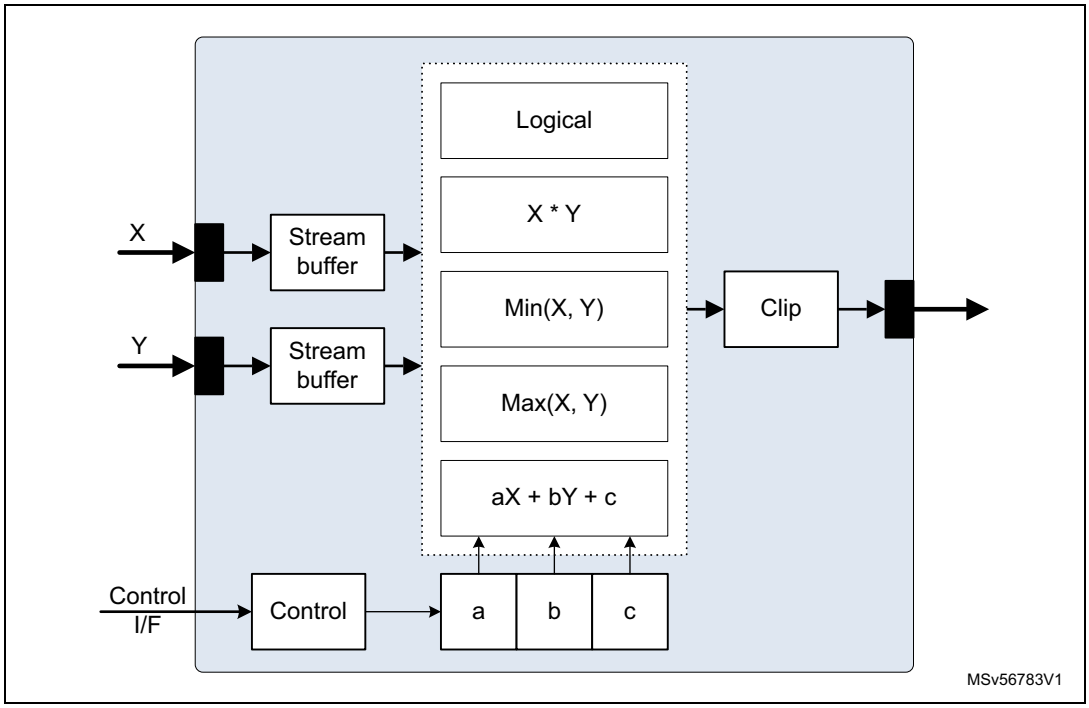
The arithmetic unit can handle outputs coming directly from the convolution accelerators. The main function is aX + bY+ c, where X and Y are input data streams, supplied via two input stream link interfaces and a, b and c are constants that are either vectors or scalars, which are preloaded into an internal memory via the configuration interface.

The arithmetic unit can be configured to perform other operations:

- x * y;
- MIN(x,y), MAX(x,y)
- Logical {AND, OR, NOT(X)}
- Bitwise {AND, OR, XOR, NOT(x)}
- Comparison operations like =, <, ≤, >, ≥
- Math operations like ABS(x), SIGN(x), and CLIP(x) with the 16-bit signed clip ranges supplied by the a coeff (min) and c coeff (max)

Based on the choice and type of coefficients, the unit can also perform element-wise operations like x - y, x + y, and similar ones.

Figure 123. Arithmetic unit (ARITH)



This unit connects to the stream switch by two input stream links and one output stream link.

- $iSL_{0,1}$: receives the input values, denoted X & Y, as raster scan or raw data. Input is saturated to 16-bit.
- oSL: produces the result output as raw data.

20.3.14 Reconfigurable buffer

The amount of data to process is usually divided using channel-wise data segmentation strategies. The data are then organized in execution epochs and channel data blocks along the three spatial dimensions. Data blocks are created considering the number of channels and the size of the incoming data. The partial data coming out from the different data blocks must then be reorganized and used in the next processing.

The reconfigurable buffer takes and stores the input data before making them available to the following units, which is useful to avoid deadlocks.

20.3.15 Epoch controller

This controller makes the NPU operation independent from the host CPU, which just provides a pointer to a 64-bit aligned “binary blob” placed in a memory space accessible through the AXI IF. The binary blob can be encrypted.

The core of the epoch controller is an FSM that decodes the control microinstructions, to appropriately configure all the processing units involved in the model execution using direct access to the NPU internal configuration bus.

The synchronization with the NPU is interrupt-based. An available step-by-step mode allows the execution of one microinstruction at a time. The execution is triggered by a write in a dedicated bit in the IRQ register.

The controller frees the AHB control bus for other uses, and improves the performance through a faster NPU programming. The binary blob is fetched through the AXI interface, which provides a larger bandwidth than the AHB. The direct access to the internal configuration bus allows bypassing all the bus external structure, where transactions from the host processor need to pass through.

20.3.16 Interrupt controller

Functional units can generate level-sensitive, active high, interrupts. These are collected by the interrupt controller, routed to four master interrupt lines, and forwarded to the host CPU.

When a master interrupt fires, the host CPU must read the INTREG register to identify the source of the current interrupt signaling. Interrupt routing to the four master interrupt lines and selective enabling are controlled by the INTORMSK and INTANDMSK mask registers, which have as many bits as interrupt sources.

- INTORMSK: an interrupt is forwarded if any of the unmasked interrupts is active.
- INTANDMSK: an interrupt is forwarded if all the unmasked interrupts are active.

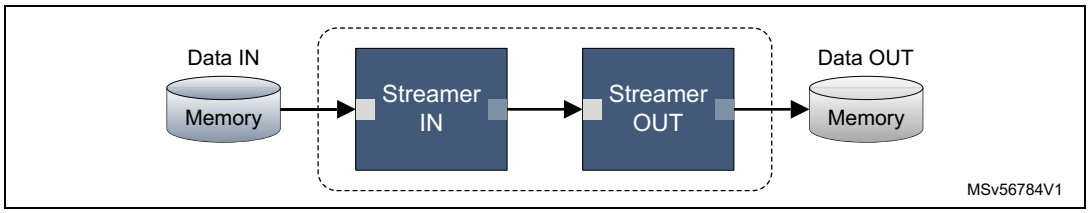
20.4 Configuration examples

The following figures illustrate typical examples of streaming processing supported by the Neural-ART 14 NPU.

20.4.1 DMA transfer

The simplest possible chain involves one input streamer and one output streamer connected back-to-back, which (although not primarily intended for that) configures the NPU as a high-bandwidth DMA.

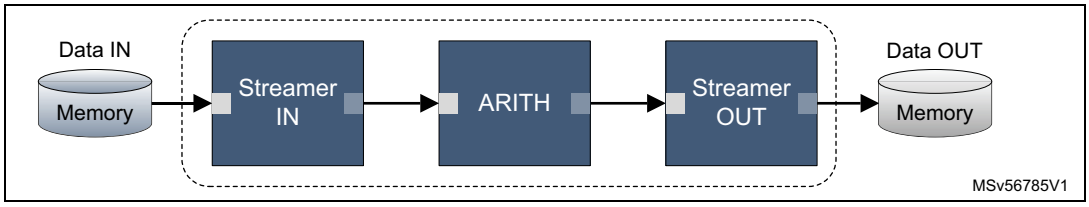
Figure 124. Memory to memory transfer



20.4.2 Simple processing

The simplest processing chain involves one input streamer and one output streamer, with one processing unit in between.

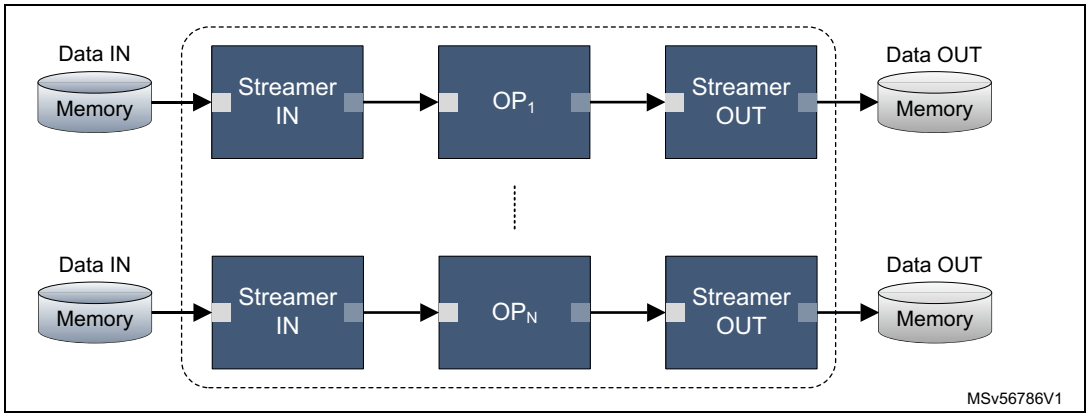
Figure 125. Simple processing



20.4.3 Multiple processing

Implements several independent simple processing chains, like the one in *Figure 125*.

Figure 126. Multiple processing

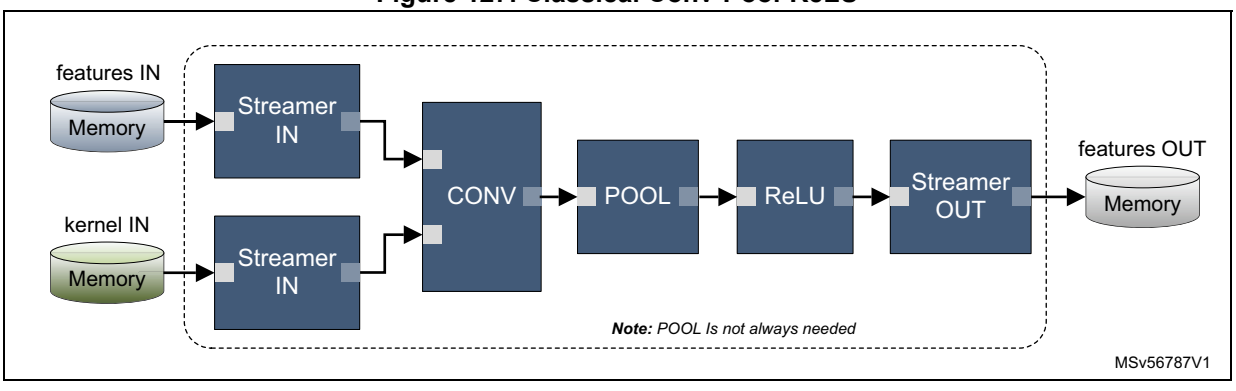


The number of independent chains is limited by the available hardware resources. It cannot exceed half the number of available stream engines, that is, five pairs of stream engines on Neural-ART 14, thus five chains.

20.4.4 Conv-Pool-ReLU

The virtual chain implementing the classical Conv-Pool-ReLU processing is illustrated in *Figure 127*.

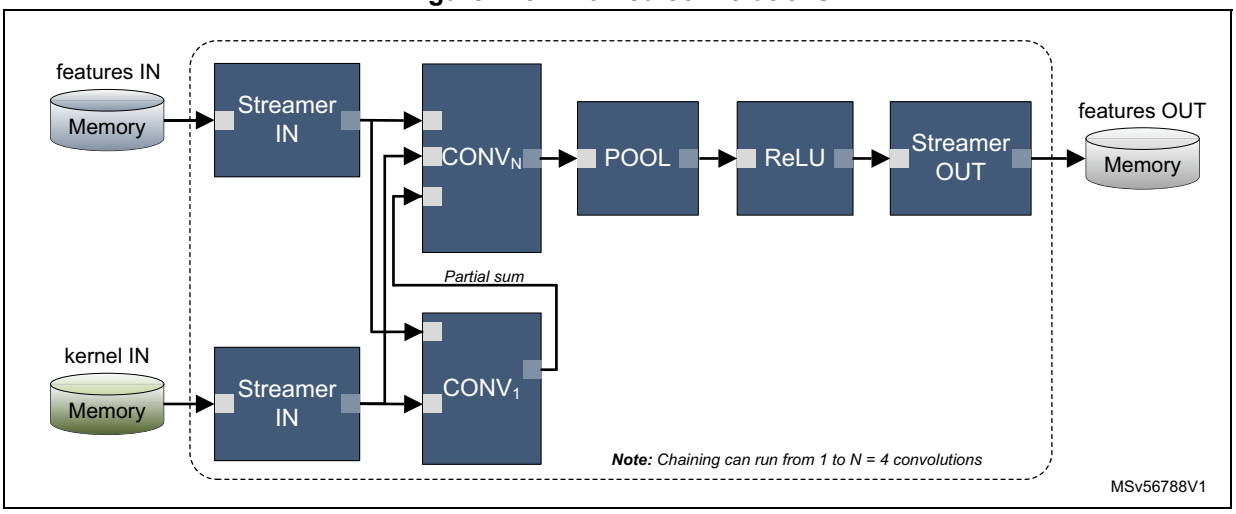
Figure 127. Classical Conv-Pool-ReLU



20.4.5 Chained convolutions

Figure 128 shows an example of chained convolutions.

Figure 128. Chained convolutions



Neural-ART 14 allows chaining up to four convolutions.

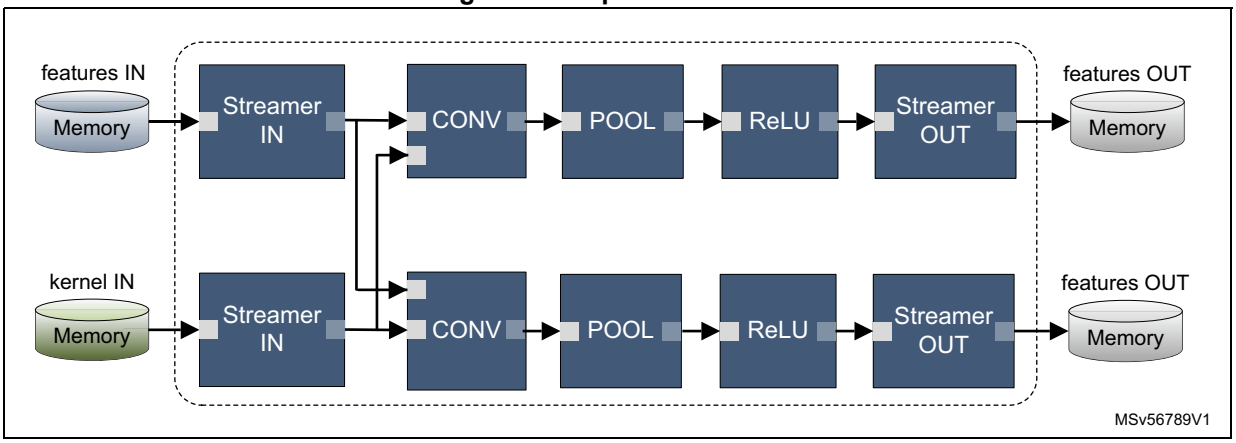
It is possible to use S CONVACCs in series, which requires (S times) more feature data bandwidth, but the same bandwidth for accumulation and output data as a single accelerator.

It is also possible to use P CONVACCs in parallel (see *Figure 126*), which reuse the same feature data requiring P times the amount of accumulation data and output data bandwidth.

20.4.6 Split convolutions

Figure 129 shows an example of split convolution.

Figure 129. Split convolution



20.5 Address space

The configuration bus address mapping depends on the specific NPU instance configuration. Each of the functional units has a 4-Kbyte configuration space, which yields a 128-Kbyte configuration space for the total IP, organized as shown in *Table 112*.

Table 112. Neural-ART 14 functional units memory base addresses(1)

Offset	Unit	Description

Offset	Unit	Description
0x1E000	EPOCHCTRL0	Epoch controller 0
0x1F000	DEBUG0	Debug and Trace unit 0

1. The base address is the offset relative to the first address location of the Neural-ART core, defined at integration level. Refer to the memory map.

20.6 System integration

20.6.1 System considerations

The amount of memory required by the NPU depends on the complexity (number of layers to execute, size of the input data) and target performance of the selected model of neural network. This amount can vary by 1.5 orders of magnitude.

To reach peak performance, the system memory must be configured with enough independent memory banks. These must have a separate AXI slave port on the system interconnect to guarantee the maximum internal memory bandwidth and to benefit of the AXI bus parallelism.

In addition to the on-chip memory, dedicated external memory interfaces are needed to access a nonvolatile memory, where the model parameters (weights and biases) are hosted. Additional RAMs can be used to address large(r) neural networks that cannot fit entirely in the embedded memory. The response time (latency) and the available bandwidth of these interfaces is a limiting factor in the achievable frame rate and efficiency of the NPU processing units (such as MACs) utilization.

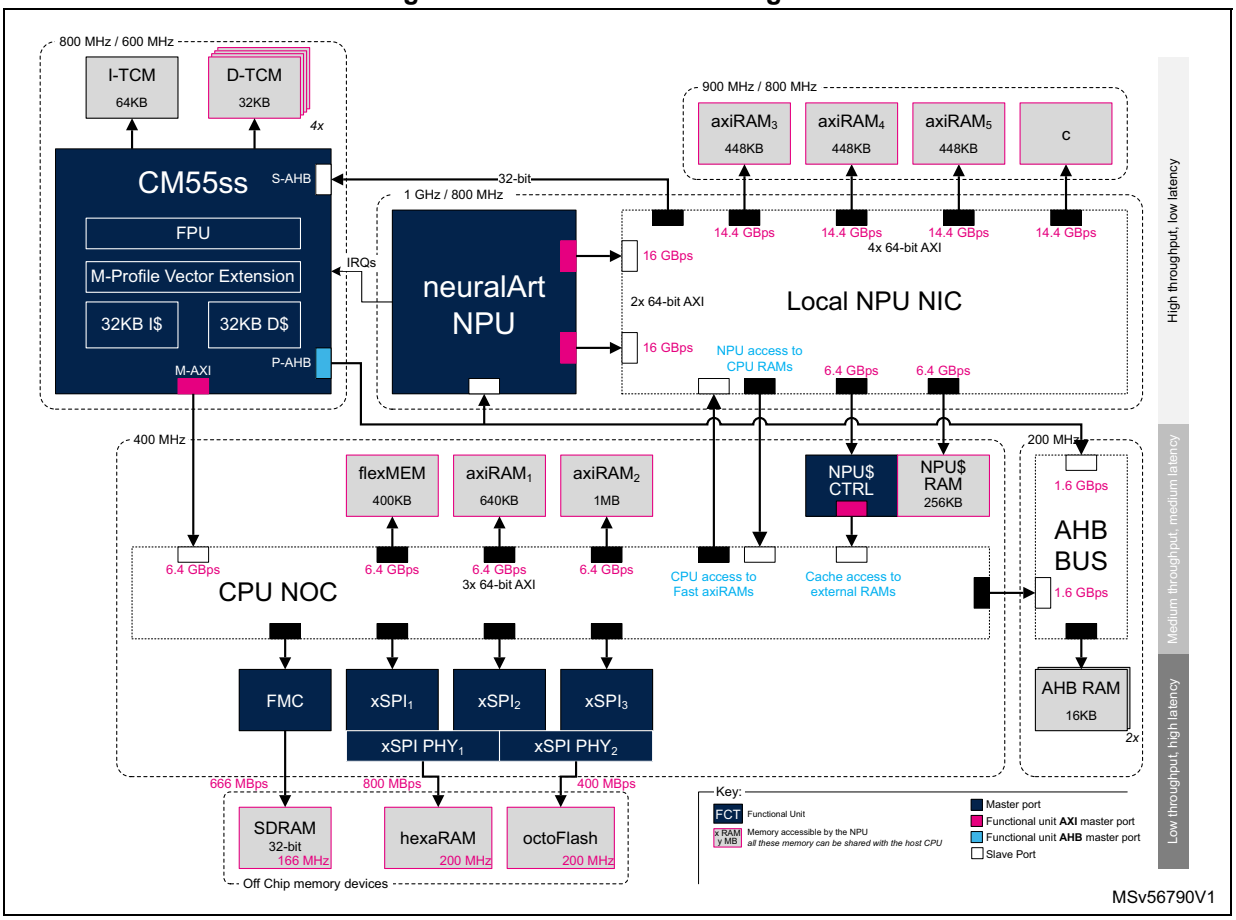
20.6.2 Architecture intent

The system architecture is designed to provide 4.2 Mbytes of contiguous system memory that can be seamlessly shared between the host and the NPU subsystems. At the same time, it offers privileged access to a meaningful high(er)-speed portion of these 4.2 Mbytes to the NPU.

A dedicated NPU cache (CACHEAXI) allows the mitigation of the bandwidth limitation when accessing external memories. When not used for caching, it can be configured as an additional RAM.

The Neural-ART 14 NPU simply connects to the system by two master AXI 64-bit ports that provide the high throughput needed for efficient acceleration of neural network models. Synchronization with the Cortex-M host CPU is through a slave AHB 32-bit port for NPU configuration, and interrupts connected to the NVIC.

Figure 130. Neural-ART 14 integration



Security

The Neural-ART 14 is not TrustZone aware. Therefore, multicontext and multitenancy are supported through the implementation of isolation compartments separated by CIDs. The AHB control interface is protected by a RISUP placed upstream. A RIMU is placed in the downstream of the AXI master interfaces, to assign CID values, so that NPU could only access the sole memories protected with that CID. Refer to the security chapter for further information.

Control interface

The Cortex-M55 host CPU configures the Neural-ART 14 NPU subsystem through the AHB slave port, which is connected to one of the ports of the AHB system bus matrix.

Data interface

The two 64-bit wide master AXI-4 ports of the NPU connect to a high-speed local interconnect that provides four 448-Kbyte banks of fast memory with a privileged, high-throughput / low-latency, asynchronous access. Each bank is implemented as four 112-Kbyte physical memory cuts, served by a full-duplex memory controller. This offers

14.4 Gbyte/s, provided reads/writes are done to different memory cuts, distant by at least 112 Kbytes.

The high-speed local NIC also connects to the main NOC through an asynchronous bridge, which gives access to medium throughput / medium latency on-chip memories:

- The system memory, organized in three memory banks.
  - A 400-Kbyte- bank, known as flexMem, which can, at setup, be allocated to either extend ITCM or DTCM, or left to the system.
  - A 624-Kbyte bank, subdivided into eight 256-Kbyte memory cuts. A bandwidth of 6.4 Gbyte/s is achievable provided reads/writes are distant by at least 256 Kbytes.
  - A 1-Mbyte bank, subdivided into four 256-Kbyte memory cuts. A bandwidth of 6.4 Gbyte/s is achievable provided reads/writes are distant by at least 256 Kbytes.
- The 256 Kbytes of the NPU cache memory (when cache is not enabled),

Finally, the NOC provides additional lower bandwidth / higher latency access to external memories connected to the FMC or xSPI controllers, with bandwidths of respectively 664 and 800 Mbyte/s.

The NPU does not have access to VENC or AHB memories.

Hardware triggers

The NPU provides four external asynchronous hardware trigger inputs. One of these is connected to the DCMIPP. The control SW can enable it to implement a CPU-less synchronization scheme between the camera pipeline and the NPU. This ancillary benefit of this pure hardware synchronization scheme is to reduce the size of the memory buffers used, as it is no longer needed to store a complete frame buffer.

Note: This synchronization scheme cannot be used if the model of CNN to execute requires preserving the input layer for the whole duration of the inference.

Virtual memPool

The actual amount of internal memory allocated to the NPU operation and the organization thereof is configurable by software.

Depending on the model of neural network to be executed, and of the size of the memory buffers it requires, the NPU compiler can dynamically decide to, either:

- access the on-chip memories in parallel, thus improving the bandwidth of the data transfers,
- consider them as fewer, virtual larger banks[a], to keep the activation data in internal memories for the sake of the performance.

The compiler can create one or more virtual memory pools, which can group two or more of the contiguous memories accessible through the bus. This decision is frequency a/o protocol agnostic and only cares about address ranges. A virtual memory pool can thus group as many memory banks as needed and can extend from axiRAM1 (main NOC, clocked at 400 MHz) to axiRAM6 (NPU NIC, clocked at 1 GHz).

External memories accessible through the FMC or xSPI interfaces are not contiguous with any other on-chip memory and cannot be part of a virtual memory pool.

a. This grouping of two or more contiguous memory banks is known as a “virtual memory pool”.

21 Chrom-ART Accelerator controller (DMA2D)

21.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode, including block based YCbCr to handle JPEG decoder output. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

21.2 DMA2D main features

The main DMA2D features are:

- Single AXI master bus architecture
- AHB slave programming interface supporting 8-,16-,32-bit accesses (except for CLUT accesses which are 32-bit)
- User-programmable working area size
- User-programmable offset for sources and destination areas expressed in pixels or bytes
- User-programmable sources and destination addresses on the whole memory space
- Up to two sources with blending operation
- Alpha value that can be modified (source value, fixed value, or modulated value)
- User programmable source and destination color format
- Up to 12 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- Block based (8x8) YCbCr support with 4:4:4, 4:2:2 and 4:2:0 chroma sub-sampling factors
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AXI bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to memory with pixel format conversion, blending and fixed color foreground, and memory-to memory with pixel format conversion, blending and fixed color background.
- Area filling with a fixed color

- Copy from an area to another
- Copy with pixel format conversion between source and destination images
- Copy from two sources with independent color format and blending
- Output buffer byte swapping to support refresh of displays through parallel interface
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

21.3 DMA2D functional description

21.3.1 General description

The DMA2D controller performs direct memory transfer. As an AXI master, it can take the control of the AXI bus matrix to initiate AXI transactions.

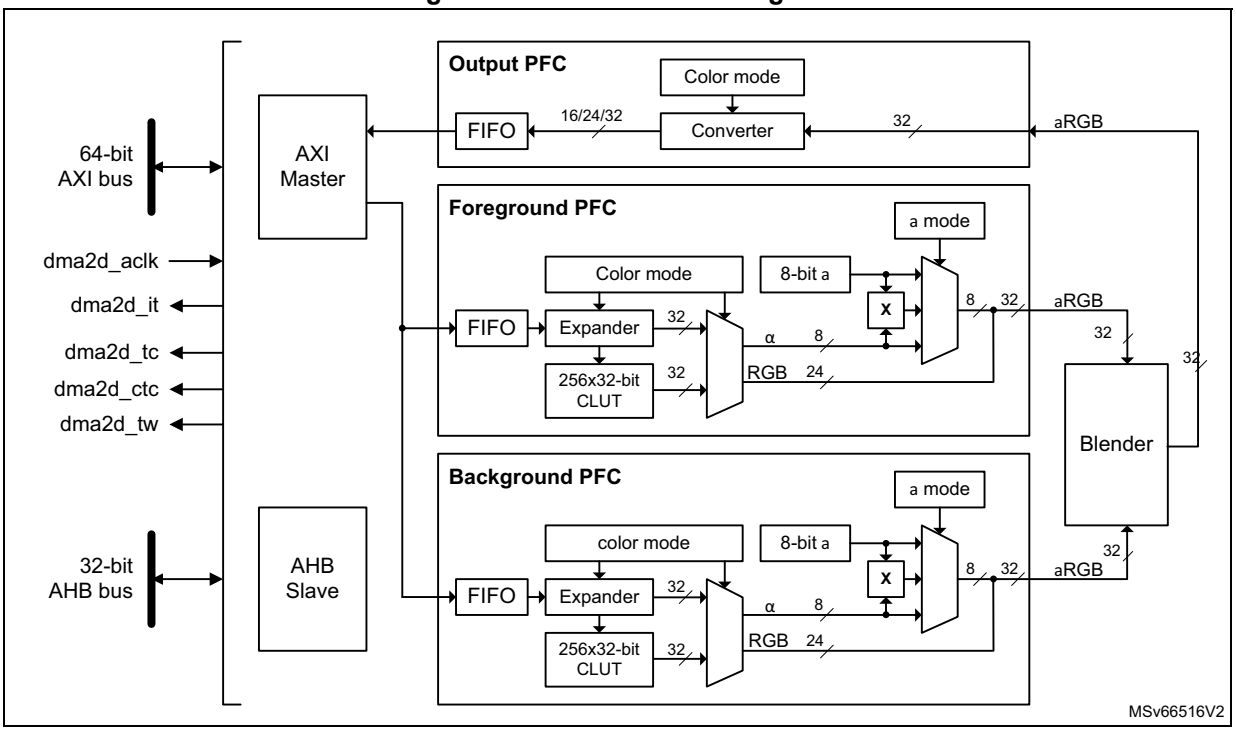
The DMA2D can operate in the following modes:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with pixel format conversion
- Memory-to-memory with pixel format conversion and blending
- Memory-to-memory with pixel format conversion, blending and fixed color foreground
- Memory-to-memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in *Figure 131*.

Figure 131. DMA2D block diagram



21.3.2 DMA2D internal signals

The internal signals of the DMA2D are given in the table below:

Table 113. DMA2D internal signals

Names	Signal type	Description
dma2d_aclk	Input	DMA2D AXI clock
dma2d_it	Output	DMA2D global interrupt request
dma2d_ctc	Output	DMA2D CLUT transfer complete trigger
dma2d_tc	Output	DMA2D transfer complete trigger
dma2d_tw	Output	DMA2D transfer watermark trigger

Table 114. DMA2D trigger interconnections

Trigger name	Direction	Trigger source/destination
dma2d_ctc	Output	hpdma_trigsel[12]
		gpdma_trigsel[12]
dma2d_tc	Output	hpdma_trigsel[13]
		gpdma_trigsel[13]
dma2d_tw	Output	hpdma_trigsel[14]
		gpdma_trigsel[14]

21.3.3 DMA2D control

The DMA2D controller is configured through DMA2D_CR. The user application can perform the following operations:

- Select the operating mode.
- Enable/disable the DMA2D interrupt.
- Start/suspend/abort ongoing data transfers.

21.3.4 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through the following control registers:

- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated, and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

21.3.5 DMA2D foreground and background PFC

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first PFC stage converts the color format. The original color format of the foreground and background pixels are configured through CM[3:0] in DMA2D_FGPFCCR and DMA2D_BGPFCCR, respectively.

The supported input formats are given in the table below.

Table 115. Supported color mode in input

CM[3:0]	Color mode
0000	ARGB8888
0001	RGB888
0010	RGB565
0011	ARGB1555
0100	ARGB4444
0101	L8

Table 115. Supported color mode in input (continued)

CM[3:0]	Color mode
0110	AL44
0111	AL88
1000	L4
1001	A8
1010	A4
1011	YCbCr (only for foreground)

The color format are coded as follows:

- Alpha value field: transparency
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode (L/AL), a CLUT is required, and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and defined in DMA2D_FGCOLR for foreground pixels, and in DMA2D_BGCOLR for background pixels.

The order of the fields in the system memory is defined in the table below.

Table 116. Data order in memory

Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]
ARGB1555	A_1[0]R_1[4:0]G_1[4:3]	G_1[2:0]B_1[4:0]	A_0[0]R_0[4:0]G_0[4:3]	G_0[2:0]B_0[4:0]
ARGB4444	A_1[3:0]R_1[3:0]	G_1[3:0]B_1[3:0]	A_0[3:0]R_0[3:0]	G_0[3:0]B_0[3:0]
L8	L_3[7:0]	L_2[7:0]	L_1[7:0]	L_0[7:0]
AL44	A_3[3:0]L_3[3:0]	A_2[3:0]L_2[3:0]	A_1[3:0]L_1[3:0]	A_0[3:0]L_0[3:0]

Table 116. Data order in memory (continued)

AL88	A_1[7:0]	L_1[7:0]	A_0[7:0]	L_0[7:0]
L4	L_7[3:0]L_6[3:0]	L_5[3:0]L_4[3:0]	L_3[3:0]L_2[3:0]	L_1[3:0]L_0[3:0]
A8	A_3[7:0]	A_2[7:0]	A_1[7:0]	A_0[7:0]
A4	A_7[3:0]A_6[3:0]	A_5[3:0]A_4[3:0]	A_3[3:0]A_2[3:0]	A_1[3:0]A_0[3:0]

The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to AM[1:0] in DMA2D_FGPFCCR or DMA2D_BGPFCCR, as shown in *Table 117*.

One of the following happens for the alpha channel:

- It is kept as it is (no modification).
- It is replaced by ALPHA[7:0] value i nDMA2D_FGPFCCR/DMA2D_BGPFCCR.
- It is replaced by the original alpha value multiplied by ALPHA[7:0] in DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

Table 117. Alpha mode configuration

AM[1:0]	Alpha mode
00	No modification
01	Replaced by value in DMA2D_xxPFCCR
10	Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255
11	Reserved

Note: To support the alternate format, the incoming alpha value can be inverted setting AI in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the Alpha value stored in the DMA2D_FGPFCCR or DMA2D_BGPFCCR, and in the CLUT.

The R and B fields can also be swapped setting RBS in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the RGB order used in the CLUT, and in DMA2D_FGCOLR or DMA2D_BGCOLR.

21.3.6 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AXI master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading

  The following sequence must be followed to load the CLUT:

a) Program the CLUT address into DMA2D_FGCMAR (foreground CLUT) or DMA2D_BGCMAR (background CLUT).

b) Program the CLUT size with CS[7:0] field in DMA2D_FGPFCCR (foreground CLUT), or DMA2D_BGPFCCR (background CLUT).

c) Set START in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE = 1 in DMA2D_CR.

- Manual loading

  The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped.The foreground CLUT (FGCLUT) is located at address offset 0x0400 and the background CLUT (BGCLUT) at address offset 0x0800.
